Note 1: Arrangements not in compliance with the provisions of this Article may be considered for the following ships:

- ships of less than 24 m in length
- cargo ships of less than 500 gross tonnage
- ships to be assigned restricted navigation notations
- non-propelled units.

### **8.2 Principle**

#### **8.2.1**

- a) Scuppers, sufficient in number and suitable in size, are to be provided to permit the drainage of water likely to accumulate in the spaces which are not located in the ship's bottom.
- b) The number of scuppers and sanitary discharge openings in the shell plating is to be reduced to a minimum either by making each discharge serve as many as possible of the sanitary and other pipes, or in any other satisfactory manner.
- c) Except otherwise specified, the design of scuppers and sanitary discharges shall generally comply with recognised national or international standard acceptable to the Society (reference is made to ISO 15749-1 to -5, as applicable).

### **8.3 Drainage from spaces below the freeboard deck or within enclosed superstructures and deckhouses on the freeboard deck**

#### **8.3.1 Normal arrangement**

Scuppers and sanitary discharges from spaces below the freeboard deck or from within superstructures and deckhouses on the freeboard deck fitted with doors complying with the provisions of Pt B, Ch 11, Sec 7 are to be led to:

- the bilge in the case of scuppers, or
- suitable sanitary tanks in the case of sanitary discharges.

#### **8.3.2 Alternative arrangement**

The scuppers and sanitary discharges may be led overboard provided that:

- the spaces drained are located above the load waterline formed by a 5° heel, to port or starboard, at a draft corresponding to the assigned summer freeboard, and
- the pipes are fitted with efficient means of preventing water from passing inboard in accordance with [8.8]

### **8.4 Drainage of superstructures or deckhouses not fitted with efficient weathertight doors**

**8.4.1** Scuppers leading from superstructures or deckhouses not fitted with doors complying with the requirements of Pt B, Ch 11, Sec 7 are to be led overboard.

### **8.5 Drainage of enclosed cargo spaces situated on the bulkhead deck or on the freeboard deck**

#### **8.5.1 General**

Means of drainage are to be provided for enclosed cargo spaces situated on the bulkhead deck of a passenger ship and on the freeboard deck of a cargo ship. The Society may permit the means of drainage to be dispensed with in any particular compartment if it is satisfied that, by reason of size or internal subdivision of such space, the safety of the ship is not impaired.

#### **8.5.2 Cases of spaces located above the waterline resulting from a 5° heel**

- a) Scuppers led through the shell from enclosed superstructures used for the carriage of cargo are permitted, provided the spaces drained are located above the waterline resulting from a 5° heel to port or starboard at a draught corresponding to the assigned summer freeboard. Such scuppers are to be fitted in accordance with the requirements stated in [8.8].
- b) In other cases, the drainage is to be led inboard in accordance with the provisions of [8.5.3].

#### **8.5.3 Cases where the bulkhead or freeboard deck edge is immersed when the ship heels 5° or less**

Where the freeboard is such that the edge of the bulkhead deck or the edge of the freeboard deck, respectively, is immersed when the ship heels 5° or less, the drainage of the enclosed cargo spaces on the bulkhead deck or on the freeboard deck, respectively, is to be led to a suitable space, or spaces, of appropriate capacity, having a high water level alarm and provided with suitable arrangements for discharge overboard.

In addition, it is to be ensured that:

- the number, size and arrangement of the scuppers are such as to prevent unreasonable accumulation of free water - see also [8.7]
- the pumping arrangements take account of the requirements for any fixed pressure water-spraying fire-extinguishing system - see also [8.7]
- water contaminated with petrol or other dangerous substances is not drained to machinery spaces or other spaces where sources of ignition may be present, and
- where the enclosed cargo space is protected by a carbon dioxide fire-extinguishing system, the deck scuppers are fitted with means to prevent the escape of the smothering gas.

### **8.6 Drainage of cargo spaces, other than ro-ro spaces, intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion**

#### **8.6.1 Prevention of build-up of free surfaces**

In cargo spaces, other than ro-ro spaces, intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion and fitted with a fixed pressure water-spraying fire-extinguishing system, the drainage arrangement is to be such as to prevent the build-up of free surfaces. If this is not possible, the adverse effect upon stability of the added weight and free surface of water are to be taken into account to the extent deemed necessary by the Society in its approval of the stability information. Refer to Pt B, Ch 3, Sec 3.

#### **8.6.2 Scupper draining**

Scuppers from cargo spaces, other than ro-ro spaces, intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion are not to be led to machinery spaces or other places where sources of ignition may be present.

## **8.7 Drainage and pumping arrangements for vehicle, special category and ro-ro spaces protected by fixed pressure water-spraying systems**

**8.7.1** When fixed pressure water-spraying fire-extinguishing systems are fitted, in view of the serious loss of stability which could arise due to large quantities of water accumulating on the deck or decks during the operation of the fixed pressure water-spraying system, the following arrangements shall be provided.

**8.7.2** In cargo ships, the drainage and pumping arrangements shall be such as to prevent the build-up of free surfaces. In such case, the drainage system shall be sized to remove no less than 125% of the combined capacity of both the water-spraying system pumps and the required number of fire hose nozzles, taking into account IMO Circular MSC.1/Circ.1320. The drainage system valves shall be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells shall be of sufficient holding capacity and shall be arranged at the side shell of the ship at a distance from each other of not more than 40 m in each watertight compartment. If this is not possible, the adverse effect upon stability of the added weight and free surface of water shall be taken into account to the extent deemed necessary by the Society in its approval of the stability information. Such information shall be included in the stability information supplied to the master as required in Pt B, Ch 3, Sec 2, [1.1.1].

**8.7.3** For passenger ships, refer to Pt D, Ch 11, Sec 4, [1.6].

**8.7.4** For closed vehicles and ro-ro spaces and special category spaces, where fixed pressure water-spraying systems are fitted, means shall be provided to prevent the blockage of drainage arrangements, taking into account IMO Circular MSC.1/Circ.1320.

## **8.8 Arrangement of discharges led overboard**

### **8.8.1 Arrangements for discharges led from spaces below the bulkhead or freeboard deck**

a) Normal arrangement:

Each separate discharge led through the shell plating from spaces below the bulkhead or freeboard deck is to be provided with one automatic non-return valve fitted with positive means of closing it from above the bulkhead or freeboard deck or.

b) Alternative arrangement when the inboard end of the discharge pipe is above the summer waterline by more than 0,01 L:

Where the vertical distance from the summer load waterline to the inboard end of the discharge pipe exceeds 0,01 L, the discharge may have two automatic non-return valves without positive means of closing, provided that the inboard valve is:

- above the deepest subdivision load line, and
- always accessible for examination under service conditions.

c) For SOLAS ships, no other alternative arrangement as those described above is accepted except for discharges led from the shell plating from spaces above the bulkhead or freeboard deck and those as provided in e).

d) For NON SOLAS ships:

1) The provisions of this sub-article are applicable only to those discharges which remain open during the normal operation of a ship. For discharges which must necessarily be closed at sea, such as gravity drains from topside ballast tanks, a single screw-down valve operated from the deck may be accepted.

2) The position of the inboard end of discharges is related to the timber summer load waterline when a timber freeboard is assigned.

3) Alternative arrangement when the inboard end of the discharge pipe is above the summer waterline by more than 0,01 L:

Where the vertical distance from the summer load waterline to the inboard end of the discharge pipe exceeds 0,01 L, the discharge may have two automatic non-return valves without positive means of closing, provided that:

- the inboard valve is above the level of the tropical load waterline so as to always be accessible for examination under service conditions, or
- where this is not practicable, a locally controlled sluice valve is interposed between the two automatic non-return valves.

4) Alternative arrangement when the inboard end of the discharge pipe is above the summer waterline by more than 0,02 L:

Where the vertical distance from the summer load waterline to the inboard end of the discharge pipe exceeds 0,02 L, a single automatic non-return valve without positive means of closing may be accepted subject to the approval of the Society.

e) Arrangement of discharges through manned machinery spaces:

Where sanitary discharges and scuppers lead overboard through the shell in way of machinery spaces, the fitting at the shell of a locally operated positive closing valve together with a non-return valve inboard may be accepted. The operating position of the valve will be given special consideration by the Society.

8.8.2 Arrangements for discharges led from other spaces

- a) Scupper and discharge pipes originating at any level and penetrating the shell either more than 450 millimetres below the freeboard deck or less than 600 millimetres above the summer load waterline are to be provided with a non-return valve at the shell. Unless required by [8.8.1], this valve may be omitted if the piping is of substantial thickness, as per Tab 25.
- b) Scupper and discharge pipes penetrating the shell less than 450 millimetres below the freeboard deck and more than 600 millimetres above the summer load waterline are not required to be provided with a non-return valve at the shell.

8.9 Summary table of overboard discharge arrangements

8.9.1 The various arrangements acceptable for scuppers and sanitary overboard discharges are summarised in Fig 3.

Figure 3 : Overboard discharge arrangement

Discharges coming from enclosed spaces below the freeboard deck or on the freeboard deck			Discharge coming from other spaces		
General requirement Reg. 22(1) where inboard end < 0,01 L above SWL	Discharge through manned machinery space	Alternatives (Reg. 22(1)) where inboard end		outboard end > 450 mm below FB deck or < 600 mm above SWL Reg. 22(4)	Otherwise Reg. 22(5)

<p>Note 1: References are those corresponding to the International Convention on Load Lines. Rules are to be additionally taken into account.</p>					

8.10 Valves and pipes

8.10.1 Materials

- a) All shell fittings and valves are to be of steel, bronze or other ductile material. Valves of ordinary cast iron or similar material are not acceptable. All scupper and discharge pipes are to be of steel or other ductile material. Refer to [2.1].
- b) Plastic is not to be used for the portion of discharge line from the shell to the first valve.

8.10.2 Thickness of pipes

- a) The thickness of scupper and discharge pipes led to the bilge or to draining tanks is not to be less than that required in [2.2].
- b) The thickness of scupper and discharge pipes led to the shell is not to be less than the minimum thickness given in Fig 3 and Tab 25.

8.10.3 Operation of the valves

- a) Where valves are required to have positive means of closing, such means is to be readily accessible and provided with an indicator showing whether the valve is open or closed.
- b) Where plastic pipes are used for sanitary discharges and scuppers, the valve at the shell is to be operated from outside the space in which the valve is located.

Where such plastic pipes are located below the summer waterline (timber summer load waterline), the valve is to be operated from a position above the freeboard deck.

Refer also to Ch 1, App 3.

Table 25 : Minimum thickness of scupper and discharge pipes led to the shell

External diameter of the pipe d (mm)	Column 1 substantial thickness (mm) (1)	Column 2 normal thickness (mm)
$d \leq 80,0$	7,00	4,50
155	9,25	4,50
180	10,00	5,00
220	12,50	5,80
$230 \leq d$	12,50	6,00

(1) For pipes connected to the shell below the freeboard deck, refer to minimum extra-reinforced wall thicknesses given in Tab 6.  
**Note 1:** Intermediate sizes may be determined by interpolation.

## 8.11 Arrangement of scuppers and sanitary discharge piping

### 8.11.1 Overboard discharges and valve connections

- Overboard discharges are to have pipe spigots extending through the shell plate and welded to it, and are to be provided at the internal end with a flange for connection to the valve or pipe flange.
- Valves may also be connected to the hull plating in accordance with the provisions of [2.8.3], item c).

### 8.11.2 Passage through cargo spaces

Where scupper and sanitary discharge pipes are led through cargo spaces, the pipes and the valves with their controls are to be adequately protected by strong casings or guards.

### 8.11.3 Passage through tanks

- As a rule, scupper and sanitary discharge pipes are not to pass through fuel oil tanks.
- Where scupper and discharge pipes pass unavoidably through fuel oil tanks and are led through the shell within the tanks, the thickness of the piping is not to be less than that given in Tab 25, column 1 (substantial thickness). It need not, however, exceed the thickness of the adjacent Rule shell plating.
- Scupper and sanitary discharge pipes are normally not to pass through fresh and drinking water tanks.
- For passage through cargo oil tanks, see Pt D, Ch 7, Sec 4.

### 8.11.4 Passage through watertight bulkheads or decks

- The intactness of machinery space bulkheads and of tunnel plating required to be of watertight construction is not to be impaired by the fitting of scuppers discharging to machinery spaces or tunnels from adjacent compartments which are situated below the freeboard deck.
- Such scuppers may, however, be led into a strongly constructed scupper drain tank situated in the machinery space or tunnel, but close to the above-mentioned adjacent compartments and drained by means of a suction of appropriate size led from the main bilge line through a screw-down non-return valve.

### 8.11.5 Discharge in refrigerated spaces

No scupper pipe from non-refrigerated spaces is to discharge in refrigerated spaces.

### 8.11.6 Discharge from galleys and their stores

Discharges from galleys and their stores are to be kept separate from other discharges and be drained overboard or in separate drainage tanks; alternatively, discharges are to be provided with adequate devices against odours and overflow.

### 8.11.7 Discharge from aft spaces

Where spaces located aft of the aft peak bulkhead not intended to be used as tanks are drained by means of scuppers discharging to the shaft tunnel, the provisions of [6.6.4] item c) are to be complied with.

### 8.11.8 Scupper tank

- The scupper tank air pipe is to be led to above the freeboard deck.
- Provision is to be made to ascertain the level of water in the scupper tank.

### 8.11.9 Drains from the funnels

Drain line from the funnel or stack top should not terminate on an exposed deck owing to the soot that may be contained in the wastewater. Except otherwise specified, this line may be connected to other lines draining exposed decks and leading directly overboard, taking into consideration the quantity of wastewater occurring.

**8.11.10 Sewage and grey water discharges**

The requirements specified below are general and should apply to any ship fitted with sewage and grey water piping systems. They are not sufficient for the compliance with MARPOL Annex IV and for additional class notation **CLEANSHIP**. Furthermore, the National Authority of the country in which the ship is to be registered may also have additional requirements.

- a) Except otherwise specified, the sewage (or black water) means:
  - drainage and other wastes from any form of toilets and urinals
  - drainage from medical premises (dispensary, sick bay, etc.) via wash basins, wash tubs and scuppers located in such premises
  - drainage from spaces containing living animals; or
  - other waste waters when mixed with the drainages defined above.
- b) Grey water means other sanitary discharges which are not sewage.
- c) In general, sewage systems should be of a design which will avoid the possible generation of toxic and flammable gases (such as hydrogen sulphide, methane, ammonia) during the sewage collection and treatment. Additional means of protection is to be suitable ventilation of the pipework and tanks.
- d) Drain lines from the hospital area should be, as far as practicable, separated from other discharges and fitted to the drain collector at the lowest level.
- e) Sewage and grey water may be collected into storage tanks together or separately, either for holding prior to transfer to a treatment unit, or for later discharge. Any tank used for holding sewage shall comply with the following:
  - suitable air pipes shall be fitted, leading to the open deck
  - design and configuration of those tanks should be such as to facilitate the effective drainage and flushing of the tanks
  - suitable means for flushing of the tanks shall be provided
  - such tanks are to be efficiently protected against corrosion
  - tanks shall have a means to indicate visually the amount of its content
  - suitable means for emptying sewage tanks through the standard discharge connection to reception facilities shall be provided. Ballast and bilge pumps are not be used for that purpose.
- f) Air pipes from the sewage and grey water systems are to be independent of all other air pipes and to be led to the outside of the ship, away from any air intake. Such pipes should not terminate in areas to which personnel have frequent access and should be clear of any sources of ignition.
- g) The overboard discharges shall be located as far from seawater inlets as possible, seen in the direction of travel. In general, the sewage outlets should be located below the summer loadline.
- h) The sewage and grey water discharge lines are to be fitted at the ships' side with screw-down valve and non-return valve. Possible characteristically arrangement is shown on Fig 4.

The non-return valve may be omitted where a pipe loop is fitting on discharge line, provided that the lowest part of the loop is at least 200 mm above the waterline with the ship on summer loadline draft and when the ship has a 5° list (see Fig 5).

**Figure 4 : Sewage and grey water overboard discharge typical arrangement**

- |                                    |                           |                              |                               |
|------------------------------------|---------------------------|------------------------------|-------------------------------|
| 1 grey water drain line            | 2 sewage water drain line | 3 bypass line for sewage     | 4 bypass line for grey water  |
| 5 sewage disposal line             | 6 shutoff gate valve      | 7 spectacle flange, optional | 8 overboard discharge         |
| 9 collector tank or treatment unit | 10 pump                   | 11 non-return valve          | 12 screw-down overboard valve |
| 13 standard discharge connection   |                           |                              |                               |

## 9 Air, sounding and overflow pipes

### 9.1 Air pipes

#### 9.1.1 Principle

Air pipes are to be fitted to all tanks, double bottoms, cofferdams, tunnels and other compartments which are not fitted with alternative ventilation arrangements, in order to allow the passage of air or liquid so as to prevent excessive pressure or vacuum in the tanks or compartments, in particular in those which are fitted with piping installations. Their open ends are to be so arranged as to prevent the free entry of sea water in the compartments.

#### 9.1.2 Number and position of air pipes

- Air pipes are to be so arranged and the upper part of compartments so designed that air or gas likely to accumulate at any point in the compartments can freely evacuate.
- Air pipes are to be fitted opposite the filling pipes and/or at the highest parts of the compartments, the ship being assumed to be on an even keel.
- In general, two air pipes are to be fitted for each compartment, except in small compartments, where only one air pipe may be accepted. When the top of the compartment is of irregular form, the position of air pipes will be given special consideration by the Society.

Note 1: Two air vents are normally required for long tanks e.g. a ballast tank in a double hull ship.

In machinery spaces, two air vents are not normally required.

- Where only one air pipe is provided, it is not to be used as a filling pipe.

#### 9.1.3 Location of open ends of air pipes

- Air pipes of double bottom compartments, tunnels, deep tanks and other compartments which can come into contact with the sea or be flooded in the event of hull damage are to be led to above the bulkhead deck or the freeboard deck.

Note 1: In ships not provided with a double bottom, air pipes of small cofferdams or tanks not containing fuel oil or lubricating oil may discharge within the space concerned.

- Air pipes of tanks intended to be pumped up are to be led to the open above the bulkhead deck or the freeboard deck.
- Air pipes other than those of flammable oil tanks may be led to enclosed cargo spaces situated above the freeboard deck, provided that:
  - overflow pipes are fitted in accordance with [9.3.4], where the tanks may be filled by pumping
  - enclosed cargo spaces are fitted with scuppers discharging overboard and being capable of draining all the water which may enter through the air pipes without giving rise to any water accumulation
  - suitable drainage arrangement is to be fitted below the air pipe outlet, leading to the nearest scupper
  - such arrangement is not to impair integrity of fire divisions or watertight decks and bulkheads subject to the damage stability requirements.
- Unless otherwise specified, in passenger ships the open end of air pipes terminating within a superstructure shall be at least 1 m above the waterline when the ship heels to an angle of 15°, or the maximum angle of heel during intermediate stages of flooding, as determined by direct calculation, whichever is the greater. Alternatively, air pipes from tanks other than oil tanks may discharge through the side of the superstructure.
- The air pipe of the scupper tank is to be led to above freeboard deck.
- The location of air pipes for flammable oil tanks is also to comply with [9.1.7].

**9.1.4 Height of air pipes**

- a) The height of air pipes extending above the freeboard deck or superstructure deck from the deck to the point where water may have access below is to be at least:
- 760 mm on the freeboard deck, and
  - 450 mm on the superstructure deck.

This height is to be measured from the upper face of the deck, including sheathing or any other covering, up to the point where water may penetrate inboard.

- b) Where these heights may interfere with the working of the ship, a lower height may be approved, provided the Society is satisfied that this is justified by the closing arrangements and other circumstances. Satisfactory means which are permanently attached are to be provided for closing the openings of the air pipes.
- c) The height of air pipes may be required to be increased on ships subject to damage stability requirements since the air pipe outlets are to be above final waterline at any damaged condition assumed by the Damage stability examination as defined in Pt B, Ch 3, App 4, [3.5.2].
- d) The height of air pipes discharging through the side of the superstructure is to be at least 2,3 m above the summer load waterline.

**9.1.5 Fitting of closing appliances**

- a) Satisfactory appliances which are permanently attached are to be provided for closing the openings of air pipes in order to prevent the free entry of water into the spaces concerned, except for pipes of tanks fitted with cross-flooding connections.
- b) Automatic closing appliances are to be fitted in the following cases:
- where air pipes to ballast and other tanks extend above the freeboard or superstructure decks
  - where, with the ship at its summer load waterline, the openings are immersed at an angle of heel of 40° or, at the angle of down-flooding if the latter is less than 40°
  - where, as per [9.1.3] item c), air pipes terminate in enclosed spaces
  - where, as per [9.1.4] item b), air pipes have a height lower than that required in [9.1.4] item a)
  - and for ships assigned timber freeboard.

See also Pt B, Ch 3, Sec 2, [2.1.2] and Pt B, Ch 3, Sec 3, [3.3.2].

- c) Automatic closing appliances are to be of a type approved by the Society. Requirements for type tests are given in [20.3.1].
- d) For ships subject to specific buoyancy or stability requirements, the fitting of closing appliances to air pipes will be given special consideration.
- e) Pressure/vacuum valves installed on cargo tanks, as per Part D, Chapter 7 and Part D, Chapter 8, can be accepted as closing appliances.

**9.1.6 Design of closing appliances**

- a) When air pipes are required to be fitted with automatic closing devices, they are to comply with the following:
- 1) Air pipe automatic closing devices are to be so designed that they will withstand both ambient and working conditions, and be suitable for use at inclinations up to and including  $\pm 40^\circ$ .
  - 2) Air pipe automatic closing devices are to be constructed to allow inspection of the closure and the inside of the casing as well as changing the seals.
  - 3) Efficient ball or float seating arrangements are to be provided for the closures. Bars, cage or other devices are to be provided to prevent the ball or float from contacting the inner chamber in its normal state and made in such a way that the ball or float is not damaged when subjected to water impact due to a tank being overfilled.
  - 4) Air pipe automatic closing devices are to be self-draining.
  - 5) The clear area through an air pipe closing device in the open position is to be at least equal to the area of the inlet.
  - 6) An automatic closing device is to:
    - prevent the free entry of water into the tanks
    - allow the passage of air or liquid to prevent excessive pressure or vacuum coming on the tank.
  - 7) In the case of air pipe closing devices of the float type, suitable guides are to be provided to ensure unobstructed operation under all working conditions of heel and trim. Where side covers are provided and their function is integral to providing functions of the closing device as outlined in [9.1.6] item a) 6), they shall have a minimum wall thickness of 6 mm. If the air pipe head can meet the tightness test in [20.3.1], item a) without the side covers attached, then the side covers are not considered to be integral to the closing device, in which case a wall less than 6 mm can be acceptable for side covers.

- 8) The maximum allowable tolerances for wall thickness of floats is not to exceed  $\pm 10\%$  of thickness.
  - 9) The inner and the outer chambers of an automatic air pipe head is to be of a minimum thickness of 6 mm.
  - 10) Casings of air pipe closing devices are to be of approved metallic materials adequately protected against corrosion.
  - 11) For galvanised steel air pipe heads, the zinc coating is to be applied by the hot method and the thickness is to be 70 to 100 microns.
  - 12) For areas of the head susceptible to erosion (e.g. those parts directly subjected to ballast water impact when the tank is being pressed up, for example the inner chamber area above the air pipe, plus an overlap of  $10^\circ$  or more either side), an additional harder coating is to be applied. This is to be an aluminium bearing epoxy, or other equivalent, coating, applied over the zinc.
  - 13) Closures and seats made of non-metallic materials are to be compatible with the media intended to be carried in the tank and to seawater and suitable for operating at ambient temperatures between  $-25^\circ\text{C}$  and  $+85^\circ\text{C}$ .
- b) Where closing appliances are not of an automatic type, provision is to be made for relieving vacuum when the tanks are being pumped out. For this purpose, a hole of approximately 10 mm in diameter may be provided in the bend of the air pipe or at any other suitable position in the closing appliance.
- c) Wooden plugs and trailing canvas are not permitted in position 1 or position 2, as defined in Pt B, Ch 3, Sec 2.

### **9.1.7 Special arrangements for air pipes of flammable oil tanks**

- a) Air pipes from fuel oil tanks and from thermal oil heating plants expansion tanks and thermal oil storage tanks, are to discharge to a safe position on the open deck where no danger will be incurred from issuing oil or gases.  
Where fitted, wire gauze diaphragms are to be of corrosion resistant material and readily removable for cleaning and replacement. The clear area of such diaphragms is not to be less than the cross-sectional area of the pipe.
- b) Air pipes of lubricating or hydraulic oil storage tanks, which are neither heated nor subject to flooding in the event of hull damage, may be led to machinery spaces, provided that in the case of overflowing the oil cannot come into contact with electrical equipment, hot surfaces or other sources of ignition.
- c) The location and arrangement of vent pipes for fuel oil service, settling and lubrication oil tanks are to be such that in the event of a broken vent pipe there is no risk of ingress of seawater or rainwater.
- d) Air pipes of fuel oil service, settling and lubrication oil tanks likely to be damaged by impact forces are to be adequately reinforced.
- e) Where seawater or rainwater may enter fuel oil service, settling and lubrication oil tanks through broken air pipes, arrangements such as water traps with:
- automatic draining, or
  - alarm for water accumulation
- are to be provided.

### **9.1.8 Construction of air pipes**

- a) Where air pipes to ballast and other tanks extend above the freeboard deck or superstructure deck, the exposed parts of the pipes are to be of substantial construction, with a minimum wall thickness of at least:
- 6,0 mm for pipes of 80 mm or smaller external diameter
  - 8,5 mm for pipes of 165 mm or greater external diameter,
- Intermediate minimum thicknesses may be determined by linear interpolation.
- b) Air pipes with height exceeding 900 mm are to be additionally supported.
- c) In each compartment likely to be pumped up, and where no overflow pipe is provided, the total cross-sectional area of air pipes is not to be less than 1,25 times the cross-sectional area of the corresponding filling pipes.
- d) The internal diameter of air pipes is not to be less than 50 mm, except for tanks of less than  $2 \text{ m}^3$ .
- e) Air pipes from several tanks or spaces may be led into a common main line, provided that:
- the tanks or spaces are not intended for liquids which are not compatible and that the arrangement could not effect unacceptable condition for the ship
  - the cross-sectional area of the air pipes main is generally not less than the aggregate cross-sectional area of the two largest pipes discharging into the main. However, a reduced value may be considered for acceptance in each particular case on the basis of back pressure calculation submitted for all normal working conditions
  - as far as practical, each separate air pipe is fitted to the common air pipe from the top side
  - where no overflow pipes are provided, the cross-sectional area of a common air pipe from several tanks is not less than 1,25 times the area of the common filling pipeline for these tanks
  - where the tanks or spaces are situated at the shell side, the connections to the air pipes main are to be above the freeboard deck. Where it is not practical, different position proposed as far as possible above the deepest load waterline may be considered for acceptance. For vessels subject to damage stability requirements these connections are to be above final waterline at any damaged condition assumed by the Damage stability examination as defined in Pt B, Ch 3, App 4, [3.5.2].

- f) Vents acting also as overflows may be accepted provided all the requirements applicable to both vents and overflows are complied with.
- g) Where tanks are fitted with cross flooding connections, the air pipes are to be of adequate area for these connections.

**9.1.9 Strength requirements to resist green sea forces for the air pipes, ventilator pipes and their closing devices located within the forward quarter length**

- a) In addition to all other requirements specified before, the following shall apply on the exposed deck over the forward 0,25 L, applicable to:
  - All ship types of sea going service of length 80 m or more, where the height of the exposed deck in way of the item is less than 0,1 L or 22 m above the summer load waterline, whichever is the lesser.
  - For application to existing ships (that are contracted for construction prior to 1 January 2004), see Part A, Chapter 6.The rule length “L” is the distance, in m, taken as defined in Pt B, Ch 1, Sec 3, [2.1.1].

The requirements do not apply to the cargo tank venting systems and the inert gas systems of tankers.

- b) Generally, the bending moments and stresses in air and ventilator pipes are to be calculated at following critical positions:
  - at penetration pieces
  - at weld or flange connections
  - at toes of supporting brackets.

Bending stresses in the net section are not to exceed 0,8 of the specified minimum yield stress or 0,2% proof stress of the steel at room temperature. Irrespective of corrosion protection, a corrosion addition to the net section of 2,0 mm is then to be applied.

Relevant drawing and calculation shall be submitted.

- c) For standard air pipes of 760 mm height closed by heads of not more than the tabulated projected area, pipe thickness and bracket heights are specified in Tab 26. Where brackets are required, three or more radial brackets are to be fitted. Brackets are to be of gross thickness 8 mm or more, of minimum length 100 mm, and height according to Tab 27 but need not extend over the joint flange for the head. Bracket toes at the deck are to be suitably supported.
- d) For other configurations, loads according to item i) are to be applied, and means of support determined in order to comply with the requirements of item b). Brackets, where fitted, are to be of suitable thickness and length according to their height. Pipe thickness is not to be taken less than as indicated in [9.1.8].
- e) For standard ventilators of 900 mm height closed by heads of not more than the tabulated projected area, pipe thickness and bracket heights are specified in Tab 27. Brackets, where required are to be as specified in item c). See also Pt B, Ch 11, Sec 12, [9].
- f) For ventilators of height greater than 900 mm, brackets or alternative means of support shall be fitted according to the arrangement acceptable to the Society. See also Pt B, Ch 11, Sec 12, [9]. Pipe thickness is not to be taken less than as indicated in [9.1.8].
- g) All component parts and connections of the air pipe or ventilator are to be capable of withstanding the loads defined in item i).
- h) Rotating type mushroom ventilator heads are not suitable for application in the areas where these requirements are applied.
- i) Applied loading may be calculated:

- The pressures  $p$ , in  $\text{kN/m}^2$ , acting on air pipes, ventilator pipes and their closing devices may be calculated from:

$$p = 0,5 \rho V^2 C_d C_s C_p$$

where:

$\rho$  : Density of sea water, equal to  $1,025 \text{ t/m}^3$

$V$  : Velocity of water over the fore deck, in  $\text{m/s}$ , to be taken equal to:

- 13,5 if  $d \leq 0,5 d_1$

- $13,5 \sqrt{2 \left(1 - \frac{d}{d_1}\right)}$

if  $0,5 d_1 < d < d_1$

$d$  : Distance, in m, from the summer load line to the exposed deck

$d_1$  : 0,1 L or 22 m, whichever is the lesser

$C_d$  : Shape coefficient, equal to:

- 0,5 for pipes
- 1,3 for air pipe or ventilator heads in general
- 0,8 for an air pipe or ventilator head of cylindrical form with its axis in the vertical direction

$C_s$  : Slamming coefficient, equal to 3,2

$C_p$  : Protection coefficient, equal to:

- 0,7 for pipes and ventilator heads located immediately behind a breakwater or a forecastle
- 1,0 elsewhere and immediately behind a bulwark.

- Forces acting in the horizontal direction on the pipe and its closing device may be calculated from formula above, using the largest projected area of each component.

**Table 26 : 760 mm air pipe thickness and bracket standards**

Nominal pipe diameter (mm)	Minimum fitted gross thickness (mm)	Maximum projected area of head (cm <sup>2</sup> )	Height of brackets (1) (mm)
40A (3)	6,0	–	520
50A (3)	6,0	–	520
65A	6,0	–	480
80A	6,3	–	460
100A	7,0	–	380
125A	7,8	–	300
150A	8,5	–	300
175A	8,5	–	300
200A	8,5 (2)	1900	300 (2)
250A	8,5 (2)	2500	300 (2)
300A	8,5 (2)	3200	300 (2)
350A	8,5 (2)	3800	300 (2)
400A	8,5 (2)	4500	300 (2)

(1) Brackets (see [9.1.9] items b) to h)) need not extend over the joint flange for the head.  
 (2) Brackets are required where the as fitted (gross) thickness is less than 10,5 mm, or where the tabulated projected head area is exceeded.  
 (3) Not permitted for new ships - see Tab 6.  
**Note 1:** For other air pipe heights, the relevant requirements of [9.1.9] are to be applied.

**Table 27 : 900 mm ventilator pipe thickness and bracket standards**

Nominal pipe diameter (mm)	Minimum fitted gross thickness, (mm)	Maximum projected area of head (cm <sup>2</sup> )	Height of brackets (mm)
80A	6,3	–	460
100A	7,0	–	380
150A	8,5	–	300
200A	8,5	550	–
250A	8,5	880	–
300A	8,5	1200	–
350A	8,5	2000	–
400A	8,5	2700	–
450A	8,5	3300	–
500A	8,5	4000	–

**Note 1:** For other ventilator heights, the relevant requirements of [9.1.9], items b) to h), are to be applied.

## 9.2 Sounding pipes

### 9.2.1 Principle

- a) Sounding devices are to be fitted to tanks intended to contain liquids as well as to all compartments which are not readily accessible at all times.
- b) For compartments normally intended to contain liquids, the following systems may be accepted in lieu of sounding pipes:
  - a level gauge of an approved type efficiently protected against shocks, or
  - a remote level gauging system of an approved type, provided an emergency means of sounding is available in the event of failure affecting such system.

### **9.2.2 Position of sounding pipes**

Sounding pipes are to be located as close as possible to suction pipes.

### **9.2.3 Termination of sounding pipes**

- a) As a general rule, sounding pipes are to end above the bulkhead deck or the freeboard deck in easily accessible places and are to be fitted with efficient, permanently attached, metallic closing appliances.
- b) In machinery spaces and tunnels, where the provisions of item a) cannot be satisfied, short sounding pipes led to readily accessible positions above the floor and fitted with efficient closing appliances may be accepted.

In ships required to be fitted with a double bottom, such closing appliances are to be of the self-closing type.

### **9.2.4 Special arrangements for sounding pipes of flammable oil tanks**

- a) Where sounding pipes are used in flammable (except lubricating) oil systems, they are to terminate in the open air, where no risk of ignition of spillage from the sounding pipe might arise. In particular, they are not to terminate in passenger or crew spaces. As a general rule, they are not to terminate in machinery spaces. However, where the Society considers that this requirement is impracticable, it may permit termination in machinery spaces on condition that the following provisions are satisfied:
  - 1) in addition, an oil-level gauge is provided meeting the provisions of [2.9.2]
  - 2) the sounding pipes terminate in locations remote from ignition hazards unless precautions are taken, such as the fitting of effective screens, to prevent the fuel oil in the case of spillage through the terminations of the sounding pipes from coming into contact with a source of ignition
  - 3) the terminations of sounding pipes are fitted with self-closing blanking devices and with a small diameter self-closing control cock located below the blanking device for the purpose of ascertaining before the blanking device is opened that fuel oil is not present. Provision is to be made so as to ensure that any spillage of fuel oil through the control cock involves no ignition hazard.
- b) For lubricating oil and fuel oil leakage tanks less than 2 m<sup>3</sup>, the oil-level gauge mentioned in a) 1) and the control cock mentioned in a) 3) need not be provided on condition that the sounding pipes are fitted with appropriate means of closure.
- c) Short sounding pipes may be used for tanks other than double bottom tanks without the additional closed level gauge provided an overflow system is fitted.

### **9.2.5 Closing appliances**

- a) Self-closing appliances are to be fitted with cylindrical plugs having counterweights such as to ensure automatic closing.
- b) Closing appliances not required to be of the self-closing type may consist of a metallic screw cap secured to the pipe by means of a chain or a shut-off valve.

### **9.2.6 Construction of sounding pipes**

- a) Sounding pipes are normally to be straight. If it is necessary to provide bends in such pipes, the curvature is to be as small as possible to permit the ready passage of the sounding apparatus.
- b) In cargo ships, the sounding arrangement of compartments by means of bent pipes passing through other compartments will be given special consideration by the Society. Such an arrangement is normally accepted only if the compartments passed through are cofferdams or are intended to contain the same liquid as the compartments served by the sounding pipes.
- c) Bent portions of sounding pipes are to have reinforced thickness and be suitably supported.
- d) The internal diameter of sounding pipes is not to be less than 32 mm. Where sounding pipes pass through refrigerated spaces, or through the insulation of refrigerated spaces in which the temperature may be below 0°C, their internal diameter is to be at least 60 mm.
- e) Doubling plates are to be placed under the lower ends of sounding pipes in order to prevent damage to the hull. When sounding pipes with closed lower ends are used, the closing plate is to have reinforced scantlings.

## **9.3 Overflow pipes**

### **9.3.1 Principle**

Overflow pipes are to be fitted to tanks:

- which can be filled by pumping and are designed for a hydrostatic pressure lower than that corresponding to the height of the air pipe, or
- where the cross-sectional area of air pipes is less than that prescribed in [9.1.8], item d).

### **9.3.2 Design of overflow systems**

- a) Overflow pipes are to be led:
  - either outside, or
  - in the case of fuel oil or lubricating oil, to an overflow tank of adequate capacity or to a storage tank having a space reserved for overflow purposes.

- b) Where tanks containing the same or different liquids are connected to a common overflow system, the arrangement is to be such as to prevent any risk of:
- intercommunication between the various tanks due to movements of liquid when emptying or filling, or due to the inclination of the ship
  - overflowing of any tank from another assumed flooded due to hull damage.
- For this purpose, overflow pipes are to be led to a high enough point above the deepest load waterline or, alternatively, non-return valves are to be fitted where necessary.
- c) Arrangements are to be made so that a compartment cannot be flooded from the sea through the overflow in the event of another compartment connected to the same overflow main being bilged. To this end, the openings of overflow pipes discharging overboard are as a rule to be placed above the deepest load waterline and are to be fitted where necessary with non-return valves on the plating, or, alternatively, overflow pipes from tanks are to be led to a point above the deepest load waterline.
- d) Where deep tanks which can be used to contain liquid or dry cargo or fuel oil are connected to a common overflow system, arrangements are to be made so that liquid or vapours from other compartments cannot enter such tanks when carrying dry cargo.
- e) Where tanks alternately containing fuel oil and ballast water are connected to a common overflow system, arrangements are to be made to prevent the ballast water overflowing into the tanks containing fuel oil and vice-versa.
- f) Additional requirements for ships subject to damage stability checks are given in [5.5.3].

### **9.3.3 Overflow tanks**

- a) Overflow tanks are to have a capacity sufficient to receive the delivery of the pumps for at least 10 minutes.
- b) Overflow tanks are to be fitted with an air pipe complying with [9.1] which may serve as an overflow pipe for the same tank. When the vent pipe reaches a height exceeding the design head of the overflow tank, suitable means are to be provided to limit the actual hydrostatic head on the tank.  
Such means are to discharge to a position which is safe in the opinion of the Society.
- c) An alarm device is to be provided to give warning when the oil reaches a predetermined level in the tank, or alternatively, a sight-flow glass is to be provided in the overflow pipe to indicate when any tank is overflowing. Such sight-flow glasses are only to be placed on vertical pipes and in readily visible positions.

### **9.3.4 Specific arrangements for construction of overflow pipes**

- a) The internal diameter of overflow pipes is not to be less than 50 mm.
- b) In each compartment which can be pumped up, the total cross-sectional area of overflow pipes is not to be less than 1,25 times the cross-sectional area of the corresponding filling pipes.
- c) The cross-sectional area of the overflow main is to be sufficient to allow the two largest pipes to discharge simultaneously into the main.
- d) Sight glasses may be accepted on overflow lines from fuel oil and lubricating oil systems, provided that:
- they are located in a vertically dropping line on readily visible and well lit position
  - they are protected against mechanical damages
  - the glass is of heat resisting type.

## **9.4 Constructional requirements applying to sounding, air and overflow pipes**

### **9.4.1 Materials**

- a) Sounding, air and overflow pipes are to be made of steel or any other material approved for the application considered.
- b) Exposed parts of sounding, air and overflow pipes are to be made of approved metallic materials.

### **9.4.2 Minimum thickness of steel pipes**

The minimum thickness of sounding, air and overflow steel pipes is given in Tab 6. See also [9.1.9].

### **9.4.3 Passage of pipes through certain spaces**

- a) Air pipes and sounding pipes led through refrigerated cargo holds or spaces are to be suitably insulated.
- b) When sounding, air and overflow pipes made of steel are permitted to pass through ballast tanks or fuel oil tanks, they are to be of reinforced thickness, in accordance with Tab 6.
- c) Sounding, air and overflow pipes passing through cargo holds are to be adequately protected.

### **9.4.4 Self-draining of pipes**

Air pipes and overflow pipes are to be so arranged as to be self-draining when the ship is on an even keel.

### **9.4.5 Name plates**

Nameplates are to be fixed at the upper part of air pipes and sounding pipes.

## 10 Cooling systems

### 10.1 Application

10.1.1 This article applies to all cooling systems using the following cooling media:

- sea water
- fresh water
- lubricating oil.

Air cooling systems will be given special consideration.

### 10.2 Principle

#### 10.2.1 General

Sea water and fresh water cooling systems are to be so arranged as to maintain the temperature of the cooled media (lubricating oil, hydraulic oil, charge air, etc.) for propulsion machinery and essential equipment within the manufacturers' recommended limits during all operations, including starting and manoeuvring, under the inclination angles and the ambient conditions specified in Ch 1, Sec 1.

#### 10.2.2 Availability of the cooling system

The cooling system is to be so designed that, in the event of one essential component being inoperative, the cooling of propulsion machinery is maintained. Partial reduction of the propulsion capability may be accepted, however, when it is demonstrated that the safe operation of the ship is not impaired.

### 10.3 Design of sea water cooling systems

#### 10.3.1 General

- a) Sea water cooling of the propulsion engines, auxiliary engines and other essential equipment is to be capable of being supplied by two different means.
- b) Where required, standby pumps are not to be connected to the sea inlet serving the other sea water pumps, unless permitted under [10.7.1], item b).

#### 10.3.2 Centralised cooling systems

- a) In the case of centralised cooling systems, i.e. systems serving a group of propulsion engines and/or auxiliary engines, reduction gears, compressors and other essential equipment, the following sea water pumps and heat exchangers are to be arranged:
  - one main cooling water pump, which may be driven by the engines, of a capacity sufficient to provide cooling water to all the equipment served
  - one independently driven standby pump of at least the same capacity
  - two heat exchangers, each having at least 50% of the total capacity necessary to provide cooling water to all the equipment served.
- b) Where the cooling system is served by a group of identical pumps, the capacity of the standby pump needs only to be equivalent to that of each of these pumps.
- c) Ballast pumps or other suitable sea water pumps of appropriate capacity may be used as standby pumps, provided arrangements are made against overpressure in the cooling system.
- d) In ships having one or more propulsion engines, each with an output not exceeding 375 kW, the independent standby pump may be replaced by a complete spare pump of appropriate capacity ready to be connected to the cooling circuit.
- e) In cases of centralised cooling systems serving only a group of auxiliary engines, the second means of cooling may consist of a connection to a cooling water pump serving the propulsion plant, provided such pump is of sufficient capacity to provide cooling water to both propulsion plant and auxiliary engines.

#### 10.3.3 Individual cooling of propulsion engines

- a) Individual cooling systems of propulsion engines are to include at least:
  - one main cooling water pump, which can be driven by the engine
  - one independently driven standby pump
  - one heat exchanger of appropriate capacity.

Where the output of the engine does not exceed 375 kW, the following arrangements may be accepted:

- one main cooling water pump, which can be driven by the engine
- one spare pump of appropriate capacity ready to be connected to the cooling circuit
- one heat exchanger of appropriate capacity.

- b) Where, in ships having more than one engine per propeller or having several propellers, each engine is served by its own cooling circuit, the second means requested in [10.3.1] is to be provided, consisting of:
- a connection to an independently driven pump, such as a ballast pump or any other suitable sea water pump of sufficient capacity provided arrangements against overpressure in the cooling system are made. (See [10.7.4], item b)), or
  - a complete spare pump identical to those serving the engines and ready to be connected to the cooling circuit.
- This second means may be omitted, however, when safety justifications are provided as regards the propulsion and manoeuvring capabilities of the ship with one cooling circuit disabled.

#### **10.3.4 Individual cooling of auxiliary engines**

Where each auxiliary engine is served by its own cooling circuit, no second means of cooling is required.

#### **10.3.5 Cooling of steam plants**

- a) Steam plants are to be fitted with:
- a main circulating pump
  - a standby pump capable of ensuring the circulation in the main condenser in the event of failure of the main circulating pump.
- b) Where the installation includes more than one propulsive unit, the standby pump is not required, provided a branch pipe is fitted between the discharges of the circulating pumps of each unit.
- c) In lieu of the main circulating pump, a sea inlet scoop system may be accepted, provided that an additional means is fitted to ensure the circulation of sea water to the condenser when the ship is manoeuvring. Such means may be:
- an additional independent pump, or
  - a connection to an available pump of sufficient capacity.

#### **10.3.6 Cooling of other essential equipment**

- a) The second means of cooling required in [10.3.1] for essential equipment may consist of a connection to a ballast pump or other suitable sea water pump of sufficient capacity, provided arrangements are made against overpressure in the cooling system (see [10.7.4], item b)).
- b) However, where such essential equipment is duplicate, this second means may be omitted when justifications are provided as regards the propulsion and manoeuvring capabilities of the ship with the cooling circuit of one set of equipment disabled.

### **10.4 Design of fresh water cooling systems**

#### **10.4.1 General**

Fresh water cooling systems are to be designed according to the applicable requirements of [10.3].

#### **10.4.2 Cooling systems**

- a) Fresh water cooling systems of essential equipment are to include at least:
- one main cooling water pump, which can be driven by the equipment
  - one independently driven standby pump.
- b) The standby pump may be omitted provided an emergency connection to a suitable sea water system is fitted and arranged with a suitable change-over device. Provisions against overpressure in the cooling system are to be made in accordance with [10.7.4], item b).
- c) The standby pump may also be omitted in the case of redundancy of the cooled equipment.

#### **10.4.3 Expansion tanks**

Fresh water expansion tanks are to be provided with at least:

- a de-aerating device
- a water level indicator
- a filling connection
- a drain.

#### **10.4.4 Protection of contamination by oil**

Suitable means are to be provided in fresh water cooling systems comprising fuel oil or lubricating oil heat exchangers in order to detect any contamination of the water by fuel oil or lubricating oil.

If cooling water is used for heating of oil, the heating coils are to be located on the pressure side of the cooling pumps and connected by welding, with no detachable connections where mixing of oil and water may occur. Alternatively a primary and secondary system arrangement may be used.

### **10.5 Design of oil cooling systems**

#### **10.5.1 General**

Oil cooling systems are to be designed according to the applicable requirements of [10.3].

**10.5.2 Second means of cooling**

The second means of cooling requested in [10.3.1] may consist of a satisfactory connection to a lubricating oil pump of sufficient capacity. Arrangements are to be made against overpressure in the cooling system.

**10.6 Control and monitoring**

**10.6.1** Alarms are to be provided for water cooling systems in accordance with Tab 28, in addition to the requirements stated for diesel engines in Ch 1, Sec 2 and for steam plants in Ch 1, Sec 4.

Note 1: Some departures from Tab 28 may be accepted by the Society in the case of ships with a restricted navigation notation.

**Table 28 : Cooling systems**

Symbol convention H = High, HH = High high, L = Low, LL = Low low, X = function is required, G = group alarm I = individual alarm R = remote	Monitoring		Automatic control				
			System			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Sea water pump pressure or flow	L	local					
Fresh water pump pressure or flow	L	local					
Level in cooling water expansion tank	L	local					

**10.7 Arrangement of cooling systems**

**10.7.1 Sea inlets**

- a) At least two sea inlets complying with [2.8] are to be provided for the cooling system, one for each means of cooling required in [10.3.1].
- b) The two sea inlets may be connected by a cross-over supplying both main cooling pump and standby cooling pump.
- c) When the second means of cooling is a spare pump, the two sea inlets are to be provided in any event, both serving the main cooling pump.
- d) The sea inlets are to be low inlets, so designed as to remain submerged under all normal navigating conditions. In general, one sea inlet is to be arranged on each side of the ship.
- e) One of the sea inlets may be that of the ballast pump or of the general service pump.

**10.7.2 Coolers**

- a) Coolers are to be fitted with isolating valves at the inlets and outlets.
- b) Coolers external to the hull (chest coolers and keel coolers) are to be fitted with isolating valves at the shell.

**10.7.3 Filters**

- a) Where propulsion engines and auxiliary engines for essential services are directly cooled by sea water, both in normal service and in emergency operating conditions, filters are to be fitted on the suction of cooling pumps.
- b) These filters are to be so arranged that they can be cleaned without interrupting the cooling water supply.

**10.7.4 Pumps**

- a) Cooling pumps for which the discharge pressure may exceed the design pressure of the piping system are to be fitted with relief valves in accordance with [2.5].
- b) Where general service pumps, ballast pumps or other pumps may be connected to a cooling system, arrangements are to be made, in accordance with [2.5], to avoid overpressure in any part of the cooling system.

**10.7.5 Air venting**

Cocks are to be installed at the highest points of the pipes conveying cooling water to the water jackets for venting air or gases likely to accumulate therein. In the case of closed fresh water cooling systems, the cock is to be connected to the expansion tank.

**11 Fuel oil systems**

**11.1 Application**

**11.1.1 Scope**

This Article applies to all fuel oil systems supplying any kind of installation.

The fuel oils used on board are to comply with Ch 1, Sec 1, [2.9].

### **11.1.2 Requirements applying to fuel oil systems and not contained in this Section**

Additional requirements are given:

- for fuel oil supply equipment forming part of engines, gas turbines, boilers, thermal heaters and incinerators, in the corresponding sections
- for the installation of purifiers, in Part C, Chapter 4,
- for the location and scantling of tanks forming part of the ship's structure, in Part B, Chapter 2 and Part B, Chapter 7
- for auxiliary vehicles refuelling facilities, in Ch 4, Sec 11.

## **11.2 Principle**

### **11.2.1 General**

- a) Fuel oil systems are to be so designed as to ensure the proper characteristics (purity, viscosity, pressure) of the fuel oil supply to engines and boilers.
- b) Fuel oil systems are to be so designed as to prevent:
  - overflow or spillage of fuel oil from tanks, pipes, fittings, etc.
  - fuel oil from coming into contact with sources of ignition
  - overheating and seizure of fuel oil.
- c) Fuel oils used for engines and boilers are to have a flashpoint complying with the provisions of Ch 1, Sec 1, [2.9].

### **11.2.2 Availability of fuel systems**

- a) Fuel oil systems are to be so designed that, in the event that any one essential auxiliary of such systems becomes inoperative, the fuel oil supply to boilers and engines can be maintained. Partial reduction of the propulsion capability may be accepted, however, when it is demonstrated that the safe operation of the ship is not impaired.
- b) Fuel oil tanks are to be so arranged that, in the event of damage to any one tank, complete loss of the fuel supply to essential services does not occur.
- c) Where engines and boilers are operated with heavy fuel oils, provisions are to be made to supply them with fuel oils which do not need to be heated.

## **11.3 General**

### **11.3.1 Arrangement of fuel oil systems**

- a) In a ship in which fuel oil is used, the arrangements for the storage, distribution and utilisation of the fuel oil are to be such as to ensure the safety of the ship and persons on board.
- b) The provisions of [5.10] are to be complied with.

### **11.3.2 Valve for oil fuel pumps**

Stop valves or cocks are to be fitted on both suction and delivery sides of oil fuel pumps. All oil fuel pumps are to be provided with pressure relief valves on the discharge side so that the discharged oil may be led to the suction side of the pump. Pressure relief valves need not be fitted when the system is served only by centrifugal pumps, so designed that the pressure delivered cannot exceed that for which the piping is designed.

### **11.3.3 Provision to prevent overpressure**

Provisions are to be made to prevent overpressure in any oil tank or in any part of the fuel oil system. Any relief valve is to discharge to a safe position.

### **11.3.4 Ventilation**

The ventilation of machinery spaces is to be sufficient under all normal conditions to prevent accumulation of oil vapour.

### **11.3.5 Access**

Spaces where fuel oil is stored or handled are to be readily accessible.

## **11.4 Design of fuel oil filling and transfer systems**

### **11.4.1 General**

- a) A system of pumps and piping for filling and transferring fuel oil is to be provided.
- b) Provisions are to be made to allow the transfer of fuel oil from any storage, settling or service tank to another tank.

### 11.4.2 Filling systems

- a) Filling pipes of fuel oil tanks are to terminate on open deck or in filling stations isolated from other spaces and efficiently ventilated. Suitable coamings and drains are to be provided to collect any leakage resulting from filling operations.  
The means shall be provided for the filling lines to prevent of possible overpressure during the bunkering operation, which could be caused by pumps from outboard filling station. For that purpose a warning label may be accepted with clearly declared design pressure of the filling lines and the local pressure gauge fitted in vicinity of the filling connection.
- b) Arrangements are to be made to avoid overpressure in the filling lines which are served by pumps on board. Where safety valves are provided for this purpose, they are to discharge to the overflow tank referred to in [9.3.3] or to other safe positions deemed satisfactory.

### 11.4.3 Independence of fuel oil transfer lines

Except where permitted in [11.4.4], the fuel oil transfer piping system is to be completely separate from the other piping systems of the ship.

### 11.4.4 Alternative carriage of fuel oil, ballast water or other liquid and dry cargo

Where certain compartments are likely to contain alternatively fuel oil, ballast water and other liquid or dry cargo, the transfer pipes supplying these compartments are to be fitted with blind flanges or other appropriate change-over devices.

### 11.4.5 Transfer pumps

- a) At least two means of transfer are to be provided. One of these means is to be a power pump. The other may consist of:
- a standby pump, or, alternatively,
  - an emergency connection to another suitable power pump.

Note 1: Where provided, purifiers may be accepted as means of transfer.

- b) Where necessary, transfer pumps are to be fitted on their discharge side with a relief valve leading back to the suction of the pump or to any other place deemed satisfactory.

## 11.5 Arrangement of fuel oil tanks and bunkers

### 11.5.1 Location of fuel oil tanks

- a) No fuel oil tank is to be situated where spillage or leakage therefrom can constitute a hazard by falling on heated surfaces.
- b) Fuel oil tanks and bunkers are not to be situated immediately above boilers or in locations where they could be subjected to high temperatures, unless specially agreed by the Society. In general, the distance between fuel oil tanks and boilers is not to be less than 450 mm. Where boilers are situated above double bottom fuel oil tanks, the distance between the double bottom tank top and the lower metallic part of the boilers is not to be less than:
- 750 mm for water tube boilers
  - 600 mm for cylindrical boilers.
- c) As far as practicable, fuel oil tanks are to be part of the ship's structure and are to be located outside machinery spaces of category A. Where fuel oil tanks, other than double bottom tanks, are necessarily located adjacent to or within machinery spaces of category A, at least one of their vertical sides is to be contiguous to the machinery space boundaries, and is preferably to have a common boundary with the double bottom tanks, and the area of the tank boundary common with the machinery spaces is to be kept to a minimum. Where such tanks are situated within the boundaries of machinery spaces of category A, they are not to contain fuel oil having a flashpoint of less than 60°C.

Note 1: Machinery spaces of category A are defined in Ch 4, Sec 1.

- d) The location of fuel oil tanks is to be in compliance with the requirements of Part B, Chapter 2, particularly as regards the installation of cofferdams, the separation between fuel oil tanks or bunkers and the other spaces of the ship, and the protection of these tanks and bunkers against any abnormal rise in temperature.
- e) Attention is drawn to the requirements of Pt D, Ch 7, Sec 4 regarding the segregation of fuel bunkers from the cargo area.

### 11.5.2 Use of free-standing fuel oil tanks

- a) In general the use of free-standing fuel oil tanks is to be avoided except on cargo ships, where their use is permitted in category A spaces.
- b) For the design and the installation of independent tanks, refer to Pt B, Ch 5, Sec 6 and Part B, Chapter 7.

### 11.5.3 Protection against oil pollution in the event of collision or grounding

- a) Application

The provisions of [11.5.3] apply to all ships with an aggregate oil fuel capacity of 600 m<sup>3</sup> and above.

They apply to all oil fuel tanks except small oil fuel tanks with a maximum individual capacity not exceeding 30 m<sup>3</sup>, provided that the aggregate capacity of such excluded tanks is not greater than 600 m<sup>3</sup>.

Note 1: For the purpose of application of this requirement, oil fuel means any oil used as fuel oil in connection with the propulsion and auxiliary machinery of the ship in which such oil is carried.

Note 2: The provisions of this requirement apply to oil fuel overflow tanks except if they are provided with an alarm for detection of oil and kept empty according to the operational procedures.

b) Maximum capacity of oil fuel tanks

Individual oil fuel tanks are not to have a capacity of over 2500 m<sup>3</sup>.

c) Oil fuel tank protection

For ships having an aggregate oil fuel capacity of 600 m<sup>3</sup> and above, oil fuel tanks are to be located at a sufficient distance from the bottom shell plating and from the side shell plating in accordance with the relevant provisions of MARPOL 73/78, Annex I, Regulation 12A.

d) Suction wells

Suction wells in oil fuel tanks may protrude in the double bottom provided that the conditions stated in MARPOL 73/78, Annex I, Regulation 12A.10 are satisfied.

e) Valves

Lines of fuel oil piping located at a distance from the ship's bottom or from the ship's side less than those referred to in item c) are to be fitted with valves or similar closing devices within, or immediately adjacent to, the oil fuel tank. These valves are to be capable of being brought into operation from a readily accessible enclosed space the location of which is accessible from the navigation bridge or propulsion machinery control position without traversing exposed freeboard or superstructure decks. The valves are to close in case of remote control system failure and are to be kept closed at sea at any time when the tank contains oil fuel except that they may be opened during oil fuel transfer operations.

## 11.6 Design of fuel oil tanks and bunkers

### 11.6.1 General

Tanks such as collector tanks, de-aerator tanks etc. are to be considered as fuel oil tanks for the purpose of application of this sub-article, and in particular regarding the valve requirements.

Tanks with a volume lower than 500 l will be given special consideration by the Society.

### 11.6.2 Scantlings

The scantlings of fuel oil tanks and bunkers are to comply with the requirements stated in Part B, Chapter 7.

### 11.6.3 Filling and suction pipes

- a) All suction pipes from fuel oil tanks and bunkers, including those in the double bottom, are to be provided with valves.
- b) For storage tanks, filling pipes may also be used for suction purposes.
- c) For fuel oil tanks which are situated higher than the double bottom tanks, the filling pipes which are connected to the tank at a point lower than the outlet of the overflow pipe, or below the top of tanks without an overflow pipe, are to be fitted with shut-off non-return valves, unless they are fitted with valves arranged in accordance with the requirements stated in [11.6.4]. For filling lines entering at the top of a tank and with inside extension towards the bottom, airholes shall be drilled in the pipe near the penetration in order to avoid the siphoning effect.
- d) For oil piping which is led through engine room bulkheads, shut-off valves are to be fitted in the engine room on the bulkhead, or close to, except where it is demonstrated that possible failure of the piping would not affect the availability of the fuel oil system or the safety of engine room, in general.
- e) The valves requested in items a), c) and d) shall be located on the tank or bulkhead itself. However, short distance pieces of rigid construction may be accepted, the length of which is not to exceed about 1,5 D of the pipe.

### 11.6.4 Remote control of valves

- a) Every fuel oil pipe which, if damaged, would allow oil to escape from a storage, settling or daily service tank having a capacity of 500 l and above situated above the double bottom, is to be fitted with a cock or valve directly on the tank capable of being closed from a safe position outside the space in which such tanks are situated in the event of a fire occurring in such space.

Note 1: For the location of the remote controls, refer to [11.10.3], item c).

- b) Such valves and cocks are also to include local control. Indicators are to be provided on the remote and local controls to show whether they are open or shut (see [2.7.3]). Where quick-closing valves are used, the indicators for remote controls may be omitted.
- c) In the special case of deep tanks situated in any shaft or pipe tunnel or similar space, valves are to be fitted on the tank but control in the event of fire may be effected by means of an additional valve on the pipe or pipes outside the tunnel or similar space. If such additional valve is fitted in the machinery space it is to be operated from a position outside this space.

Note 2: For cargo ships of less than 500 gross tonnage and non-propelled ships where the fuel oil transfer installation is designed for manual operation, suction valves from fuel oil tanks and bunkers, with the exception of daily service tanks, need not be arranged with remote controls provided they are maintained closed except during transfer operations. Such valves are, however, to be readily accessible and instruction plates are to be fitted in their vicinity specifying that they are to be kept closed except during transfer operations.

### 11.6.5 Drain pipes

Where fitted, drain pipes are to be provided with self-closing valves or cocks.

### **11.6.6 Air and overflow pipes**

Air and overflow pipes are to comply with [9.1] and [9.3].

### **11.6.7 Sounding pipes and level gauges**

- a) Safe and efficient means of ascertaining the amount of fuel oil contained in any fuel oil tank are to be provided.
- b) Sounding pipes of fuel oil tanks are to comply with the provisions of [9.2].
- c) Oil-level gauges complying with [2.9.2] may be used in place of sounding pipes.
- d) Gauge cocks for ascertaining the level in the tanks are not to be used.

## **11.7 Design of fuel oil heating systems**

### **11.7.1 General**

- a) Where heavy fuel oil is used, a suitable heating system is to be provided for storage tanks, settling tanks and service tanks in order to ensure that the fuel oil has the correct fluidity and the fuel pumps operate efficiently.
- b) Where necessary for pumping purposes, storage tanks containing heavy fuel oil are to be provided with heating systems.
- c) Where necessary, pumps, filters, pipes and fittings are to be provided with heat tracing systems.
- d) Where main or auxiliary engines are supplied with fuel oil which needs to be heated, arrangements are to be made so that the engines can still operate if one oil heating system or the heating power source is out of action. Such arrangements may consist of an alternative supply of the engines in accordance with [11.9.2].

### **11.7.2 Tank heating systems**

- a) Oil fuel in storage tanks are not to be heated to temperatures within 10°C below the flashpoint of the fuel oil, except that, where oil fuel in service tanks, settling tanks and any other tanks in supply system is heated, the following arrangements are to be provided:
  - the length of the vent pipes from such tanks and/or a cooling device is sufficient for cooling the vapours to below 60°C, or the outlet of the vent pipes is located 3 m away from a source of ignition
  - the vent pipes are fitted with flame screens
  - there are no openings from the vapour space of the fuel tanks into machinery spaces (bolted manholes are acceptable)
  - enclosed spaces are not to be located directly over such fuel tanks, except for vented cofferdams
  - electrical equipment is not to be fitted in the vapour space of the tanks, unless it is certified to be intrinsically safe.
- b) The temperature of the heating medium is not to exceed 220°C.
- c) Automatic control sensors are to be provided for each heated tank to maintain the temperature of the fuel oil below the limits prescribed in item a).

For storage tanks, the manual control may be accepted subject to special consideration by the Society in each case.
- d) Heated tanks are to be provided with temperature measuring systems.
- e) The heating coils inlet and outlet connections at the tank are to be fitted with suitable means for closing. For steam heating coils, additional means are to be provided between tank outlet and closing device to enable testing the condensate for presence of oil.

Heating pipes and coils inside the tanks are to be of material suitable for the heated fluid.

For steel pipes, the thickness is not to be less than the values given in column 4, with Note (4), of Tab 6.

The heating coils within the tanks are to have welded connections and are to be supported in such a way that they are not subject to non permissible stress due to vibration or thermal extension.

### **11.7.3 Fuel oil heaters**

- a) Where steam heaters or heaters using other heating media are provided in fuel oil systems, they are to be fitted with at least a high temperature alarm or a low flow alarm in addition to a temperature control, except where temperatures dangerous for the ignition of the fuel oil cannot be reached.
- b) Electric heating of fuel oil is to be avoided as far as practicable.
- c) However, when electric heaters are fitted, means are to be provided to ensure that heating elements are permanently submerged during operation. In all cases a safety temperature switch is to be fitted in order to avoid a surface temperature of 220°C and above. It is to be:
  - independent from the automatic control sensor
  - designed to cut off the electrical power supply in the event of excessive temperature
  - provided with manual reset.
- d) Fuel oil heaters are to be fitted with relief valves leading back to the pump suction concerned or to any other place deemed satisfactory.

## **11.8 Design of fuel oil treatment systems**

### **11.8.1 General**

- a) Heavy fuel oils used in diesel engines are to be purified and filtered according to the engine manufacturer's requirements.
- b) Provisions are to be made to avoid inadvertent entry of non-purified heavy fuel into the daily service tanks, in particular through the overflow system.

Note 1: The "fuel oil treatment system" does not cover the use of additives.

### **11.8.2 Drains**

- a) Settling tanks or, where settling tanks are not provided, daily service tanks, are to be provided with drains permitting the evacuation of water and impurities likely to accumulate in the lower part of such tanks.
- b) Efficient means are to be provided for draining oily water escaping from the drains.

### **11.8.3 Purifiers**

- a) Where fuel oil needs to be purified, at least two purifiers are to be installed on board, each capable of efficiently purifying the amount of fuel oil necessary for the normal operation of the engines.

Note 1: On ships with a restricted navigation notation where fuel oil needs to be purified, one purifier only may be accepted.

- b) Subject to special consideration by the Society, the capacity of the standby purifier may be less than that required in a), depending on the arrangements made for the fuel oil service tanks to satisfy the requirement in [11.9.2].
- c) The standby purifier may also be used for other services.
- d) Each purifier is to be provided with an alarm in case of failures likely to affect the quality of the purified fuel oil.
- e) Fuel oil purifiers are to be installed as required in Part C, Chapter 4.

## **11.9 Design of fuel supply systems**

### **11.9.1 General**

- a) Except otherwise specified, the propulsion machinery and auxiliary engines which are able to use the same type of fuel may be supplied from the same fuel source, provided that the following is satisfied:
  - the viscosity, inlet pressure and outlet pressure required by the engine's manufacturer are to be identical
  - the fuel oil preparation unit is to comply with the provisions of [11.9.4]
  - the capacity of fuel oil preparation unit is to be sufficient for maximum continuous rating of all supplied engines in normal working conditions
  - the fuel oil lines supplying propulsion machinery and those supplying auxiliary engines are to be so arranged that a failure within one of those lines is not to render the other lines inoperable
  - the arrangement to stop propulsion from outside the machinery spaces is not to affect the main electrical power supply.
- b) In ships where heavy fuel oil and marine diesel oil are used, a change-over system from one fuel to the other is to be provided. This system is to be so designed as to avoid:
  - overheating of marine diesel oil
  - inadvertent ingress of heavy fuel oil into marine diesel oil tanks.
- c) When necessary, arrangements are to be made for cooling the marine diesel oil from engine return lines.

See also Part F for requirements associated with the applicable additional class notations.

### **11.9.2 Fuel oil service tanks**

- a) A service tank is a fuel oil tank which contains only fuel of a quality ready for use i.e. fuel of a grade and quality that meet the specification required by the equipment manufacturer. A service tank is to be declared as such and not to be used for any other purpose.
- b) In general, two fuel oil service tanks for each type of fuel used on board necessary for propulsion and vital systems, or equivalent arrangements, are to be provided. Each tank is to have a capacity of at least 8 h at maximum continuous rating of the propulsion plant and normal operating load at sea of the generator plant.

- c) For "one fuel ship", where main and auxiliary engines and boiler(s) are operated with Heavy Fuel Oil (HFO), the arrangements complying with this regulation or acceptable "equivalent arrangements" shall be provided.

The arrangements complying with this regulation shall comprise at least the following tanks:

- two (2) HFO service tanks, each of a capacity sufficient for at least 8 h operation of main engine(s), auxiliary engines and auxiliary boiler(s), and
- one (1) Marine Diesel Oil (MDO) service tank for initial cold starting or repair work of engines or boilers.

Acceptable "equivalent arrangements" shall comprise at least:

- one (1) HFO service tank with a capacity sufficient for at least 8 h operation of main engine(s), auxiliary engines and auxiliary boiler(s), and
- one (1) MDO service tank with a capacity sufficient for at least 8 h operation of main engine(s), auxiliary engines and auxiliary boiler(s), and
- for pilot burners of auxiliary boilers, if provided, an additional MDO service tank for 8 h may be required.

This arrangement only applies where main and auxiliary engines can operate with HFO under all load conditions and, in the case of main engines, during manoeuvring.

- d) Where main engines and auxiliary boiler(s) are operated with Heavy Fuel Oil (HFO) and auxiliary engines are operating with Marine Diesel Oil (MDO), the arrangements complying with this regulation or acceptable "equivalent arrangements" shall be provided.

The arrangements complying with this regulation shall comprise at least the following tanks:

- two (2) HFO service tanks, each of a capacity sufficient for at least 8 h operation of main engine(s) and auxiliary boiler(s), and
- two (2) MDO service tanks each of a capacity sufficient for at least 8 h operation of auxiliary engines.

Acceptable "equivalent arrangements" shall comprise at least:

- one (1) HFO service tank with a capacity sufficient for at least 8 h operation of main engine(s) and auxiliary boiler(s), and
- two (2) MDO service tanks, each of a capacity sufficient for:
  - 4 h operation of main engine(s), auxiliary engines and auxiliary boiler(s), or
  - 8 h operation of auxiliary engines and auxiliary boiler(s).

- e) The "equivalent arrangements" in items c) and d) apply, provided the propulsion and vital systems using two types of fuel support rapid fuel change over and are capable of operating in all normal operating conditions at sea with both types of fuel (MDO and HFO).
- f) The arrangement of oil fuel service tanks is to be such that one tank can continue to supply oil fuel when the other is being cleaned or opened up for repair.
- g) The use of a settling tank with or without purifiers, or purifiers alone, and one service tank is not acceptable as an "equivalent arrangement" to two service tanks.

Note 1: This requirement [11.9.2] need not be applied to cargo ships of less than 500 gross tonnage and non-propelled ships.

### 11.9.3 Fuel oil supply to boilers

- a) In ships where boilers burning oil under pressure are installed to supply steam to the propulsion machinery or auxiliary machinery serving essential services, the fuel oil supply system is to include at least the following equipment:
- Two independently driven fuel oil service pumps, each one of a capacity sufficient to supply the boilers at their rated output. The pumps are to be arranged such that one may be overhauled while the other is in service.
  - Filters or strainers fitted on the suction lines and so arranged that they can be cleaned without interrupting the fuel supply. For that purpose, two filters or strainers fitted in parallel, or one duplex type with a change over facility, may be accepted.
  - Two heaters in the case that fuel oil heating is required, each one of a capacity sufficient to supply heated fuel oil to the boilers at their normal operating capacity. The heaters are to be arranged such that one may be overhauled while the other is in service.
- For boiler plants where exhaust gas boiler is fitted, such that steam service essential for propulsion can be supplied without the operation of the fuel oil system of the auxiliary boiler and that other essential services, as defined in Pt A, Ch 1, Sec 1, [1.2.1], are not to remain inoperable, only one fuel oil heater may be accepted.
- b) The fuel oil supply system is to be capable of supplying the fuel oil necessary to generate enough steam for propulsion purposes and essential services with one unit out of action.
- c) A quick-closing valve is to be provided on the fuel supply to the burners of each boiler, arranged to be easily operated in case of emergency, either directly or by remote control.
- d) The fuel supply to the burners is to be capable of being automatically cut off when required under Ch 1, Sec 3, [5.1.8].

- e) Burners are to comply with Ch 1, Sec 3, [2.2.5].
- f) Where burners are provided with fuel oil flow-back to the pump suctions or other parts under pressure, non-return devices are to be provided to prevent fuel oil from flowing back to the burners when the oil supply is cut off.
- g) Where fuel oil is supplied to the burners by gravity, a double filter satisfying the provisions of item a) is to be provided in the supply line.
- h) Fuel oil supply systems are to be entirely separate from feed, bilge, ballast and other piping systems.

#### **11.9.4 Fuel oil supply to internal combustion engines**

- a) The suctions of engine fuel pumps are to be so arranged as to prevent the pumping of water and sludge likely to accumulate after decanting at the lower part of service tanks.
- b) Internal combustion engines intended for main propulsion are to be fitted with at least two filters, or similar devices, so arranged that one of the filters can be overhauled while the other is in use.

Note 1: Where the propulsion plant consists of:

- two or more engines, each one with its own filter, or
- one engine with an output not exceeding 375 kW,  
the second filter may be replaced by a readily accessible and easily replaceable spare filter.

- c) Oil filters fitted in parallel are to be so arranged as to minimise the possibility of a filter under pressure being opened by mistake.

Filter chambers are to be provided with suitable means for:

- venting when put into operation
- de-pressurising before being opened.

Valves or cocks used for this purpose are to be fitted with drain pipes led to a safe location.

- d) Oil filters are to be so located that in the event of a leakage the fuel oil cannot be pulverised onto the exhaust manifold.
- e) When a fuel oil booster pump is fitted which is essential to the operation of the main engine, a standby pump, connected ready for immediate use, is to be provided.  
The standby pump may be replaced by a complete spare pump of appropriate capacity ready to be connected, in the following cases:
  - where two or more main engines are fitted, each with its own booster pump
  - in ships having main engines each with an output not exceeding 375 kW.
- f) Where fuel oils require pre-heating in order to have the appropriate viscosity when being injected in the engine, the following equipment is to be provided in the fuel oil line:
  - one viscosity control and monitoring system
  - two pre-heaters, one serving as a standby for the other.
- g) Excess fuel oil from pumps or injectors is to be led back to the service or settling tanks, or to other tanks intended for this purpose.
- h) De-aeration tanks fitted in pressurised fuel oil return lines are to be equipped with at least:
  - an automatic venting valve or equivalent device discharging to the daily service tank or to other safe place deemed satisfactorily having a device for flow detection.
  - a non-return valve in the return line from the engines.
- i) For high pressure fuel oil pipes and other components which may be built-in or attached to the engine, see Ch 1, Sec 2, [2.5].  
Anyhow, the components of a diesel engine fuel oil system are to be designed considering the maximum peak pressure which will be experienced in service, including any high pressure pulses which are generated and transmitted back into the fuel supply and spill lines by the action of fuel injection pumps.
- j) Connections within the fuel supply and spill lines are to be constructed having regard to their ability to prevent pressurised fuel oil leaks while in service and after maintenance.
- k) In multi-engine installations which are supplied from the same fuel source, means of isolating the fuel supply and spill piping to individual engines are to be provided. The means of isolation are not to affect the operation of the other engines and shall be operable from a position not rendered inaccessible by a fire on any of the engines.

### **11.10 Control and monitoring**

#### **11.10.1 Monitoring**

Alarms and safeguards are to be provided for fuel oil systems in accordance with Tab 29.

Note 1: Some departures from Tab 29 may be accepted by the Society in the case of ships with a restricted navigation notation.

#### **11.10.2 Automatic controls**

Automatic temperature control is to be provided for:

- steam heaters or heaters using other media
- electric heaters.

**11.10.3 Remote controls**

- a) The remote control arrangement of valves fitted on fuel oil tanks is to comply with [11.6.4].
- b) The power supply to:
  - fuel oil burning pumps
  - transfer pumps and other pumps of the fuel oil system, and
  - fuel oil purifiers,
 is to be capable of being stopped from a position within the space containing the pumps and from another position located outside such space and always accessible in the event of fire within the space.
- c) Remote control of the valve fitted to the emergency generator fuel tank is to be in a separate location from that of other valves fitted to tanks in the engine room.  
 “Separate location” does not mean separate spaces.
- d) The positions of the remote controls are also to comply with Part C, Chapter 3.

**11.11 Construction of fuel oil piping systems**

**11.11.1 Materials**

- a) Fuel oil pipes and their valves are to be of steel or other approved material, except that the use of flexible pipes may be accepted provided they comply with [2.6.4].
- b) The materials and/or their surface treatment used for the storage and distribution of oil fuel are to be selected such that they do not introduce contamination or modify the properties of the fuel. In addition to the criterion given in Tab 5, the use of copper or zinc compounds in oil fuel distribution and utilisation piping is not permitted except for small diameter pipes in low pressure systems.

**11.11.2 Pipe thickness**

The thickness of pipes conveying heated fuel oil, as well as their flanges, is to be calculated for a design pressure determined in accordance with Tab 4.

**Table 29 : Fuel oil systems**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			System			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Fuel oil overflow tank level	H (1)						
Air pipe water trap level on fuel oil tanks	H (2)						
Fuel oil temperature after heaters	H (4)	local		X (5)			
Sludge tank level		local					
Fuel oil settling tank temperature	H (3)	local					
Fuel oil level in daily service tank	L+H (1)	local					
Fuel oil daily service tank temperature	H (3)	local					

(1) Or sightglasses on the over flow pipe, see [9.3.4], item d).  
 (2) Or alternative arrangement as per [9.1.7], item c).  
 (3) Applicable where heating arrangements are provided.  
 (4) Or low flow alarm in addition to temperature control when heated by steam or other media.  
 (5) Cut off of electrical power supply when electrically heated.

**11.11.3 Pipe connections**

- a) Connections and fittings of pipes containing fuel oil are to be suitable for a design pressure according to Tab 3 and Tab 4.
- b) Connections of pipes conveying heated fuel oil are to be made by means of close-fitting flanges, with joints made of a material impervious to oil heated to 160°C and as thin as possible.

**11.12 Arrangement of fuel oil piping systems**

**11.12.1 Passage of fuel oil pipes through tanks**

- a) Fuel pipes are not to pass through tanks containing boiler feed water, fresh water, other flammable oil or liquid cargo, unless they are contained within tunnels.
- b) Transfer pipes passing through ballast tanks are to have a reinforced thickness complying with Tab 6.

### **11.12.2 Passage of pipes through fuel oil tanks**

Boiler feed water, fresh water or liquid cargo pipes are not to pass through fuel oil tanks, unless such pipes are contained within tunnels.

### **11.12.3 Segregation of fuel oil purifiers**

Purifiers for heated fuel oil are to be in accordance with Ch 4, Sec 6, [4.1.2].

## **12 Lubricating oil systems**

### **12.1 Application**

**12.1.1** This Article applies to lubricating oil systems serving diesel engines, steam and gas turbines, reduction gears, clutches and controllable pitch propellers, for lubrication or control purposes.

It also applies to separate oil systems intended for the cooling of engine pistons.

### **12.2 Principle**

#### **12.2.1 General**

- a) Lubricating oil systems are to be so designed as to ensure reliable lubrication of the engines, turbines and other equipment, including electric motors, intended for propulsion:
  - over the whole speed range, including starting, stopping and, where applicable, manoeuvring
  - for all the inclinations angles stated in Ch 1, Sec 1
- b) Lubricating oil systems are to be so designed as to ensure sufficient heat transfer and appropriate filtration of the oil.
- c) Lubricating oil systems are to be so designed as to prevent oil from entering into contact with sources of ignition.

#### **12.2.2 Availability**

- a) Lubricating oil systems are to be so designed that, in the event that any one pump is inoperative, the lubrication of the engines and other equipment is maintained. Partial reduction of the propulsion capability may be accepted, however, when it is demonstrated that the safe operation of the ship is not impaired.
- b) An emergency lubricating system, such as a gravity system, is to be provided to ensure sufficient lubrication of equipment which may be damaged due to a failure of the pump supply.

### **12.3 General**

#### **12.3.1 Arrangement of lubricating oil systems**

- a) The arrangements for the storage, distribution and utilisation of oil used in pressure lubrication systems are to be such as to ensure the safety of the ship and persons on board.
- b) The provisions of [5.10] are to be complied with, where applicable.

#### **12.3.2 Filtration**

- a) In forced lubrication systems, a device is to be fitted which efficiently filters the lubricating oil in the circuit.
- b) The filters provided for this purpose for main machinery and machinery driving electric propulsion generators are to be so arranged that they can be easily cleaned without stopping the lubrication of the machines.
- c) The fineness of the filter mesh is to comply with the requirements of the engine or turbine manufacturers.
- d) Where filters are fitted on the discharge side of lubricating oil pumps, a relief valve leading back to the suction or to any other convenient place is to be provided on the discharge of the pumps.

#### **12.3.3 Purification**

Where lubricating oil needs to be purified, the arrangement of the purifiers are to comply with [11.8.3].

#### **12.3.4 Heat transfer**

Lubricating oil heaters are to comply with [11.7.3].

## 12.4 Design of engine lubricating oil systems

### 12.4.1 Lubrication of propulsion engines

- a) Main engines are to be provided with at least two power lubricating pumps, of such a capacity as to maintain normal lubrication with any one pump out of action.
- b) In the case of propulsion plants comprising:
  - more than one engine, each with its own lubricating pump, or
  - one engine with an output not exceeding 220 kW, one of the pumps mentioned in item a) may be a spare pump ready to be connected to the lubricating oil system, provided disassembling and reassembling operations can be carried out on board in a short time.

### 12.4.2 Lubrication of auxiliary engines

- a) For auxiliary engines with their own lubricating pump, no additional pump is required.
- b) For auxiliary engines with a common lubricating system, at least two pumps are to be provided. However, when such engines are intended for non-essential services, no additional pump is required.

### 12.4.3 Piston cooling

The requirements in [12.4.2] are also applicable to separate oil systems intended for the cooling of pistons.

## 12.5 Design of steam turbine lubrication systems

### 12.5.1 General

An alarm device is to be provided giving audible warning in the event of damage or of an appreciable reduction of the oil pressure.

### 12.5.2 Lubrication of propulsive turbines and turbogenerators

- a) Propulsive turbines and turbogenerators are to be provided with:
  - one main lubricating pump, and
  - one independently driven standby pump of at least the same capacity.
- b) Lubricating systems for propulsive turbines and turbogenerators are to be provided with a device which stops the steam supply to the turbines (see [12.7.1]).

### 12.5.3 Emergency lubrication of propulsive turbines and turbogenerators

- a) Propulsive turbines and turbogenerators are to be provided with an emergency lubricating system arranged for automatic start (see [12.7.1]).
- b) When a gravity system is provided for the purpose of a), it is to ensure an adequate lubrication for not less than six minutes and, in the case of turbogenerators, for a period at least equal to the stopping period after unloading.
- c) When the emergency supply is fulfilled by means of an emergency pump, it is to be so arranged that its operation is not affected by a failure of the power supply.
- d) Suitable arrangements for cooling the bearings after stopping may also be required.

### 12.5.4 Lubrication of auxiliary turbines intended for essential services

- a) Auxiliary turbines intended for essential services are to be provided with:
  - one main lubricating pump, and
  - one independently driven standby pump of at least the same capacity.
- b) The standby pump is to be capable of supplying satisfactory lubrication to the turbines during starting and stopping operations.

## 12.6 Design of lubricating oil tanks

### 12.6.1 Remote control of valves

Lubricating oil tanks with a capacity of 500 litres and above are to be fitted with remote controlled valves in accordance with the provisions of [11.6.4].

The remote controlled valves need not be arranged for storage tanks on which valves are normally closed except during transfer operation, or where it is determined that an unintended operation of a quick closing valve on the oil lubricating tank would endanger the safe operation of the main propulsion and essential auxiliary machinery.

### 12.6.2 Filling and suction pipes

Filling and suction pipes are to comply with the provisions of [11.6.3].

### 12.6.3 Air and overflow pipes

Air and overflow pipes are to comply with the provisions of [9.1] and [9.3].

**12.6.4 Sounding pipes and level gauges**

- a) Safe and efficient means of ascertaining the amount of lubricating oil contained in the tanks are to be provided.
- b) Sounding pipes are to comply with the provisions of [9.2].
- c) Oil-level gauges complying with [2.9.2] may be used in place of sounding pipes.
- d) Gauge cocks for ascertaining the level in the tanks are not to be used.

**12.6.5 Oil collecting tanks for engines**

- a) In ships required to be fitted with a double bottom, wells for lubricating oil under main engines may be permitted by the Society provided it is satisfied that the arrangements give protection equivalent to that afforded by a double bottom complying with Pt B, Ch 2, Sec 2.
- b) Where, in ships required to be fitted with a double bottom, oil collecting tanks extend to the outer bottom, a valve is to be fitted on the oil drain pipe, located between the engine sump and the oil drain tank. This valve is to be capable of being closed from a readily accessible position located above the working platform.  
Alternative arrangements will be given special consideration.

- c) Oil collecting pipes from the engine sump to the oil collecting tank are to be submerged at their outlet ends.

**12.7 Control and monitoring**

**12.7.1** In addition to the requirements in:

- Ch 1, Sec 2 for diesel engines,
- Ch 1, Sec 4 for steam turbines,
- Ch 1, Sec 5 for gas turbines and
- Ch 1, Sec 6 for gears,

alarms are to be provided for lubricating oil systems in accordance with Tab 30.

Note 1: Some departures from Tab 30 may be accepted by the Society in the case of ships with a restricted navigation notation.

**Table 30 : Lubricating oil systems**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			System			Auxiliary	
	Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start
Air pipe water trap level of lubricating oil tank <b>(1)</b>	H						
Sludge tank level		local					
<b>(1)</b> See [9.1.7].							

**12.8 Construction of lubricating oil piping systems**

**12.8.1 Materials**

The materials used in the storage and distribution of lubricating oil are to be selected such that they do not introduce contaminants or modify the properties of the oil. In addition to the criterion given in Tab 5, the use of cadmium or zinc in lubricating oil systems, where they may normally come into contact with the oil, is not permitted.

**12.8.2 Air and overflow pipes**

Air and overflow pipes are to comply with [9.1] and [9.3], including [5.10], as applicable.

**12.8.3 Sounding pipes and level gauges**

- a) Safe and efficient means of ascertaining the amount of oil contained in any lubricating oil tank are to be provided.
- b) Sounding pipes of lubricating oil tanks are to comply with the provisions of [9.2].
- c) Oil-level gauges complying with [2.9.2] may be used in place of sounding pipes.
- d) Gauge cocks for ascertaining the level in the tanks are not to be used.

## 13 Thermal oil systems

### 13.1 Application

**13.1.1** This Article applies to all thermal oil systems involving organic liquids heated below their initial boiling temperature at atmospheric pressure by means of:

- oil fired heaters,
- exhaust gas heaters, or
- electric heaters.

### 13.2 Principle

#### 13.2.1 General

Thermal oil systems are to be so designed as to:

- avoid overheating of the thermal oil and contact with air
- take into account the compatibility of the thermal oil with the heated products in case of contact due to leakage of coils or heater tubes
- prevent oil from coming into contact with sources of ignition.

#### 13.2.2 Availability

Thermal oil systems are to be so designed that, in the event that any one essential auxiliary is inoperative, the thermal oil supply to essential services can be maintained. Partial reduction of the propulsion capability may be accepted, however, when it is demonstrated that the safe operation of the ship is not impaired.

### 13.3 General

#### 13.3.1 Limitations on use of thermal oil

- a) The oil is to be used in the temperature ranges specified by the producer. The delivery temperature is, however, to be kept 50°C below the oil distillation point.
- b) Thermal oil is not to be used for the direct heating of:
  - accommodation
  - fresh drinking water
  - liquid cargoes with flashpoints below 60°C, except where permitted in Part D, Chapter 7.

#### 13.3.2 Location of thermal oil system components

- a) Thermal oil heaters are normally to be located in spaces separated from main and auxiliary machinery spaces, as required in Ch 1, Sec 1, [3.7.3].
- b) Where demonstrated that the arrangement required in item a) is not practical, thermal oil heaters located in machinery spaces and protected by adequate screening may be accepted, subject to special consideration by the Society for each particular case.
- c) Drainage of spaces where thermal oil system components are located is to comply with [5.10.4], item f).

Note 1: For the purpose of application of Part C, Chapter 4, spaces where thermal oil heaters are located are to be considered as machinery spaces of category A.

#### 13.3.3 Provision for quick drainage and alternative arrangements

- a) Inlet and outlet valves of oil fired and exhaust fired heaters are to be arranged for remote closing from outside the compartment where they are situated.  
As an alternative, thermal oil systems are to be arranged for quick gravity drainage of the thermal oil contained in the system into a draining tank.
- b) The expansion tank is to be arranged for quick gravity drainage into a draining tank.  
However, where the expansion tank is located in a low fire risk space, the quick drainage system may be replaced by a remote controlled closing device for isolating the expansion tank.  
The quick drainage system and the alternative closing device are to be capable of being controlled from inside and outside the space containing the expansion tank.

#### 13.3.4 Ventilation

- a) Spaces containing thermal oil heaters are to be suitably mechanically ventilated.
- b) Ventilation is to be capable of being stopped from outside these spaces.

## **13.4 Design of thermal oil heaters and heat exchangers**

### **13.4.1 Thermal oil heaters**

Oil fired and exhaust-fired thermal oil heaters are to be designed, equipped and controlled in accordance with the requirements specified in Ch 1, Sec 3.

### **13.4.2 Heat exchangers**

Heat exchangers are to be designed and equipped in accordance with the requirements specified in Ch 1, Sec 3.

## **13.5 Design of storage, expansion and draining tanks**

### **13.5.1 Storage and draining tanks**

- a) The capacity of the storage tank is to be sufficient to compensate the losses expected in service.
- b) The capacity of the draining tank is to be sufficient to collect the quantity of thermal oil contained in the system, including the expansion tank.
- c) Storage and draining tanks may be combined.

### **13.5.2 Expansion tanks**

- a) The capacity of the expansion tank is to be sufficient to allow volume variations, due to temperature changes, of all the circulating oil.
- b) The expansion tank is to be so designed, installed and connected to the circuit as to ensure that the temperature inside the tank remains below 50°C.

### **13.5.3 Drain pipes**

Where provided, drains pipes of thermal oil tanks are to be fitted with self-closing valves or cocks.

### **13.5.4 Air pipes**

- a) Air pipes fitted to the expansion and drainage tanks are to be suitably sized to allow the quick gravity drainage referred to in [13.3.3].
- b) The applicable requirements of [9.1] are to be complied with.

### **13.5.5 Overflow pipes**

- a) The expansion tank is to be fitted with an overflow pipe led to the drainage tank. This overflow pipe may be combined with the quick draining line provided for in [13.3.3], item b).
- b) The applicable requirements of [9.3] are to be complied with.

### **13.5.6 Sounding pipes and level gauges**

- a) Sounding pipes are to comply with the provisions of [9.2].
- b) Level gauges are to comply with the provisions of [2.9.2].

## **13.6 Design of circulation and heat exchange systems**

### **13.6.1 Circulating pumps**

At least two circulating pumps are to be provided, of such a capacity as to maintain a sufficient flow in the heaters with any one pump out of action.

However, for circulating systems supplying non-essential services, one circulating pump only may be accepted.

### **13.6.2 Filters**

A device which efficiently filters the thermal oil is to be provided in the circuit.

In the case of essential services, the filters provided for this purpose are to be so arranged that they can be easily cleaned without stopping the thermal oil supply.

The fineness of the filter mesh is to comply with the requirements of the thermal oil heating installation manufacturer.

## **13.7 Control and monitoring**

### **13.7.1 Monitoring**

In addition to the requirements specified in Ch 1, Sec 3, [3.3.1], item c) and Ch 1, Sec 3, [5.3] for thermal heaters and heat exchangers, alarms and safeguards for thermal oil systems are to be provided in accordance with Ch 1, Sec 3, Tab 23.

Note 1: Some departures from Ch 1, Sec 3, Tab 23 may be accepted by the Society in the case of ships with a restricted navigation notation.

### **13.7.2 Remote control**

a) Remote control is to be arranged for:

- shut-off of circulating pumps
- quick drainage of the thermal oil system and expansion tank, or shut-off of the alternative devices (see [13.3.3])
- shut-off of the fuel supply to the oil fired heaters or of the exhaust gas supply to the exhaust gas heaters (see Ch 1, Sec 3, [5.3]).

The shut-off of the exhaust gas supply may be ensured either by the engine shut down or by an exhaust gas bypass.

b) Such control is to be possible from the space containing the thermal oil heaters and from another position located outside such space.

## **13.8 Construction of thermal oil piping systems**

### **13.8.1 Materials**

a) Materials are to comply with the provisions of [11.11.1].

b) Casings of pumps, valves and fittings are to be made of steel or other ductile material.

### **13.8.2 Pipe connections**

a) Pipe connections are to comply with Article [2.4] and to be suitable for the design temperature of the thermal oil system.

b) Screw couplings of a type approved by the Society may be accepted for pipes of an outside diameter not exceeding 15 mm provided they are fitted with cutting rings or equivalent arrangements.

c) The materials of the joints are to be impervious to thermal oil.

## **13.9 Thermal oil piping arrangements**

### **13.9.1 Passage of thermal oil pipes through certain spaces**

a) Thermal oil pipes are not to pass through accommodation or public spaces or control stations.

b) Unless they are located in tight manifolds, provided with appropriate means of internal inspection and with a leak collecting system, heat transfer oil pipes are not allowed in main and auxiliary machinery spaces specified in Ch 1, Sec 1, [3.7.4].

### **13.9.2 Discharge of relief valves**

Relief valves are to discharge to the drain tank.

### **13.9.3 Provision for de-aerating**

Provisions are to be made for automatic evacuation of air, steam and gases from the thermal oil system to a safe location.

## **14 Hydraulic systems**

### **14.1 Application**

#### **14.1.1 Hydraulic installations intended for essential services**

Unless otherwise specified, this Article applies to all hydraulic power installations intended for essential services as defined in Pt A, Ch 1, Sec 1, [1.2.1] and Ch 2, Sec 1, [3.2].

The hydraulic piping arrangement is also to comply with the provisions of:

- [5.10]
- Ch 1, Sec 7, [2.6] for clutches
- Ch 1, Sec 8, [2.6.2] for the blade pitch control system of controllable pitch propellers, and
- Ch 1, Sec 14, [2.6] for steering gears.

#### **14.1.2 Hydraulic installations not serving essential services**

Hydraulic power installations not serving essential services but located in spaces where sources of ignition are present are to comply with the provisions of [5.10], [14.3.2], [14.3.3], [14.4.4], [14.4.5] and [14.5.3].

#### **14.1.3 Low pressure or low power hydraulic installations**

Hydraulic power installations with a design pressure of less than 2,5 MPa and hydraulic power packs of less than 5 kW will be given special consideration by the Society.

#### **14.1.4 Very high pressure hydraulic installations**

Hydraulic power installations with a design pressure exceeding 35 MPa will be given special consideration by the Society.

## **14.2 Principles**

### **14.2.1 Design requirements**

As far as practicable, hydraulic systems are to be so designed as to:

- avoid any overload of the system
- maintain the actuated equipment in the requested position (or the driven equipment at the requested speed)
- avoid overheating of the hydraulic oil
- prevent hydraulic oil from coming into contact with sources of ignition.

### **14.2.2 Availability**

- a) As a rule, hydraulic systems are to be so designed that, in the event that any one essential component becomes inoperative, the hydraulic power supply to essential services can be maintained. Partial reduction of the propulsion capability may be accepted, however, when it is demonstrated that the safe operation of the ship is not impaired.
- b) When a hydraulic power system is simultaneously serving one essential system and other systems, it is to be ensured that:
  - operation of such other systems, or
  - a single failure in the installation external to the essential system, is not detrimental to the operation of the essential system.
- c) Provision b) applies in particular to steering gear.
- d) Hydraulic systems serving lifting or hoisting appliances, including platforms, ramps, hatch covers, lifts, etc., are to be so designed that a single failure of any component of the system may not result in a sudden undue displacement of the load or in any other situation detrimental to the safety of the ship and persons on board.

## **14.3 General**

### **14.3.1 Definitions**

- a) A power unit is the assembly formed by the hydraulic pump and its driving motor.
- b) An actuator is a component which directly converts hydraulic pressure into mechanical action.

### **14.3.2 Limitations of use of hydraulic oils**

- a) Oils used for hydraulic power installations are to have a flashpoint not lower than 150°C and be suitable for the entire service temperature range.
- b) The hydraulic oil is to be replaced in accordance with the specification of the installation manufacturer.

### **14.3.3 Location of hydraulic power units**

- a) Generally, the hydraulic power units are to be located outside machinery spaces containing the boilers, main engine, its auxiliaries or other sources of ignition. See Ch 1, Sec 1, [3.7.4].

This applies in particular for hydraulic equipment delivering pressure over 15 bar to the following equipment:

- controllable pitch propellers or main transverse thrust units
  - clutches
  - turbine manoeuvring steam valves
  - exhaust gas valves of diesel engines or gas damper control systems
  - hydraulically operated valves and pumps.
- b) Where demonstrated that the arrangement required in item a) is not practical, at least the following is to be provided:
    - Shields or similar protections are to be fitted around such hydraulic equipment as in order to avoid any accidental oil spray or mist to the hot surfaces or other sources of ignition.
    - The low level alarm required for hydraulic tanks of these circuits is to be triggered as soon as possible.
    - The automatic stop of hydraulic pumps is to be operated in the same circumstances, except where this stop can lead to propulsion stop.

## **14.4 Design of hydraulic pumps and accessories**

### **14.4.1 Power units**

- a) Hydraulic power installations are to include at least two power units so designed that the services supplied by the hydraulic power installation can operate simultaneously with one power unit out of service. A reduction of the performance may be accepted.
- b) Low power hydraulic installations not supplying essential services may be fitted with a single power unit, provided that alternative means, such as a hand pump, are available on board.

### **14.4.2 Pressure reduction units**

Pressure reduction units used in hydraulic power installations are to be duplicated.

**14.4.3 Filtering equipment**

- a) A device is to be fitted which efficiently filters the hydraulic oil in the circuit.
- b) Where filters are fitted on the discharge side of hydraulic pumps, a relief valve leading back to the suction or to any other convenient place is to be provided on the discharge of the pumps.

**14.4.4 Provision for cooling**

Where necessary, appropriate cooling devices are to be provided.

**14.4.5 Provision against overpressure**

- a) Safety valves of sufficient capacity are to be provided at the high pressure side of the installation.
- b) Safety valves are to discharge to the low pressure side of the installation or to the service tank.

**14.4.6 Provision for venting**

Cocks are to be provided in suitable positions to vent the air from the circuit.

**14.4.7 Provision for drainage**

Provisions are to be made to allow the drainage of the hydraulic oil contained in the installation to a suitable collecting tank.

**14.5 Design of hydraulic tanks and other components**

**14.5.1 Hydraulic oil service tanks**

- a) Service tanks intended for hydraulic power installations supplying essential services are to be provided with at least:
  - a level gauge complying with [2.9.2]
  - a temperature indicator
  - a level switch complying with [14.6.2].
- b) The free volume in the service tank is to be at least 10% of the tank capacity.

**14.5.2 Hydraulic oil storage tanks**

- a) Hydraulic power installations supplying essential services are to include a storage tank of sufficient capacity to refill the whole installation should the need arise in case of necessity.
- b) For hydraulic power installations of less than 5 kW, the storage means may consist of sealed drums or tins stored in satisfactory conditions.

**14.5.3 Hydraulic accumulators**

The hydraulic side of the accumulators which can be isolated is to be provided with a relief valve or another device offering equivalent protection in case of overpressure.

**14.6 Control and monitoring**

**14.6.1 Indicators**

Arrangements are to be made for connecting a pressure gauge where necessary in the piping system.

**14.6.2 Monitoring**

Alarms and safeguards for hydraulic power installations intended for essential services, except steering gear, for which the provisions of Ch 1, Sec 14 apply, are to be provided in accordance with Tab 31.

Note 1: Some departures from Tab 31 may be accepted by the Society in the case of ships with a restricted navigation notation.

Note 2: Tab 31 does not apply to steering gear.

**Table 31 : Hydraulic oil systems**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			System			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Pump pressure	L						
Service tank level	L (1) (2)						X (2)
<p>(1) The low level alarm is to be activated before the quantity of lost oil reaches 100 litres or 70% of the normal volume in the tank, whichever is the less.</p> <p>(2) For hydraulics cranes where no electrical system has been provided, the requirement may be waived if the level gauge, the pressure gauge and the temperature gauge indicators are always visible by the crane operator. In addition, a warning label shall be placed on the tank reminding that, prior to start any operation of the crane, the oil level is to be checked.</p>							

## 15 Steam systems

### 15.1 Application

#### 15.1.1 Scope

This Article applies to all steam systems intended for essential and non-essential services.

Steam systems with a design pressure of 10 MPa or more will be given special consideration.

### 15.2 Principle

#### 15.2.1 Availability

- a) Where a single boiler is installed, the steam system may supply only non-essential services.
- b) Where more than one boiler is installed, the steam piping system is to be so designed that, in the event that any one boiler is out of action, the steam supply to essential services can be maintained.

### 15.3 Design of steam lines

#### 15.3.1 General

- a) Every steam pipe and every connected fitting through which steam may pass is to be designed, constructed and installed such as to withstand the maximum working stresses to which it may be subjected.
- b) When the design temperature of the steam piping system exceeds 400°C, calculations of thermal stresses are to be submitted to the Society as specified in [2.3].
- c) Steam connections on boilers and safety valves are to comply with the applicable requirements of Ch 1, Sec 3.

#### 15.3.2 Provision against overpressure

- a) If a steam pipe or fitting may receive steam from any source at a higher pressure than that for which it is designed, a suitable reducing valve, relief valve and pressure gauge are to be fitted.
- b) When, for auxiliary turbines, the inlet steam pressure exceeds the pressure for which the exhaust casing and associated piping up to the exhaust valves are designed, means to relieve the excess pressure are to be provided.

#### 15.3.3 Provision for dumping

In order to avoid overpressure in steam lines due to excessive steam production, in particular in systems where the steam production cannot be adjusted, provisions are to be made to allow the excess steam to be discharged to the condenser by means of an appropriate dump valve.

#### 15.3.4 Provision for draining

Means are to be provided for draining every steam pipe in which dangerous water hammer action might otherwise occur.

#### 15.3.5 Steam heating pipes

- a) When heating coils are fitted in compartments likely to contain either fuel oil or liquid or dry cargoes, arrangements such as blind flanges are to be provided in order to disconnect such coils in the event of carriage of dry or liquid cargoes which are not to be heated.
- b) The number of joints on heating coils is to be reduced to the minimum consistent with dismantling requirements.

#### 15.3.6 Steam lines in cargo holds

- a) Live and exhaust steam pipes are generally not to pass through cargo holds, unless special provisions are made with the Society's agreement.
- b) Where steam pipes pass through cargo holds in pipe tunnels, provision is to be made to ensure the suitable thermal insulation of such tunnels.
- c) When a steam smothering system is provided for cargo holds, provision is to be made to prevent spurious damage of the cargo by steam or condensate leakage.

#### 15.3.7 Steam lines in accommodation spaces

Steam lines are not to pass through accommodation spaces, unless they are intended for heating purposes.

#### 15.3.8 Turbine connections

- a) A sentinel valve or equivalent is to be provided at the exhaust end of all turbines. The valve discharge outlets are to be visible and suitably guarded if necessary.
- b) Bled steam connections are to be fitted with non-return valves or other approved means to prevent steam and water returning to the turbines.

### **15.3.9 Strainers**

- a) Efficient steam strainers are to be provided close to the inlets to ahead and astern high pressure turbines or, alternatively, at the inlets to manoeuvring valves.
- b) Where required by the manufacturer of the auxiliaries, steam strainers are also to be fitted in the steam lines supplying these auxiliaries.

## **16 Boiler feed water and condensate systems**

### **16.1 Application**

**16.1.1** This Article applies to:

- feed water systems of oil fired and exhaust gas boilers
- steam drain and condensate systems.

### **16.2 Principle**

#### **16.2.1 General**

Boiler feed water and condensate systems are to be so designed that:

- reserve feed water is available in sufficient quantity to compensate for losses
- feed water is free from contamination by oils or chlorides
- feed water for propulsion systems is suitably de-aerated.

#### **16.2.2 Availability**

- a) Feed water systems are to be so designed that, in the event of failure of any one component, the steam supply to essential services can be maintained or restored.
- b) Condensate systems are to be so designed that, in the event of failure of:
  - one condensate pump, or
  - the arrangements to maintain vacuum in the condenser,the steam supply to essential services can be maintained. Partial reduction of the propulsion capability may be accepted.

### **16.3 Design of boiler feed water systems**

#### **16.3.1 Number of feed water systems**

- a) Every steam generating system which supplies essential services is to be provided with not less than two separate feed water systems from and including the feed pumps, noting that a single penetration of the steam drum is acceptable.
- b) The requirement stated in a) may be dispensed with for boilers heated exclusively by engine exhaust gases or by steam for which one feed system is considered as sufficient, provided an alternative supply of steam is available on board.
- c) Each boiler is to be provided with feed regulators as specified in Ch 1, Sec 3, [3.2.9].

#### **16.3.2 Feed pumps**

- a) The following pumps are to be provided:
  - at least one main feed pump of sufficient capacity to supply the boilers under nominal conditions, and
  - one standby feed pump.
- b) The capacity of the standby pump may be less than that of the main feed pumps provided it is demonstrated that, taking into account the reduction of the propulsion capability, the ship remains safely operable.
- c) Main feed pumps may be either independent or driven by the main turbines. The standby feed pump is to be independent.
- d) In twin-screw ships in which there is only one independent feed pump, each main turbine is to be fitted with a driven pump. Where all feed pumps are independent, they are to be so arranged as to be capable of dealing with the feed water necessary to supply steam either to both turbines or to one turbine only.
- e) Independent feed pumps for main boilers are to be fitted with a delivery control and regulating system.
- f) Unless overpressure is prevented by the feed pump characteristics, means are to be provided which will prevent overpressure in the feed water system.
- g) The pressure head of feed pumps is to take into account the maximum service pressure in the boiler as well as the pressure losses in the discharge piping. The suction head of feed pumps is to be such as to prevent cavitation as far as possible.
- h) Feed pumps and pipes are to be provided with valves so arranged that any one pump can be overhauled while the boilers are operating at full load.

### **16.3.3 Harbour feed pumps**

- a) Where main turbine driven pumps are provided and there is only one independent pump, a harbour feed pump or an ejector is to be fitted in addition to provide the second means for feeding the boilers which are in use when the main turbine is not working.
- b) The harbour feed pump may be used for the general service of the ship, but in no case is this pump to be used to convey liquid fuel, lubricating oil or oily water.
- c) The suction pipes of the harbour feed pump from the hotwell, from reserve feed water tanks and from filters are to be fitted with non-return valves.

### **16.3.4 Feed water tanks**

- a) All ships fitted with main boilers or auxiliary boilers for essential services are to be provided with reserve feed water tanks.
- b) Boilers are to be provided with means to supervise and control the quality of the feed water. Suitable arrangements are to be provided to preclude, as far as practicable, the entry of oil or other contaminants which may adversely affect the boiler.
- c) Feed water tanks are not to be located adjacent to fuel oil tanks. Fuel oil pipes are not to pass through feed water tanks.
- d) For main boilers, one or more evaporators are to be provided, the capacity of which is to compensate for the losses of feed water due to the operation of the machines, in particular where the fuel supplied to the boilers is atomised by means of steam.

### **16.3.5 Provision for de-aerating feed water**

A de-aerator is to be provided to ensure the de-aeration of the feed water intended for main boilers before it enters such boilers.

## **16.4 Design of condensate systems**

### **16.4.1 Condensers**

- a) Appropriate arrangements, such as air ejectors, are to be provided to maintain vacuum in the main condenser or restore it to the required value.
- b) Cooling of the main condenser is to comply with the provisions of [10.3.5].

### **16.4.2 Condensate pumps**

- a) Condensate pumps are to include at least:
  - one main condensate pump of sufficient capacity to transfer the maximum amount of condensate produced under nominal conditions, and
  - one independently driven standby condensate pump.
- b) The standby condensate pump may be used for other purposes.

### **16.4.3 Condensate observation tanks**

Any condensate from the steam heating pipes provided for fuel oil tanks and bunkers, cargo tanks and fuel oil or lubricating oil heaters is to be led to an observation tank or some other device of similar efficiency located in a well-lighted and readily accessible position.

## **16.5 Control and monitoring**

### **16.5.1 General**

The provisions of this sub-article apply only to feed water and condensate systems intended for propulsion.

### **16.5.2 Monitoring**

Alarms and safeguards are to be provided for feed water and condensate systems in accordance with Tab 32.

Note 1: Some departures from Tab 32 may be accepted by the Society in the case of ships with a restricted navigation notation.

### **16.5.3 Automatic controls**

Automatic level control is to be provided for:

- de-aerators,
- condensers.

Table 32 : Boiler feed and condensate system

Symbol convention H = High, HH = High high, L = Low, LL = Low low, X = function is required, G = group alarm, I = individual alarm, R = remote	Monitoring		Automatic control				
			System			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Sea water flow or equivalent	L						
Condenser pressure	H	local					
	HH			X			
Water level in main condenser (unless justified)	H	local					
Feed water salinity	H	local					
Feed water pump delivery pressure	L	local					
						X	
Feed water tank level	L						

## 16.6 Arrangement of feed water and condensate piping

### 16.6.1

- a) Feed water pipes are not to pass through fuel oil or lubricating oil tanks.
- b) Pipes connected to feed water tanks are to be so arranged as to prevent the contamination of feed water by fuel oil, lubricating oil or chlorides.

## 16.7 Arrangement of feed water system for shell type exhaust gas heated economizer

16.7.1 Every shell type exhaust gas heated economizer, that may be isolated from the steam piping system, is to be provided with arrangements for pre-heating and de-aeration, addition of water treatment or combination thereof to control the quality of feed water to within the manufacturer's recommendations.

## 17 Compressed air systems

### 17.1 Application

17.1.1 This Article applies to compressed air systems intended for essential services, and in particular to:

- starting of engines,
- control and monitoring.

### 17.2 Principle

#### 17.2.1 General

- a) As a rule, compressed air systems are to be so designed that the compressed air delivered to the consumers:
  - is free from oil and water, as necessary
  - does not have an excessive temperature.
- b) Compressed air systems are to be so designed as to prevent overpressure in any part of the systems.

#### 17.2.2 Availability

- a) Compressed air systems are to be so designed that, in the event of failure of one air compressor or one air receiver intended for starting, control purposes or other essential services, the air supply to such services can be maintained. The filling connections of the compressed air receivers shall be fitted with a non-return valve.
- b) The compressed air system for starting the main and auxiliary engines is to be arranged so that the necessary initial charge of starting air can be developed on board ship without external aid. If, for this purpose, an emergency air compressor or an electric generator is required, these units are to be powered by a hand-starting oil engine or a hand-operated compressor.
- c) Where compressed air is necessary to restore propulsion, the arrangements for bringing main and auxiliary machinery into operation are to have capacity such that the starting energy and any power supplies for engine operation are available within 30 minutes of a dead ship condition. For definition of the "dead ship condition", see Ch 1, Sec 1, [1.4.2] and Ch 2, Sec 1, [3.17.1].

The procedure for such condition and relevant calculation is to be submitted.

- d) Where the compressed air is necessary for the air whistle or other safety services, it is to be available from two compressed air receivers. At least one of them is to be starting air receiver for main engines. The separate connection, dedicated for this purpose, is to be provided directly from the compressed air main.

### **17.3 Design of starting air systems**

#### **17.3.1 Air supply for starting the main and auxiliary engines**

- a) The total capacity of the compressed air available for starting purpose is to be sufficient to provide, without replenishment, not less than 12 consecutive starts alternating between ahead and astern of each main engine of the reversible type, and not less than 6 consecutive starts of each main non-reversible type engine connected to a controllable pitch propeller or other device enabling the start without opposite torque.

At least 3 consecutive starts is to be possible for each engine driving electric generators and engines for other purposes. The capacity of a starting system serving two or more of the above specified purposes is to be the sum of the capacity requirements.

- b) For multi-engine propulsion plants, the capacity of the starting air receivers is to be sufficient to ensure at least 3 consecutive starts per engine. However, the total capacity is not to be less than 12 starts and need not exceed 18 starts.

Regardless of the above, for any other specific installation the number of starts may be specially considered by the Society and depending upon the arrangement of the engines and the transmission of their output to the propellers in each particular case.

#### **17.3.2 Number and capacity of air compressors**

- a) Where main and auxiliary engines are arranged for starting by compressed air, two or more air compressors are to be fitted with a total capacity sufficient to supply within one hour the quantity of air needed to satisfy the provisions of [17.3.1] charging the receivers from atmospheric pressure. This capacity is to be approximately equally divided between the number of compressors fitted, excluding the emergency compressor fitted in pursuance of item c) below.
- b) At least one of the compressors is to be independent of the engines for which starting air is supplied and is to have a capacity of not less than 50% of the total required in item a).
- c) Where, for the purpose of [17.2.2], an emergency air compressor is fitted, this unit is to be power driven by internal combustion engine, electric motor or steam engine.

Suitable hand starting arrangement or independent electrical starting batteries may be accepted. In the case of small installations, a hand-operated compressor of approved capacity may be accepted.

#### **17.3.3 Number and capacity of air receivers**

- a) Where main engines are arranged for starting by compressed air, at least two air receivers are to be fitted of approximately equal capacity and capable of being used independently.
- b) The total capacity of air receivers is to be sufficient to provide without replenishment the number of starts required in [17.3.1]. When other users such as auxiliary engine starting systems, control systems, whistle, etc. are connected to the starting air receivers, their air consumption is also to be taken into account.

Compressed air receivers are to comply with the requirements of Ch 1, Sec 3.

#### **17.3.4 Air supply for starting the emergency generating set**

Where starting air arrangement is one of two independent means of starting required in Ch 1, Sec 2, [3.1.3] for the emergency generator, the following is to be complied with:

- a) The starting air arrangement is to include a compressed air vessel, storing the energy dedicated only for starting of the emergency generator. The capacity of the compressed air available for starting purpose is to be sufficient to provide, without replenishment, at least three consecutive starts.
- b) The compressed air starting systems may be maintained by the main or auxiliary compressed air receivers through a non-return valve fitted in the emergency generator space, or by an emergency air compressor which, if electrically driven, is supplied from the emergency switchboard.
- c) All of these starting, charging and energy storing devices are to be located in the emergency generator space and is not to be used for any purpose other than the operation of the emergency generating set.

## **17.4 Design of control and monitoring air systems**

### **17.4.1 Air supply**

- a) The control and monitoring air supply to essential services is to be available from two sources of a sufficient capacity to allow normal operation with one source out of service.
- b) At least one air vessel fitted with a non-return valve is to be dedicated for control and monitoring purposes, unless the installation is provided with local independent mechanical control and a means for communication with the wheelhouse is permanently fitted at position of local control. For notation **AUT**, see also Pt F, Ch 3, Sec 4, [5.2.2].
- c) Pressure reduction units used in control and monitoring air systems intended for essential services are to be duplicated, unless an alternative air supply is provided.
- d) Failure of the control air supply is not to cause any sudden change of the controlled equipment which may be detrimental to the safety of the ship.

### **17.4.2 Pressure control**

Arrangements are to be made to maintain the air pressure at a suitable value in order to ensure satisfactory operation of the installation.

### **17.4.3 Air treatment**

In addition to the provisions of [17.8.3], arrangements are to be made to ensure cooling, filtering and drying of the air prior to its introduction in the monitoring and control circuits.

## **17.5 Design of air compressors**

### **17.5.1 Prevention of excessive temperature of discharged air**

Air compressors are to be so designed that the temperature of discharged air cannot exceed 95°C. For this purpose, the air compressors are to be provided where necessary with:

- suitable cooling means
- fusible plugs or alarm devices set at a temperature not exceeding 120°C.

### **17.5.2 Prevention of overpressure**

- a) Air compressors are to be fitted with a relief valve complying with [2.5.3].
- b) Means are to be provided to prevent overpressure wherever water jackets or casings of air compressors may be subjected to dangerous overpressure due to leakage from air pressure parts.
- c) Water space casings of intermediate coolers of air compressors are to be protected against any overpressure which might occur in the event of rupture of air cooler tubes.

### **17.5.3 Crankcase relief valves**

Air compressors having a crankcase volume of at least 0,6 m<sup>3</sup> are to be fitted with crankcase explosion relief valves satisfying the provisions of Ch 1, Sec 2, [2.3.4].

### **17.5.4 Provision for draining**

Air compressors are to be fitted with a drain valve.

## **17.6 Control and monitoring of compressed air systems**

### **17.6.1 Monitoring**

Alarms and safeguards are to be provided for compressed air systems in accordance with Tab 33.

Note 1: Some departures from Tab 33 may be accepted by the Society in the case of ships with a restricted navigation notation.

### **17.6.2 Automatic controls**

Automatic pressure control is to be provided for maintaining the air pressure in the air receivers within the required limits.

Table 33 : Compressed air systems

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			System			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Compressor lubricating oil pressure (except where splash lubrication)	L						
Air pressure after reducing valves	L + H	local					
Starting air pressure before main shut-off valve	L	local + R (1)					
Air vessel pressure	L						

(1) Remote indication is required if starting of air compressor are remote controlled, from wheelhouse for example

### 17.7 Materials

17.7.1 Pipes and valve bodies in control and monitoring air systems and in other air systems intended for non-essential services may be made of plastic in accordance with the provisions of Ch 1, App 3.

### 17.8 Arrangement of compressed air piping systems

#### 17.8.1 Prevention of overpressure

Suitable pressure relief arrangements are to be provided for all systems.

#### 17.8.2 Air supply to compressors

- a) Provisions are to be made to reduce to a minimum the entry of oil into air pressure systems.
- b) Air compressors are to be located in spaces provided with sufficient ventilation.

#### 17.8.3 Air treatment and draining

- a) Provisions are to be made to drain air pressure systems.
- b) Efficient oil and water separators, or filters, are to be provided on the discharge of compressors, and drains are to be installed on compressed air pipes wherever deemed necessary.

#### 17.8.4 Lines between compressors, receivers and engines

All discharge pipes from starting air compressors are to be lead directly to the starting air receivers, and all starting pipes from the air receivers to main or auxiliary engines are to be entirely separate from the compressor discharge pipe system.

#### 17.8.5 Protective devices for starting air mains

Non-return valves and other safety devices are to be provided on the starting air mains of each engine in accordance with the provisions of Ch 1, Sec 2, [3.1.1].

## 18 Exhaust gas systems

### 18.1 General

#### 18.1.1 Application

This Article applies to:

- exhaust gas pipes from engines and gas turbines
- smoke ducts from boilers and incinerators.

#### 18.1.2 Principle

Exhaust gas systems are to be so designed as to:

- limit the risk of fire
- prevent gases from entering manned spaces
- prevent water from entering engines.

### **18.1.3 Exhaust gas pollution prevention systems**

Additional requirements for the installation of exhaust gas pollution prevention systems and storage and use of chemical treatment fluids consumed in the associated process are given in Ch 1, Sec 11.

Additional requirements for the installation of onboard carbon capture and storage systems are given in Ch 1, Sec 12.

## **18.2 Design of exhaust systems**

### **18.2.1 General**

Exhaust systems are to be so arranged as to minimise the intake of exhaust gases into manned spaces, air conditioning systems and engine intakes.

### **18.2.2 Limitation of exhaust line surface temperature**

- a) Exhaust gas pipes and silencers are to be either water cooled or efficiently insulated where:
  - their surface temperature may exceed 220°C, or
  - they pass through spaces of the ship where a temperature rise may be dangerous.
- b) The insulation of exhaust systems is to comply with the provisions of Ch 1, Sec 1, [3.7.1].

### **18.2.3 Limitation of pressure losses**

Exhaust gas systems are to be so designed that pressure losses in the exhaust lines do not exceed the maximum values permitted by the engine or boiler manufacturers.

### **18.2.4 Intercommunication of engine exhaust gas lines or boiler smoke ducts**

- a) Exhaust gas from different engines is not to be led to a common exhaust main, exhaust gas boiler or economiser, unless each exhaust pipe is provided with a suitable isolating device.
- b) Smoke ducts from boilers discharging to a common funnel are to be separated to a height sufficient to prevent smoke passing from a boiler which is operating to a boiler out of action.

### **18.2.5 Boilers designed for alternative oil firing and exhaust gas operation**

Where boilers are designed for alternative oil firing and exhaust gas operation, the exhaust gas pipe from the engine is to be fitted with an isolating device and safety arrangements to prevent the starting of the fuel oil burning units if the isolating device is not in the closed position.

### **18.2.6 Exhaust gas pipe terminations**

- a) Where exhaust pipes are led overboard close to the load waterline, means are to be provided to prevent water from entering the engine or the ship.
- b) Where exhaust pipes are water cooled, they are to be so arranged as to be self-draining overboard.

### **18.2.7 Control and monitoring**

A high temperature alarm is to be provided in the exhaust gas manifolds of thermal oil heaters to detect any outbreak of fire.

## **18.3 Materials**

### **18.3.1 General**

Materials of exhaust gas pipes and fittings are to be resistant to exhaust gases and suitable for the maximum temperature expected.

### **18.3.2 Use of plastics**

The use of non-metallic materials may be accepted in water cooled systems in accordance with the provisions of Ch 1, App 3.

## **18.4 Arrangement of exhaust piping systems**

### **18.4.1 Provision for thermal expansion**

- a) Exhaust pipes and smoke ducts are to be so designed that any expansion or contraction does not cause abnormal stresses in the piping system, and in particular in the connection with engine turboblowers.
- b) The devices used for supporting the pipes are to allow their expansion or contraction.

### **18.4.2 Provision for draining**

- a) Drains are to be provided where necessary in exhaust systems, and in particular in exhaust ducting below exhaust gas boilers, in order to prevent water flowing into the engine.
- b) Where exhaust pipes are water cooled, they are to be so arranged as to be self-draining overboard.

### **18.4.3 Flexible hoses**

The use of flexible hoses in water cooled exhaust systems will be given special consideration by the Society.

#### **18.4.4 Silencers**

Engine silencers are to be so arranged as to provide easy access for cleaning and overhaul.

## **19 Oxyacetylene welding systems**

### **19.1 Application**

**19.1.1** This Article applies to centralised fixed plants for oxyacetylene welding installed on ships. It may also be applied, at the discretion of the Society, to other plants using liquefied gas, such as propane.

### **19.2 Definitions**

#### **19.2.1 Centralised plants for oxyacetylene welding**

A centralised plant for oxyacetylene welding is a fixed plant consisting of a gas bottle room, distribution stations and distribution piping, where the total number of acetylene and oxygen bottles exceeds 4.

#### **19.2.2 Gas bottle rooms**

A gas bottle room is a room containing acetylene and oxygen bottles, where distribution headers, non-return and stop valves, pressure reducing devices and outlets of supply lines to distribution stations are also installed.

#### **19.2.3 Distribution stations**

Distribution stations are adequately protected areas or cabinets equipped with stop valves, pressure regulating devices, pressure gauges, non-return valves and oxygen as well as acetylene hose connections for the welding torch.

### **19.3 Design of oxyacetylene welding systems**

#### **19.3.1 General**

Except on pontoons and service working ships, no more than two distribution stations are normally permitted.

#### **19.3.2 Acetylene and oxygen bottles**

- a) The bottles are to be tested under attendance of the Society or by a body recognised by the Society.
- b) Bottles with a capacity exceeding 50 litres are not permitted.
- c) Bottles supplying the plant and spare bottles are to be installed in the gas bottle room. Installation within accommodation spaces, service spaces, control stations and machinery spaces is not permitted.
- d) Bottles are to be installed in a vertical position and are to be safely secured. The securing system is to be such as to allow the ready and easy removal of the bottles.

#### **19.3.3 Piping systems**

- a) In general, the acetylene and oxygen piping systems are to comply with the following provisions:
  - all valves and fittings as well as welding torches and associated supply hoses are to be adapted to this specific service and suitable for the conditions expected in the different parts of the system
  - acetylene piping is to be of stainless steel or copper alloy containing less than 65% copper and seamless drawn
  - oxygen piping is to be of copper or stainless steel and seamless drawn
  - the connections between the various pipe sections are to be carried out by means of butt welding. Other types of connections including threaded connections and flange connections are not permitted
  - only a minimum number of unavoidable connections are permitted provided they are located in a clearly visible position.
- b) High pressure lines (i.e. lines between bottles and pressure reducing devices) are to be installed inside the gas bottle room and are to comply with the following provisions:
  - acetylene and oxygen piping and associated fittings are to be suitable for a design pressure of 29,5 MPa
  - a non-return valve is to be installed on the connection of each acetylene and oxygen bottle to the header
  - stop valves are to be provided on the bottles and kept shut when distribution stations are not working.
- c) Low pressure lines (i.e. lines between pressure reducing devices and distribution stations) are to comply with the following provisions:
  - for low pressure lines, black steel pipes seamless drawn could be also acceptable provided that:
    - a thickness is not less than 2,5 mm when installed in the open air
    - a thickness is not less than 2,0 mm when installed indoor
  - supply lines to each distribution station are to include, at the station inlet:
    - a stop valve to be kept shut when the station is not working
    - devices to protect the supply lines from backflow of gas or flame passage.
- d) Safety valves are to be provided on the low pressure side of the pressure reducing devices and led to the open air at least 3 m above the deck in a safe location where no source of ignition is present.

## 19.4 Arrangement of oxyacetylene welding systems

### 19.4.1 Gas bottle rooms

- a) The gas bottle room is to be located in an independent space over the highest continuous deck and provided with direct access from outside. The limiting bulkheads and decks are to be gas-tight and made of steel.
- b) When the total number of gas bottles, including possible spare bottles which are not connected to the plant, does not exceed 8, acetylene and oxygen bottles may be installed in the same room. Otherwise, acetylene and oxygen bottles are to be separated by a gas-tight bulkhead.
- c) The bottle room is to be adequately insulated and ventilated so that the temperature inside does not exceed 40°C. If the temperature cannot be controlled by means of natural ventilation, mechanical and independent ventilation is to be provided. Air outlets are to be led at least 3 m away from ignition sources and ventilation intakes and are to be equipped with flameproof wire gauze.
- d) The gas bottle room is not to be used for other services on board. Flammable oil or gas piping, except that related to the oxyacetylene welding plant, is not to be led through this room.

Note 1: On pontoons and service working ships, gas bottles may be installed on open deck in a safe position to the satisfaction of the Society. In such case, appropriate protection is to be provided:

- for gas bottles, against sunrays and atmospheric agents, by means of watertight covers,
- for the associated valves, piping and fittings, by means of steel covers, metal grids or similar devices.

Such means of protection are to be easily removable to allow bottle removal, when necessary.

When the total number of bottles exceeds 8, acetylene bottles are to be separated from oxygen bottles.

### 19.4.2 Distribution stations

Distribution stations are to be located in the engine room or in the workshop, in a well-ventilated position and protected against possible mechanical damage.

Note 1: On pontoons and service working ships, distribution stations may be installed in the open air, enclosed in a cabinet with a locked door, or in controlled access areas, to the satisfaction of the Society.

### 19.4.3 Piping

- a) Piping is not to be led through accommodation or service spaces.
- b) Piping is to be protected against any possible mechanical damage.
- c) In way of deck or bulkhead penetrations, piping is to be suitably enclosed in sleeves so arranged as to prevent any fretting of the pipe with the sleeve.

### 19.4.4 Signboards

Signboards are to be posted on board the ship in accordance with Tab 34.

**Table 34 : Signboards**

Location of the signboard	Signboard to be posted
in the gas bottle room	diagram of the oxyacetylene plant
	"no smoking"
in way of: <ul style="list-style-type: none"> <li>• bottle stop valves</li> <li>• distribution station stop valves</li> </ul>	"to be kept shut when distribution stations are not working"
in way of the pressure reducing devices	indication of the maximum allowable pressure at the pressure reducing device outlet
in way of the safety valve discharge outlet	"no smoking"

## 20 Certification, inspection and testing of piping systems

### 20.1 Application

20.1.1 This Article defines the certification and workshop inspection and testing programme to be performed on:

- the various components of piping systems
- the materials used for their manufacture.

On board testing is dealt with in Ch 1, Sec 18.

**20.2 Type tests of flexible hoses and expansion joints**

**20.2.1 General**

- a) Prototype test programmes are to be submitted by the manufacturer and are to be sufficiently detailed to demonstrate performance in accordance with the specified standards.
- b) Prototype test programmes are to be made in accordance with recognised standards which are suitable for the intended service of the flexible hose or of an expansion joint.
- c) Tests are to take into consideration the maximum anticipated in-service pressures, vibration frequencies and forces due to the installation.
- d) All flexible hose assemblies or expansion joints are to be satisfactorily prototype burst tested to an international standard (see Note 1) to demonstrate that they are able to withstand a pressure not less than 4 times their design pressure without indication of failure or leakage.

Note 1: The international standards (e.g. EN or SAE standards) for burst testing of non-metallic hoses require the pressure to be increased until burst without any holding period. Burst is to occur at a pressure greater than 4 times the maximum working pressure.

**20.2.2 Flexible hoses**

- a) For flexible hoses which are to comply with [2.6], prototype tests are to be carried out for each size of hose assembly. However, for ranges with more than 3 different diameters, the prototype tests are to be carried out for at least:
  - the smallest diameter
  - the largest diameter
  - intermediate diameters selected based on the principle that prototype tests carried out for a hose assembly with a diameter D are considered valid only for the diameters ranging between 0,5 D and 2 D.
 For fire resistance tests the specimens are to be selected in accordance with ISO 15540:2016.
- b) The flexible hoses subjected to the tests are to be fitted with their connections.
- c) Type approval tests are to be carried out in accordance with the prototype test programmes required in [2.6.4], including, but not limited to, the scope of testing specified in Tab 35 for metallic flexible hoses and in Tab 36 for non-metallic flexible hoses.

**20.2.3 Expansion Joints**

- a) For the expansion joints which are to comply with [2.6], relevant type approval tests are to be carried out on a representative sampling on each type and for each pressure range.
- b) The expansion joints subjected to the tests are to be fitted with their connections.
- c) Type approval tests are to be carried out in accordance with the prototype test programmes required in [2.6.4], including, but not limited to, the scope of testing specified in Tab 37 for metallic expansion joints and in Tab 38 for non-metallic expansion joints.
- d) Exemptions from prototype burst test may be granted for expansion joints of large diameter used on sea water lines and to large diameter expansion joints used on exhaust gas lines, except for those which are fitted directly on engines. Testing may be limited to pressure test.

**Table 35 : Type tests and procedures for metallic flexible hoses depending on the application**

	Burst	Pliability (bending)	Cycle test: U bend (Hoses up to 100 DN)	Cycle test: Cantilever bend (Hoses above DN 100)	Pressure and elongation	Impulse	Vibration

 (4) For rubber expansion joints only.  
 (5) For piping systems subject to pressure pulsation.  
 (6) Where fitted to engines, pumps, compressors or other sources of high vibrations

**20.3 Type tests of air pipe closing appliances**

**20.3.1 Testing of air pipe automatic closing devices**

Each type and size of air pipe automatic closing device is to be surveyed and type tested at the manufacturer’s works or a recognized laboratory accepted by the Society. The test requirements for an air pipe automatic closing device are to include the following:

a) Determination of the flow characteristics

The flow characteristics of the air pipe closing device are to be determined.

Measuring of the pressure drop versus rate of volume flow is to be carried out using water and with any intended flame or insect screens in place.

b) Tightness test during immersion/emerging in water

An automatic closing device is to be subjected to a series of tightness tests involving not less than two immersion cycles under each of the following conditions:

- The automatic closing device is to be submerged slightly below the water surface at a velocity of approximately 4 m/min. and then returned to the original position immediately. The quantity of leakage is to be recorded.
- The automatic closing device is to be submerged to a point slightly below the surface of the water. The submerging velocity is to be approximately 8 m/min and the air pipe vent head is to remain submerged for not less than 5 minutes. The quantity of leakage is to be recorded.
- Each of the above tightness tests is to be carried out in the normal position as well as at an inclination of 40° under the strictest conditions for the device. In cases where such strictest conditions are not clear, tests are to be carried out at an inclination of 40° with the device opening facing in three different directions: upward, downward, sideways (left or right). See Fig 6 and Fig 7.

The maximum allowable leakage per cycle is not to exceed 2 ml/mm of nominal diameter of inlet pipe during any individual test.

**Figure 6 : Example of normal position**

Figure 7 : Examples of inclination of 40° with different directions of the device opening

c) Discharge / Reverse flow test:

1) The air pipe head is to allow the passage of air to prevent excessive vacuum developing in the tank.

Reverse flow test:

- A reverse flow test is to be performed. A vacuum pump or another suitable device is to be connected to the opening of the air pipe leading to the tank. The flow velocity is to be applied gradually at a constant rate until the float gets sucked and blocks the flow, and
- The velocity at the point of blocking is to be recorded. A mention of 80% of the value recorded is to be stated in the type approval certificate.

2) Alternative to the reverse flow test:

- For pipe heads of 400 mm nominal diameter and above, as an alternative to the reverse flow test, a numerical simulation test based on computational fluid dynamics (CFD), to be carried out in conjunction with limited representative testing to establish the validity of the CFD modelling and results, may be accepted
- CFD predictions for air pipe heads can be validated against the available actual reverse flow test results of same size and type of air pipe heads
- The accuracy of the CFD modelling and the major assumptions used for the calculation are to be documented
- Mesh convergence studies are to be carried out and documented, and
- The velocity at the point of blocking is to be recorded. A mention of 80% of the value recorded is to be stated in the type approval certificate.

20.3.2 Testing of non-metallic floats

Impact and compression loading tests are to be carried out on the floats before and after pre-conditioning, as per Tab 39.

a) Impact test

The impact test may be conducted on a pendulum type testing machine. The floats are to be subjected to 5 impacts of 2,5 Nm each and are not to suffer permanent deformation, cracking or surface deterioration at this impact loading.

Subsequently the floats are to be subjected to 5 impacts of 25 Nm each. At this impact energy level, some localised surface damage at the impact point may occur. No permanent deformation or cracking of the floats is to appear.

b) Compression loading test

Compression tests are to be conducted with the floats mounted on a supporting ring of a diameter and bearing area corresponding to those of the float seating with which the tested float is intended to be used. For ball type float, loads are to be applied through a concave cap of the same internal radius as the test float and bearing on an area of the same diameter as the seating. For a disc type float, loads are to be applied through a disc of equal diameter as the float.

A load of 350 kg is to be applied over one minute and maintained for 60 minutes. The deflection is to be measured at intervals of 10 minutes after attachment of the full load. The record of deflection against time is to show no continuing increase in deflection and, after release of the load, there is to be no permanent deflection.

20.3.3 Testing of metallic floats

Tests are to be conducted in accordance with [20.3.2], item a) above. The tests are to be carried out at room temperature and in the dry condition.

Table 39 : Pre-conditioning of floats

Test condition	Test temperature		
	-25°C	+20°C	+85°C
Dry	+	+	+
After immersing in water	+	+	+
After immersing in fuel oil	-	+	-

**Note 1:** Immersing in water and fuel oil is to be for at least 48 hours.

## 20.4 Testing of materials

### 20.4.1 General

- a) Requirements for material tests are given in NR216 Materials and Welding.
- b) The requirements of this Article do not apply to piping systems subjected to low temperatures, such as cargo piping of liquefied gas carriers.

### 20.4.2 Tests for materials

- a) Where required in Tab 40, materials used for pipes, valves and other accessories are to be subjected to the following tests:
  - tensile test at ambient temperature
  - flattening test or bend test, as applicable
  - when designed to be used at high temperatures on the basis of their high-temperature strength characteristics, a hot tensile test is to be performed on one test specimen per serie and per size, except if one of the following conditions is met:
    - the design temperature is below 200°C
    - the mechanical properties of the material at high temperature have been approved according to a recognized standard
    - the scantling of the pipes is based on reduced values of the permissible stress.
- b) Plastic materials are to be subjected to the tests specified in Ch 1, App 3.
- c) For piping systems included in engine, turbine or gearbox installation in contact with flammable fluids, requirements mentioned in Ch 1, Sec 1, [3.7.2] are to be applied when other materials than steel are used. Especially, piping systems might need to be tested according to ISO 19921:2005 / 19922:2005.

## 20.5 Hydrostatic testing of piping systems and their components

### 20.5.1 General

Pneumatic tests are to be avoided wherever possible. Where such testing is absolutely necessary in lieu of the hydraulic pressure test, the relevant procedure is to be submitted to the Society for acceptance prior to testing.

### 20.5.2 Hydrostatic pressure tests of piping

- a) Hydrostatic pressure tests are to be carried out to the Surveyor's satisfaction for:
  - all class I and II pipes and their integral fittings
  - all steam pipes, feed water pipes, compressed air pipes, and fuel oil and other flammable oil pipes with a design pressure greater than 0,35 MPa and their associated integral fittings.
- b) These tests are to be carried out after completion of manufacture and before installation on board and, where applicable, before insulating and coating.

Note 1: Classes of pipes are defined in [1.5.2].

- c) Pressure testing of small bore pipes (less than 15 mm) may be waived at the discretion of the Surveyor, depending on the application.
- d) Where the design temperature does not exceed 300°C, the test pressure is to be equal to 1,5 p.
- e) Where the design temperature exceeds 300°C, the test pressure is to be as follows:
  - for carbon and carbon-manganese steel pipes, the test pressure is to be equal to 2 p
  - for alloy steel pipes, the test pressure  $P_H$  is to be determined by the following formula, but need not exceed 2 p:

$$P_H = 1,5 \frac{K_{100}}{K_T} p$$

where:

$K_{100}$  : Permissible stress for 100°C, as stated in Tab 11

$K_T$  : Permissible stress for the design temperature, as stated in Tab 11.

Note 2: Where alloy steels not included in Tab 11 are used, the permissible stresses will be given special consideration.

- f) Where it is necessary to avoid excessive stress in way of bends, branches, etc., the Society may give special consideration to the reduction of the test pressure to a value not less than 1,5 p. The membrane stress is in no case to exceed 90% of the yield stress at the testing temperature.
- g) While satisfying the condition stated in b), the test pressure of pipes located on the discharge side of centrifugal pumps driven by steam turbines is not to be less than the maximum pressure liable to be developed by such pumps with closed discharge at the operating speed of their overspeed device.
- h) Hydrostatic testing may be carried out after assembly on board of the piping sections under the conditions stated in Ch 1, Sec 18, [3.12.1].

For pressure tests of piping after assembly on board, see Ch 1, Sec 18, [3.12.1], Ch 1, Sec 18, [3.12.2] and Ch 1, Sec 18, [3.12.3].

For pressure tests of plastic pipes after assembly on board, see Ch 1, App 3, [4.9].

### 20.5.3 Hydrostatic tests of valves, fittings and heat exchangers

- a) Valves and fittings non-integral with the piping system and intended for class I and II pipes are to be subjected to hydrostatic tests in accordance with standards recognised by the Society, at a pressure not less than 1,5 times the design pressure  $P$  defined in [1.3.2].
- b) Valves and distance pieces intended to be fitted on the ship side below the load waterline are to be subjected to hydrostatic tests under a pressure not less than 0,5 MPa.
- c) The shells of appliances such as heaters, coolers and heat exchangers which may be considered as pressure vessels are to be tested under the conditions specified in Ch 1, Sec 3.
- d) The nests of tubes or coils of heaters, coolers and heat exchangers are to be submitted to a hydraulic test under the same pressure as the fluid lines they serve.
- e) For coolers of internal combustion engines, see Ch 1, Sec 2.

### 20.5.4 Hydrostatic tests of fuel oil bunkers and tanks not forming part of the ship's structure

Fuel oil bunkers and tanks not forming part of the ship's structure are to be subjected to a hydrostatic test under a pressure corresponding to the maximum liquid level in such spaces or in the air or overflow pipes, with a minimum of 2,40 m above the top. The minimum height is to be 3,60 m for tanks intended to contain fuel oil with a flashpoint below 60°C.

### 20.5.5 Hydrostatic tests of pumps and compressors

- a) Cylinders, covers and casings of pumps and compressors are to be subjected to a hydrostatic test under a pressure at least equal to the test pressure  $p_H$ , in MPa, determined by the following formulae:
  - $p_H = 1,5 p$  where  $p \leq 4$
  - $p_H = 1,4 p + 0,4$  where  $4 < p \leq 25$
  - $p_H = p + 10,4$  where  $p > 25$where:  
 $p$  : Design pressure, in MPa, as defined in [1.3.2].  
 $p_H$  is not to be less than 0,4 MPa.
- b) While satisfying the condition stated in a), the test pressure for centrifugal pumps driven by steam turbines is not to be less than 1,05 times the maximum pressure likely to be recorded with closed discharge at the operating speed of the overspeed device.
- c) Intermediate coolers of compressors are to undergo a hydrostatic test under a pressure at least equal to the pressure  $p_H$  defined in a). When determining  $p_H$ , the pressure  $p$  to be considered is that which may result from accidental communication between the cooler and the adjoining stage of higher pressure, allowance being made for any safety device fitted on the cooler.
- d) The test pressure for water spaces of compressors and their intermediate coolers is not to be less than 1,5 times the design pressure in the space concerned, subject to a minimum of 0,2 MPa.
- e) For air compressors and pumps driven by internal combustion engines, see Ch 1, Sec 2.

### 20.5.6 Hydrostatic test of flexible hoses and expansion joints

- a) Each flexible hose or expansion joint, together with its connections, is to undergo a hydrostatic test under a pressure at least equal to 1,5 times the maximum service pressure.
- b) During the test, the flexible hose or expansion joint is to be repeatedly deformed from its geometrical axis.

## 20.6 Testing of piping system components during manufacturing

### 20.6.1 Pumps

- a) Bilge and fire pumps are to undergo a performance test.
- b) Rotors of centrifugal feed pumps for main boilers are to undergo a balancing test.

### 20.6.2 Centrifugal separators

Centrifugal separators used for fuel oil and lubricating oil are to undergo a running test, normally with a fuel water mixture.

## 20.7 Inspection and testing of piping systems

20.7.1 The inspections and tests required for piping systems and their components are summarised in Tab 40.

**Table 40 : Inspection and testing at works for piping systems and their components**

Item (5)		Tests for the materials (1)		Inspections and tests for the product (1)		
		Tests required (7)	Type of material certificate (2)	During manufacturing (NDT)	After completion	Type of product certificate (2)
Raw pipes	class I, ND ≥ 50 class II, ND ≥ 100	[20.4.2]	C (3)	[3.6.2], [3.6.3] (4)	[20.5.3]	C (3)
	class I, ND < 50 class II, ND < 100		W			W (3)
Valves and fittings	class I, ND ≥ 50 class II, ND ≥ 100	[20.4.2]	C	[3.6.2], [3.6.3] (4)	[20.5.3]	C (3)
	class I, ND < 50 class II, ND < 100		W			C (3)
Pipes, valves and fittings connected to: • the ship side • the collision bulkhead • fuel oil and lubricating oil tanks and under static pressure	ND ≥ 100	[20.4.2]	C (3)	[3.6.2], [3.6.3] (4)	[20.5.3], b)	C (3)
	ND < 100		W			
Flexible hoses and expansion joints		[20.4.2]	W		[20.5.6]	C (3)
Pumps and compressors within piping systems covered by Sections of Part C, Chapter 1 (9)	when belonging to a class I piping system	[20.4.2]	C (3)		[20.5.5]	C (3)
	when belonging to a class II piping system	[20.4.2]	W		[20.5.5]	C (3)
	bilge and fire pump	[20.4.2]	W		[20.5.5] [20.6.1], a)	C (3)
	feed pumps for main boilers	[20.4.2]	C (3)	[3.6.2], [3.6.3] (4) (8)	[20.5.5] [20.6.1], b)	C (3)
	forced circulation pumps for main boilers	[20.4.2]	C (3)		[20.5.5]	C (3)
	when belonging to one of the following class III piping systems if design pressure exceeds 0,35 MPa: • boiler feed water or forced circulating • fuel oil or other flammable oil • compressed air	[20.4.2]	W		[20.5.5]	C (3)
	when belonging to other class III piping systems				[20.5.5]	W
Centrifugal separators					[20.6.2]	C (3)

Item (5)		Tests for the materials (1)		Inspections and tests for the product (1)		
		Tests required (7)	Type of material certificate (2)	During manufacturing (NDT) (6)	After completion	Type of product certificate (2)
Prefabricated pipeline	classes I and II with ND ≥ 65 or t ≥ 10			[3.6.2], [3.6.3] (6)	[20.5.2]	C (3)
	classes I and II with ND < 65 or t < 10			[3.6.2], [3.6.3] (6)	[20.5.2]	W
	class III where design pressure exceeds 0,35 MPa, as follows: <ul style="list-style-type: none"> <li>• steam pipes and feed water pipes</li> <li>• compressed air pipes</li> <li>• fuel oil or other flammable oil pipes</li> </ul>				[20.5.2]	W

(1) [x.y.z] = test required, as per referent regulation. In general, the material are to comply with [2.1.2]  
 (2) "C" indicates that a Society certificate is required. "W" indicates that a manufacturer's document is required. See NR216 Materials and Welding, Ch 1, Sec 1, [4.2]  
 (3) Or alternative type of certificate, depending on the Survey Scheme. See NR320 Certification scheme of materials and equipment.  
 (4) If of welded construction.  
 (5) ND = Nominal diameter of the pipe, valve or fitting, in mm.  
 Class of piping systems is to be determined in accordance with [1.5.2].  
 (6) For welded connections.  
 (7) Where required by the table, material tests are to be carried out for the components subject to pressure, such as valve body, pump and compressor casings, etc. They are also to be carried out for the assembling bolts of feed water pumps and forced circulating pumps serving main boilers. Requirements for material testing are detailed in NR 216 Materials and Welding, Ch 2, Sec 2.  
 (8) For main parts, before assembling.  
 (9) For other pumps and compressors, see additional Rules relevant for related system.

# Section 11 Exhaust Gas Pollution Prevention System

## 1 General

### 1.1 Application

**1.1.1** This Section applies to installation, storage of chemical treatment fluids, piping system and equipment dedicated to the treatment of exhaust gas.

**1.1.2** The requirements of this Section are additional to those of Ch 1, Sec 10, [18].

#### 1.1.3

- a) Requirements for exhaust gas pipes from engines, gas turbines, boilers and incinerators are given in Ch 1, Sec 10, [18].
- b) General requirements applying to the installation of any exhaust gas pollution prevention system are contained in Article [2].
- c) Additional requirements for the storage and use of urea as reductant in SCR are given in Article [3].
- d) Additional requirements for the storage and use of sodium hydroxide (NaOH) or calcium hydroxide (Ca(OH)<sub>2</sub>) in exhaust gas cleaning system - scrubbers are given in Article [4].
- e) Additional requirements for any other chemical treatment fluids used in exhaust gas are given in Article [5].

**1.1.4** When an onboard carbon capture and storage system is installed, the ship is to comply with the requirements of Ch 1, Sec 12.

### 1.2 Definitions

#### 1.2.1 Exhaust gas pollution prevention system

Exhaust gas pollution prevention system means any system including scrubber (or exhaust gas cleaning system), SCR (selective catalytic Reduction) and EGR (Exhaust Gas Recirculation), used to reduce polluting emissions from the exhaust gas.

#### 1.2.2 Chemical treatment fluid

Unless otherwise specified, chemical treatment fluid means any chemical consumed in a process for the treatment of exhaust gas.

#### 1.2.3 Exhaust gas cleaning system (EGCS)

EGCS refers to SO<sub>x</sub> scrubbers' complete installation, including:

- a scrubbing vessel, used to remove sulphur content from the exhaust of marine engines or boilers,
- a treatment plant to manage the washwater after the scrubbing process, and
- a sludge management system (a holding tank with outboard discharge to port facilities).

#### 1.2.4 Selective catalytic reduction (SCR) equipment

SCR means equipment used to reduce NO<sub>x</sub> emissions from the exhaust of marine engines using selective catalytic reduction process.

#### 1.2.5 Exhaust gas recirculation (EGR)

EGR means exhaust gas recirculation, i.e. a means method used to reduce NO<sub>x</sub> emissions at the exhaust of marine engines at the source using partial recirculation of the exhaust gas to the engine air inlet.

### 1.3 Documents to be submitted

**1.3.1** The documents listed in Tab 1 are to be submitted.

In case of a retrofit, all drawings showing modifications related to the exhaust gas pollution prevention system installation are to be submitted. Especially, attention is drawn on the documents listed in Tab 2.

**Table 1 : Documents to be submitted**

No.	I/A (1)	Document (2)
1	A	General arrangement of the exhaust gas pollution prevention system
2	A	Diagrams of sea water and / or fresh water piping systems (3)
3	A	Diagram of washwater treatment and sludge piping systems (3)
4	A	Diagram of chemical piping system, including filling, storage and dosing (3)
5	I	Risk analysis report covering a failure of the exhaust gas pollution prevention system, a leakage of washwater, sludge or chemical, or a fire, as detailed in [2.4.3], [3.1.1] or [5] when applicable
(1) A = to be submitted for approval ; I = to be submitted for information		
(2) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems		
(3) Where applicable, depending on the design of the exhaust gas pollution prevention system		

**Table 2 : Documents to be submitted in case of a retrofit**

No.	I/A (1)	Document
1	I	General arrangement and Machinery general arrangement
2	A	Fire control plan
3	A	Damage control plan, damage stability booklet and tank capacity plan
4	A	Ventilation, extinction and detection
5	A	Power supply arrangement
6	A	Single line diagram of the control system
7	A	List of alarms and monitored parameters and safety systems
8	I	Test program of the control system
9	A	Ship electrical power balance
10	I	Instruction and operation manuals
11	A	Diagram of scrubber installation, fixation diagram, strength calculation for scrubber transverse supports
12	A	Structural modification (Holes and Penetrations drawing, modification of the Sea Chest, Funnel and Casing)
13	A	Diagrams of the exhaust gas pollution prevention system and exhaust gas piping
14	A	Pressure losses calculation in the exhaust line
15	A	Diagram of ancillaries system modification (compressed air, ventilation,...)
16	A	Diagram of the tanks vent system
17	A	Diagram of the bilge system
18	A	Filling up piping system for chemical products and storage of the product and preparation/handling of the product
19	I	Risk analysis (availability of essential systems of ship related to failure of exhaust gas pollution prevention system, use of chemical products)
20	A	Exhaust gas boiler modification
21	I	Test program and reports
(1) A: For approval ; I : For information		

## 2 Installation requirements

### 2.1 General

**2.1.1** Exhaust gas pollution prevention systems are to be designed, arranged and installed in accordance with the following requirements.

EGCS are to be tested in accordance with the requirements of [2.5], under the survey and to the satisfaction of the Society's Surveyor.

### 2.2 Installation requirements

#### 2.2.1 Design

Attention is drawn on IMO Guidelines regarding the environmental performance of equipment such as ECGS and SCR systems. For ships with the additional class notation **EGCS-SCRUBBER**, the provisions of Pt F, Ch 9, Sec 7, [2] are to be complied with.

**2.2.2** Tank design and construction requirements are given in Pt B, Ch 2, Sec 2, [10].

**2.2.3** The chemical treatment fluids tanks are to be included in the ship's stability calculation.

**2.2.4** Additional requirements about retention of treatment water on board are to be fulfilled in case **CLEANSHIP** notation is granted (see Pt F, Ch 9, Sec 2, [2.10]).

## **2.3 Availability**

**2.3.1** The availability of the machinery served by the exhaust gas pollution prevention system is to be substantiated by a risk analysis.

The exhaust gas pollution prevention equipment is to be so arranged that, in the case of failure of such equipment, propulsion power and auxiliary power supplying essential functions are not affected. Where necessary, a bypass is to be installed.

In case of blackout, automatic starting of engines, if provided, is to remain effective as if no exhaust gas pollution prevention system were installed and not detrimental to the exhaust gas pollution prevention installation.

## **2.4 Arrangement**

### **2.4.1 Exhaust systems connections**

As mentioned in Ch 1, Sec 10, [18.2.4], no interconnection is permitted between different exhaust piping systems for engines. In case of one exhaust gas pollution prevention system used for several installations, interconnections may be acceptable with additional devices installed as follows:

- Individual isolating devices for exhaust pipes are to be provided on each individual exhaust pipe; and
- Forced ventilation is to be installed at the outlet of the common exhaust pipe, preventing any backflow of exhaust gases in individual exhaust ducts in any possible working conditions.

As an alternative to forced ventilation, exhaust systems interconnections might be accepted on a case-by-case basis and considering an exhaust gas back pressure analysis according to the guidance given in Ch 1, App 7, to the satisfaction of the Society.

### **2.4.2 Bypass**

When the exhaust gas pollution prevention system may be bypassed, proper means are to be installed providing double barrier upstream from the exhaust gas pollution prevention system, in order to enable safe inspection in exhaust gas pollution prevention equipment in any working configuration of combustion units.

### **2.4.3 Filling systems for chemical treatment fluids**

Filling systems for chemical treatment fluids are to be located in places where no interference with other ship activities would happen. In case interference is unavoidable, a risk analysis is to be provided in order to evaluate occurrence and level of danger for crew and passengers if any.

Filling systems are to fulfil the requirements of Ch 1, Sec 10, [11.4.2]. Drainage of coamings if any and outlet of safety valves are to be led to a tank designed for that purpose.

### **2.4.4 Materials**

Materials used for equipment and piping systems are to be suitable with fluids conveyed, not leading to early corrosion or creating hazardous gases when in contact with treatment liquid or vapours. This requirement is also valid for drip trays, fans and ducts being part of exhaust gas pollution prevention system.

### **2.4.5 Discharge water piping**

Piping intended to convey discharge water from exhaust gas pollution prevention systems are to be protected against corrosion either by selection of their constituent materials or by an appropriate coating or treatment, with due consideration of the expected composition and acidity of the discharge water. In addition, the distance piece between the overboard discharge valve and the shell plating is to have at least extra-reinforced wall thickness as defined in Ch 1, Sec 10, Tab 6.

Attention is also drawn on distance piece thickness survey requirements given in Pt A, Ch 3, Sec 1, [3.1.6].

The discharge outlet is to be widely separated from the ship seawater inlet. In addition, surfaces of the hull, seachests, and hull appendages in the vicinity of the discharge outlet are to be suitably protected against the corrosive effects of low pH discharge water.

### **2.4.6 Control and monitoring**

Alarms and indications are to be provided in accordance with Tab 3.

For ships to be granted an **AUT** additional class notation, those alarms and indications are to be provided at the centralised control position, see Pt F, Ch 3, Sec 1, [4.8.9].

Information related to exhaust gas pollution prevention device and washwater, discharge measurements is to be made available in a control station.

## 2.5 Certification, Inspection and testing

### 2.5.1 EGC unit tower

Welded joints are to be made in accordance with qualified welding procedures by qualified welders. Welder's certificates, welding procedures and their qualification records are to be submitted to the Society for review.

Welded joints, including the inside wherever possible, are to be visually examined by the manufacturer.

Magnetic particle or liquid penetrant testing is to be performed on welded joints selected according to manufacturer's plan.

### 2.5.2 Inspection and testing of EGCS components

Inspection and testing of EGCS components are defined in Tab 4.

**Table 3 : Control and monitoring for exhaust gas pollution prevention systems**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control					
			System			Auxiliary		
			Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start
Identification of system parameter								
Failure of exhaust fans (each fan)	X							
Exhaust temperature before entering in plastic parts or Cooling medium flow	H L	local local						
Chemical treatment fluids storage tank level (1)	H (2)	local (2)						
(1) Not applicable to process tanks								
(2) High level alarm is to be independent from the tank level indicator.								

**Table 4 : Inspection and testing at works for EGCS components**

Item	Tests for the materials (1)		Inspections and tests for the product (1)		
	Tests required (2)	Type of material certificate (3)	During manufacturing (NDT)	After completion	Type of product certificate (3)
Water pumps				Ch 1, Sec 10, [20.5.5]	W
Treatment chemical pumps	Ch 1, Sec 10, [20.4.2]	W		Ch 1, Sec 10, [20.5.5]	C (4)
EGC unit tower		W	[2.5.1]		C (4)
(1) [x.y.z] = test required, as per referent regulation. In general, the material are to comply with Ch 1, Sec 10, [2.1.2]					
(2) Where required by the table, material tests are to be carried out for the components subject to pressure, such as valve body, pump and compressor casings, etc. Requirements for material testing are detailed in NR 216 Materials and Welding					
(3) C = class certificate ; W = works' certificate (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2])					
(4) Or alternative type of certificate, depending on the Survey Scheme. See NR320 Certification scheme of materials and equipment					

## 3 Storage and use of SCR reductant

### 3.1 Application

**3.1.1** The following requirements apply to urea/water solutions used in SCR. However, the requirements [3.2.3], [3.2.5], [3.3.1], [3.3.2] and [3.5.1] do not apply to daily tanks and buffer tanks with a volume below 500L.

For other reductants falling in the scope of IMDG Code like aqueous ammonia or anhydrous ammonia, the following conditions are to be fulfilled:

- It is to be demonstrated that the use of urea based reductant is not practicable and, in case of use of anhydrous ammonia, that the use of aqueous ammonia is not practicable either

Note 1: It is reminded that use of anhydrous ammonia may require the agreement of the Flag Administration.

- A risk analysis is to be provided regarding the loading, carriage and use of the product
- Requirements mentioned in Article [5] are to be fulfilled.

### 3.2 Storage tank

**3.2.1** The storage tank is to be arranged so that any leakage will be contained and prevented from making contact with heated surfaces. All pipes or other tank penetrations are to be provided with manual closing valves attached to the tank.

**3.2.2** The storage tank may be located in the engine room.

**3.2.3** Each urea storage tank is to be provided with temperature and level monitoring arrangements. High and low level alarms together with high and low temperature alarms are also to be provided.

**3.2.4** Where urea based ammonia solution is stored in integral tanks, these tanks are to be coated with appropriate anti-corrosion coating and are not to be located adjacent to any fuel oil or fresh water tank.

**3.2.5** Urea storage tanks are to be arranged so that they can be emptied of urea and ventilated by means of portable or permanent systems.

### **3.3 Ventilation**

**3.3.1** If a urea storage tank is installed in a closed compartment, the area is to be served by an effective mechanical ventilation system of the extraction type providing not less than 6 air changes per hour. This ventilation system is to be independent from the ventilation systems of accommodation, service spaces, or control stations. The ventilation system is to be capable of being controlled from outside the compartment. A warning notice requiring the use of such ventilation before entering the compartment is to be provided outside the compartment adjacent to each point of entry.

Alternatively, where a urea storage tank is located within an engine room, a separate ventilation system is not required when the general ventilation system for the space is arranged so as to provide an effective movement of air in the vicinity of the storage tank and is maintained in operation continuously except when the storage tank is empty and has been thoroughly ventilated.

**3.3.2** The requirements specified in [3.3.1] also apply to closed compartments normally entered:

- when they are adjacent to the urea integral tanks and there are possible leak points (e.g. manhole, fittings) from these tanks; or
- when the urea piping systems pass through these compartments, unless the piping system is made of steel or other equivalent material with melting point above 925°C and with fully welded joints.

### **3.4 Piping**

**3.4.1** The reductant piping and venting systems are to be independent of other ship service piping and/or systems. Reductant piping systems are not to be located in accommodation, service spaces, or control stations. The vent pipes of the storage tank are to terminate in a safe location on the weather deck and the tank venting system is to be arranged to prevent entrance of water into the urea tank.

### **3.5 Materials**

**3.5.1** Reductant tanks are to be of steel or other equivalent material with a melting point above 925°C. Pipes/piping systems are to be of steel or other equivalent material with melting point above 925°C, except downstream of the tank valve, provided this valve is metal seated and arranged as fail-to-closed or with quick closing from a safe position outside the space in the event of fire. In such case, type approved plastic piping may be accepted even if it has not passed a fire endurance test.

Reductant tanks and pipes/piping systems are to be made with a material compatible with the reductant or coated with appropriate anti-corrosion coating.

Copper is to be avoided for equipment and piping systems in contact with fluids containing ammonia.

### **3.6 Protection of crew members**

**3.6.1** For the protection of crew members, the ship is to have on board suitable personnel protective equipment. Eyewash are to be provided, the location and number of these eyewash stations are to be derived from the detailed installation arrangements.

## **4 Chemical treatment fluids used for exhaust gas cleaning systems**

### **4.1 Application**

**4.1.1** The following requirements apply to sodium hydroxide (NaOH) or calcium hydroxide (Ca(OH)<sub>2</sub>) used in exhaust gas cleaning system, which are carried on board in bulk.

### **4.2 Storage tank**

**4.2.1** The storage tank for chemical treatment fluids is to be arranged so that any leakage will be contained and prevented from making contact with heated surfaces. All pipes or other tank penetrations are to be provided with manual closing valves attached to the tank.

In cases where such valves are provided below the top of tank, they are to be arranged with quick acting shut-off valves capable of being remotely operated from a position accessible even in the event of chemical treatment fluid leakages.

**4.2.2** The storage tank may be located in the engine room.

**4.2.3** Each storage tank for chemical treatment fluids is to be provided with level monitoring arrangements and high/low level alarms. In cases where heating and/or cooling systems are provided, high and/or low temperature alarms or temperature monitoring are also to be provided accordingly.

**4.2.4** The storage tanks are to have sufficient strength to withstand a pressure corresponding to the maximum height of a fluid column in the overflow pipe, with a minimum of 2,4 m above the top plate taking into consideration the specific density of the treatment fluid.

**4.2.5** Where chemical treatment fluid is stored in integral tanks these tanks are to be coated with appropriate anti-corrosion coating and are to be segregated by cofferdams, void spaces, pump rooms, empty tanks or other similar spaces so as to not be located adjacent to accommodation, cargo spaces containing cargoes which react with chemical treatment fluids in a hazardous manner as well as any food stores, oil tanks and fresh water tanks.

**4.2.6** Storage tanks for chemical treatment fluids are to be arranged so that they can be emptied of the fluids and ventilated by means of portable or permanent systems.

### **4.3 Ventilation**

**4.3.1** If a storage tank for chemical treatment fluids is installed in a closed compartment, the area is to be served by an effective mechanical ventilation system of the extraction type providing not less than 6 air changes per hour which is independent from the ventilation systems of accommodation, service spaces, or control stations. The ventilation system is to be capable of being controlled from outside the compartment. A warning notice requiring the use of such ventilation before entering the compartment shall be provided outside the compartment adjacent to each point of entry.

**4.3.2** If the storage tank is located in the engine room, a separate ventilation system is not required when the general ventilation system for the space providing not less than 6 air changes per hour is arranged so as to provide an effective movement of air in the vicinity of the storage tank and is maintained in operation continuously except when the storage tank is empty and has been thoroughly ventilated.

**4.3.3** The requirements specified in [4.3.1] also apply to closed compartments normally entered by persons:

- when they are adjacent to the integral storage tank for chemical treatment fluids and there are possible leak points (e.g. manhole, fittings) from these tanks; or
- when the treatment fluid piping systems pass through these compartments, unless the piping system is made of steel or other equivalent material with melting point above 925 °C and with fully welded joints.

### **4.4 Piping**

**4.4.1** The chemical treatment fluid piping and venting systems are to be independent of other ship service piping and/or systems. The chemical treatment fluid piping systems are not to be located in accommodation, service spaces, or control stations. The vent pipes of the storage tank are to terminate in a safe location on the weather deck and the tank venting system is to be arranged to prevent entrance of water into the tank for chemical treatment fluids.

**4.4.2** Regardless of design pressure and temperature, piping systems containing chemical treatment fluids only are to comply with the requirements applicable to Class I piping systems. As far as practicable, e.g. except for the flange connections that connect to tank valves, the piping systems are to be joined by welding.

### **4.5 Materials**

**4.5.1** Storage tanks and pipes/piping systems for chemical treatment fluids which transfer undiluted chemical treatment fluids are to be of steel or other equivalent material with a melting point above 925 °C.

**4.5.2** Storage tanks and pipes/piping systems for chemical treatment fluids are to be made with a material compatible with chemical treatment fluids, or coated with appropriate anti-corrosion coating.

Aluminium and zinc are to be avoided for equipment and piping systems in contact with fluids like caustic soda (NaOH).

### **4.6 Containment of leakage**

**4.6.1** The following connections are to be screened and fitted with drip trays to prevent the spread of any spillage where they are installed:

- detachable connections between pipes (flanged connections and mechanical joints, etc.)
- detachable connections between pipes and equipment such as pumps, strainers, heaters, valves
- detachable connections between equipment such as pumps, strainers, heaters, valves.

The drip trays are to be fitted with drain pipes which lead to appropriate tanks, such as residue tanks, which are fitted with high level alarm, or are to be fitted with alarms for leak detection. In cases where such tank is an integral tank, [4.2.5] is to be applied to the tank.

## **4.7 Protection of crew members**

**4.7.1** For the protection of crew members, the ship is to have on board suitable personal protective equipment (PPE). The number of PPE carried onboard is to be appropriate for the number of personnel engaged in regular handling operations or that may be exposed in the event of a failure; but in no case is there to be less than two sets available on board.

**4.7.2** Personal protective equipment (PPE) is to consist of protective clothing, boots, gloves and tight-fitting goggles.

**4.7.3** Eyewash and safety showers are to be provided, the location and number of these eyewash stations and safety showers are to be derived from the detailed installation arrangements. As a minimum, the following stations are to be provided:

- in the vicinity of transfer or treatment pump locations. If there are multiple transfer or treatment pump locations on the same deck then one eyewash and safety shower station may be considered for acceptance provided that the station is easily accessible from all such pump locations on the same deck.
- an eyewash station and safety shower is to be provided in the vicinity of a chemical bunkering station on-deck. If the bunkering connections are located on both port and starboard sides, then consideration is to be given to providing two eyewash stations and safety showers, one for each side.
- an eyewash station and safety shower is to be provided in the vicinity of any part of the system where a spillage/drainage may occur and in the vicinity of system connections/components that require periodic maintenance.

## **4.8 Safety measures against the residues which have hazardous properties**

**4.8.1** Tanks for residues generated from the exhaust gas cleaning process are to satisfy the following requirements:

- the tanks are to be independent from other tanks, except in cases where these tanks are also used as the over flow tanks for chemical treatment fluids storage tank.
- tank capacities are to be decided in consideration of the number and kinds of installed exhaust gas cleaning systems as well as the maximum number of days between ports where residue can be discharged ashore. In the absence of precise data, a figure of 30 days is to be used.
- where residue tanks used in closed loop chemical treatment systems are also used as the overflow tanks for chemical treatment fluids storage tank, the requirements for storage tanks apply.

## **5 Storage and use of other substances mentioned in IMDG Code**

### **5.1 Application**

**5.1.1** For exhaust gas pollution prevention systems using chemical treatment fluids other than those mentioned in [3] and [4], the following requirements are to be followed. Additionally a risk analysis is to be conducted, in order to eliminate or mitigate the hazards to personnel brought by the use of such exhaust gas pollution prevention systems, to an extent equivalent to systems complying with Article [3] and Article [4].

### **5.2 Risk analysis**

**5.2.1** For compartment containing chemical treatment fluid tanks a risk analysis is to be provided, taking into account normal or abnormal operating conditions (failure, fluid leakage, fire) regarding human health and damage to essential equipment contained in compartment.

**5.2.2** In case of use of substances classed in IMO IMDG Code in categories 1, 2.1, 3, 4.1, 4.2, 4.3, 5.1, 6.1, 8 or 9, application of IEC standard 60079-10-1 is required regarding electric installations, hazardous areas definition and ventilation, and a specific risk analysis is to be submitted.

### **5.3 Containment of leakage**

**5.3.1** In case substances mentioned in IMO IMDG Code are used in exhaust gas pollution prevention systems, drainage and/or bilge pumping of compartments where such systems are located is to be separated from ship bilge system. Retention of potential leakages using drip trays associated to spill kits is to be implemented. Draining pipes from drip trays are to be led to a tank designed for that purpose.

### **5.4 Storage tank**

**5.4.1** Chemical treatment fluids tanks are not to be contiguous with tanks containing sea water, fresh water, fuel, lubricating tanks. A ventilated cofferdam between treatment chemical tanks and above mentioned tanks is an acceptable solution. Arrangement of the ventilation system is to be in accordance with [5.5].

Chemical treatment fluids tanks are not to be located in category A machinery spaces unless a specific risk analysis, as required in [5.2], is submitted to the Society for approval.

Chemical treatment fluids tanks when located adjacent to or within a compartment used for other purposes are to be surrounded by coamings delimitating space fitted with a high level alarm.

Bilge system of this compartment may be connected to ship bilge system provided arrangements are made to isolate this bilge suction. An additional fixed pumping system is to be installed in order to pump liquid with chemical substance from bilge and inside drip trays to draining tank. Isolation means and additional pumping system are to be remotely controlled.

**5.4.2** Toxic or flammable product pipes, which, if damaged, would allow the product to escape from a tank, are to be fitted with a quick closing valve directly on the tank, capable of being closed from a safe position outside the compartment involved.

**5.4.3 Overflow**

Overflow pipes of chemical treatment fluids tanks are to be led to a specific tank dedicated for one kind of product. If several chemical treatment fluids tanks exist for a same product, overflow tank may be common.

**5.4.4 Sounding and air pipes**

Sounding pipes and air pipes are to end in an open space above freeboard deck. Means in order to prevent water entry through these pipe ends in any circumstances are to be provided.

**5.5 Ventilation**

**5.5.1** Ventilation of compartments where chemical treatment fluids are stored or used is to be of the extraction type providing not less than 6 air changes per hour. This ventilation system is to be separated from any other ventilation system. The ventilation system is to be capable of being controlled from outside the compartment. A warning notice requiring the use of such ventilation before entering the compartment is to be provided outside the compartment adjacent to each point of entry.

The ventilation system is to be included in the risk analysis requested in [5.2].

**5.6 Piping**

**5.6.1** Piping systems involved in process are not to pass through accommodations, control stations or service spaces.

# Section 12 Onboard Carbon Capture and Storage Systems

## 1 General

### 1.1 Application

**1.1.1** This Section applies to ships fitted with an onboard carbon capture and storage (CCS) system intended to separate the carbone dioxide (CO<sub>2</sub>) from the exhaust gases and store it on board.

Note 1: Such ships will be assigned the additional service feature **OCC**, as defined in Pt A, Ch 1, Sec 2, [4.16].

**1.1.2** This Section addresses CCS systems where CO<sub>2</sub> is:

- emitted from an internal combustion engine, a boiler or a fuel cell supplied with carbon-based fuel
- separated using an absorption process with amine-based chemical solvent

Note 1: Other technologies or solvents will be considered on a case-by-case basis.

- compressed / liquefied
- stored
- offloaded.

**1.1.3** This Section covers the design and installation of the CCS system, with respect to ship safety. The performance of the system is not covered. In particular, the following aspects are not addressed by this Section:

- CO<sub>2</sub> capture rate
- quality of the captured CO<sub>2</sub> for later use
- possible formation and emission of polluting substances (such as nitrosamines)
- quality of the solvent (degradation)
- solvent storage capacity
- CO<sub>2</sub> storage capacity.

Note 1: The attention is drawn to national or international regulations on CCS systems, concerning in particular their emissions and performance.

### 1.2 Documentation to be submitted

**1.2.1** The documents listed in Tab 1 are to be submitted.

**1.2.2** In the case where a CCS system is retrofitted to an existing ship, the documents listed in Tab 2 are to be provided in addition to those referred to in [1.2.1].

### 1.3 Definitions

#### 1.3.1 Carbon capture and storage (CCS) system

The carbon capture and storage (CCS) system consists of the following:

- solvent system
- separation system
- CO<sub>2</sub> system.

#### 1.3.2 CO<sub>2</sub> system

CO<sub>2</sub> system means all equipment necessary for:

- the compression and liquefaction of the CO<sub>2</sub>
- the transfer and storage of the CO<sub>2</sub> and
- the offloading of CO<sub>2</sub>

#### 1.3.3 Fuel

Fuel in the context of this Section means a carbon-based fuel such as oil fuel, LNG, LPG, methanol or ethanol.

#### 1.3.4 Fuel consumer

Fuel consumer means internal combustion engine, boiler or fuel cell from which CO<sub>2</sub> present in the exhaust gases is captured.

**1.3.5 Separation system**

Separation system means all equipment necessary for the separation of the CO<sub>2</sub> from the exhaust gases emitted by the fuel consumers. It includes in particular:

- the exhaust gas cooler
- the exhaust gas blower
- the absorber
- the desorber (regenerator or stripper).

**1.3.6 Solvent / rich solvent / lean solvent / waste solvent**

- Solvent means a chemical (e.g. amine-based solvent) intended for the absorption of CO<sub>2</sub> or an aqueous solution thereof.
- Rich solvent means the solvent which contains captured CO<sub>2</sub>.
- Lean solvent means the solvent from which CO<sub>2</sub> has been separated.
- Waste solvent means the solvent that needs to be replaced due to degradation.

**1.3.7 Solvent system**

Solvent system means all equipment necessary for the filling, storage, transfer, cooling and heating of the clean, working and waste solvent. It includes in particular:

- pumps
- heat exchangers
- tanks.

**1.3.8 Triple point**

Triple point is the temperature and pressure at which a material exists simultaneously as a solid, liquid, and gas. For carbon dioxide, the triple point is -56,6 °C and 5,18 bar abs.

	A	• Ingress protection (IP) of the electrical panels and associated devices (junction boxes, electrical motors, etc.)
	A	• Interconnection diagram or document describing the link between the CCS and the ship's alarm system
9	A	List of alarms and safeties of the CCS system
10	A	Characteristics and certifications of the electrical devices added during the integration of the CCS system: electrical cables, detectors, etc.
11	A	Single line diagram showing the power electrical arrangement to supply the CCS system
12	I	Type of cables to be installed provided with the related Type Approval Certificates
13	A	For spaces containing CCS system components: • Diagram of the ventilation system
	A	• Diagram of the bilge system
	A	• Fire detection arrangements
	A	• Fire-extinguishing arrangements
	I	• Structural fire protection • Eye-washing showers and personal protective equipment (PPE) storage spaces
<p>(1) A = to be submitted for approval ; I = to be submitted for information                  (2) Performance data of the CCS system need not be provided                  (3) The variation of the ship deadweight during the CCS operation, due to the simultaneous consumption of fuel and capture of CO<sub>2</sub>, is to be taken into account, considering the conversion factor CF given in IMO Resolution MEPC.308 (73)</p>		

## **1.4 Risk analysis**

### **1.4.1 Failure mode and effects analysis**

A failure mode and effects analysis (FMEA) is to be carried out to determine the possible failures and their effects on the operation of the CCS system.

### **1.4.2 HAZID and HAZOP analysis**

HAZID and HAZOP analysis are to be carried out for the whole CCS system, including:

- the solvent loading, storage and offloading installation and
- the CO<sub>2</sub> compression, liquefaction, storage and offloading installation.

The HAZID and HAZOP are to cover at least the following events:

- solvent leakage
- CO<sub>2</sub> leakage
- failure of a CCS system component or abnormal operation.

The HAZID and HAZOP analysis are to address:

- the flammability of the solvent
- the toxicity of the solvent
- the toxicity and the asphyxiating effect of the carbon dioxide in case of exposure of the crew members or passengers
- the availability of propulsion and main source of power, see [2.1.4].

## **2 Design and construction of the carbon capture and storage system**

### **2.1 General**

**2.1.1** The components of the CCS system and their associated piping systems and fittings are to be of a design and construction adequate for the intended service in accordance with the provisions of Part C, Chapter 1, in particular:

- Heat exchangers are to comply with the provisions of Ch 1, Sec 3.
- Solvent and CO<sub>2</sub> vapour piping systems are to comply with the provisions of Ch 1, Sec 10.
- The design of the liquid CO<sub>2</sub> piping system is to comply with the relevant provisions of Pt D, Ch 9, Sec 5.

### **2.1.2 Inclinations**

The CCS system is to be so designed that it can withstand the loads corresponding to the static and dynamic inclination angles specified in Ch 1, Sec 1, [2.4.1].

### **2.1.3 Ambient conditions**

The CCS system is to be designed for the ambient conditions specified in Ch 1, Sec 1, [2.5.1].

### **2.1.4 Availability**

The CCS system is to be so designed that the exhaust back-pressure allowed by the fuel consumer manufacturer is not exceeded over the operating range at which the fuel consumer is intended to operate. Where necessary, an exhaust gas blower is to be installed. For internal combustion engines, see Ch 1, Sec 11, [2.4.1] and Ch 1, App 7.

Note 1: Increased exhaust back pressure may affect the engine performance, in particular its specific fuel consumption.

The CCS system is to be so designed that in case of failure of a CCS system component, the normal operation of the fuel consumer can be maintained. This is to be demonstrated by the risk analysis.

### **2.1.5 Arrangements for solvent replacement**

Where necessary, arrangements for storage and transfer are to be made to allow the replacement of the solvent, in accordance with the operating manual of the plant.

## **2.2 Materials**

**2.2.1** Materials used in the components of the CCS system containing the solvent are to be resistant to corrosion, taking into account the exhaust gas composition, the nature of the solvent and the temperature in the concerned areas. The risk of corrosion due to the presence of impurities is to be taken into account.

**2.2.2** Storage tanks and pipes / piping systems for the solvent are to be made with a material compatible with the solvent, or coated with appropriate anticorrosion coating. The melting point of the material is not to be less than 925 °C.

Note 1: Materials having lower melting point may be utilized provided their use is specially considered on a case-by-case basis in relation to the risk of fire.

**2.2.3** In general, copper and aluminum as well as their alloys, zinc and galvanized steel are not to be used in any component of the CCS system in contact with the solvent.

**2.2.4** Materials used in the components containing liquefied CO<sub>2</sub> are to comply with the provisions of Pt D, Ch 9, Sec 6.

**2.2.5** Materials used in CO<sub>2</sub> tanks and piping system are to be suitable for the lowest temperature that may occur in service, which is defined as the saturation temperature of the CO<sub>2</sub> at the set pressure of the automatic safety system intended to maintain the CO<sub>2</sub> at a pressure above the triple point.

### **2.3 Design and construction of the separation system**

**2.3.1** Welded joints of the exhaust gas cooler, absorber and desorber shells are to be made in accordance with qualified welding procedures by qualified welders. Welder's certificates, welding procedures and their qualification records are to be submitted to the Society for review.

### **2.4 Design and construction of the solvent filling, storage, transfer, cooling and heating systems**

#### **2.4.1 General**

The requirements of the present sub-article apply to storage tanks and piping systems containing the solvent. They also apply to the tank and piping systems intended for the storage and transfer of waste solvent

Regardless of design pressure and temperature, piping systems containing solvent are to comply with the requirements applicable to class I piping systems. Vent and drain pipes, irrespective of the service temperature, belong to class III.

#### **2.4.2 Leakage prevention and containment**

The solvent filling, storage tank and transfer system are to be arranged so that any leakage will be contained and prevented from making contact with heated surfaces. All tank pipes or other tank penetrations are to be provided with manual closing valves attached to the tank. In cases where such valves are provided below top of tank, they are to be arranged with quick acting shutoff valves which are to be capable of being remotely operated from a position remaining accessible in the event of solvent leakages.

#### **2.4.3 Protection against high or low temperatures**

The solvent storage tank is to be protected from excessively high or low temperatures applicable to the particular concentration of the solvent solution. Depending on the operational area of the ship, this may require the fitting of heating and/or cooling systems.

#### **2.4.4 Integral tanks**

The solvent may be stored in integral tanks provided they are coated with appropriate anti-corrosion coating.

Solvent tanks are to be segregated from accommodation, cargo spaces containing cargoes which react with the solvent in a hazardous manner as well as any food stores, oil tanks and fresh water tanks by cofferdams, void spaces, pump rooms, empty tanks or other similar spaces.

Solvent storage tanks are to be located aft of the collision bulkhead and forward of the after peak bulkhead.

#### **2.4.5 Independence of piping systems**

The solvent piping and venting systems are to be independent of other ship service piping and/or systems.

#### **2.4.6 Prevention of contamination by the solvent**

Means, such as pH or pressure monitoring, are to be provided to detect any contamination of the water cooling or heating system or steam heating system by the solvent through heat exchangers.

#### **2.4.7 Use of electric heaters**

When electric heaters are used to supply heat to the desorber, a safety temperature switch is to be fitted in order to avoid excessive heating. It is to be:

- independent from the automatic temperature control sensor
- designed to cut off the electrical power supply in the event of excessive temperature
- provided with manual reset.

#### **2.4.8 Pipe connections**

As far as practicable, e.g. except for the flange connections that connect to tank valves, the piping systems are to be joined by welding.

The following connections are to be screened and fitted with drip trays to prevent the spread of any spillage where they are installed:

- a) detachable connections between pipes (flanged connections and mechanical joints, etc.)
- b) detachable connections between pipes and equipment such as pumps, strainers, heaters, valves
- c) detachable connections between equipment mentioned in item b).

## **2.5 Design and construction of the CO<sub>2</sub> separation system**

### **2.5.1 Exhaust gas cooling and treatment**

Exhaust gases are to be suitably cooled and treated so that their temperature and contaminant content (in particular SO<sub>x</sub> and NO<sub>x</sub>) are within the range required for the CO<sub>2</sub> absorption process.

Where exhaust gas cooling is made through a Direct Contact Cooling (DCC) exchanger, it is to comply with the applicable requirements of Ch 1, Sec 11.

The discharge water from the exhaust gas cooling system is to meet the relevant quality criteria laid down in IMO Resolution MEPC.340 (77): 2021 Guidelines for exhaust gas cleaning systems.

### **2.5.2 Heating system**

The capacity of the rich solvent heating system is to be within the range required for the CO<sub>2</sub> desorption process.

## **2.6 Design of the CO<sub>2</sub> compression, liquefaction and storage systems**

### **2.6.1 Gaseous CO<sub>2</sub> piping**

Regardless of design pressure and temperature, piping systems containing gaseous CO<sub>2</sub> are to comply with the requirements applicable to Class I piping systems.

Remotely closable valves are to be provided where necessary to isolate a section of the CO<sub>2</sub> piping system in case of leakage.

The pipes conveying gaseous captured CO<sub>2</sub> are to be so marked that they can be readily distinguished from any pipe containing CO<sub>2</sub> intended for fire extinguishing. The pipes may pass through accommodations providing that:

- they are of substantial thickness (see Ch 1, Sec 10, Tab 6)
- they are joined only by welding
- they are not fitted with drains or other openings within such spaces.

The pipes are not to pass through refrigerated spaces.

### **2.6.2 Liquid CO<sub>2</sub> storage tanks**

CO<sub>2</sub> storage tanks are to comply with the provisions of:

- Pt D, Ch 9, Sec 4 for the tank design
- Pt D, Ch 9, Sec 7 for tank pressure and temperature control
- Pt D, Ch 9, Sec 17, [21], for tank pressure control and monitoring and safety valve arrangement.

In particular, the following requirements are to be considered:

- a) The pressure and temperature of CO<sub>2</sub> at the triple point depend on its purity. Where the CO<sub>2</sub> is stored at a pressure and temperature close to the triple point, the set pressure of the tank instrumentation is to be properly adjusted in order to prevent the tank contents from changing from the liquid to the solid state.
- b) With the exception of tanks designed to withstand the critical pressure of CO<sub>2</sub>, one of the following means are to be provided to maintain the tank pressure and temperature within their design range at all times:
  - reliquefaction of CO<sub>2</sub> vapours
  - liquid CO<sub>2</sub> cooling
  - pressure accumulation.
- c) Venting of the CO<sub>2</sub> vapours is not an acceptable means to maintain the tank pressure and temperature within their design range, except in emergency situations.

### **2.6.3 Compressed CO<sub>2</sub> storage tanks**

Tanks intended for the storage of high pressure compressed CO<sub>2</sub> are to comply with the design principles given in Ch 4, Sec 15, [4.1.3].

## **2.7 Control and monitoring**

### **2.7.1 Alarms and indications are to be provided in accordance with Tab 3.**

For ships to be granted an **AUT** additional class notation, those alarms and indications are to be provided at the centralised control position, see Pt F, Ch 3, Sec 1, [4.8.12].

Table 3 : Control and monitoring for carbon capture and storage system (CSS)

Symbol convention: H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			System			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Standby Start	Stop
Exhaust gas temperature at the absorber inlet	H + L	X					
Solvent temperature at the regenerator (stripper) inlet	H + L	X					
Solvent temperature at the regenerator (stripper) outlet	H + L	X					
Solvent storage tank level	H (1)	X					
	L						
Solvent storage tank temperature	H	X					
	L						
Drain tank level	H (1)	X					
Compressed CO <sub>2</sub> storage tank pressure	H	X					
Liquid CO <sub>2</sub> storage temperature	H	X					
(1) High level alarm is to be independent from the tank level indicator							

### 3 Arrangement and installation of the solvent components

#### 3.1 Solvent tanks and piping system

##### 3.1.1 Location of the solvent piping systems

The solvent piping systems are not to be located in accommodation, service spaces, or control stations. The vent pipes of the storage tank are to terminate in a safe location on the open deck, away from passageways, ventilation inlets and outlets and from any opening to accommodation, service spaces or control stations and the tank venting system is to be arranged to prevent entrance of water into the tank for solvents.

##### 3.1.2 Drip trays

Drip trays are to be fitted in way of the solvent system components where leakage may occur. They are to be provided with leak detection arrangements and with drain pipes which lead to dedicated drain tank. Drain tanks are to be fitted with a high level alarm. In case this dedicated drain tank is an integral tank, it is to comply with the requirements of [2.4.4].

##### 3.1.3 Monitoring and alarms

The storage tank is to be provided with level monitoring arrangements and high/low level alarms. Additionally, high and/or low temperature alarms or temperature monitoring are also to be provided.

#### 3.2 Absorbers

3.2.1 A common absorber may be used by several engines provided that:

- a remotely operated and effective isolation device with means for leakage detection is provided on each engine exhaust line, in order to prevent exhaust gases from an engine in operation to penetrate into an engine not in operation, which could cause corrosion damage and result in exhaust gases entering the engine compartment
- where necessary a forced ventilation is installed in accordance with Ch 1, Sec 11, [2.4.1].

#### 3.3 Solvent leakage detection

3.3.1 Except where the liquid spill detectors required for the drip trays (see [3.1.2]) are proved to be sufficient by the risk analysis, permanently installed solvent vapour detectors are to be fitted in all enclosed spaces where a leakage from the solvent system is likely to occur, as evidenced by the risk analysis.

3.3.2 The detection of solvent liquid or vapour leakage is to activate an alarm and the automatic closing of an isolating valve located outside the space where the leakage has occurred.

3.3.3 The solvent vapour detectors are to be located in areas where the solvent may accumulate.

3.3.4 Two portable solvent vapour detection equipment are to be available on board the ship.

### **3.4 Bilge system and scuppers**

**3.4.1** Bilge and scuppers lines from spaces containing a potential source of solvent leakage are to be independent from bilge lines serving other spaces.

**3.4.2** Bilge water and drained water from spaces containing a potential source of solvent leakage is to be retained on board in dedicated holding tanks for subsequent discharge to reception facilities.

### **3.5 Ventilation**

**3.5.1** Enclosed spaces where solvent storage tanks are installed are to be served by an effective mechanical ventilation system of the extraction type providing not less than 6 air changes per hour. This ventilation system is to be independent from the ventilation systems serving accommodation, service spaces, or control stations. The ventilation system is to be capable of being controlled from outside the space. A warning notice requiring the use of such ventilation before entering the space is to be provided outside the compartment adjacent to each point of entry.

**3.5.2** The provisions of [3.5.1] also apply to the following spaces, if normally entered.

- a) spaces adjacent to the integral solvent storage tanks and containing possible leak points (e.g. manhole, fittings) from these tanks
- b) spaces containing solvent piping systems, unless they have fully welded joints.

**3.5.3** Where the solvent storage tank is located within the engine room, a separate ventilation system, as per [3.5.1] is not required when the general ventilation system for the space providing not less than 6 air changes per hour is arranged so as to provide an effective movement of air in the vicinity of the storage tank and is maintained in operation continuously except when the storage tank is empty and has been thoroughly ventilated.

**3.5.4** The exhausts of the ventilation systems required in [3.5.1] to [3.5.3] are to be located at least 3m away from inlets for other ventilation systems and from normal passageways.

### **3.6 Fire safety**

**3.6.1** Applicable requirements for spaces intended for the storage or handling of solvent are listed in:

- Ch 4, Sec 3, [3.3] for fire detection arrangements
- Ch 4, Sec 3, [7] for fire-extinguishing arrangements
- Ch 4, Sec 5 for fire integrity requirements.

## **4 Arrangement and installation of the CO<sub>2</sub> system components**

### **4.1 CO<sub>2</sub> tanks**

#### **4.1.1 CO<sub>2</sub> tank location**

CO<sub>2</sub> tank location is to comply with the requirements of Pt D, Ch 9, Sec 2, [4] as applicable to type 3G ships.

CO<sub>2</sub> tank may be installed on the open deck, in a dedicated compartment or in the cargo area of tankers or offshore supply vessels. Where the CO<sub>2</sub> tank is installed in an enclosed space, the access is to be arranged only from the open deck and the access door is to open outwards.

#### **4.1.2 CO<sub>2</sub> tank venting**

Discharge piping from safety relief valves are to be designed so that they prevent clogging by dry ice formation upon safety release. Where arrangements are made to avoid dry ice formation, it should be demonstrated that the outlet flow velocity does not reach the critical speed (sonic velocity). Protective screens are not to be fitted to the outlets of relief valve discharge piping.

#### **4.1.3 Longitudinal strength and stability**

The impact of the liquid stored in CO<sub>2</sub> tank on the ship's longitudinal strength and stability is to be taken into account as indicated in Pt B, Ch 3, App 2, [1.2.19].

### **4.2 CO<sub>2</sub> vapour detection**

#### **4.2.1 CO<sub>2</sub> concentration monitoring**

Spaces containing CO<sub>2</sub> tanks, CO<sub>2</sub> compression and liquefaction equipment and other enclosed spaces where CO<sub>2</sub> could accumulate are to be fitted with continuous monitoring for CO<sub>2</sub> build-up.

### **4.3 Ventilation**

**4.3.1** Spaces containing CO<sub>2</sub> tanks, CO<sub>2</sub> compression and liquefaction equipment and other enclosed spaces where CO<sub>2</sub> could accumulate are to be continuously ventilated with minimum six air changes per hour such that any release of CO<sub>2</sub> will be

effectively dispersed in order to prevent the formation of a low oxygen atmosphere. The ventilation system serving such spaces is to be independent mechanical ventilation of the extraction type.

**4.3.2** Where the spaces referred to in [4.3.1] may be entered in normal operation, the ventilation capacity is to be automatically increased to 10 air changes per hour in case of CO<sub>2</sub> leakage detection.

## 5 Personal protection

### 5.1 Protective equipment

**5.1.1** For the protection of crew members, the ship is to have on board personal protective equipment (PPE) suitable for solvent handling. The number of PPE carried on board is to be appropriate for the number of personnel engaged in regular handling operations or that may be exposed in the event of a failure; but in no case is there to be less than two sets available on board.

**5.1.2** Personal protective equipment (PPE) is to consist of:

- low temperature- and solvent-resistant protective clothing, boots, gloves and tight-fitting goggles and
- two self-contained breathing apparatus.

### 5.2 Emergency equipment

**5.2.1** Eyewash and safety showers are to be provided, the location and number of these eyewash stations and safety showers are to be derived from the detailed installation arrangements.

## 6 Certification and surveys at works

### 6.1 General

**6.1.1** Certification and workshop inspections are to be performed on:

- the various components of CCS system
- the materials used for their manufacture.

### 6.2 Type approval

**6.2.1** The following CCS components are to be of a type approved by the Society:

- Solvent system:
  - Hoses, see Ch 1, Sec 10, [20.2]
- CO<sub>2</sub> system:
  - Pumps, see Pt D, Ch 9, Sec 5, [13.2]
  - Expansion bellows, see Pt D, Ch 9, Sec 5, [13.4]
  - Hoses, see Pt D, Ch 9, Sec 5, [11.7].

### 6.3 Inspection and testing

**6.3.1** The CCS components are to be inspected and tested at works in accordance with the requirements of Tab 4.

**Table 4 : Inspection and testing for the CCS system components**

Item	Tests for the materials		Inspections and tests for the product		
	Tests required	Type of material certificate	During manufacturing (NDT)	After completion	Type of product certificate
<b>EXHAUST GAS SYSTEM AND SEPARATION SYSTEM</b>					
Exhaust gas (direct contact) cooler shell			Magnetic particle or liquid penetrant testing (1)	Ch 1, Sec 10, [20.5.5]	C
Exhaust gas blower				Ch 1, Sec 10, [20.5.5]	C

<b>(1)</b> To be performed on welded joints selected according to manufacturer's plan <b>(2)</b> For parts in contact with the fluid <b>(3)</b> For welded joints					

# Section 13 Ballast Water Management Systems

## 1 General

### 1.1 Application

#### 1.1.1 Installation

Requirements for the installation of ballast water management systems (BWMS), are given in Articles [2] to [4] and:

- Ch 4, Sec 3, [3.3] for fire detection arrangement in spaces containing a ballast water management system
- Ch 4, Sec 6, [7] for fire-extinguishing arrangements for ballast water management rooms
- Ch 4, Sec 5 for fire integrity requirements applicable to ballast water management room (BWMR) and to spaces intended for the storage of liquid or solid chemicals for BWMS.

#### 1.1.2 Certification

Requirements for the certification of ballast water management systems (BWMS) are given in Article [5].

### 1.2 Acronyms

1.2.1 The following acronyms are used in this Section:

AOT	: Advanced oxidation technology
BWM	: Ballast water management
BWMP	: Ballast water management plan
BWMR	: Ballast water management room
BWMS	: Ballast water management system
IGG	: Inert gas generator
TAC	: Type approval certificate
TiO <sub>2</sub>	: Titanium dioxide catalyst used in combination with UV treatment
TRC	: Treatment rated capacity.

### 1.3 Definitions

1.3.1 Ballast water management system (BWMS) means any system which processes ballast water such that it meets or exceeds the ballast water performance standard in Regulation D-2 of IMO BWM Convention. The BWMS includes ballast water equipment, all associated piping arrangements as specified by the manufacturer, control and monitoring equipment and sampling facilities. The categorization of BWMS technologies is given in Tab 1. Applicability of the requirements for each BWMS technology is in accordance with Tab 2.

Taking into consideration future developments of BWMS technologies, some additional technologies may be considered in Tab 1.

1.3.2 Cargo area of tankers is defined:

- for oil tankers and FLS tankers, in Pt D, Ch 7, Sec 1, [1.2.1]
- for chemical tankers, in paragraph 1.3.6 of the IBC Code as amended by IMO resolutions up to MSC.460 (101)
- for gas carriers, in Pt D, Ch 9, Sec 1, [4.1.8]
- for offshore support vessels, in Pt E, Ch 3, Sec 1, [1.5.6].

1.3.3 Dangerous gas means any gas which may develop an atmosphere being hazardous to the crew and/or the ship due to flammability, explosivity, toxicity, asphyxiation, corrosivity or reactivity and for which due consideration of the hazards is required, e.g. hydrogen (H<sub>2</sub>), hydrocarbon gas, oxygen (O<sub>2</sub>), carbon dioxide (CO<sub>2</sub>), carbon monoxide (CO), ozone (O<sub>3</sub>), chlorine (Cl<sub>2</sub>) and chlorine dioxide (ClO<sub>2</sub>), etc.

1.3.4 Dangerous liquid means any liquid that is identified as hazardous in the Material Safety Data Sheet or other documentation relating to this liquid.

**1.3.5** Hazardous area is defined in Ch 2, Sec 1, [3.25]. When a gas atmosphere is present, the following hazards may also be present: toxicity, asphyxiation, corrosivity and reactivity.

**1.3.6** Non-hazardous area means an area which is not a hazardous area as defined in [1.3.5].

**1.3.7** A ballast water management room (BWMR) is any space containing equipment belonging to the BWMS. A space containing remote controls for the BWMS or a space dedicated to the storage of liquid or solid chemicals for BWMS need not be considered as a BWMR for the purposes of this Section.

**1.4 Documents to be submitted**

**1.4.1** The documents listed in Tab 3 are to be submitted.

**1.4.2** In the case of installation of a BWMS on an existing ship, the documents listed in Tab 4 are to be submitted in addition to those required in [1.4.1].

**Table 1 : Categorization of BWMS technologies**

		BWMS's Technology category										
		1	2	3a	3b	3c	4	5	6	7a	7b	8
Characteristics		In-line UV or UV + Advanced Oxidation Technology (AOT) or UV + TiO <sub>2</sub> or UV + Plasma	In-line Flocculation	In-line membrane separation and de-oxygenation (injection of N <sub>2</sub> from a N <sub>2</sub> Generator)	In-line-de-oxygenation (injection of Inert Gas from Inert Gas Generator)	In-tank de-oxygenation with Inert Gas Generator	In-line full flow electrolysis	In-line side stream electrolysis (2)	In-line (stored) chemical injection	In-line side- stream ozone injection without gas/liquid separation tank and without discharge treatment tank	In-line side-stream ozone injection with gas/liquid separation tank and discharge water treatment tank	In-tank pasteurization and de-oxygenation with N <sub>2</sub> generator
Des-infection when ballasting	Making use of active substance			X		In-tank technology: No treatment when ballasting or de-ballasting	X	X	X	X	X	In-tank technology: No treatment when ballasting or de-ballasting
	Full flow of ballast water is passing through the BWMS	X	X	X	X		X				X	
	Only a small part of ballast water is passing through the BWMS to generate the active substance								X			
After-treatment when de-ballasting	Full flow of ballast water is passing through the BWMS	X									X	
	Injection of neutralizer						X	X	X	X	X	
	Not required by the Type Approval Certificate issued by the Flag Administration		X	X								
Examples of dangerous gas as defined in [1.3.3]			(1)	O <sub>2</sub> N <sub>2</sub>	CO <sub>2</sub> CO		H <sub>2</sub> Cl <sub>2</sub>	H <sub>2</sub> Cl <sub>2</sub>	(1)	O <sub>2</sub> O <sub>3</sub> N <sub>2</sub>	O <sub>2</sub> N <sub>2</sub>	
<p>(1) To be investigated on a case by case basis based on the result of the IMO (GESAMP) MEPC report for Basic and Final approval in accordance with the G9 Guideline.</p> <p>(2) In-line side stream electrolysis may also be applied in-tank in circulation mode (no treatment when ballasting or de-ballasting).</p>												

**Table 2 : Applicability of the requirements for each BWMS technology**

Applicable requirements	BWMS's Technology category										
	1	2	3a	3b	3c	4	5	6	7a	7b	8
	In-line UV or UV + Advanced Oxidation Technology (AOT) or UV + TiO <sub>2</sub> or UV + Plasma	In-line Flocculation	In-line membrane separation and de-oxygenation (injection of N <sub>2</sub> from a N <sub>2</sub> Generator)	In-line-de-oxygenation (injection of Inert Gas from Inert Gas Generator)	In-tank de-oxygenation with Inert Gas Generator	In-line full flow electrolysis	In-line side stream electrolysis	In-line (stored) chemical injection	In-line side-stream ozone injection without gas/liquid separation tank and without discharge treatment tank	In-line side-stream ozone injection with gas/liquid separation tank and discharge water treatment tank	In-tank pasteurization and de-oxygenation with N <sub>2</sub> generator

**Table 3 : List of documents to be submitted**

No.	I/A (1)	Document (2)
1	A	Diagram of the ballast system (inside and outside machinery spaces)
2	A	Diagram of the BWMS with location of ballast water sampling facilities
3	I	Type Approval Certificate of the BWMS
4	A	In case active substances are used: <ul style="list-style-type: none"> <li>Storage tanks and day tanks containing chemicals including: <ul style="list-style-type: none"> <li>Filling, drain system, venting system, drip trays, soundings,...</li> <li>Tanks capacity in regards of the expected rate of consumption, capacity of the ballast water system and required endurance</li> </ul> </li> <li>Safety documentation for active substance used, such as material safety data sheet (MSDS) from supplier</li> </ul>
5	I	Technical description of the BWMS's operating principles, containing also operational and maintenance procedures, and backup procedures in case of equipment malfunction. It is to include a risk assessment if at least one of the following conditions is met: <ul style="list-style-type: none"> <li>The system uses noxious chemical</li> <li>Dangerous gases or vapors may accumulate within the ballast system during operation</li> <li>Accelerated corrosion or deterioration of tank coating may occur due to the treated ballast water</li> </ul>
6	I	Technical installation specification which was submitted in support of the BWMS statutory approval, with: <ul style="list-style-type: none"> <li>Initial calibration procedures</li> <li>Installation commissioning procedures</li> </ul>
7	I	BWMS safety and manual operating containing chemical injection procedures, alarm systems, measures in case of emergency, etc. Equipment manuals for major components of the BWMS
8	A	Electrical load analysis, demonstrating the adequacy of the generating plant capacity under normal operating conditions of ballasting and de-ballasting given in the ballast water management plan (BWMP) (3)
<p>(1) A = to be submitted for approval I = to be submitted for information.  (2) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.  (3) For retrofit installation to existing ships, a revised electrical load analysis with preferential trips of non-essential services can be accepted.</p>		

**Table 4 : List of additional documents to be submitted in the case of installation of a BWMS on an existing ship**

No.	I/A (1)	Document (2)
1	A	General arrangement plan of the BWMS in the ship
2	I	Shipboard test plan for sea and/or quay trial
3	A	Other piping and instrument diagram, if the BWMS is connected to others systems (control air, bilge, fresh water, cooling system,...)
4	A	General arrangement of the electrical components: <ul style="list-style-type: none"> <li>General layout specifying the interconnection of the major electrical components of the system</li> <li>Ingress protection (IP) of the electrical panels and associated devices (junction boxes, electrical motors, etc.)</li> <li>Interconnection diagram or document describing the link between the BWMS and the ship's alarm system</li> </ul>
5	A	Safety and protection: <ul style="list-style-type: none"> <li>List of alarms and safeties of the system</li> <li>List of electrical sensors/components in hazardous areas, when applicable</li> <li>Characteristics and certifications of the electrical devices added during the integration of the BWMS: electrical cables, detectors, etc.</li> </ul>
6	A	Single line diagram showing the power electrical arrangement to supply the BWMS unit
7	I	Type of cables to be installed provided with the related Type Approval Certificates
8	A	Structural fire protection plan, including fire categorization, at least for the modified/new spaces, and including traces of the previous arrangement
<p>(1) A = to be submitted for approval I = to be submitted for information.  (2) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.  (3) The installation of the BWMS may have an impact on the ship's stability, such as on the lightweight, position of the center of gravity, position of watertight bulkhead (the watertight integrity). In order to evaluate the impact of the added weight of the BWMS on the stability, the weight of the added BWMS and the exact position of its center of gravity (VCG, LCG, and TCG) are to be provided. Subject to the Society's satisfaction, the submission of the documents may not be required.</p>		

No.	I/A (1)	Document (2)
9	A	Type approval certificates of newly installed materials with regards to fire protection, including especially pipe and/or cable penetrations in fire divisions
10	A	Ventilation, fire extinguishing and detection systems, to be documented if the integration of BWMS on board the ship has impact on such systems
11	A	Updated fire control plan
12	A	Updated hazardous area plan
13	A	In case the installation of the BWMS requires structural modifications of the vessel (relocation of watertight bulkheads, new openings, new pipe routings in the damage zone which may lead to progressive flooding) (3): <ul style="list-style-type: none"> <li>• Updated damage control plan and booklet</li> <li>• Updated damage stability booklet</li> </ul>
14	A	In case a deviation from lightship displacement or longitudinal center of gravity exceeding the recommended deviation is found, in comparison with the approved stability booklet (3): <ul style="list-style-type: none"> <li>• Inclining experiment report</li> <li>• Updated trim and stability booklet</li> </ul>
15	A	Updated structural drawings, reflecting the new arrangement, and including the supporting structure and information on reaction loads
16	I	In case of capacity creation: Updated capacity plan, including the density of the liquid to be loaded

(1) A = to be submitted for approval I = to be submitted for information.  
(2) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.  
(3) The installation of the BWMS may have an impact on the ship's stability, such as on the lightweight, position of the center of gravity, position of watertight bulkhead (the watertight integrity). In order to evaluate the impact of the added weight of the BWMS on the stability, the weight of the added BWMS and the exact position of its center of gravity (VCG, LCG, and TCG) are to be provided. Subject to the Society's satisfaction, the submission of the documents may not be required.

## 2 Installation

### 2.1 General requirements

#### 2.1.1 Maximum treatment rated capacity

In case the maximum capacity of the ballast pump(s) exceeds the maximum treatment rated capacity (TRC) of the BWMS specified in the TAC issued by the Flag Administration, there should be a limitation on the BWMP giving a maximum allowable flow rate for operating the ballast pump(s) that is not to exceed the maximum TRC of the BWMS.

Additionally, in case the TRC is exceeded the system shall give an alarm which is to be recorded.

#### 2.1.2 By-pass or override arrangements

- The BWMS is to be provided with bypass or override arrangement to effectively isolate it from any essential ship system to which it is connected.
- Any by-pass or override operation is to trigger an audible and visual alarm and these events are to be automatically recorded in control equipment. This requirement is also applicable to gravity ballast pipes.
- Where the ship's ballast pump flow rates need to be limited in order to ensure operation of the BWMS within the limits of the BWMS TAC, the arrangement of the bypasses or overrides of the BWMS is to be consistent with the approved Operation Maintenance and Safety Manual by the Flag Administration's type approval.

### 2.2 Location and arrangement of BWMR and chemical substance storage rooms

#### 2.2.1 BWMS using chemical substances

For BWMS storing, introducing or generating chemicals, the BWMR and chemical substance storage rooms are not to be located in the accommodation area. Any ventilation exhaust or other openings from these rooms are to be located not less than 3m from entrances, air inlets and openings to accommodation spaces.

This requirement need not apply in case the BWMS is located in the engine room.

### **2.2.2 Ozone-based BWMS**

Ozone-based BWMS ( i.e. cat.7a and 7b) are to be located in dedicated compartment, separated from any other space by gastight boundaries. Access to the BWMR from any other enclosed space is to be through airlock only, except if the only access to that space is from the open deck.

Access to the ozone based BWMR may be provided through the engine room only provided:

- access from the engine room to the BWMR is through airlock
- an alarm repeater is provided in the BWMR, which will repeat any alarm activated in the engine room.

A sign is to be affixed on the door providing personnel with a warning that ozone may be present and with the necessary instructions to be followed before entering the room.

### **2.2.3 Doors**

BWMR containing equipment for BWMS of the following types are to be equipped with tested gastight and self-closing doors without any holding back arrangements:

- BWMS storing, introducing or generating chemical substances
- de-oxygenation based on inert gas generator
- electrolysis
- ozone injection.

Doors leading to the open deck need however not to be self-closing.

## **2.3 Location of chemical substance storage tanks**

**2.3.1** When the chemical substances are stored inside integral tanks, the ship's shell plating is not to form any boundary of the tank.

**2.3.2** Tanks containing chemicals are to be segregated from accommodation, service spaces, control stations, machinery spaces not related to the BWMS and from drinking water and stores for human consumption by means of a cofferdam, void space, cargo pump-room, empty tank, oil fuel storage tank, BWMR or other similar space. On-deck stowage of permanently attached deck tanks or installation of independent tanks in otherwise empty hold spaces should be considered as satisfying this provision.

## **2.4 Piping systems**

**2.4.1** All valves, piping fittings and flanges are to comply with the relevant requirements of Ch 1, Sec 10. In addition, special consideration may be given to the material used for this service with the agreement of the Society.

**2.4.2** Where a vacuum or overpressure may occur in the ballast piping or in the ballast tanks due to the height difference or injection of inert gas or nitrogen ( $N_2$ ), a suitable protection device is to be provided (i.e. P/V valves, P/V breakers, P/V breather valves or pressure safety relief valve or high/low pressure alarms). The pressure and vacuum settings of the protection device are not to exceed the design pressure of the ballast piping (BWMS categories 3a and 3b) or ballast tank (BWMS categories 3a, 3b and 3c), as relevant.

**2.4.3** For BWMS categories 3a, 3b and 3c, the inert gas or nitrogen product enriched air from the inert gas system and from the protection devices installed on the ballast tanks (i.e. P/V valves, P/V breakers or P/V breather valves) are to discharge to a safe location on the open deck. See [2.9].

**2.4.4** When cavitation is the BWMS treatment process (for example by use of pressure vacuum reactor working in combination with a vertical ballast water drop line) or part of the BWMS treatment process (for example by use of "smart pipe" or "special pipe" in BWMS category 7b or by use of "venturi pipe" in BWMS technology 3b) or by use other means, the design and the wall thickness or grade of materials or inside coating or surface treatment of the part of the piping where the cavitation is taking place is to be specifically considered.

## **2.5 Electrical and automation systems**

**2.5.1** The capacity of the generating plant is to be sufficient to support the operation of the BWMS under normal operating conditions of ballasting and de-ballasting given in the Ballast Water Management Plan (BWMP).

**2.5.2** Overcurrent or overvoltage protection is to be installed to protect UV type BWMS.

**2.5.3** Electrolysis reactors are to be provided with at least two independent means of monitoring operation. The monitoring system is to initiate audible and visual alarms and automatic shutdown of the BWMS in the event that an anomaly is detected. If a pressure relief valve is also provided, the vent of this valve is to be led to a safe location on the open deck, as clarified in Tab 8. The valve is to be positioned to optimally remove gas from the electrolysis reactor.

**2.5.4** When it is required to have an automatic shutdown of the BWMS for safety reasons, this is to be initiated by a safety system independent of the BWM control system.

**2.5.5** For ships to be assigned an **AUT** additional class notation, alarms and indications required by the present sub-article are to be provided at the centralised control position, see Pt F, Ch 3, Sec 1, [4.8.10].

## **2.6 Hazardous areas**

### **2.6.1 Extension of hazardous areas related to the cargo vapours**

When the concerned ballast tanks are hazardous areas, an extension of hazardous area is to be considered at the outlet of the protection devices: with reference to IEC 60092-502:1999 §4.2.2.9 the areas on open deck, or semi-enclosed spaces on open deck, within 1,5 m of their outlets are to be categorized hazardous zone 1 and with reference to IEC 60092-502:1999 §4.2.3.1, an additional 1,5 m surrounding the 1,5 m hazardous zone 1 is to be categorized hazardous zone 2. Any source of ignition such as anchor windlass or opening into chain locker is to be located outside the hazardous areas.

### **2.6.2 Hazardous areas related to the flammable vapours from the treatment substances or generated by the BWMS**

Where products covered by IEC 60092-502:1999 are stored on board or generated during operation of the BWMS, the requirements of this standard are to be followed in order to:

- define hazardous areas and acceptable electrical equipment
- design ventilation systems.

**2.6.3** Electric and electronic components are not to be installed in a hazardous area unless they are of a certified safe type for use in this area. Cable penetrations of decks and bulkheads are to be sealed when a pressure difference between the areas is to be maintained.

## **2.7 Inert gas systems**

**2.7.1** Inert gas systems installed for de-oxygenation BWMS (categories 3a, 3b, 3c and 8) are to be designed in accordance with the following requirements:

- a) Ch 4, Sec 15, [13]:
  - Ch 4, Sec 15, [13.1.1], items b) and c)
  - Ch 4, Sec 15, [13.2.1]  
Ch 4, Sec 15, [13.2.2], items a), b), c) and f)  
Ch 4, Sec 15, [13.2.4] except requirements for low pressure gas alarm in items e) 1) and e) 3)
  - Ch 4, Sec 15, [13.3.2], items a) 2), b), d) 2), e) and f)  
Ch 4, Sec 15, [13.3.3] except item b) requirement for an alarm for insufficient fuel oil supply to the oil-fired inert gas generator
  - Ch 4, Sec 15, [13.4.2], items c) and d)  
Ch 4, Sec 15, [13.4.3]
  - For inert gas systems installed for in-tank de-oxygenation BWMS (category 8):  
Ch 4, Sec 15, [13.2.3] items a) and b) except b) 6), b) 7) and b) 10).

In general, when applying Ch 4, Sec 15, [13] requirements to inert-gas based BWMS, the following modifications are to be considered:

- the terms “cargo tank” and “cargo piping” are to be replaced by “ballast water tank” or “ballast water piping” as relevant
  - the term “cargo control room” is to be replaced by “BWMS control station” as relevant
  - requirements for slop tanks on combination carriers are to be disregarded
  - when applying Ch 4, Sec 15, [13.2.4] item e) 1), the acceptable oxygen content is to be specified by the manufacturer, 5% oxygen content need not necessarily be applied.
- b) Pt D, Ch 7, Sec 6, [5.2.2]  
Pt D, Ch 7, Sec 6, [5.3.1]  
Pt D, Ch 7, Sec 6, [5.3.3]  
Pt D, Ch 7, Sec 6, [5.3.7]  
Pt D, Ch 7, Sec 6, [5.3.8]  
Pt D, Ch 7, Sec 6, [5.4.4]. In applying Pt D, Ch 7, Sec 6, [5.4.4], the terms “cargo tanks” and “cargo piping” are to be understood as “ballast tanks” and “ballast piping” respectively. For de-oxygenation BWMS (categories 3a, 3b, 3c and 8), the requirements in item a) prevail.

## 2.8 Ventilation systems

**2.8.1** The ventilation systems for BWMR containing BWMS of the following types is to be independent of the ventilation systems serving any other spaces:

- BWMS storing, introducing or generating chemical substances
- de-oxygenation, including pasteurization and de-oxygenation (cat.3 and cat.8 as per Tab 1)
- electrolysis
- ozone injection.

**2.8.2** The ventilation exhaust for BWMR containing a nitrogen generator is to be located in the lower part of the room in order to efficiently evacuate dangerous gases (as defined in [1.3.3]) heavier than air.

**2.8.3** The ventilation exhaust for BWMR containing electrolysis systems is to be located so as to be able to efficiently evacuate dangerous gases (as defined in [1.3.3]) that could be generated during the electrolysis process. Due regard is to be paid to the expected quantity and density of such gases when designing the ventilation exhaust.

**2.8.4** The following requirements apply to ventilation ducts serving BWMR for ozone-based BWMS:

- the part of the ducts located outside of the BWMR are to be made of steel having a thickness of at least 3 mm for ducts with a free cross-sectional area of less than 0,075 m<sup>2</sup>, at least 4 mm for ducts with a free cross-sectional area of between 0,075 m<sup>2</sup> and 0,45 m<sup>2</sup>, and at least 5 mm for ducts with a free cross-sectional area of over 0,45 m<sup>2</sup>
- the ducts are to be suitably supported and stiffened
- the outside openings of the ducts are to be fitted with protective screens of not more than 13 mm square mesh.

**2.8.5** The ventilation system for BWMR containing ozone-based BWMS or ventilation system for hydrogen de gas arrangement as required by [4.3.6] is to be interlocked with the BWMS such that:

- in case of loss of ventilation (primary and secondary), a visual and audible alarm is to be triggered both inside and outside the BWMR and at a place where a responsible member of the crew is on duty. If the ventilation is not restored after a pre-set time, the BWMS is then to be automatically shut down. Any need for cooldown necessary for safe shutdown is to be considered in the shutdown sequence
- it is not possible to start the BWMS without the ventilation running.

For ventilation systems serving BWMR and containing or conveying a dangerous gas, relevant requirements in [4] are to be satisfied.

**2.8.6** An adequate power ventilation system is to be provided in enclosed BWMR.

**2.8.7** The ventilation capacity is to be at least 30 air changes per hour where explosive or toxic gases may be generated during operation of the BWMS. The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (G9 Guidelines) and "safety hazard" as listed in Chapter 17 of IBC code are to be used as references for identifying those cases.

The ventilation capacity may be reduced as per Tab 5.

**Table 5 : Reduced ventilation capacity**

Type of BWMS	Reduced ventilation capacity (air changes per hour) (1)
Flocculation-type BWMS	6
De-oxygenation, including pasteurization and de-oxygenation (cat.3 and cat.8 as per Tab 1)	6
Full flow electrolysis	6
Side-stream electrolysis	20
Ozone injection	20
Chemical injection	6

(1) More stringent ventilation capacity requirements may arise from other applicable rules, e.g. Part D, Chapter 8 for spaces located in the cargo area of ships having the service notation **chemical tanker**.

## 2.9 Safe locations for venting

**2.9.1** Safe locations referred to in [2.4.3] are to comply with the provisions of Tab 6.

**2.9.2** Safe location needs to address the specific types of discharges separately.

**2.9.3** Signboards or similar warnings at the discharge areas are to be provided.

Table 6 : Safe locations for venting

Nature of the discharged gas	Concerned BWMS category	Origin of the discharge or vent	Acceptable safe locations of the discharge or vent outlet on the open deck
Inert gas or nitrogen product enriched air	In-line (categories 3a and 3b) and in-tank (categories 3c and 8) de-oxygenation BWMS	Protection devices installed on the ballast tanks, nitrogen or inert gas generators, nitrogen buffer tank (if any)	<ul style="list-style-type: none"> <li>Not within 3 m of areas traversed by personnel</li> <li>Not within 6 m of air intakes for machinery (engines and boilers) and all ventilation inlets/outlets.</li> </ul>
	In-line ozone injection BWMS (categories 7a and 7b)	Oxygen generator	
Oxygen-enriched air	In-line and in-tank de-oxygenation BWMS (categories 3a and 8)	Nitrogen generator	<ul style="list-style-type: none"> <li>Outside of hazardous area</li> <li>Not within 3 m of any source of ignition and from deck machinery, which may include anchor windlass and chain locker openings, and equipment which may constitute an ignition hazard</li> <li>Not within 3 m of areas traversed by personnel</li> <li>Not within 6 m of air intakes for machinery (engines and boilers) and all ventilation inlets.</li> </ul>
	In-line ozone injection BWMS (categories 7a and 7b)	Protection devices or vents from oxygen generator, compressed oxygen vessel, the ozone generator and ozone destructor devices	
Hydrogen by-product enriched gas	In-line full flow electrolysis BWMS (category 4), in-line side-stream electrolysis BWMS (category 5) and in-line injection BWMS using chemical which is stored onboard (category 6)	Hydrogen de-gas arrangement (when provided)	<ul style="list-style-type: none"> <li>Not within 5 m of any source of ignition and from deck machinery, which may include anchor windlass and chain locker openings, and equipment which may constitute an ignition hazard</li> <li>Not within 3 m of areas traversed by personnel</li> <li>Not within 5 m of air intakes from non-hazardous enclosed spaces.</li> </ul> <p>(1)</p>
Gas from O <sub>3</sub> destructor device (ODS)	In-line ozone injection BWMS (categories 7a and 7b)	ODS fulfilling the following conditions: <ul style="list-style-type: none"> <li>the ODS are duplicated; and</li> <li>the manufacturer justified that the quantity of consumable (activated carbon) used by the ODS is sufficient for the considered life cycle of the BWMS</li> <li>ozone detection is arranged in the vicinity of the discharge outlet from the vent outlet of the ODS to alarm the crew in case the ODS is not working.</li> </ul>	The safe locations defined for oxygen-enriched air apply
		ODS not fulfilling one of the above conditions	<ul style="list-style-type: none"> <li>Outside of hazardous area</li> <li>Not within 3 m of any source of ignition</li> <li>Not within 6 m of areas traversed by personnel</li> <li>Not within 6 m of air intakes for machinery (engines and boilers) and all ventilation inlets.</li> </ul>
<p>(1) The areas on open deck, or semi-enclosed spaces on open deck, within 3 m of the outlets are to be categorized hazardous area zone 1 plus an additional 1,5 m surrounding the 3 m hazardous area zone 1 is to be categorized hazardous area zone 2. Electrical apparatus located in the above hazardous areas zone 1 and zone 2 is to be suitable for at least IIC T1.</p>			

## 2.10 Personal equipment

**2.10.1** Suitable protection equipment are to be available on board for the protection of the crew members who are engaged in the servicing, maintenance and repair of BWMS storing, introducing or generating chemicals, as recommended by the product manufacturers. The protection equipment is to consist of large aprons, special gloves with long sleeves, suitable footwear, coveralls of chemical-resistant materials, and tight fitting goggles or face shields or both. The protective clothing and equipment are to cover all skin so that no part of the body is unprotected. This protection equipment is to be provided separately without taking into account equipment required by other mandatory requirements.

**2.10.2** Work clothes and protective equipment are to be kept in easily accessible places and in special lockers. Such equipment are not to be kept within accommodation spaces, with the exception of new, unused equipment and equipment which has not been used since undergoing a thorough cleaning process. Notwithstanding the above, storage rooms for such equipment may be located within accommodation spaces if adequately segregated from living spaces such as cabins, passageways, dining rooms, bathrooms, etc.

**2.10.3** When a BWMS storing, introducing or generating chemicals is installed on board, suitably marked decontamination showers and an eyewash are to be available in a convenient location in close proximity to the BWMS and the chemical store room(s).

**2.10.4** An emergency escape breathing apparatus (EEBD) is to be provided in the BWMR. This emergency escape breathing apparatus may be one of the EEBDs provided in accordance with the requirements of SOLAS II-2/13.

An EEBD need not be required for BWMS of cat.1 as per Tab 1.

**2.10.5** A personal ozone detector, calibrated as per the manufacturer's specifications, is to be provided for each person engaged in the servicing, maintenance and repair of BWMS utilizing ozone.

**2.10.6** A two-way portable radiotelephone apparatus dedicated for the BWMS service, maintenance and repair is to be provided, in addition to those required by SOLAS for fire-fighting purposes. This two-way radiotelephone apparatus is to be properly identified in order to avoid mix-up with the apparatus intended for fire-fighting operations. Where the BWMS may release explosive gases, this two-way radiotelephone apparatus is to be of a certified safe type suitable for use in zone 1 hazardous areas, as defined in IEC Publication 60079. Where the BWMS stores, utilizes or introduces chemicals, the apparatus is to undergo deep cleaning or de-contamination after use.

A two-way portable radiotelephone apparatus need not be required for BWMS of cat.1 as per Tab 1.

## 3 Additional requirements for tankers and offshore service vessels

### 3.1 Application

**3.1.1** The requirements of this Article apply to:

- oil tankers and FLS tankers (excluding ships carrying only products with flashpoint > 60°C)
- chemical tankers
- gas carriers
- offshore support vessels carrying flammable or hazardous liquid substances in bulk.

### 3.2 Location of BWMS

**3.2.1** BWMS using ozone generators (categories 7a and 7b) and de-oxygenation BWMS using inert gas generator by treated flue gas from main or auxiliary boilers or gas from an oil or gas-fired gas generator (categories 3b and 3c) are to be located outside the cargo area in accordance with Ch 4, Sec 15, [13.3.2], item a) 2).

This requirement does not apply to nitrogen generators.

**3.2.2** In-line full flow electrolysis BWMS (category 4), in-line side-stream electrolysis BWMS (category 5) and in-line injection BWMS using chemical which is stored on board (category 6) can be located inside the hazardous areas with due consideration of the requirement of [2.6.3] but are not to be located inside the cargo pump room unless it is demonstrated by the BWMS manufacturer that the additional hazards that could be expected from dangerous liquids and dangerous gases stored or evolved from the BWMS (for example H<sub>2</sub> generation):

- do not lead to an upgrade of the hazardous area categorization of the cargo pump room
- are not reactive with the cargo vapours expected to be present in the cargo pump room
- are not reactive with the fire-extinguishing medium provided inside the cargo pump room
- are not impacting the performance of the existing fire-fighting systems provided inside the cargo pump room
- are not introducing additional hazards inside the cargo pump room such as toxicity hazards that would not have been addressed before by suitable counter measures.

In-line full flow electrolysis BWMS (category 4) may be accepted in cargo compressor rooms of liquefied gas carriers and inside cargo pump rooms of oil tankers or chemical tankers if that cargo pump room is located above the cargo tank deck.

For submerged cargo pumps, the room containing the hydraulic power unit or electric motors is not to be considered as the “cargo pump room”.

Ballast pump rooms and other pump rooms not containing the cargo pumps are not to be considered as the “cargo pump room”.

### **3.3 Independent BWMS**

**3.3.1** In general, two independent BWMS are required i.e. one for ballast tanks located within the cargo area and the other one for ballast tanks located outside cargo area. Specific arrangements where only one single In-line BWMS (categories 1, 2, 3a, 3b, 4, 5, 6, 7a and 7b) could be accepted are given in [3.7].

### **3.4 Case of tankers where the fore peak ballast tank and other ballast tanks within the cargo area are served by a common piping system**

**3.4.1** When the fore peak tank is ballasted with the piping system serving the other ballast tanks within the cargo area in accordance with Pt D, Ch 7, Sec 4, [2.3.8] or Pt D, Ch 8, Sec 3, [5.1.3], the ballast water of the fore peak tank is to be processed by the BWMS processing the ballast water of the other ballast tanks within the cargo area.

### **3.5 Isolation means**

**3.5.1** Isolation between ballast piping serving the ballast tanks inside and outside of the cargo area is to be in accordance with [3.5.2] to [3.5.8]

**3.5.2** Interconnection between the ballast piping serving the ballast tanks located within the cargo area and the ballast piping serving the ballast tanks located outside the cargo area may be accepted if appropriate isolation arrangement is provided in accordance with [3.7].

**3.5.3** The means of appropriate isolation described in [3.5.6] is necessary for the interconnection specified in [3.5.6] regardless of the diameter of the piping.

**3.5.4** As indicated in [3.7], the means of appropriate isolation described in [3.5.6] is necessary for the interconnection specified in [3.5.6] in the case of the active substance piping such as N<sub>2</sub> gas piping, inert gas piping, neutralizer piping, fresh water piping for filter cleaning, compressed air piping for remaining water purge and sea water piping for adjusting the salinity etc.

**3.5.5** The means of appropriate isolation described in [3.5.6] for the interconnection specified in [3.5.6] need not be applied to the sampling lines described in [3.6].

**3.5.6** The means of appropriate isolation is to be one of the following (see Tab 7):

- a) Two non-return valves with positive means of closing in series with a spool piece (also mentioned “means of dis-connection” in [3.7])

Note 1: As an alternative to positive means of closure, an additional valve having such means of closure may be provided between the non-return valve and the spool piece.

- b) Two non-return valves with positive means of closing in series with a liquid seal at least 1,5 m in depth, provided with freeze protection arrangement in the case of ships operating in cold weather conditions

Note 2: As an alternative to positive means of closure, an additional valve having such means of closure may be provided between the non-return valve and the liquid seal.

Note 3: A portable heating system may be accepted as freeze protection arrangement.

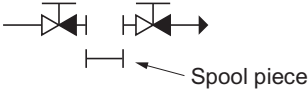

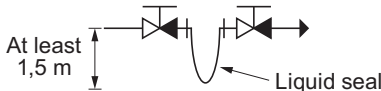

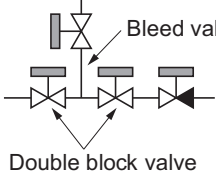

- c) Automatic double block and bleed valves and a non-return valve with positive means of closing.

Note 4: As an alternative to positive means of closure, an additional valve having such means of closure may be provided after the non-return valve.

**3.5.7** The means of appropriate isolation mentioned in [3.5.6] is to be provided on the open deck in the cargo area.

**3.5.8** When the fore peak tank is ballasted with the piping system serving the other ballast tanks within the cargo area in accordance with Pt D, Ch 7, Sec 4, [2.3.8] or Pt D, Ch 8, Sec 3, [5.1.3], the means of appropriate isolation described in [3.5.6] and [3.5.7] is not required in between the fore peak tank and the common ballast water piping serving the other ballast water tanks within the cargo area.

Table 7 : Isolation mean

Two non-return valves with positive means of closing in series with a spool piece	Two non-return valves with positive means of closing in series with a liquid sea	Automatic double block and bleed valves and a non-return valve with positive means of closing
		

3.6 Sampling arrangements

3.6.1 In general, sampling lines which are connected to the ballast water piping system serving the tanks in the cargo area and provided for the purpose of the following:

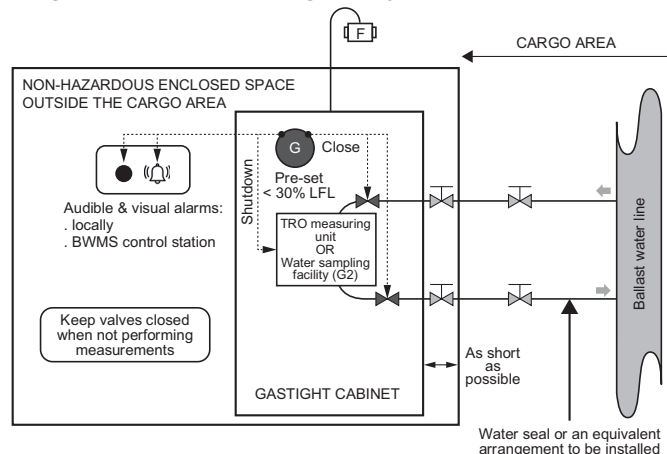

- for any BWMS: ballast water sampling required by the G2 Guideline of the BWM Convention (2004)
- for BWMS technologies categories 4, 5, 6, 7a and 7b: total residual oxidant (TRO) analysis in closed loop system

are not to be led into a non-hazardous enclosed space outside the cargo area.

However, the sampling lines may be led into a non-hazardous enclosed space outside the cargo area provided the following requirements are fulfilled (See Fig 1):

- The sampling facility (for BWMS monitoring/control) is to be located within a gastight enclosure (hereinafter, referred to as a 'cabinet'), and the following 1) through 4) are to be complied
  - in the cabinet, a stop valve is to be installed on each sampling line
  - gas detection equipment is to be installed in the cabinet and the valves specified in item a) 1) are to be automatically closed upon activation of the gas detection equipment
  - audible and visual alarm signals are to be activated both locally and at the BWMS control station when the concentration of explosive gases reaches a pre-set value, which is not to be higher than 30% of the lower flammable limit (LFL). Upon activation of the alarm, the electrical power to the cabinet is to be automatically disconnected except for electrical equipment of certified safe type
  - the cabinet is to be vented to a safe location in a non-hazardous area on the open deck and the vent is to be fitted with a flame arrester.
- The standard internal diameter of sampling pipes is to be the minimum necessary in order to achieve the functional requirements of the sampling system.
- The cabinet is to be installed as close as possible to the bulkhead facing the cargo area, and the sampling lines located outside the cargo area are to be routed on their shortest ways.
- Stop valves are to be located in the non-hazardous enclosed space outside the cargo area, in both the suction and return lines close to the penetrations through the bulkhead facing the cargo area. A warning plate stating "Keep valve closed when not performing measurements" is to be posted near the valves. Furthermore, in order to prevent backflow, a water seal or equivalent arrangement is to be installed on the hazardous area side of the return pipe.
- A stop valve is to be installed on the cargo area for each sampling line (i.e. both the suction and return lines).
- The samples which are extracted from the ballast water piping system serving the tanks within the cargo area are not to be discharged to a tank located outside the cargo area nor to a piping line supplying the spaces located outside the cargo area.

Figure 1 : Arrangement of the sampling facility when located outside the cargo area

### 3.7 Acceptability of single BWMS installation on tankers

#### 3.7.1 Acceptable arrangements of single BWMS for in-line BWMS's technologies

Arrangement of one single BWMS located outside the cargo area of tankers may be accepted in accordance with the provisions of Tab 8.

The detailed arrangements of BWMS are given in [3.7.2].

Note 1: [3.7] does not cover In-tank technologies categories 3c and 8.

#### 3.7.2 Detailed arrangements of single BWMS installed outside the cargo area

The detailed arrangements of single BWMS installed outside the cargo area are listed in Tab 9 and shown in Fig 2 to Fig 8.

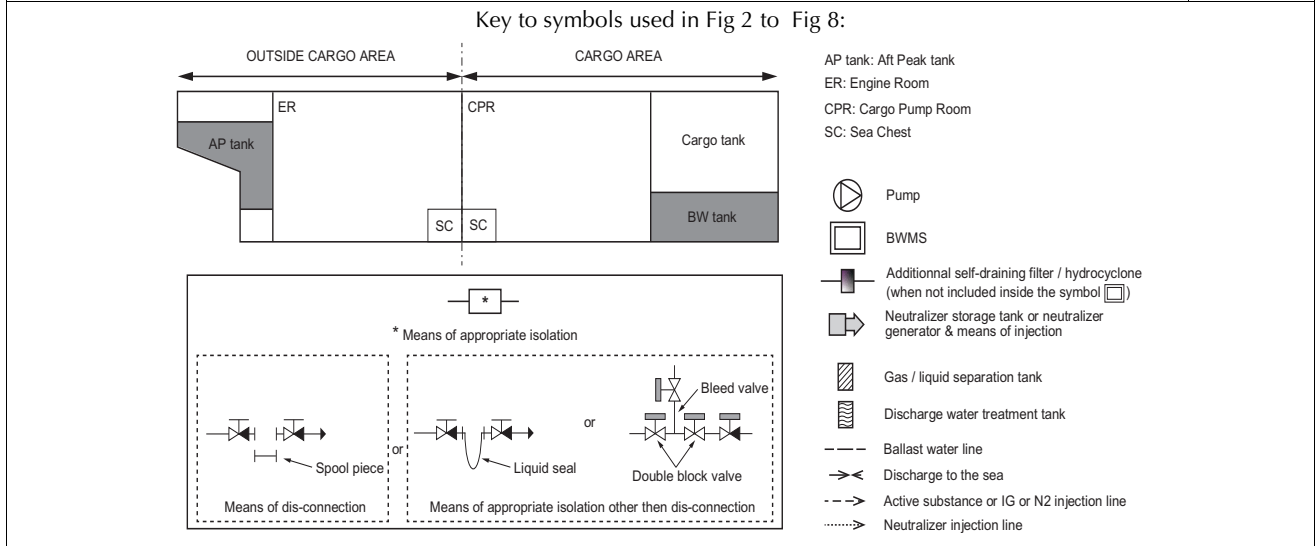

The key to symbols used in these figures are given in Tab 9.

**Table 8 : Acceptable arrangements of one single BWMS depending on the BWMS' technology category**

Characteristics		BWMS's Technology category								
		1	2	3a	3b	4	5	6	7a	7b
		In-line UV or UV + Advanced Oxidation Technology (AOT) or UV + TiO <sub>2</sub> or UV + Plasma	In-line Flocculation	In-line membrane separation and de-oxygenation (injection of N <sub>2</sub> from a N <sub>2</sub> Generator)	In-line-de-oxygenation (injection of Inert Gas from Inert Gas Generator)	In-line full flow electrolysis	In-line side stream electrolysis (3)	In-line (stored) chemical injection	In-line side- stream ozone injection without gas/liquid separation tank and without discharge treatment tank	In-line side- stream ozone injection with gas/liquid separation tank and without discharge water treatment tank
Des-infection when ballasting	Making use of active substance		X			X	X	X	X	X
	Full flow of ballast water is passing through the BWMS	X	X	X	X	X				X
	Only a small part of ballast water is passing through the BWMS to generate the active substance						X			
After-treatment when de-ballasting	Full flow of ballast water is passing through the BWMS	X								X
	Injection of neutralizer					X	X	X	X	X
	Not required by the Type Approval Certificate issued by the Flag Administration		X	X						
Examples of dangerous gas as defined in [1.3.3]			(1)	O <sub>2</sub> N <sub>2</sub>	CO <sub>2</sub> CO	H <sub>2</sub> Cl <sub>2</sub>	H <sub>2</sub> Cl <sub>2</sub>	(1)	O <sub>2</sub> , O <sub>3</sub> , N <sub>2</sub>	
Arrangement of one single BWMS	BWMS is located outside the cargo area	Not acceptable	Case 1.2 (2)	Case 1.3a (2)	Case 1.3b	Case 1.4 (2)	Case 1.5	Case 1.6	Case 1.7a	Case 1.7b (2)
<p>(1) To be investigated on a case by case basis based on the result of the IMO (GESAMP) MEPC report for Basic and Final approval in accordance with the G9 Guideline.</p> <p>(2) Only «Means of dis-connection» as described in [3.5.6], item a) are to be applied.</p> <p>(3) In-line side stream electrolysis may also be applied in-tank in circulation mode (no treatment when ballasting or deballasting).</p>										

**Table 9 : Detailed arrangements of single BWMS installed outside the cargo area**

Case 1.2 (Technology category 2): Flocculation	See Fig 2
Case 1.3a (Technology category 3a): De-oxygenation with N <sub>2</sub> generator	See Fig 2
Case 1.3b (Technology category 3b): De-oxygenation with Inert Gas Generator	See Fig 3
Case 1.4 (Technology category 4): Full-flow electrolysis	See Fig 4
Case 1.5 (Technology category 5): Side-stream electrolysis	See Fig 5
Case 1.6 (Technology category 6): Stored chemical injection	See Fig 6
Case 1.7a (Technology category 7a): Side-stream ozone injection without gas-liquid separation tank and without discharge water treatment tank	See Fig 7
Case 1.7b (Technology category 7b): Side-stream ozone injection with gas-liquid separation tank and discharge water treatment tank	See Fig 8

## 4 Special requirements for BWMS generating dangerous gas or dealing with dangerous liquids

### 4.1 Application

4.1.1 The provisions of this Article apply to BWMS categories 2, 3a, 3b, 3c, 4, 5, 6, 7a, 7b and 8.

### 4.2 BWMS involving the generation of a dangerous gas

4.2.1 Gas detection equipment is to be fitted in the spaces where dangerous gas could be present, and an audible and visual alarm is to be activated both locally and at the BWMS control station in the event of leakage.

The gas detectors are to be located as close as possible to the BWMS components where the dangerous gas may accumulate.

For flammable gases and explosive atmosphere including but not limited to H<sub>2</sub>, the construction, testing and performance of the gas detection devices is to be in accordance with IEC 60079-29-1:2016, IEC 60079-29-2:2015, IEC 60079-29-3:2014 and / or IEC 60079-29-4:2009, as applicable.

Where other hazards are considered like toxicity, asphyxiation, corrosive and reactivity hazards, a recognized standard acceptable to the Society is to be selected with due consideration of the specific gases to be detected and due consideration of the performance of the detection device with regards to the specific atmosphere where it is used.

4.2.2 In spaces where inert gas generator systems are fitted (BWMS categories 3b and 3c) or nitrogen generators are fitted (BWMS categories 3a and 8), at least two oxygen sensors are to be positioned at appropriate locations, as required by Ch 4, Sec 15, [13.2.4], item e), 4), to alarm when the oxygen level falls below 19%. The alarms are to be both audible and visual and are to be activated:

- inside the space
- at the entry into the space
- inside the BWMS control station.

For BWMS categories 7a and 7b, at least two oxygen sensors are to be positioned at appropriate locations in the following spaces:

- spaces where ozone generators are fitted
- spaces where ozone destructors are fitted
- spaces where ozone piping is routed

to alarm when the oxygen level rises above 23%. The alarms are to be both audible and visual and are to be activated at the following locations:

- inside the space
- at the entry into the space
- inside the BWMS control station.

Automatic shutdown of the BWMS is to be arranged when the oxygen level rises above 25%. Audible and visual alarms independent from those specified in the preceding paragraph are to be activated prior to this shutdown.

**4.2.3** For BWMS In-line side-stream ozone injection categories 7a and 7b, at least one ozone sensor is to be provided at the vicinity of the discharge outlet to the open deck from the ozone destructors addressed in Tab 6 to alarm when the ozone concentration level rises above 0,1 ppm. The alarms are to be both audible and visual and are to be activated in the BWMS control room. In addition, at least two ozone sensors are to be positioned at appropriate locations in the following spaces:

- spaces where ozone generators are fitted
- spaces where ozone destructors are fitted
- spaces where ozone piping is routed

to alarm when the ozone concentration level rises above 0,1 ppm. The alarms are to be both audible and visual and are to be activated at the following locations:

- inside the space
- at the entry into the space
- inside the BWMS control station.

Automatic shutdown of the BWMS is to be arranged when the ozone concentration measured from one of the two sensors inside the space rises above 0,2 ppm.

**4.2.4** Inside double walled spaces or pipe ducts constructed as the special safeguard for the purpose of [4.3.1] sensors are to be provided for the detection of H<sub>2</sub> leakages (BWMS categories 4, 5 and 6 when relevant) or O<sub>2</sub> leakages (BWMS categories 7a and 7b) or O<sub>3</sub> leakages (BWMS categories 7a and 7b). The sensors are to activate an alarm at the high level settings and automatic shutdown of the BWMS at the high-high level settings described in [4.2.1] to [4.2.3].

Note 1: As an alternative to the sensor for the gas detection, monitored under-pressurization inside the double walled spaces or pipe ducts may be provided with an automatic alarm and shutdown of the BWMS in case of loss of the under-pressurization. The monitoring can be achieved either by monitoring the pressure inside the double walled spaces or pipe ducts or by monitoring the exhaust fan.

**4.2.5** For in-line full flow electrolysis BWMS (category 4), in-line side-stream electrolysis BWMS (category 5) and in-line injection BWMS using chemical which is stored on board (category 6): the hydrogen de-gas arrangement (when provided) is to be provided with redundant ventilation fans and redundant monitoring of the ventilation system.

In addition the ventilation fan is to be certified explosion proof and have spark arrestor to avoid ignition sources to enter the ventilation systems whereas remaining H<sub>2</sub> gas may be present in dangerous concentrations.

Audible and visual alarms and automatic shutdown of the BWMS are to be arranged for respectively high and high-high levels of H<sub>2</sub>. The open end of the hydrogen by-product enriched gas relieving device is to be led to a safe location on the open deck. Refer to [4.3.10].

**4.2.6** The open ends of inert gas or nitrogen gas enriched air (BWMS categories 3a, 3b, 3c and 8) or oxygen-enriched air (BWMS categories 3a, 7a, 7b and 8) are to be led to a safe location on the open deck. Refer to [4.3.10].

### **4.3 Piping conveying dangerous gas or liquid**

**4.3.1** Where the piping is conveying active substances, by-products or neutralizers that are containing dangerous gases or dangerous liquids as defined respectively in [1.3.3] and [1.3.4], the following requirements are to be satisfied.

Requirement [4.3.2] to [4.3.9] is applicable to the injection lines conveying the dangerous gas or dangerous liquids but not applicable to the ballast water lines where the dangerous gas or dangerous liquids are diluted.

Note 1: The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (G9 Guideline) may be used for assessing the hazards that could be expected from the media conveyed by the BWMS piping.

**4.3.2** Irrespective of design pressure and temperature, the piping is to be either of Class I (without special safeguard) or Class II (with special safeguard) as required by Ch 1, Sec 10, Tab 3. The selected materials, the testing of the material, the welding, the non-destructive tests of the welding, the type of connections, the hydrostatic tests and the pressure tests after assembly on board are to be as required in Ch 1, Sec 10, [2] to Ch 1, Sec 10, [5]. Mechanical joints, where allowed, are to be selected in accordance with Ch 1, Sec 10, Tab 18.

For piping class II with special safeguards conveying dangerous gas like hydrogen (H<sub>2</sub>), oxygen (O<sub>2</sub>) or ozone (O<sub>3</sub>), the special safeguards are to be either double walled pipes or pipe duct. For piping class II with special safeguards conveying dangerous liquids, other special safeguards may be considered like shielding, screening, etc.

Plastic pipes may be accepted after due assessment of the dangerous gas or dangerous liquids conveyed inside. When plastic pipes are accepted, the requirements of Ch 1, App 3 apply.

**4.3.3** The length of pipe and the number of connections are to be minimised.

**4.3.4** Inside double walled space or pipe ducts constructed as the special safeguard for the purpose of [4.3.2] are to be equipped with mechanical exhaust ventilation leading to a safe location on the open deck. Refer to [4.3.10].

**4.3.5** The routing of the piping system is to be kept away from any source of heating, ignition and any other source that could react hazardously with the dangerous gas or liquid conveyed inside. The pipes are to be suitably supported and protected from mechanical damage.

**4.3.6** Pipes carrying acids are to be arranged so as to avoid any projection on crew in case of a leakage.

**4.3.7** H<sub>2</sub> by-product enriched air vent pipes (BWMS categories 4, 5 and 6) or O<sub>2</sub> enriched air vent pipes (BWMS categories 3a, 7a, 7b and 8) or O<sub>3</sub> piping (BWMS categories 7a and 7b) are not to be routed through accommodation spaces, services spaces and control stations.

**4.3.8** O<sub>2</sub> enriched air vent pipes (BWMS categories 3a, 7a, 7b and 8) are not to be routed through hazardous areas unless arranged inside double walled pipes or pipe ducts constructed as the special safeguard for the purpose of [4.3.2] and provided with suitable gas detection as described in [4.2.4] and mechanical exhaust ventilation as described in [4.3.4].

**4.3.9** The routing of H<sub>2</sub> by-product enriched air vent pipes (BWMS categories 4, 5 and 6) or O<sub>2</sub> enriched air vent pipes (BWMS categories 3a, 7a, 7b and 8) is to be as short and straight as possible. When necessary, horizontal portions may be arranged with a minimum slope in accordance with the manufacturer's recommendation.

**4.3.10** Safe locations referred to in [4.2.1] are to comply with the provisions of Tab 6.

## **4.4 Handling and storage of chemicals and preparations used to treat ballast water**

### **4.4.1 Procedures**

For BWMS using chemical substances or dangerous gas which are stored on board for either:

- storage or preparation of the active substances (BWMS categories 2 and 6)
- storage or preparation of the neutralizers (BWMS categories 4, 5, 6, 7a and 7b)
- recycling the wastes produced by the BWMS (BWMS category 2)

procedures are to be in accordance with the Material Safety Data Sheet and IMO Circular BWM.2/Circ.20 "Guidance to ensure safe handling and storage of chemicals and preparations used to treat ballast water and the development of safety procedures for risks to the ship and crew resulting from the treatment process".

### **4.4.2 Design, construction, arrangement and testing of tanks containing chemical substances**

- a) The materials, inside coating used for the chemical storage tanks, piping and fittings are to be resistant to such chemicals substances.
- b) Chemical substances (even if they are not defined as dangerous liquid in the sense of [1.3.4] and gas storage tanks are to be designed, constructed, tested, inspected, certified and maintained in accordance with:
  - for independent tanks permanently fixed on board containing dangerous liquids (eg. sulfuric acid H<sub>2</sub>SO<sub>4</sub>) or dangerous gas (eg. oxygen O<sub>2</sub>):  
Ch 1, Sec 3
  - for independent tanks permanently fixed on board not containing dangerous liquid (eg. sodium sulphite, sodium biosulphite or sodium thiosulphate neutralizers) and not containing dangerous gas (eg. nitrogen N<sub>2</sub>):  
Ch 1, Sec 3 or other recognized standard accepted by the Society
  - for portable tanks:  
IMO IMDG Code or other recognized standard accepted by the Society.
- c) Dangerous liquids and dangerous gas storage tank air pipes are to be led to a safe location on the open deck. Refer to [4.3.10].
- d) An operation manual containing chemical injection procedures, alarm systems, measures in case of emergency, etc. is to be kept on board.
- e) Dangerous liquid storage tanks and their associated components like pumps and filters, are to be provided with spill trays or secondary containment system of sufficient volume to contain potential leakages from tank openings, gauge glasses, pumps, filters and piping fittings.

Further to the safety and/or pollution assessment of the concerned chemical substances, consideration is to be provided for segregation of the drains from such spill trays (or secondary containment system) or piping systems from engine room bilge system or from cargo pump room bilge system, as applicable. When necessary, arrangement is to be provided within the spill trays (or within the secondary containment system) for the detection of dangerous liquid or dangerous gas as defined respectively in [1.3.3] and [1.3.4].

Note 1: The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (G9 Guideline) may be used for this assessment.

## **5 Certification**

### **5.1 Type approval and design review**

**5.1.1** BWMS are to be of a type approved by the Society. For this purpose:

- a) They are to be type approved by the Administration according to IMO Code for approval of ballast water management systems (BWMS Code, IMO Resolution MEPC.300(72)).

Note 1: It should be noted that some flag Authorities request the IMO Type Approval to be issued on their behalf.

- b) Their design is to comply with the requirements of:
- Ch 1, Sec 3 for pressure vessels
  - Ch 1, Sec 10 for piping
  - Ch 2, Sec 15 for the type approval tests of electrical components
  - Ch 3, Sec 3 for the computer-based systems

Note 2: In general, monitoring functions of BWMS belong to system category I under the application of Ch 3, Sec 3. However, in case a bypass valve is integrated in the valve remote control system, the bypass valve belongs to the system category II Ballast transfer remote control system.

- Ch 3, Sec 6 for the type approval tests of automation systems.

The relevant documentation to be submitted is listed in Tab 10.

**Table 10 : Documentation and information to be submitted for type approval of BWMS**

No.	Documentation and information to be submitted	Approval status (1)
1	BWMS specifications / Limitations	I
2	Dedicated technical manual of the BWMS	I
3	General drawings of the BWMS	A
4	General Arrangement	A
5	Main Piping diagram	A
6	Main Electrical diagram	A
7	List of components	I
8	Manufacturer's procedures for production check and production tests	I
9	Manufacturer's procedures for onboard installation checks, onboard installation tests and installation commissioning procedures	I
10	Type approval certificates of the BWMS	I
11	Pressure vessels: Documents and information according to Ch 1, Sec 3, Tab 3	See Ch 1, Sec 3, Tab 3
12	Storage tanks for chemicals substances: detailed drawings	A
13	Piping systems: Documents according to Ch 1, Sec 10, Tab 1 and Ch 1, Sec 10, Tab 2	See Ch 1, Sec 10, Tab 1 and Ch 1, Sec 10, Tab 2
14	Electrical power and control cabinets: detailed drawings / diagrams with list of components	A
15	Sensors and valve actuators: • detailed drawings / diagrams with location	A
16	• list and reference of type approval	I
17	Electrical cables: list and reference of type approval	I
(1) A = For approval ; I = For information		

**5.2 Risk assessment**

**5.2.1** A risk assessment is to be conducted in a generic manner during the design review mentioned in [5.1.1] and submitted to the Society for approval for the following BWMS categories:

- BWMS category 4: in all cases
- BWMS category 5: in all cases
- BWMS category 6: when one of the MSDS indicates that the chemical substance stored on board is either flammable, toxic, corrosive or reactive
- BWMS category 7a and 7b: in all cases.

Note 1: The IMO reports issued during the basic and final approval procedures of the BWMS that make use of active substances (G9 Guideline) may be used as a reference for this assessment.

**5.2.2** The recommended risk assessment techniques for BWMS and other guidances are listed below but not limited to:

- FMEA, FMECA, HAZID, HAZOP, etc
- ISO 31010 - Risk Assessment Techniques
- ISO/TS 18683, Section 7: Risk assessment.

**5.2.3** The risk assessment is to ensure that the equipment supplied by the BWMS's manufacturer is intrinsically safe and/or provides mitigation measures to the hazards created by the BWMS which have been identified during the design review mentioned in [5.1.1] but that need to be implemented during the installation on board.

**5.3 Inspection and testing**

**5.3.1** A BV product certificate (Society Certificate (C)) is required for the BWMS and its components including pressure vessels, piping class I or II, filters, switchboards, etc.

**5.3.2** The tests listed in Tab 11 are to be carried out with the attendance of the Surveyor.

**Table 11 : Tests for BWMS to be carried out during manufacturing with the attendance of the Surveyor**

Equipment to be tested	Tests to be carried out
BWMS	Functional tests: <ul style="list-style-type: none"><li>• normal operations</li><li>• forced operations</li><li>• test of fault alarms</li><li>• test of bypass alarms</li><li>• test of remote starting/stop</li></ul>
Pressure vessels and their fittings	Pressure test (see Ch 1, Sec 3, [9.3.2]) Water tightness test
Skid piping and relevant fittings	Pressure test (see Ch 1, Sec 10, [20.5]) Tightness test
Valves for fresh water and backwash	Pressure test (see Ch 1, Sec 10, [20.5]) Tightness test Functional test
Chemical storage tank	Hydraulic test
Sensors and valve actuators	Functional test

# Section 14      Steering Gear

## 1 General

### 1.1 Application

#### 1.1.1 Scope

Unless otherwise specified, the requirements of this Section apply to the steering gear systems of all mechanically propelled ships, and to the steering mechanism of thrusters used as means of propulsion.

#### 1.1.2 Application to ships having additional service feature SPxxx or SPxxx-capable

Ships having additional service feature **SPxxx** or **SPxxx-capable** are to comply with the requirements of this Section, considering the ship:

- as a passenger ship, when xxx is greater than 240
- as a cargo ship, when xxx is less than or equal to 240.

where:

xxx : Total number of persons onboard including crew, special personnel and passengers (maximum twelve).

#### 1.1.3 Cross references

In addition to those provided in this Section, steering gear systems are also to comply with the requirements of:

- Ch 1, Sec 18, as regards sea trials
- Pt B, Ch 12, Sec 1, as regards the rudder and the rudder stock
- Pt D, Ch 7, Sec 4, [7], when fitted to oil tankers, chemical tankers or gas carriers
- Pt D, Ch 15, Sec 4, [24], when fitted to fishing vessels.

### 1.2 Documentation to be submitted

#### 1.2.1 Documents to be submitted for all steering gear

Before starting construction, all plans and specifications listed in Tab 1 are to be submitted to the Society for approval.

#### 1.2.2 Additional documents

The following additional documents are to be submitted:

- analysis in relation to the risk of single failure, where required by [2.4.2]
- analysis in relation to the risk of hydraulic locking, where required by [2.4.5]
- fatigue analysis and/or fracture mechanics analysis, where required by Pt D, Ch 7, Sec 4, [7.2.2] and Pt D, Ch 7, Sec 4, [7.3.1].

### 1.3 Definitions

#### 1.3.1 Steering system

Steering system means ship's directional control system, including main steering gear, auxiliary steering gear, steering gear control system and rudder if any.

#### 1.3.2 Steering gear control system

*Steering gear control system is the equipment by which orders are transmitted from the navigation bridge to the steering gear power units. Steering gear control systems comprise transmitters, receivers, hydraulic control pumps and their associated motors, motor controllers, piping and cables.*

Steering gear control system is also understood to cover the equipment required to control the steering gear power actuating system.

#### 1.3.3 Main steering gear

*Main steering gear is the machinery, rudder actuators, steering gear power units, if any, and ancillary equipment and the means of applying torque to the rudder stock (e.g. tiller or quadrant) necessary for effecting movement of the rudder for the purpose of steering the ship under normal service conditions.*

#### 1.3.4 Steering gear power unit

Steering gear power unit is:

- in the case of electric steering gear, an electric motor and its associated electrical equipment
- in the case of electrohydraulic steering gear, an electric motor and its associated electrical equipment and connected pump
- in the case of other hydraulic steering gear, a driving engine and connected pump.

**1.3.5 Auxiliary steering gear**

Auxiliary steering gear is the equipment other than any part of the main steering gear necessary to steer the ship in the event of failure of the main steering gear but not including the tiller, quadrant or components serving the same purpose.

**1.3.6 Power actuating system**

Power actuating system is the hydraulic equipment provided for supplying power to turn the rudder stock, comprising a steering gear power unit or units, together with the associated pipes and fittings, and a rudder actuator. The power actuating systems may share common mechanical components, i.e. tiller, quadrant and rudder stock, or components serving the same purpose.

**1.3.7 Rudder actuator**

Rudder actuator is the component which directly converts hydraulic pressure into mechanical action to move the rudder.

**1.3.8 Maximum ahead service speed**

Maximum ahead service speed is the greatest speed which the ship is designed to maintain in service at sea at the deepest seagoing draught.

**1.3.9 Maximum astern speed**

Maximum astern speed is the speed which it is estimated the ship can attain at the designed maximum astern power at the deepest seagoing draught.

**1.3.10 Maximum working pressure**

Maximum working pressure is the maximum expected pressure in the system when the steering gear is operated to comply with the provisions of [2.2.1], item b).

**1.3.11 Hydraulic locking**

Hydraulic locking means all situations where two hydraulic systems (usually identical) oppose each other in such a way that it may lead to loss of steering. It can either be caused by pressure in the two hydraulic systems working against each other or by hydraulic "bypass" meaning that the systems puncture each other and cause pressure drop on both sides or make it impossible to build up pressure.

**Table 1 : Documents to be submitted for steering gear**

No.	I/A (2)	Description of the document (1)
1	I	Assembly drawing of the steering gear including sliding blocks, guides, stops and other similar components
2	I	General description of the installation and of its functioning principle
3	I	Operating manuals of the steering gear and of its main components
4	I	Description of the operational modes intended for steering in normal and emergency conditions
5	A	For hydraulic steering gear, the schematic layout of the hydraulic piping of power actuating systems, including the hydraulic fluid refilling system, with indication of: <ul style="list-style-type: none"> <li>• the design pressure</li> <li>• the maximum working pressure expected in service</li> <li>• the diameter, thickness, material specification and connection details of the pipes</li> <li>• the hydraulic fluid tank capacity</li> <li>• the flashpoint of the hydraulic fluid</li> </ul>
6	I	For hydraulic pumps of power units, the assembly longitudinal and transverse sectional drawings and the characteristic curves
7	A	Assembly drawings of the rudder actuators and constructional drawings of their components, with, for hydraulic actuators, indication of: <ul style="list-style-type: none"> <li>• the design torque</li> <li>• the maximum working pressure</li> <li>• the relief valve setting pressure</li> </ul>
8	I	Constructional drawings of the relief valves for protection of the hydraulic actuators, with indication of: <ul style="list-style-type: none"> <li>• the setting pressure</li> <li>• the relieving capacity</li> </ul>
9	A	Diagrams of the electric power circuits
10	A	Functional diagram of control, monitoring and safety systems including the remote control from the navigating bridge, with indication of the location of control, monitoring and safety devices
11	A	Constructional drawings of the strength parts providing a mechanical transmission of forces to the rudder stock (tiller, quadrant, connecting rods and other similar items), with the calculation notes of the shrink-fit connections
12	I/A	For azimuth thrusters used as steering means, the specification and drawings of the steering mechanism and, where applicable, documents 2 to 6 and 8 to 11 above
<p>(1) Constructional drawings are to be accompanied by the specification of the materials employed and, where applicable, by the welding details and welding procedures.</p> <p>(2) A = to be submitted for approval ; I = to be submitted for information.</p>		

## 1.4 Symbols

**1.4.1** The following symbols are used for strength criteria of steering gear components:

$V$  : Maximum service speed, in knots, with the ship on summer load waterline. When the speed is less than 10 knots,  $V$  is to be replaced by the value  $(V+20)/3$

$d_s$  : Rule diameter of the rudder stock in way of the tiller, in mm, defined in Pt B, Ch 12, Sec 1, [4] and calculated with a material factor  $k_1 = 1$

$d_{se}$  : Actual diameter of the upper part of the rudder stock in way of the tiller, in mm (in the case of a tapered coupling, this diameter is measured at the base of the assembly)

$T_R$  : Rule design torque of the rudder stock given, in kN.m, by the following formula:

$$T_R = 13,5 \cdot d_s^3 \cdot 10^{-6}$$

$T_E$  : For hand emergency operation, design torque due to forces induced by the rudder, in kN.m, given by the following formulae:

$$T_E = 0,62 \cdot \left( \frac{V_E + 2}{V + 2} \right)^2 \cdot T_R$$

where:

- $V_E = 7$  where  $V \leq 14$
- $V_E = 0,5 V$  where  $V > 14$

$T_G$  : For main hydraulic or electrohydraulic steering gear, torque induced by the main steering gear on the rudder stock when the pressure is equal to the setting pressure of the relief valves protecting the rudder actuators

Note 1: for hand-operated main steering gear, the following value is to be used:

$$T_G = 1,25 \cdot T_R$$

$T_A$  : For auxiliary hydraulic or electrohydraulic steering gears, torque induced by the auxiliary steering gear on the rudder stock when the pressure is equal to the setting pressure of the relief valves protecting the rudder actuators

Note 2: for hand-operated auxiliary steering gear, the following value is to be used:

$$T_A = 1,25 \cdot T_E$$

$T'_G$  : For steering gear which can activate the rudder with a reduced number of actuators, the value of  $T_G$  in such conditions

$\sigma$  : Normal stress due to the bending moments and the tensile and compressive forces, in N/mm<sup>2</sup>

$\tau$  : Tangential stress due to the torsional moment and the shear forces, in N/mm<sup>2</sup>

$\sigma_a$  : Permissible stress, in N/mm<sup>2</sup>

$\sigma_c$  : Combined stress, determined by the following formula:

$$\sigma_c = \sqrt{\sigma^2 + 3\tau^2}$$

$R$  : Value of the minimum specified tensile strength of the material at ambient temperature, in N/mm<sup>2</sup>

$R_e$  : Value of the minimum specified yield strength of the material at ambient temperature, in N/mm<sup>2</sup>

$R'_e$  : Design yield strength, in N/mm<sup>2</sup>, determined by the following formulae:

- $R'_e = R_e$ , where  $R \geq 1,4 R_e$
- $R'_e = 0,417 (R_e + R)$  where  $R < 1,4 R_e$

## 2 Design and construction

### 2.1 General

**2.1.1** *Unless expressly provided otherwise, every ship shall be provided with main steering gear and auxiliary steering gear to the satisfaction of the Society.*

### 2.2 Strength, performance and power operation of the steering gear

#### 2.2.1 Main steering gear

*The main steering gear and rudder stock shall be:*

- of adequate strength and capable of steering the ship at maximum ahead service speed which shall be demonstrated*
- capable of putting the rudder over from 35° on one side to 35° on the other side with the ship at its deepest seagoing draught and running ahead at maximum ahead service speed and, under the same conditions, from 35° on either side to 30° on the other side in not more than 28 s*

*Where it is impractical to demonstrate compliance with this requirement during sea trials with the ship at its deepest seagoing draught and running ahead at the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch, ships may demonstrate compliance with this requirement by one of the following methods:*

- 1) *during sea trials the ship is at even keel and the rudder fully submerged whilst running ahead at the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch; or*

Note 1: "even keel" means that the vessel is in an acceptable trim condition

Note 2: "fully submerged" means  $A_T$  is greater than  $0.95 \cdot A_F$ , where  $A_T$  and  $A_F$  are defined in [2.2.3].

- 2) *where full rudder immersion during sea trials cannot be achieved, an appropriate ahead speed shall be calculated using the submerged rudder blade area in the proposed sea trial loading condition. The calculated ahead speed shall result in a force and torque applied to the main steering gear which is at least as great as if it was being tested with the ship at its deepest seagoing draught and running ahead at the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch; or*
- 3) *the rudder force and torque at the sea trial loading condition have been reliably predicted and extrapolated to the full load condition. The speed of the ship shall correspond to the number of maximum continuous revolutions of the main engine and maximum design pitch of the propeller;*

Specific requirements of [2.2.3] are to be applied for trials not performed at full load condition;

- c) *operated by power where necessary to meet the requirements of b) and in any case when the Society requires a rudder stock of over 120 mm diameter in way of the tiller, excluding strengthening for navigation in ice, and*
- d) *so designed that they will not be damaged at maximum astern speed; however, this design requirement need not be proved by trials at maximum astern speed and maximum rudder angle.*

Note 3: The mentioned diameter is to be taken as having been calculated for rudder stock of mild steel with a yield stress of 235 N/mm<sup>2</sup>, i.e. with a material factor  $k_1 = 1$ .

### **2.2.2 Auxiliary steering gear**

The auxiliary steering gear and rudder stock shall be:

- a) *of adequate strength and capable of steering the ship at navigable speed and of being brought speedily into action in an emergency*
- b) *capable of putting the rudder over from 15° on one side to 15° on the other side in not more than 60s with the ship at its deepest seagoing draught and running ahead at one half of the maximum ahead service speed or 7 knots, whichever is the greater.*

*Where it is impractical to demonstrate compliance with this requirement during sea trials with the ship at its deepest seagoing draught and running ahead at one half of the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch or 7 knots, whichever is greater, ships may demonstrate compliance with this requirement by one of the following methods:*

- 1) *during sea trials the ship is at even keel and the rudder fully submerged whilst running ahead at one half of the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch or 7 knots, whichever is greater; or*

Note 1: "even keel" means that the vessel is in an acceptable trim condition.

Note 2: "fully submerged" means  $A_T$  is greater than  $0.95 \cdot A_F$ , where  $A_T$  and  $A_F$  are defined in [2.2.3].

- 2) *where full rudder immersion during sea trials cannot be achieved, an appropriate ahead speed shall be calculated using the submerged rudder blade area in the proposed sea trial loading condition. The calculated ahead speed shall result in a force and torque applied to the auxiliary steering gear which is at least as great as if it was being tested with the ship at its deepest seagoing draught and running ahead at one half of the speed corresponding to the number of maximum continuous revolutions of the main engine and maximum design pitch or 7 knots, whichever is greater; or*
- 3) *the rudder force and torque at the sea trial loading condition have been reliably predicted and extrapolated to the full load condition;*

Specific requirements of [2.2.3] are to be applied for trials not performed at full load condition;

and

- c) *operated by power where necessary to meet the requirements of b) and in any case when the Society requires a rudder stock of over 230 mm diameter in way of the tiller, excluding strengthening for navigation in ice.*

Note 3: The mentioned diameter is to be taken as having been calculated for rudder stock of mild steel with a yield stress of 235 N/mm<sup>2</sup>, i.e. with a material factor  $k_1 = 1$ .

### **2.2.3 Steering gear test with the vessel not at the deepest seagoing draught**

In order to meet the performance stated in item b) of [2.2.1] and item b) of [2.2.2] the following requirements are applicable.

When it is justified that the trials cannot practically be performed with the vessel at the deepest seagoing draught, the loading condition can be accepted on the conditions that:

- a) The estimated steering actuator hydraulic pressure in the deepest seagoing draught condition  $P_F$  has been extrapolated from the maximum measured actuator hydraulic pressure in the trial condition  $P_T$  using one of the following methods:

- 1)  $P_F$  is obtained according to the following formula:

$$P_F = P_T \cdot \alpha$$

$$\alpha = 1,25 \left( \frac{A_F}{A_T} \right) \left( \frac{V_F}{V_T} \right)^2$$

where:

- $P_F$  : estimated steering actuator hydraulic pressure in the deepest seagoing draught condition
- $P_T$  : maximum measured actuator hydraulic pressure in the trial condition.
- $\alpha$  : extrapolation factor
- $A_F$  : total immersed projected area of the movable part of the rudder in the deepest seagoing condition
- $A_T$  : total immersed projected area of the movable part of the rudder in the trial condition
- $V_F$  : contractual design speed of the vessel corresponding to the maximum continuous revolutions of the main engine at the deepest seagoing draught
- $V_T$  : measured speed of the vessel (considering current) in the trial condition.

Note 1: Above formulae assumes that the rudder actuator system pressure is shown to have a linear relationship to the rudder stock torque.

2) The following methodology is applied for determination of  $P_F$ :

- The designer or builder uses computational fluid dynamic (CFD) studies or experimental investigations to predict the estimated rudder stock moment at the full sea going draught condition and service speed  $Q_F$ . These calculations or experimental investigations are to be to the satisfaction of the Society.
- the rudder torque at the trial loading condition  $Q_T$  have been reliably predicted based on the maximum measured actuator hydraulic pressure in the trial condition  $P_T$
- The estimated steering actuator hydraulic pressure in the deepest seagoing draught condition is obtained according to the following formula:

$$P_F = P_T \frac{Q_F}{Q_T}$$

b) Where constant volume fixed displacement pumps are utilised, the estimated steering actuator hydraulic pressure at the deepest draught  $P_F$  is to be less than the specified maximum working pressure of the rudder actuator.

Where a variable delivery pump is utilised, the pump data is to be supplied and interpreted to estimate the delivered flow rate corresponding to the deepest seagoing draught in order to calculate the estimated steering time, not to be greater than to the required time specified in [2.2.1] or [2.2.2], as applicable.

c) In any case for the main steering gear trial, the speed of the ship corresponding to the number of maximum continuous revolution of main engine and maximum design pitch applies.

## 2.3 Control of the steering gear

### 2.3.1 Main and auxiliary steering gear control

Steering gear control shall be provided:

- a) for the main steering gear, both on the navigation bridge and in the steering gear compartment
- b) where the main steering gear is arranged in accordance with [2.4.2], by two independent control systems, both operable from the navigation bridge and the steering gear compartment. This does not require duplication of the steering wheel or steering lever. Where the control system consists in a hydraulic telemotor, a second independent system need not be fitted, except in a tanker, chemical tanker or gas carrier of 10 000 gross tonnage and upwards

The two independent steering gear control systems are to be:

- so arranged that a mechanical or electrical failure in one of them will not render the other one inoperative, and
- in accordance with [2.3.3]

c) for the auxiliary steering gear, in the steering gear compartment and, if power operated, it shall also be operable from the navigation bridge and to be independent of the control system for the main steering gear.

Note 1: The term "steering gear control system" is to be understood to cover "the equipment required to control the steering gear power actuating system".

### 2.3.2 Control systems operable from the navigating bridge

Any main and auxiliary steering gear control system operable from the navigating bridge shall comply with the following:

- if electrical, it shall be served by its own separate circuit supplied from a steering gear power circuit from a point within the steering gear compartment, or directly from switchboard busbars supplying that steering gear power circuit at a point on the switchboard adjacent to the supply to the steering gear power circuit
- means shall be provided in the steering gear compartment for disconnecting any control system operable from the navigation bridge from the steering gear it serves
- the system shall be capable of being brought into operation from a position on the navigating bridge
- in the event of failure of electrical power supply to the control system, an audible and visual alarm shall be given on the navigation bridge, and
- short-circuit protection only shall be provided for steering gear control supply circuits.

### **2.3.3 Installation**

- a) Duplicated steering gear control systems with their associated components are to be separated as far as practicable.
- b) Wires, terminals and the components for duplicated steering gear control systems installed in units, control boxes, switchboards or bridge consoles are to be separated as far as practicable.  
Where physical separation is not practicable, separation may be achieved by means of a fire-retardant plate.
- c) All electrical components of the steering gear control systems are to be duplicated. This does not require duplication of the steering wheel or steering lever.
- d) If a joint steering mode selector switch (uniaxial switch) is employed for both steering gear control systems, the connections for the control systems are to be divided accordingly and separated from each other by an isolating plate or air gap.
- e) In the case of double follow-up control, the amplifier is to be designed and fed so as to be electrically and mechanically separated. In the case of non-follow-up control and follow-up control, it is to be ensured that the follow-up amplifier is protected selectively.
- f) Control circuits for additional control systems, e.g. steering lever or autopilot, are to be designed for all-pole disconnection.
- g) The feedback units and limit switches, if any, for the steering gear control systems are to be separated electrically and mechanically connected to the rudder stock or actuator separately.

## **2.4 Availability**

### **2.4.1 Arrangement of main and auxiliary steering gear**

*The main steering gear and the auxiliary steering gear shall be so arranged that the failure of one will not render the other inoperative.*

### **2.4.2 Omission of the auxiliary steering gear**

*Where the main steering gear comprises two or more identical power units, auxiliary steering gear need not be fitted, provided that:*

- a) *in a passenger ship, the main steering gear is capable of operating the rudder as required in [2.2.1] while any one of the power units is out of operation*
- b) *in a cargo ship, the main steering gear is capable of operating the rudder as required in [2.2.1] while operating with all power units*
- c) *the main steering gear is so arranged that after a single failure in its piping system or in one of the power units, the defect can be isolated so that steering capability can be maintained or speedily regained.*

*Steering gear other than of the hydraulic type is to achieve standards equivalent to the requirements of this paragraph to the satisfaction of the Society.*

### **2.4.3 Hydraulic power supply**

The hydraulic system intended for main and auxiliary steering gear is to be independent of all other hydraulic systems of the ship.

### **2.4.4 Non-duplicated components**

*Special consideration is to be given to the suitability of any essential component which is not duplicated.*

### **2.4.5 Hydraulic locking**

Where the steering gear is so arranged that more than one system (either power or control) can be simultaneously operated, the risk of hydraulic locking caused by single failure is to be considered.

### **2.4.6 Additional requirements for ships of 70 000 gross tonnage and above**

*In ships of 70,000 gross tonnage and upwards, the main steering gear shall comprise two or more identical power units complying with the provisions of [2.4.2].*

## **2.5 Mechanical components**

### **2.5.1 General**

- a) All steering gear components and the rudder stock are to be of sound and reliable construction to the satisfaction of the Society.
- b) Any non-duplicated essential component is, where appropriate, to utilise anti-friction bearings, such as ball bearings, roller bearings or sleeve bearings, which are to be permanently lubricated or provided with lubrication fittings
- c) The construction is to be such as to minimise local concentration of stress.
- d) All steering gear components transmitting mechanical forces to the rudder stock, which are not protected against overload by structural rudder stops or mechanical buffers, are to have a strength at least equivalent to that of the rudder stock in way of the tiller.

**2.5.2 Materials and welds**

- a) All steering gear components transmitting mechanical forces to the rudder stock (such as tillers, quadrants, or similar components) are to be of steel or other approved ductile material complying with the requirements of NR216 Materials and Welding. In general, such material is to have an elongation of not less than 12% and a tensile strength not greater than 650 N/mm<sup>2</sup>.
- b) The use of grey cast iron is not permitted, except for redundant parts with low stress level, subject to special consideration by the Society. It is not permitted for cylinders.
- c) The welding details and welding procedures are to be submitted for approval.
- d) All welded joints within the pressure boundary of a rudder actuator or connecting parts transmitting mechanical loads are to be full penetration type or of equivalent strength.

**2.5.3 Scantling of components**

The scantling of steering gear components is to be determined considering the design torque  $M_T$  and the permissible value  $\sigma_a$  of the combined stress, as given in:

- Tab 2 for components which are protected against overloads induced by the rudder
- Tab 3 for components which are not protected against overloads induced by the rudder.

**Table 2 : Scantling of components protected against overloads induced by the rudder**

Conditions of use of the components	$M_T$	$\sigma_a$
Normal operation	$T_G$	<ul style="list-style-type: none"> <li>• if <math>T_G \leq 1,25 T_R</math>: <math>\sigma_a = 1,25 \sigma_0</math></li> <li>• if <math>1,25 T_R &lt; T_G &lt; 1,50 T_R</math>: <math>\sigma_a = \sigma_0 T_G/T_R</math></li> <li>• if <math>T_G \geq 1,50 T_R</math>: <math>\sigma_a = 1,50 \sigma_0</math></li> </ul> where $\sigma_0 = 0,55 R'_e$
Normal operation, with a reduced number of actuators	$T'_G$	<ul style="list-style-type: none"> <li>• if <math>T'_G \leq 1,25 T_R</math>: <math>\sigma_a = 1,25 \sigma_0</math></li> <li>• if <math>1,25 T_R &lt; T'_G &lt; 1,50 T_R</math>: <math>\sigma_a = \sigma_0 T'_G/T_R</math></li> <li>• if <math>T'_G \geq 1,50 T_R</math>: <math>\sigma_a = 1,50 \sigma_0</math></li> </ul> where $\sigma_0 = 0,55 R'_e$
Emergency operation achieved by hydraulic or electrohydraulic steering gear	lower of $T_R$ and $0,8 T_A$	$0,69 R'_e$
Emergency operation, with a reduced number of actuators	lower of $T_R$ and $0,8 T'_G$	$0,69 R'_e$
Emergency operation achieved by hand	$T_E$	$0,69 R'_e$

**Table 3 : Scantling of components not protected against overloads induced by the rudder**

Conditions of use of the components	$M_T$	$\sigma_a$
Normal operation	$T_R$	$0,55 R'_e$
Normal operation, with a reduced number of actuators	lower of $T_R$ and $0,8 T'_G$	$0,55 R'_e$
Emergency operation achieved by hydraulic or electrohydraulic steering gear	lower of $T_R$ and $0,8 T_A$	$0,69 R'_e$
Emergency operation, with a reduced number of actuators	lower of $T_R$ and $0,8 T'_G$	$0,69 R'_e$
Emergency operation achieved by hand	$T_E$	$0,69 R'_e$

**2.5.4 Tillers, quadrants and rotors**

- a) The scantling of the tiller is to be determined as follows:
  - the depth  $H_0$  of the boss is not to be less than  $0,75 \cdot d_s$
  - the radial thickness of the boss in way of the tiller is not to be less than the greater of:
    - $0,3 \cdot d_s \cdot \sqrt{\frac{235}{R'_e}}$
    - $0,25 \cdot d_s$

- the section modulus of the tiller arm in way of the end fixed to the boss is not to be less than the value  $Z_{br}$ , in cm<sup>3</sup>, calculated from the following formula:

$$Z_{br} = \frac{0,147 \cdot d_s^3}{1000} \cdot \frac{L'}{L} \cdot \frac{R_e}{R'_e}$$

where:

L : Distance from the centreline of the rudder stock to the point of application of the load on the tiller (see Fig 1)

$L'$  : Distance between the point of application of the above load and the root section of the tiller arm under consideration (see Fig 1)

- the width and thickness of the tiller arm in way of the point of application of the load are not to be less than one half of those required by the above formula
- in the case of double arm tillers, the section modulus of each arm is not to be less than one half of the section modulus required by the above formula.

**Figure 1 : Tiller arm**

b) The scantling of the quadrants is to be determined as specified in a) for the tillers. When quadrants having two or three arms are provided, the section modulus of each arm is not to be less than one half or one third, respectively, of the section modulus required for the tiller.

Arms of loose quadrants not keyed to the rudder stock may be of reduced dimensions to the satisfaction of the Society, and the depth of the boss may be reduced by 10 per cent.

c) Keys are to satisfy the following provisions:

- the key is to be made of steel with a yield stress not less than that of the rudder stock and that of the tiller boss or rotor without being less than 235 N/mm<sup>2</sup>
- the width of the key is not to be less than 0,25.d<sub>s</sub>
- the thickness of the key is not to be less than 0,10.d<sub>s</sub>
- the ends of the keyways in the rudder stock and in the tiller (or rotor) are to be rounded and the keyway root fillets are to be provided with small radii of not less than 5 per cent of the key thickness.

d) Bolted tillers and quadrants are to satisfy the following provisions:

- the diameter of the bolts is not to be less than the value d<sub>b</sub>, in mm, calculated from the following formula:

$$d_b = 153 \sqrt{\frac{T_R}{n(b + 0,5d_{se})} \cdot \frac{235}{R_{eb}}}$$

where:

n : Number of bolts located on the same side in respect of the stock axis (n is not to be less than 2)

b : Distance between bolts and stock axis, in mm (see Fig 2)

R<sub>eb</sub> : Yield stress, in N/mm<sup>2</sup>, of the bolt material

**Figure 2 : Bolted tillers**

- the thickness of each of the tightening flanges of the two parts of the tiller is not to be less than the following value:

$$1,85 \cdot d_b \cdot \sqrt{\frac{n \cdot (b - 0,5 \cdot D_e)}{H_0} \cdot \frac{R_{eb}}{R_e}}$$

Where:

$D_e$  : External boss diameter, in mm (average value)

- in order to ensure the efficient tightening of the coupling around the stock, the two parts of the tiller are to be bored together with a shim having a thickness not less than the value  $j$ , in mm, calculated from the following formula:

$$j = 0,0015 \cdot d_s$$

e) Shrink-fit connections of tiller (or rotor) to stock are to satisfy the following provisions:

- the safety factor against slippage is not to be less than:
  - 1 for keyed connections
  - 2 for keyless connections
- the friction coefficient is to be taken equal to:
  - 0,15 for steel and 0,13 for spheroidal graphite cast iron, in the case of hydraulic fit
  - 0,17 in the case of dry shrink fitting
- the combined stress according to the von Mises criterion, due to the maximum pressure induced by the shrink fitting and calculated in way of the most stressed points of the shrunk parts, is not to exceed 80 per cent of the yield stress of the material considered

Note 1: Alternative stress values based on FEM calculations may also be considered by the Society.

- the entrance edge of the tiller bore and that of the rudder stock cone are to be rounded or bevelled.

### 2.5.5 Piston rods

The scantling of the piston rod is to be determined taking into account the bending moments, if any, in addition to compressive or traction forces and is to satisfy the following provisions:

a)  $\sigma_c \leq \sigma_a$

where:

$\sigma_c$  : Combined stress as per [1.4.1]

$\sigma_a$  : Permissible stress as per [2.5.3]

b) in respect of the buckling strength:

$$\frac{4}{\pi D_2^2} \cdot \left( \omega F_c + \frac{8M}{D_2} \right) \leq 0,9 \sigma_a$$

with:

$D_2$  : Piston rod diameter, in mm

$F_c$  : Compression force in the rod, in N, when it extends to its maximum stroke

$M$  : Possible bending moment in the piston rod, in N.mm, in way of the fore end of the cylinder rod bearing

$$\omega = \beta + \sqrt{\beta^2 - \alpha}$$

$$\alpha = 0,0072 \left( \frac{\ell_s}{D_2} \right)^2 \frac{R_e}{235}$$

$$\beta = 0,48 + 0,5\alpha + 0,1\sqrt{\alpha}$$

$\ell_s$  : Length, in mm, of the maximum unsupported reach of the cylinder rod.

## 2.6 Hydraulic system

### 2.6.1 General

- a) *The design pressure for calculations to determine the scantlings of piping and other steering gear components subjected to internal hydraulic pressure shall be at least 1,25 times the maximum working pressure to be expected under the operational conditions specified in [3], taking into account any pressure which may exist in the low pressure side of the system.*  
*At the discretion of the Society, high cycle and cumulative fatigue analysis may be required for the design of piping and components, taking into account pulsating pressures due to dynamic loads.*
- b) The power piping for hydraulic steering gear is to be arranged so that transfer between units can be readily effected.
- c) Arrangements for bleeding air from the hydraulic system are to be provided, where necessary.
- d) The hydraulic piping system, including joints, valves, flanges and other fittings, is to comply with the requirements of Ch 1, Sec 10 for class I piping systems, and in particular with the requirements of Ch 1, Sec 10, [14], unless otherwise stated.

### **2.6.2 Materials**

- a) Ram cylinders, pressure housings of rotary vane type actuators, hydraulic power piping, valves, flanges and fittings are to be of steel or other approved ductile material.
- b) In general, such material is to have an elongation of not less than 12% and a tensile strength not greater than 650 N/mm<sup>2</sup>.  
Grey cast iron may be accepted for valve bodies and redundant parts with low stress level, excluding cylinders, subject to special consideration.

### **2.6.3 Isolating valves**

Shut-off valves, non-return valves or other appropriate devices are to be provided:

- to comply with the availability requirements of [2.4]
- to keep the rudder steady in position in case of emergency.

In particular, for all ships with non-duplicated actuators, isolating valves are to be fitted at the connection of pipes to the actuator, and are to be directly fitted on the actuator.

### **2.6.4 Flexible hoses**

- a) Flexible hoses may be installed between two points where flexibility is required but are not to be subjected to torsional deflexion (twisting) under normal operation. In general, the hose is to be limited to the length necessary to provide for flexibility and for proper operation of machinery.
- b) Hoses are to be high pressure hydraulic hoses according to recognised standards and suitable for the fluids, pressures, temperatures and ambient conditions in question.
- c) They are to be of a type approved by the Society.
- d) The burst pressure of hoses is to be not less than four times the design pressure.

### **2.6.5 Relief valves**

- a) *Relief valves shall be fitted to any part of the hydraulic system which can be isolated and in which pressure can be generated from the power source or from external forces. The setting of the relief valves shall not exceed the design pressure. The valves shall be of adequate size and so arranged as to avoid an undue rise in pressure above the design pressure.*
- b) The setting pressure of the relief valves is not to be less than 1,25 times the maximum working pressure.
- c) The minimum discharge capacity of the relief valve(s) is not to be less than the total capacity of the pumps which can deliver through it (them), increased by 10%. Under such conditions, the rise in pressure is not to exceed 10% of the setting pressure. In this respect, due consideration is to be given to the foreseen extreme ambient conditions in relation to oil viscosity.

### **2.6.6 Hydraulic oil reservoirs**

*Hydraulic power-operated steering gear shall be provided with the following:*

- *a low level alarm for each hydraulic fluid reservoir to give the earliest practicable indication of hydraulic fluid leakage. Audible and visual alarms shall be given on the navigation bridge and in the machinery space where they can be readily observed.*
- *a fixed storage tank having sufficient capacity to recharge at least one power actuating system including the reservoir, where the main steering gear is required to be power operated. The storage tank shall be permanently connected by piping in such a manner that the hydraulic systems can be readily recharged from a position within the steering gear compartment and shall be provided with a contents gauge.*

Note 1: For cargo ships of less than 500 gross tonnage and for fishing vessels, the storage means may consist of a readily accessible drum, of sufficient capacity to refill one power actuating system if necessary.

### **2.6.7 Hydraulic pumps**

- a) Hydraulic pumps are to be type tested in accordance with the provisions of [6.1.1].
- b) Special care is to be given to the alignment of the pump and the driving motor.

### **2.6.8 Filters**

- a) *Hydraulic power-operated steering gear shall be provided with arrangements to maintain the cleanliness of the hydraulic fluid taking into consideration the type and design of the hydraulic system.*
- b) Filters of appropriate mesh fineness are to be provided in the piping system, in particular to ensure the protection of the pumps.

### **2.6.9 Accumulators**

Accumulators, if fitted, are to be designed in accordance with Ch 1, Sec 10, [14.5.3].

### **2.6.10 Rudder actuators**

- a) Rudder actuators, other than non-duplicated rudder actuators fitted to tankers, chemical carriers and gas carriers of 10000 gross tonnage and above, are to be designed in accordance with the relevant requirements of Ch 1, Sec 3 for class 1 pressure vessels also considering the following provisions.
- b) The permissible primary general membrane stress is not to exceed the lower of the following values:

$$\frac{R}{A} \quad \text{or} \quad \frac{R_c}{B}$$

where A and B are given in Tab 4.

- c) Oil seals between non-moving parts, forming part of the external pressure boundary, are to be of the metal upon metal or equivalent type.
- d) Oil seals between moving parts, forming part of the external pressure boundary, are to be duplicated, so that the failure of one seal does not render the actuator inoperative. Alternative arrangements providing equivalent protection against leakage may be accepted.
- e) The strength and connection of the cylinder heads (or, in the case of actuators of the rotary type, the fixed vanes) acting as rudder stops are to comply with the provisions of [5.3.1].

**Table 4 : Value of coefficients A and B**

Coefficient	Steel	Cast steel	Nodular cast iron
A	3,5	4	5
B	1,7	2	3

## 2.7 Electrical systems

### 2.7.1 General design

The electrical systems of the main steering gear and the auxiliary steering gear are to be so arranged that the failure of one will not render the other inoperative.

### 2.7.2 Power circuit supply

- a) Electric or electrohydraulic steering gear comprising one or more power units is to be served by at least two exclusive circuits fed directly from the main switchboard; however, one of the circuits may be supplied through the emergency switchboard.
- b) Auxiliary electric or electrohydraulic steering gear, associated with main electric or electrohydraulic steering gear, may be connected to one of the circuits supplying the main steering gear.
- c) The circuits supplying electric or electrohydraulic steering gear are to have adequate rating for supplying all motors which can be simultaneously connected to them and may be required to operate simultaneously.
- d) When, in a ship of less than 1600 gross tonnage, auxiliary steering gear which is required by [2.2.2], item c) to be operated by power is not electrically powered or is powered by an electric motor primarily intended for other services, the main steering gear may be fed by one circuit from the main switchboard.
- e) Where the rudder stock is required to be over 230 millimetres in diameter in way of the tiller, excluding strengthening for navigation in ice, an alternative power supply either from the emergency source of electrical power or from an independent source of power located in the steering gear compartment is to be provided, sufficient at least to supply the steering gear power unit such that the latter is able to perform the duties of auxiliary steering gear.

This power source is to be activated automatically, within 45 seconds, in the event of failure of the main source(s) of electrical power.

The independent source is to be used only for this purpose.

The alternative power source is also to supply the steering gear control system, the remote control of the power unit and the rudder angle indicator.

- f) In every ship of 10 000 gross tonnage and upwards, the alternative power supply is to have a capacity for at least 30 minutes of continuous operation and in any other ship for at least 10 minutes.

### 2.7.3 Motors and associated control gear

- a) To determine the required characteristics of the electric motors for power units, the breakaway torque and maximum working torque of the steering gear under all operating conditions are to be considered. The ratio of pull-out torque to rated torque is to be at least 1,6.
- b) Motors for steering gear power units may be rated for intermittent power demand.  
The rating is to be determined on the basis of the steering gear characteristics of the ship in question; the rating is always to be at least:
  - S3 - 40% for motors of electric steering gear power units
  - S6 - 25% for motors of electrohydraulic steering gear power units and for convertors.
- c) Each electric motor of a main or auxiliary steering gear power unit is to be provided with its own separate motor starter gear, located within the steering gear compartment.

### **2.7.4 Supply of motor control circuits and steering gear control systems**

- a) Each control for starting and stopping of motors for power units is to be served by its own control circuits supplied from its respective power circuits.
- b) Any electrical main and auxiliary steering gear control system operable from the navigating bridge is to be served by its own separate circuit supplied from a steering gear power circuit from a point within the steering gear compartment, or directly from switchboard busbars supplying that steering gear power circuit at a point on the switchboard adjacent to the supply to the steering gear power circuit. The power supply systems are to be protected selectively.
- c) The remote control of the power unit and the steering gear control systems is to be supplied also by the alternative power source when required by [2.7.2], item e).

### **2.7.5 Circuit protection**

- a) Short-circuit protection is to be provided for each control circuit and each power circuit of electric or electrohydraulic main and auxiliary steering gear.
- b) No protection other than short-circuit protection is to be provided for steering gear control system supply circuits.
- c) Protection against excess current (e.g. by thermal relays), including starting current, if provided for power circuits, is to be for not less than twice the full load current of the motor or circuit so protected, and is to be arranged to permit the passage of the appropriate starting currents.
- d) Steering gear motor circuits obtaining their power supply via an electronic converter, e.g. for speed control, and which are limited to full load current are exempt from the requirement to provide protection against excess current, including starting current, of not less than twice the full load current of the motor. The required overload alarm is to be set to a value not greater than the normal load of the electronic converter.

Note 1: "Normal load" is the load in normal mode of operation that approximates as close as possible to the most severe conditions of normal use in accordance with the manufacturer's operating instructions.

- e) Where fuses are fitted, their current ratings are to be two step higher than the rated current of the motors. However, in the case of intermittent service motors, the fuse rating is not to exceed 160% of the rated motor current.
- f) The instantaneous short-circuit trip of circuit breakers is to be set to a value not greater than 15 times the rated current of the drive motor.
- g) The protection of control circuits is to correspond to at least twice the maximum rated current of the circuit, though not, if possible, below 6 A.

### **2.7.6 Starting and stopping of motors for steering gear power units**

- a) Motors for power units are to be capable of being started and stopped from a position on the navigation bridge and from a point within the steering gear compartment.
- b) Means are to be provided at the position of motor starters for isolating any remote control starting and stopping devices (e.g. by removal of the fuse-links or switching off the automatic circuit breakers).
- c) Main and auxiliary steering gear power units are to be arranged to restart automatically when power is restored after a power failure.

### **2.7.7 Installation**

- a) Duplicated electric power circuits are to be separated as far as practicable.
- b) Cables for duplicated electric power circuits with their associated components are to be separated as far as practicable. They are to follow different routes separated both vertically and horizontally, as far as practicable, throughout their entire length.
- c) Actuators controlling the power systems of the steering gear, e.g. magnetic valves, are to be duplicated and separated.

## **2.8 Alarms and indications**

### **2.8.1 Power units**

- a) *In the event of a power failure to any one of the steering gear power units, an audible and visual alarm shall be given on the navigating bridge.*
- b) *Means for indicating that the motors of electric and electrohydraulic steering gear are running shall be installed on the navigating bridge and at a suitable main machinery control position.*
- c) *Where a three-phase supply is used, an alarm shall be provided that will indicate failure of any one of the supply phases.*
- d) *An overload alarm shall be provided for each motor of electric or electrohydraulic steering gear power units.*
- e) *The alarms required in c) and d) shall be both audible and visual and situated in a conspicuous position in the main machinery space or control room from which the main machinery is normally controlled.*

### **2.8.2 Hydraulic system**

- a) Hydraulic oil reservoirs are to be provided with the alarms required in [2.6.6].
- b) Where hydraulic locking, caused by a single failure, may lead to loss of steering, an audible and visual alarm, which identifies the failed system, is to be provided on the navigating bridge.

Note 1: This alarm is to be activated when, for example:

- the position of the variable displacement pump control system does not correspond with the given order, or
- an incorrect position in the 3-way valve, or similar, in the constant delivery pump system is detected.

**2.8.3 Control system**

*In the event of a failure of electrical power supply to the steering gear control systems, an audible and visual alarm shall be given on the navigating bridge.*

**2.8.4 Rudder angle indication**

The angular position of the rudder is to be:

- indicated on the navigating bridge, if the main steering gear is power operated. The rudder angle indication is to be independent of the steering gear control system and be supplied through the emergency switchboard, or by an alternative and independent source of electrical power such as that referred to in [2.7.2], item e);
- recognisable in the steering gear compartment.

**2.8.5 Steering gear failure**

The steering gear failures likely to cause uncontrolled movements of rudder are to be clearly identified. In the event of detection of such failure, the rudder is to stop in the current position without manual intervention or, subject to the discretion of the Society, is to return to the midship/neutral position. For mechanical failures such as sticking valves and failure of static components (pipes, cylinders), the system response without manual intervention is not mandatory, and the operator can follow instructions on the signboard in case of such failures, in accordance with [5.5.1].

Additionally for hydraulic locking failure, refer also to [2.8.2] item b).

**2.8.6 Summary table**

Displays and alarms are to be provided in the locations indicated in Tab 5.

**Table 5 : Location of displays and alarms**

Item	Display	Alarms (audible and visible)	Location		
			Navigation Bridge	Engine Control Room (3)	Steering gear compartment
Indication that electric motor of each power unit is running	X		X	X	
Rudder angle indicator	X		X		X
Power failure of each power unit		X	X	X	
Power failure of each control system		X	X	X	
Overload of electric motor of each power unit		X	X	X	
Phase failure of electric motor of each power unit		X	X	X	
Earth fault on AC and DC circuits		X	X	X	
Control system failures	Loop failures in closed loop systems, both command and feed back loops (1)	X	X	X	
	Data communication errors	X	X	X	
	Programmable system failures (Hardware and software failures)	X	X	X	
	Deviation between rudder order and feedback (2)	X	X	X	
Low level of each hydraulic fluid reservoir		X	X	X	
Hydraulic lock		X	X		
<p>(1) Normally short circuit, broken connections and earth faults</p> <p>(2) Deviation alarm is to be initiated if the rudder’s actual position does not reach the set point within acceptable time limits for the closed loop control systems (e.g. follow-up control and autopilot). Deviation alarm may be caused by mechanical, hydraulic or electrical failures.</p> <p>(3) Common alarm may be accepted if individual alarms are available locally.</p>					

### 3 Design and construction - Requirements for ships equipped with several rudders

#### 3.1 Principle

##### 3.1.1 General

In addition to the provisions of Article [2], ships equipped with two or more aft rudders are to comply with the provisions of the present Article.

##### 3.1.2 Availability

Where the ship is fitted with two or more rudders, each having its own actuation system, the latter need not be duplicated.

##### 3.1.3 Equivalent rudder stock diameter

Where the rudders are served by a common actuating system, the diameter of the rudder stock referred to in [2.2.1], item c), is to be replaced by the equivalent diameter  $d$  obtained from the following formula:

$$d = \sqrt[3]{\sum_i d_i^3}$$

with:

$d_i$  : Rule diameter of the upper part of the rudder stock of each rudder in way of the tiller, excluding strengthening for navigation in ice.

#### 3.2 Synchronisation

##### 3.2.1 General

A system for synchronising the movement of the rudders is to be fitted, either:

- by a mechanical coupling, or
- by other systems giving automatic synchronising adjustment.

##### 3.2.2 Non-mechanical synchronisation

Where the synchronisation of the rudder motion is not achieved by a mechanical coupling, the following provisions are to be met:

- a) the angular position of each rudder is to be indicated on the navigation bridge
- b) the rudder angle indicators are to be independent from each other and, in particular, from the synchronising system
- c) in case of failure of the synchronising system, means are to be provided for disconnecting this system so that steering capability can be maintained or rapidly regained. See also Pt D, Ch 7, Sec 4, [7.2.2].

### 4 Design and construction - Requirements for ships equipped with thrusters as steering means

#### 4.1 Principle

##### 4.1.1 General

The main and auxiliary steering gear referred to in Article [3] may consist of thrusters of the following types:

- azimuth thrusters
- water-jets
- cycloidal propellers

complying with the provisions of Ch 1, Sec 15, as far as applicable.

##### 4.1.2 Control system

Where the steering means of the ship consists of two or more thrusters, their control system is to include a device ensuring an automatic synchronisation of the thruster rotation, unless each thruster is so designed as to withstand any additional forces resulting from the thrust exerted by the other thrusters.

#### 4.2 Steering arrangements

##### 4.2.1 General

The requirements in this sub-article apply to ships fitted with alternative propulsion and steering arrangements, such as but not limited to, azimuthing propulsors or water jet propulsion systems.

##### 4.2.2 Steering arrangements for ships fitted with multiple steering-propulsion units

For a ship fitted with multiple steering-propulsion units, such as, but not limited to, azimuthing propulsors or water jet propulsion systems, each of the steering-propulsion units is to be provided with a main steering gear and an auxiliary steering gear or with

two or more identical steering actuating systems in compliance with [4.2.7]. The main steering gear and the auxiliary steering gear are to be so arranged that the failure of one of them will not render the other one inoperative.

#### **4.2.3 Steering arrangements for ships fitted with single steering-propulsion unit**

For a ship fitted with a single steering-propulsion unit, the steering gear is to be provided with two or more steering actuating systems complying with [4.2.7]. A detailed risk assessment is to be submitted in order to demonstrate that in the case of any single failure in the steering gear, control system and power supply, the ship steering is maintained.

#### **4.2.4 Design of components used in steering arrangements**

All components used in steering arrangements for ship directional control are to be of sound reliable construction to the satisfaction of the Administration or recognized organizations acting on its behalf. Special consideration should be given to the suitability of any essential component which is not duplicated. Any such essential component is, where appropriate, to utilize anti-friction bearings such as ball bearings, roller bearings or sleeve bearings which should be permanently lubricated or provided with lubrication fittings.

#### **4.2.5 Main steering arrangements**

The main steering arrangements for ship directional control are to be:

- of adequate strength and capable of steering the ship at maximum ahead service speed which should be demonstrated
- capable of changing direction of the steering-propulsion unit from one side to the other at declared steering angle limits at an average turning speed of not less than 2,3°/s with the ship running ahead at maximum ahead service speed
- for all ships, operated by power; and
- so designed that they will not be damaged at maximum astern speed; this design requirement need not be proved by trials at maximum astern speed and declared steering angle limits.

Note 1: Declared steering angle limits are the operational limits in terms of maximum steering angle, or equivalent, according to manufacturers' guidelines for safe operation, also taking into account the ship's speed or propeller torque/speed or other limitation; the "declared steering angle limits" are to be declared by the directional control system manufacturer for each ship specific non-traditional steering mean.

Note 2: Ship manoeuvrability tests, such as those in the Standards for ship manoeuvrability (IMO Resolution MSC.137(76)) should be carried out with steering angles not exceeding the declared steering angle limits.

#### **4.2.6 Auxiliary steering arrangements**

The auxiliary steering arrangements for ship directional control are to be:

- of adequate strength and capable of steering the ship at navigable speed and of being brought speedily into action in an emergency
- capable of changing direction of the ship's directional control system from one side to the other at declared steering angle limits at an average turning speed, of not less than 0.5°/s; with the ship running ahead at one half of the maximum ahead service speed or 7 knots, whichever is the greater; and
- for all ships, operated by power where necessary to meet the requirements of SOLAS regulation II-1/29.4.2 and in any ship having power of more than 2,500 kW propulsion power per steering-propulsion unit.

Note 1: The definition of "declared steering angle limits", set out in [4.2.5], applies.

Note 2: Ship manoeuvrability tests, such as those in the Standards for ship manoeuvrability (IMO Resolution MSC.137(76)) should be carried out with steering angles not exceeding the declared steering angle limits.

#### **4.2.7 Omission of the auxiliary steering gear**

- a) For a ship fitted with a single steering-propulsion unit where the main steering gear comprises two or more identical power units and two or more identical steering actuators, an auxiliary steering gear need not be fitted provided that the steering gear:
  - in a passenger ship, is capable of satisfying the requirements in [4.2.5] while any one of the power units is out of operation
  - in a cargo ship, is capable of satisfying the requirements in [4.2.5] while operating with all power units; and
  - is arranged so that after a single failure in its piping system or in one of the power units, steering capability can be maintained or speedily regained.
- b) For a ship fitted with multiple steering-propulsion units, where each main steering system comprises two or more identical steering actuating systems, an auxiliary steering gear need not be fitted provided that each steering gear:
  - in a passenger ship, is capable of satisfying the requirements in [4.2.5] while any one of the steering gear steering actuating systems is out of operation
  - in a cargo ship, is capable of satisfying the requirements in [4.2.5] while operating with all steering gear steering actuating systems
  - is arranged so that after a single failure in its piping or in one of the steering actuating systems, steering capability can be maintained or speedily regained; and
  - the above capacity requirements apply regardless whether the steering systems are arranged with common or dedicated power units.

Note 1: For the purposes of alternative steering arrangements, the steering gear power unit should be considered as defined in [1.3.4]. For electric steering gears, refer to [1.3.4]; electric steering motors should be considered as part of the power unit and actuator.

#### 4.2.8 Case of the steering-propulsion units having a residual steering capability when propulsion power is lost

This requirement applies to steering-propulsion units having a certain proven steering capability due to ship speed also in case propulsion power has failed.

Where the propulsion power exceeds 2,500 kW per thruster unit, an alternative power supply, sufficient at least to supply the steering arrangements which complies with the requirements of [2.2.2], item b), and also its associated control system and the steering gear response indicator, is to be provided automatically, within 45 s, either from the emergency source of electrical power or from an independent source of power located in the steering gear compartment. This independent source of power is to be used only for this purpose. In every ship of 10,000 gross tonnage and upwards, the alternative power supply is to have a capacity for at least 30 min of continuous operation and in any other ship for at least 10 min.

#### 4.2.9 Additional requirement for ships fitted with multiple electric or electrohydraulic steering systems

For a ship fitted with multiple electric or electrohydraulic steering systems, the requirements of [2.7.2], items a), b) and c), are to be applied to each of the steering systems.

### 4.3 Use of water-jets

4.3.1 The use of water-jets as steering means will be given special consideration by the Society.

## 5 Arrangement and installation

### 5.1 Steering gear room arrangement

5.1.1 *The steering gear compartment shall be:*

- a) *readily accessible and, as far as practicable, separated from machinery spaces, and*
- b) *provided with suitable arrangements to ensure working access to steering gear machinery and controls. These arrangements shall include handrails and gratings or other non-slip surfaces to ensure suitable working conditions in the event of hydraulic fluid leakage.*

### 5.2 Rudder actuator installation

#### 5.2.1

- a) Rudder actuators are to be installed on foundations of strong construction so designed as to allow the transmission to the ship structure of the forces resulting from the torque applied by the rudder and/or by the actuator, considering the strength criteria defined in [2.5.3] and [5.3.1]. The structure of the ship in way of the foundations is to be suitably strengthened.
- b) Where the rudder actuators are bolted to the hull, the grade of the bolts used is not to be less than 8.8. Unless the bolts are adjusted and fitted with a controlled tightening, strong shocks are to be fitted in order to prevent any lateral displacement of the rudder actuator.

### 5.3 Overload protections

#### 5.3.1 Mechanical rudder stops

- a) The steering gear is to be provided with strong rudder stops capable of mechanically stopping the rotation of the rudder at an angle slightly greater than its maximum working angle. Alternatively, these stops may be fitted on the ship to act on another point of the mechanical transmission system between the rudder actuator and the rudder blade. These stops may be built in with the actuator design.
- b) The scantlings of the rudder stops and of the components transmitting to the ship's structure the forces applied on these stops are to be determined for the greater value of the torques  $T_R$  or  $T_G$ .

Where  $T_G \geq 1,5T_R$ , the rudder stops are to be fitted between the rudder actuator and the rudder stock, unless the rudder stock as well as all the components transmitting mechanical forces between the rudder actuator and the rudder blade are suitably strengthened.

#### 5.3.2 Rudder angle limiters

- a) Power-operated steering gear is to be provided with positive arrangements, such as limit switches, for stopping the gear before the rudder stops are reached. These arrangements are to be synchronised with the gear itself and not with the steering gear control.
- b) For power-operated steering gears and where the rudder may be oriented to more than 35° at very reduced speed, it is recommended to fit a limit system 35° for full speed. A notice is to be displayed at all steering wheel stations indicating that rudder angles of more than 35° are to be used only at very reduced speed.

#### 5.3.3 Relief valves

Relief valves are to be fitted in accordance with [2.6.5].

### **5.3.4 Buffers**

Buffers are to be provided on all ships fitted with mechanical steering gear. They may be omitted on hydraulic gear equipped with relief valves or with calibrated bypasses.

## **5.4 Means of communication**

**5.4.1** *A means of communication is to be provided between the navigation bridge and the steering gear compartment.*

If electrical, it is to be fed through the emergency switchboard or to be sound powered.

## **5.5 Operating instructions**

**5.5.1** For steering gear comprising two identical power units intended for simultaneous operation, both normally provided with their own (partly or mutually) separate control systems, the following standard notice is either to be placed on a signboard fitted at a suitable place on the steering control post on the bridge or incorporated into the operation manual:

CAUTION

IN SOME CIRCUMSTANCES WHEN 2 POWER UNITS ARE RUNNING SIMULTANEOUSLY, THE RUDDER MAY NOT RESPOND TO THE HELM. IF THIS HAPPENS STOP EACH PUMP IN TURN UNTIL CONTROL IS REGAINED.

# **6 Certification, inspection and testing**

## **6.1 Type tests of hydraulic pumps**

**6.1.1** Each type of power unit pump is to be subjected in the workshop to a type test of not less than 100 hours' duration.

The test arrangements are to be such that the pump may run both:

- in idling conditions, and
- at maximum delivery capacity at maximum working pressure.

During the test, idling periods are to be alternated with periods at maximum delivery capacity at maximum working pressure. The passage from one condition to another is to occur at least as quickly as on board.

During the test, no abnormal heating, excessive vibration or other irregularities are permitted.

After the test, the pump is to be disassembled and inspected.

Note 1: Type tests may be waived for a power unit which has been proven to be reliable in marine service.

## **6.2 Testing of materials**

### **6.2.1 Components subject to pressure or transmitting mechanical forces**

a) Materials of components subject to pressure or transmitting mechanical forces, specifically:

- cylindrical shells of hydraulic cylinders, rams and piston rods
- tillers, quadrants
- rotors and rotor housings for rotary vane steering gear
- hydraulic pump casings
- and hydraulic accumulators, if any,

are to be duly tested, including examination for internal defects, in accordance with the requirements of NR216 Materials and Welding.

b) A works' certificate may be accepted for low stressed parts, provided that all characteristics for which verification is required are guaranteed by such certificate.

### **6.2.2 Hydraulic piping, valves and accessories**

Tests for materials of hydraulic piping, valves and accessories are to comply with the provisions of Ch 1, Sec 10, [20.4].

## **6.3 Inspection and tests during manufacturing**

### **6.3.1 Components subject to pressure or transmitting mechanical forces**

a) The mechanical components referred to in [6.2.1] are to be subjected to appropriate non-destructive tests. For hydraulic cylinder shells, pump casings and accumulators, refer to Ch 1, Sec 3.

b) Defects may be repaired by welding only on forged parts or steel castings of weldable quality. Such repairs are to be conducted under the supervision of the Surveyor in accordance with the applicable requirements of NR216 Materials and Welding.

### **6.3.2 Hydraulic piping, valves and accessories**

Hydraulic piping, valves and accessories are to be inspected and tested during manufacturing in accordance with Ch 1, Sec 10, [20], for a class I piping system.

## **6.4 Inspection and tests after completion**

### **6.4.1 Hydrostatic tests**

- a) Hydraulic cylinder shells and accumulators are to be subjected to hydrostatic tests according to the relevant provisions of Ch 1, Sec 3.
- b) Hydraulic piping, valves and accessories and hydraulic pumps are to be subjected to hydrostatic tests according to the relevant provisions of Ch 1, Sec 10, [20.5].

### **6.4.2 Shipboard tests**

After installation on board the ship, the steering gear is to be subjected to the tests detailed in Ch 1, Sec 18, [3.13].

### **6.4.3 Sea trials**

For the requirements of sea trials, refer to Ch 1, Sec 18.

# Section 15 Thrusters

## 1 General

### 1.1 Application

#### 1.1.1 Thrusters developing power equal to 110 kW or more

The requirements of this Section apply to the following types of thrusters developing power equal to 110 kW or more:

- transverse thrusters intended for manoeuvring
- thrusters intended for propulsion and steering.

For azimuth thrusters intended for dynamic positioning, the additional requirements in Pt F, Ch 11, Sec 5 are to be complied with.

Thrusters intended for propulsion and steering of ships with an **ICE CLASS** notation are to comply with the additional requirements of Part F, Chapter 8. Transverse thrusters intended for manoeuvring of ships with an **ICE CLASS** notation are required to comply with additional requirement Pt F, Ch 8, Sec 3, [3.5.1] only. Thrusters intended for propulsion and steering of ships with an additional class notation **POLAR CLASS** or a service notation **icebreaker** are to comply with the relevant requirements of NR527.

#### 1.1.2 Thrusters developing power less than 110 kW

Thrusters of less than 110 kW are to be built in accordance with sound marine practice and tested as required in [3.2] to the satisfaction of the Surveyor.

### 1.2 Definitions

#### 1.2.1 Thruster

A thruster is a propeller installed in a revolving nozzle or in a special transverse tunnel in the ship, or a water-jet. A thruster may be intended for propulsion, manoeuvring and steering or any combination thereof. Propulsion propellers in fixed nozzles are not considered thrusters (see Ch 1, Sec 8, [1.1.1]).

#### 1.2.2 Transverse thruster

A transverse thruster is an athwartship thruster developing a thrust in a transverse direction for manoeuvring purposes.

#### 1.2.3 Azimuth thruster

An azimuth thruster is a thruster which has the capability to rotate through 360° in order to develop thrust in any direction.

#### 1.2.4 Water-jet

A water-jet is equipment constituted by a tubular casing (or duct) enclosing an impeller. The shape of the casing is such as to enable the impeller to produce a water-jet of such intensity as to give a positive thrust. Water-jets may have means for deviating the jet of water in order to provide a steering function.

### 1.3 Thrusters intended for propulsion

**1.3.1** In general, at least two azimuth thrusters are to be fitted in ships where these are the sole means of propulsion. Single azimuth thruster installations will be specially considered by the Society on a case by case basis.

This requirement also applies to water-jets.

### 1.4 Documentation to be submitted

#### 1.4.1 Plans to be submitted for athwartship thrusters and azimuth thrusters

For thrusters developing power equal to 110 kW or more, the plans listed in Tab 1 are to be submitted.

#### 1.4.2 Plans to be submitted for water-jets

The plans listed in Tab 2 are to be submitted.

#### 1.4.3 Additional data to be submitted

The data and documents listed in Tab 3 are to be submitted by the manufacturer together with the plans.

**Table 1 : Plans to be submitted for athwartship thrusters and azimuth thrusters**

No.	A/I (1)	ITEM
General requirements for all thrusters		
1	I	General arrangement of the thruster
2	A	Propeller, including the applicable details mentioned in Ch 1, Sec 8
3	A	Bearing details
4	A	Propeller and intermediate shafts
5	A	Gears, including the applicable details mentioned in Ch 1, Sec 6
Specific requirements for transverse thrusters		
6	A	Structure of the tunnel showing the materials and their thickness
7	A	Structural equipment or other connecting devices which transmit the thrust from the propeller to the tunnel
8	A	Sealing devices (propeller shaft gland and thruster-tunnel connection)
9	A	For the adjustable pitch propellers: pitch control device and corresponding monitoring system
Specific requirements for rotating and azimuth thrusters		
10	A	Structural items (nozzle, bracing, etc.)
11	A	Structural connection to hull
12	A	Rotating mechanism of the thruster
13	A	Thruster control system
14	A	Piping systems connected to thruster
(1) A = to be submitted for approval I = to be submitted for information		

**Table 2 : Plans to be submitted for water-jets**

No.	A/I (1)	ITEM
1	I	General arrangement of the water-jet
2	A	Casing (duct) (location and shape) showing the materials and the thicknesses as well as the forces acting on the hull
3	A	Details of the shafts, flanges, keys
4	I	Sealing gland
5	A	Bearings
6	A	Impeller
7	A	Steering and reversing buckets and their control devices as well as the corresponding hydraulic diagrams
(1) A = to be submitted for approval I = to be submitted for information		

**Table 3 : Data and documents to be submitted for athwartship thrusters, azimuth thrusters and water-jets**

No.	A/I (1)	ITEM
1	I	Rated power and revolutions
2	I	Rated thrust
3	A	Material specifications of the major parts, including their physical, chemical and mechanical properties
4	A	Where parts of thrusters are of welded construction, all particulars on the design of welded joints, welding procedures, heat treatments and non-destructive examinations after welding
5	I	Where applicable, background information on previous operating experience in similar applications
(1) A = to be submitted for approval I = to be submitted for information		

## 2 Design and Construction

### 2.1 Materials

#### 2.1.1 Propellers

For requirements relative to material intended for propellers, see Ch 1, Sec 8, [2.1.1].

#### 2.1.2 Other thruster components

For the requirements relative to materials intended for other parts of the thrusters, such as gears, shaft, couplings, etc., refer to the applicable parts of the Rules.

### 2.2 Transverse thrusters and azimuth thrusters

#### 2.2.1 Prime movers

- a) Diesel engines intended for driving thrusters are to comply with the applicable requirements of Ch 1, Sec 2.
- b) Electric motors intended for driving thrusters and their feeding systems are to comply with the requirements of Ch 2, Sec 4. In particular:
  - provisions are to be made to prevent starting of the motors whenever there are insufficient generators in operation
  - intermittent duty thrusters will be the subject of special consideration by the Society.

#### 2.2.2 Propellers

- a) For propellers of thrusters intended for propulsion, the requirements of Ch 1, Sec 8, [2.5] apply.
- b) For propellers of thrusters intended for manoeuvring only, the requirements of Ch 1, Sec 8, [2.5] also apply, although the increase in thickness of 10% does not need to be applied.

#### 2.2.3 Shafts

- a) For propeller shafts of thrusters intended for propulsion, the requirements of Ch 1, Sec 7, [2.2.3] apply.
- b) For propellers of thrusters intended for manoeuvring only, the minimum diameter  $d_s$  of the shaft, in mm, is not to be less than the value obtained by the following formula:

$$d_s = [(C \cdot M_T)^2 + (D \cdot M)^2]^{1/6} \cdot \left(\frac{1}{1-Q^4}\right)^{1/3}$$

where:

$M_T$  : Maximum transmitted torque, in N·m; where not indicated,  $M_T$  may be assumed as 9550 (P/N)

where:

P : Maximum power of the thruster prime mover, in kW

N : Rotational speed of the propeller, in rev/min

M : Bending moment, in N·m, at the shaft section under consideration

C : Coefficient equal to:

$$C = 10,2 + \frac{28000}{R_{S,MIN}}$$

D : Coefficient equal to:

$$D = \frac{170000}{412 + R_{S,MIN}}$$

$R_{S,MIN}$  : Minimum yield strength of the shaft material, in N/mm<sup>2</sup>

Q : 0 for solid shafts

The ratio between the diameter of the hole and the external diameter of the shaft, in the case of hollow shafts. If  $Q \leq 0,3$ , Q may be assumed equal to 0.

The above diameter is to be increased by 10% in the case of keyed connection to the propeller in way of key.

#### 2.2.4 Gears

- a) Gears of thrusters intended for propulsion are to be in accordance with the applicable requirements of Ch 1, Sec 6, applying the safety factors for propulsion gears.
- b) Gears of thrusters intended for manoeuvring only are to be in accordance with the applicable requirements of Ch 1, Sec 6, applying the safety factors for auxiliary gears.

**2.2.5 Nozzles and connections to hull for azimuth thrusters**

- a) For the requirements relative to the nozzle structure, see Part B, Chapter 12.
- b) The scantlings of the nozzle connection to the hull and the welding type and size will be specially considered by the Society, which reserves the right to require detailed stress analysis in the case of certain high power installations.
- c) For steerable thrusters, the equivalent rudder stock diameter is to be calculated in accordance with the requirements of Part B, Chapter 12.

**2.2.6 Transverse thruster tunnel**

- a) The thickness of the tunnel is not to be less than the adjacent part of the hull.
- b) Special consideration will be given by the Society to tunnels connected to the hull by connecting devices other than welding.

**2.3 Water-jets**

**2.3.1 Shafts**

The diameter of the shaft supporting the impeller is not to be less than the diameter  $d_2$ , in mm, obtained by the following formula:

$$d_2 = 100fh \cdot \left(\frac{P}{N}\right)^{1/3} \cdot \left(\frac{1}{1-Q^4}\right)^{1/3}$$

where:

- P : Power, in kW
- N: : Rotational speed, in rpm
- f : Calculated as follows:

$$f = \left(\frac{560}{R_m + 160}\right)^{1/3}$$

where  $R_m$  is the ultimate tensile strength of the shaft material, in N/mm<sup>2</sup>

- h: :
  - h = 1 when the shaft is only transmitting torque loads, and when the weight and thrust of the propeller are totally supported by devices located in the fixed part of the thruster
  - h = 1,22 where the impeller is fitted with key or shrink-fitted.
- Q : 0 for solid shafts  
The ratio between the diameter of the hole and the external diameter of the shaft, in the case of hollow shafts. If  $Q \leq 0,3$ , Q may be assumed equal to 0.

The shafts are to be protected against corrosion by means of either a continuous liner or an oil-gland of an approved type, or by the nature of the material of the shaft.

**2.3.2 Guide vanes, shaft support**

- a) Guide vanes and shaft supports, if any, are to be fitted in accordance with direction of flow. Trailing and leading edges are to be fitted with rounded profiles.
- b) Fillet radius are generally not be less than the maximum local thickness of concerned element. Fatigue strength calculation is to be submitted.

**2.3.3 Stator and impellers**

- a) Design is to take into account the loads developed in free going conditions and also in peculiar manoeuvres like crash stop.
- b) Tip clearance is to take into account vibratory behaviours, displacements and any other expansion mode in all operating conditions of the water jet.
- c) Fillet radii are generally not to be less than the maximum local thickness of concerned element.
- d) There is to be no natural frequency of stator blades or rotor blades in the vicinity of the excitation frequencies due to hydrodynamic interaction between stator blades and rotor blades. Calculations are to be submitted for maximum speed and any currently used speed.

**2.3.4 Nozzle and reversing devices**

Design of nozzle and reversing devices are to take into account the loads developed in all operating conditions of the water jet, including transient loads.

**2.3.5 Steering performance**

Steering performance and emergency steering availability are to be at least equivalent to the requirements in Ch 1, Sec 14, [4.2] and Ch 1, Sec 14, [4.3].

## 2.4 Alarm, monitoring and control systems

### 2.4.1 Steering thruster controls

- a) Controls for steering are to be provided from the navigating bridge, the machinery control station and locally.
- b) Means are to be provided to stop any running thruster at each of the control stations.
- c) A thruster angle indicator is to be provided at each steering control station. The angle indicator is to be independent of the control system.

### 2.4.2 Alarm and monitoring equipment

Tab 4 summarises the minimum alarm and monitoring requirements for propulsion and steering thrusters. See also Ch 1, Sec 14, [4].

**Table 4 : Azimuth thrusters**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Thruster			Auxiliary	
	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Identification of system parameter							
Steering oil pressure	L						
Oil tank level	L						

## 3 Testing and certification

### 3.1 Material tests

#### 3.1.1 Propulsion and steering thrusters

All materials intended for parts transmitting torque and for propeller/impeller blades are to be tested in accordance with the requirements of Ch 1, Sec 8, [4.1] in the presence of a Surveyor.

#### 3.1.2 Transverse thrusters

Material testing for parts of athwartship thrusters does not need to be witnessed by a Surveyor, provided full test reports are made available to him.

### 3.2 Testing and inspection

#### 3.2.1 Thrusters

Thrusters are to be inspected as per the applicable requirements in Ch 1, Sec 8, [4.2].

#### 3.2.2 Prime movers

Prime movers are to be tested in accordance with the requirements applicable to the type of mover used.

### 3.3 Certification

#### 3.3.1 Certification of thrusters

Thrusters are to be individually tested and certified by the Society.

#### 3.3.2 Mass produced thrusters

Mass produced thrusters may be accepted within the framework of the type approval program of the Society.

# Section 16 Refrigerating Installations

## 1 General

### 1.1 Application

#### 1.1.1 Refrigerating installations on all ships

The minimum safety requirements addressed in this Section are to be complied with for any refrigerating plant installed on board a ship to be classed by the Society. These requirements do not cover any operation or availability aspect of the plants, which are not the subject of class requirements, unless an additional notation is requested.

#### 1.1.2 Additional notations

Where one or more of the following additional notations:

- REF-CARGO
- REF-CONT
- REF-STORE

is requested, the requirements of Part F, Chapter 7 are to be complied with, as applicable.

## 2 Minimum design requirements

### 2.1 Refrigerating installation components

#### 2.1.1 General

In general, the specific requirements stated in Part C of the Rules for various machinery and equipment are also applicable to refrigerating installation components.

#### 2.1.2 Pressure vessels and heat exchangers

- a) Pressure vessels of refrigerating plants are to comply with the relevant requirements of Ch 1, Sec 3.
- b) Vessels intended to contain ammonia or toxic substances are to be considered as class 1 pressure vessels as indicated in Ch 1, Sec 3, [1.4].
- c) The materials used for pressure vessels are to be appropriate to the fluid that they contain. Where ammonia is the refrigerant, copper, bronze, brass and other copper alloys are not to be used.
- d) Notch toughness of steels used in low temperature plants is to be suitable for the thickness and the lowest design temperature. A check of the notch toughness properties may be required where the working temperature is below minus 40°C.

#### 2.1.3 Piping systems

- a) Refrigerant pipes are generally to be regarded as pressure pipes.
- b) Refrigerant, brine and sea water pipes are to satisfy the requirements of Ch 1, Sec 10 as applicable.
- c) Refrigerant pipes are to be considered as belonging to the following classes:
  - class I: where they are intended for ammonia or toxic substances
  - class II: for other refrigerants
  - class III: for brine.
- d) In general, the pipes conveying the cooling medium are not to come into direct contact with the ship's structure; they are to be carefully insulated on their run outside the refrigerated spaces, and more particularly when passing through bulkheads and decks.
- e) The materials used for the pipes are to be appropriate to the fluids that they convey. Copper, brass, bronze and other copper alloys are not to be used for pipes likely to convey ammonia. Methods proposed for joining such pipes are to be submitted to the Society for consideration.
- f) Notch toughness of the steels used is to be suitable for the application concerned.
- g) Where necessary, cooling medium pipes within refrigerated spaces or embedded in insulation are to be externally protected against corrosion; for steel pipes, this protection is to be ensured by galvanisation or equivalent. All useful precautions are to be taken to protect the joints of such pipes against corrosion.
- h) The use of plastic pipes will be considered by the Society on a case by case basis.

## **2.2 Refrigerants**

### **2.2.1 Prohibited refrigerants**

The use of the following refrigerants is not allowed for shipboard installations:

- Methyl chloride
- R11 - Trichloromonofluoromethane (C Cl<sub>3</sub> F)
- Ethane
- Ethylene
- Other substances with lower explosion limit in air of less than 3,5%.

### **2.2.2 Statutory requirements**

Particular attention is to be paid to any limitation on the use of refrigerants imposed by the Administration of the State whose flag the ship is flying.

### **2.2.3 Toxic or flammable refrigerants**

The arrangement of refrigerating machinery spaces of plants using toxic or flammable refrigerants will be the subject of special consideration by the Society.

For specific requirements on spaces intended for plants using ammonia as a refrigerant, see [2.3].

## **2.3 Special requirements for ammonia (R717)**

### **2.3.1 Refrigerating machinery compartment**

a) Ammonia refrigerating machinery is to be installed in dedicated gastight spaces, complying with items b) to e).

Ammonia plants with a quantity of ammonia not greater than 25 kg are however allowed to be located in the engine room, provided that the requirements of [2.3.2] are fulfilled.

Note 1: For fishing vessels, refer to Pt D, Ch 15, Sec 4, [21.3.1].

b) At least two access doors are to be provided. One of these doors is to lead directly to the open deck. The doors are to open outwards and are to be self-closing.

c) Dedicated spaces containing ammonia machinery (including process vessels) are to be fitted with:

- 1) A negative ventilation system independent of ventilation systems serving other ship spaces and having a capacity not less than 30 air changes per hour based upon the total volume of the space. Other suitable arrangements which ensure an equivalent effectiveness may be considered. Provision is to be made for starting and stopping the ventilation fans from outside the space.

Where the access to the ammonia machinery space is from an accommodation or machinery space, the ventilation of the ammonia machinery space may not be designed to keep it under negative pressure with respect to the adjacent space, provided that the access is through an airlock.

- 2) A fixed ammonia detector system with audible and visual alarms inside and outside the space. This system is also to stop the compressor when a dangerous gas concentration is reached.
- 3) Water screens above all access doors, operable manually from outside the space. Water for the water screens may be supplied from the fire pumps.
- 4) an independent bilge system.

d) At least two sets of breathing apparatus and protective clothing are to be available outside and in the vicinity of the ammonia machinery space.

e) Ammonia piping is not to pass through accommodation spaces.

### **2.3.2 Ammonia plant located in the engine room**

When installation of an ammonia plant is allowed in the engine room in accordance with the provision of [2.3.1] item a), the area where the ammonia machinery is installed is to be served by a hood with a negative pressure ventilation system, having a capacity of not less than 30 air changes per hour, independent from any other ship ventilation system, so as to prevent any leakage of ammonia from dissipating into other areas in the engine room.

A water spray system is to be provided for the said area, covering the whole ammonia machinery and operable locally and from the outside of the engine room.

The provisions of items c) 2), d) and e) of requirement [2.3.1] are also to be complied with.

# Section 17 Turbochargers

## 1 General

### 1.1 Application

**1.1.1** These requirements are applicable for turbochargers with regard to design approval, type testing and certification and their matching on engines.

Turbochargers are to be type approved, either separately or as a part of an engine. The requirements are written for exhaust gas driven turbochargers, but apply in principle also for engine driven chargers.

**1.1.2** The requirements escalate with the size of the turbochargers. The parameter for size is the engine power (at MCR) supplied by a group of cylinders served by the actual turbocharger (e.g. for a V-engine with one turbocharger for each bank the size is half of the total engine power).

**1.1.3** Turbochargers are categorised in three groups depending on served power by cylinder groups with:

- Category A:  $\leq 1000$  kW
- Category B:  $> 1000$  kW and  $\leq 2500$  kW
- Category C:  $> 2500$  kW.

### 1.2 Documentation to be submitted

**1.2.1** The Manufacturer is to submit to the Society the documents as such:

- On request for approval as described in Tab 1 for category A turbochargers
- For approval or information as described in Tab 2 for category B and C turbochargers
- For approval or information as described in Tab 3 for category C turbochargers

**Table 1 : Documentation to be submitted for approval on request for Category A turbochargers**

No.	Document
1	Containment test report
2	Cross sectional drawing with principal dimensions and names of components
3	Test program

**Table 2 : Documentation to be submitted for Category B and C turbochargers**

No.	I/A (1)	Document
1	I	Cross sectional drawing with principal dimensions and materials of housing components for containment evaluation
2	A	Documentation of containment in the event of disc fracture, see [2.2]
3	I	Operational data and limitation as: (2) <ul style="list-style-type: none"> <li>• Maximum permissible operating speed (rpm)</li> <li>• Alarm level for over-speed</li> <li>• Maximum permissible exhaust gas temperature before turbine</li> <li>• Alarm level for exhaust gas temperature before turbine</li> <li>• Minimum lubrication oil inlet pressure</li> <li>• Lubrication oil inlet pressure low alarm set point</li> <li>• Maximum lubrication oil outlet temperature</li> <li>• Lubrication oil outlet temperature high alarm set point</li> <li>• Maximum permissible vibration levels, i.e. self- and externally generated vibration</li> </ul>
4	A	Arrangement of lubrication system, all variants within a range.
5	I	Type test reports.
6	A	Test program.
<p>(1) A = to be submitted for approval I = to be submitted for information</p> <p>(2) Alarm levels may be equal to permissible limits but shall not be reached when operating the engine at 110% power or at any approved intermittent overload beyond the 110%.</p>		

Table 3 : Documentation to be submitted for Category C turbochargers

No	I/A (1)	Document
1	A	Drawings of the housing and rotating parts including details of blade fixing
2	I	Material specifications (chemical composition and mechanical properties) of all parts mentioned above
3	A	Welding details and welding procedure of above mentioned parts, if applicable
4	A	Documentation (2) of safe torque transmission when the disc is connected to the shaft by an interference fit, see [2.3]
5	I	Information on expected lifespan, considering creep, low cycle fatigue and high cycle fatigue
6	I	Operation and maintenance manuals (2)
(1) A = to be submitted for approval; I = to be submitted for information		
(2) Applicable to two sizes in a generic range of turbochargers.		

## 2 Design and construction

### 2.1 General

**2.1.1** The turbochargers are to be designed to operate under conditions given in Ch 1, Sec 1, Tab 1 and Ch 1, Sec 2, [1.3.3]. The component lifetime and the alarm level for speed are to be based on 45°C air inlet temperature.

**2.1.2** The air inlet of turbochargers is to be fitted with a filter.

### 2.2 Containment

**2.2.1** Turbochargers are to ensure containment in the event of a rotor burst. This means that, in case of a rotor burst, no part may penetrate the casing of the turbocharger or escape through the air intake. For documentation purposes (test/calculation), it is to be assumed that the discs disintegrate in the worst possible way.

**2.2.2** For category B and C turbochargers, containment is to be documented by testing. A generic range of turbochargers may be deemed to ensure containment based on testing of one specific unit. Testing of a large unit is preferred as this is considered conservative for all smaller units in the generic range. In any case, it is to be documented (e.g. by calculation) that the selected test unit really is representative for the whole generic range.

Note 1: A generic range means a series of turbochargers which are of the same design, but scaled to each other.

**2.2.3** The minimum test speeds, relative to the maximum permissible operating speed, are:

- For the compressor: 120%.
- For the turbine: 140% or the natural burst speed, whichever is lower.

**2.2.4** Containment tests are to be performed at working temperature.

**2.2.5** A numerical analysis (simulation) of sufficient containment integrity of the casing based on calculations by means of a simulation model may be accepted in lieu of the practical containment test, provided that:

- The numerical simulation model has been tested and its suitability/accuracy has been proven by direct comparison between calculation results and the practical containment test for a reference application (reference containment test). This test is to be performed at least once by the manufacturer for acceptance of the numerical simulation method in lieu of tests.
- The corresponding numerical simulation for the containment is performed for the same speeds as specified for the containment test.
- Material properties for high-speed deformations are to be applied in the numeric simulation. The correlation between normal properties and the properties at the pertinent deformation speed are to be substantiated.
- The design of the turbocharger regarding geometry and kinematics is similar to the turbocharger that was used for the reference containment test. In general, totally new designs will call for a new reference containment test.

### 2.3 Disc-shaft shrinkage fit

**2.3.1** Where the disc of category C turbochargers is connected to the shaft with interference fit, calculations are to be performed to substantiate safe torque transmission during all relevant operating conditions such as maximum speed, maximum torque and maximum temperature gradient combined with minimum shrinkage amount.

### 2.4 Alarms and monitoring

**2.4.1** For all turbochargers of Categories B and C, indications and alarms as listed in Tab 4 are required.

**2.4.2** In addition to [2.4.1], the general requirements given in Part C, Chapter 3 apply.

**Table 4 : Alarms and monitoring**

No	Monitored Parameters	Category of turbochargers				Notes
		B		C		
		Alarm	Indication	Alarm	Indication	
1	Speed	High (1)	X (1)	High (1)	X (1)	
2	Exhaust gas at each turbocharger inlet, temperature	High (2)	X (2)	High	X	High temp. alarms for each cylinder at engine is acceptable (3)
3	Lub. oil at turbocharger outlet, temperature			High	X	If not forced system, oil temperature near bearings
4	Lub. oil at turbocharger inlet, pressure	Low	X	Low	X	Only for forced lubrication systems (4)
<p>(1) On turbocharging systems where turbochargers are activated sequentially, speed monitoring is not required for the turbocharger(s) being activated last in the sequence, provided all turbochargers share the same intake air filter and they are not fitted with waste gates.</p> <p>(2) For Category B turbochargers, the exhaust gas temperature may be alternatively monitored at the turbocharger outlet, provided that the alarm level is set to a safe level for the turbine and that correlation between inlet and outlet temperatures is substantiated.</p> <p>(3) Alarm and indication of the exhaust gas temperature at turbocharger inlet may be waived if alarm and indication for individual exhaust gas temperature is provided for each cylinder and the alarm level is set to a value safe for the turbocharger.</p> <p>(4) Separate sensors are to be provided if the lubrication oil system of the turbocharger is not integrated with the lubrication oil system of the diesel engine or if it is separated by a throttle or pressure reduction valve from the diesel engine lubrication oil system.</p>						

### 3 Certification, inspection and testing

#### 3.1 Type tests

3.1.1 Category B or C turbochargers are to be type tested according to the present sub-article.

3.1.2 The type test for a generic range of turbochargers may be carried out either on an engine (for which the turbocharger is foreseen) or in a test rig.

3.1.3 Turbochargers are to be subjected to at least 500 load cycles at the limits of operation. This test may be waived if the turbocharger together with the engine is subjected to this kind of low cycle testing, see Ch 1, Sec 2, [4.1.4].

3.1.4 The suitability of the turbocharger for such kind of operation is to be preliminarily stated by the manufacturer.

3.1.5 The rotor vibration characteristics are to be measured and recorded in order to identify possible sub-synchronous vibrations and resonances.

3.1.6 The type test is to be completed by a hot running test at maximum permissible speed combined with maximum permissible temperature for at least one hour. After this test, the turbocharger is to be opened for examination, with focus on possible rubbing and the bearing conditions.

#### 3.2 Workshop inspections and testing

3.2.1 Category B and C turbochargers inspections and testings as well as their associated certificates are to be done in accordance with Tab 5.

#### 3.3 Certification

3.3.1 The manufacturer is to adhere to a certification scheme according to NR320 to ensure that the designer’s specifications are met, and that manufacturing is in accordance with the approved drawings.

- For category C turbochargers, certification scheme for IBV product is to be selected. Each turbocharger is to be delivered with a Class certificate.
- For category B turbochargers, certification scheme for HBV product is to be selected. Each turbocharger is to be delivered with a works’ certificate.

**Table 5 : Inspections and testings**

No	Inspections and testings	Type of certificate <b>(1)</b>	
		category B	category C
1	Chemical composition of material for the rotating parts.	W	W
2	Mechanical properties of the material of a representative specimen for the rotating parts and the casing	W	W
3	UT and crack detection of rotating parts	W	W
4	Dimensional inspection of rotating parts	W	W
5	Rotor balancing	W	C
6	Hydraulic testing of cooling spaces to 4 bars or 1.5 times maximum working pressure, whichever is higher	W	C
7	Overspeed test of all compressor wheels for a duration of 3 minutes at either 20% above alarm level speed at room temperature or 10% above alarm level speed at 45°C inlet temperature when tested in the actual housing with the corresponding pressure ratio. The overspeed test may be waived for forged wheels that are individually controlled by an approved non-destructive method	W	C
<b>(1)</b> C indicates that a Society certificate is required; W indicates that a manufacturer's document is required			

# Section 18 Tests on Board

## 1 General

### 1.1 Application

**1.1.1** This Section covers shipboard tests, both at the moorings and during sea trials. Such tests are additional to the workshop tests required in the other Sections of this Chapter.

For computerized machinery systems, requirements contained in Part C, Chapter 3 shall be referred to.

### 1.2 Purpose of shipboard tests

**1.2.1** Shipboard tests are intended to demonstrate that the main and auxiliary machinery and associated systems are functioning properly, in respect of the criteria imposed by the Rules. The tests are to be witnessed by a Surveyor.

### 1.3 Documentation to be submitted

**1.3.1** A comprehensive list of the shipboard tests intended to be carried out by the shipyard is to be submitted to the Society. For each test, the following information is to be provided:

- scope of the test
- parameters to be recorded.

## 2 General requirements for shipboard tests

### 2.1 Trials at the moorings

**2.1.1** Trials at the moorings are to demonstrate the following:

- a) satisfactory operation of the machinery
- b) quick and easy response to operational commands
- c) protection of the various installations, as regards:
  - the protection of mechanical parts
  - the safeguards for personnel
- d) accessibility for cleaning, inspection and maintenance.

Where the above features are not deemed satisfactory and require repairs or alterations, the Society reserves the right to require the repetition of the trials at the moorings, either wholly or in part, after such repairs or alterations have been carried out.

### 2.2 Sea trials

#### 2.2.1 Scope of the tests

Sea trials are to be conducted after the trials at the moorings and are to include the following:

- a) demonstration of the proper operation of the main and auxiliary machinery, including monitoring, alarm and safety systems, under realistic service conditions
- b) check of the propulsion capability when one of the essential auxiliaries becomes inoperative
- c) detection of dangerous vibrations by taking the necessary readings when required.

## 3 Shipboard tests for machinery

### 3.1 Conditions of sea trials

#### 3.1.1 Displacement of the ship

Except in cases of practical impossibility, or in other cases to be considered individually, the sea trials are to be carried out at a displacement as close as possible to the deadweight (full load) or to one half of the deadweight (half load).

#### 3.1.2 Power of the machinery

- a) The power developed by the propulsion machinery in the course of the sea trials is to be as close as possible to the power for which classification has been requested. In general, this power is not to exceed the maximum continuous power at which the weakest component of the propulsion system can be operated. In cases of diesel engines and gas turbines, it is not to exceed the maximum continuous power for which the engine type concerned has been approved.

- b) Where the rotational speed of the shafting is different from the design value, thereby increasing the stresses in excess of the maximum allowable limits, the power developed in the trials is to be suitably modified so as to confine the stresses within the design limits.

### **3.1.3 Determination of the power and rotational speed**

- a) The rotational speed of the shafting is to be recorded in the course of the sea trials, preferably by means of a continuous counter.
- b) In general, the power is to be determined by means of torsionometric readings, to be effected with procedures and instruments deemed suitable by the Society.

As an alternative, for reciprocating internal combustion engines and gas turbines, the power may be determined by measuring the fuel consumption and on the basis of the other operating characteristics, in comparison with the results of bench tests of the prototype engine.

Other methods of determining the power may be considered by the Society on a case by case basis.

## **3.2 Starting from dead ship conditions**

**3.2.1** The capability of the machinery installations to be brought into operation from a dead ship condition without external aid is to be demonstrated.

**3.2.2** The capability of the propulsion to be restored from dead ship conditions within 30 minutes is to be demonstrated.

## **3.3 Navigation and manoeuvring tests**

### **3.3.1 Speed trials**

- a) Where required by the Rules (see Pt A, Ch 1, Sec 2, [4.16.2]), the speed of the ship is to be determined using procedures deemed suitable by the Society.
- b) The ship speed is to be determined as the average of the speeds taken in not less than two pairs of runs in opposite directions.

### **3.3.2 Astern trials**

- a) *The ability of the machinery to reverse the direction of thrust of the propeller in sufficient time, and so to bring the ship to rest within reasonable distance from maximum ahead service speed, shall be demonstrated and recorded.*
- b) *The stopping times, ship headings and distances recorded on trials, together with the results of trials to determine the ability of ships having multiple propellers to navigate and manoeuvre with one or more propellers inoperative, shall be available on board for the use of the Master or designated personnel.*
- c) *Where the ship is provided with supplementary means for manoeuvring or stopping, the effectiveness of such means shall be demonstrated and recorded as referred to in paragraphs a) and b).*
- d) For electric propulsion systems, see [3.9].
- e) Main propulsion systems are to undergo tests to demonstrate the astern response characteristics. The tests are to be carried out at least over the manoeuvring range of the propulsion system and from all control positions. A test plan is to be provided by the yard and accepted by the surveyor. If specific operational characteristics have been defined by the manufacturer these shall be included in the test plan.
- f) The reversing characteristics of the propulsion plant, including the blade pitch control system of controllable pitch propellers, are to be demonstrated and recorded during trials.

## **3.4 Tests of boilers**

### **3.4.1 General**

The satisfactory operation of the main and auxiliary boilers supplying essential services is to be ascertained in all operating conditions during the trials at the moorings and the sea trials.

### **3.4.2 Tests to be performed**

After installation on board, the following tests are to be carried out in the presence of the Surveyor:

- a) Test in the hot condition of boilers and superheaters
- b) Accumulation tests and setting of safety valves of boilers and superheaters
- Safety valves are to be set to lift at a pressure not exceeding 103% of the design pressure
  - For boilers fitted with superheaters, the safety valves of the latter are to be set to lift before or, at the latest, at the same time as the valves of the saturated steam chest

- c) Verification that, at the maximum steaming rate, the boiler pressure does not exceed 110% of the design pressure when the stop valves of the boiler, except those which must remain open for the burning operation, are closed. The boiler is to be fed so that the water level remains normal throughout the test. The test is to last:
  - 15 minutes for fire tube boilers
  - 7 minutes for water tube boilers.
- d) Test and simulation of all safety devices, alarms, shut-off and automatic starting of standby equipment.

### 3.4.3 Alternative requirement

- a) When it is recognised, for certain types of boilers, that accumulation tests might endanger the superheaters, the omission of such tests may be considered.
- b) Such omission can be permitted, however, only if the drawings and the size of safety valves have been reviewed by the Society, and provided that the safety valves are of a type whose relieving capacity has been established by a test carried out in the presence of the Surveyor, or in other conditions deemed equivalent to those of the actual boiler.
- c) When the Society does not agree to proceed with an accumulation test, the valve manufacturer is to supply, for each safety valve, a certificate specifying its relieving capacity for the working conditions of the boiler. In addition, the boiler manufacturer is to supply a certificate specifying the maximum steam capacity of the boiler.

## 3.5 Tests of diesel engines

### 3.5.1 Objectives

The purpose of the shipboard testing is to verify compatibility with power transmission and driven machinery in the system, control systems and auxiliary systems necessary for the engine and integration of engine / shipboard control systems, as well as other items that had not been dealt with in the FAT (Factory Acceptance Testing).

### 3.5.2 Starting capacity

Starting manoeuvres are to be carried out in order to verify that the capacity of the starting media satisfies the required number of start attempts.

### 3.5.3 Monitoring and alarm system

The monitoring and alarm systems are to be checked to the full extent for all engines, except items already verified during the works trials.

### 3.5.4 Test loads

- a) Test loads for various engine applications are given below. In addition, the scope of the trials may be expanded depending on the engine application, service experience, or other relevant reasons.
- b) The suitability of the engine to operate on fuels intended for use is to be demonstrated.
- c) Tests other than those listed below may be required by statutory instruments (e.g. EEDI verification).
- d) Propulsion engines driving fixed pitch propeller or impeller.
  - At rated engine speed  $n_0$ : at least 4 hours.
  - At engine speed  $1,032 n_0$  (if engine adjustment permits): 30 min.
  - At approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer.
  - Minimum engine speed to be determined.
  - The ability of reversible engines to be operated in reverse direction is to be demonstrated.

Note 1: During stopping tests according to IMO Resolution MSC.137 (76), see [3.5.5] for additional requirements in the case of a barred speed range.

- e) Propulsion engines driving controllable pitch propellers.
  - At rated engine speed  $n_0$  with a propeller pitch leading to rated engine power (or to the maximum achievable power if 100% cannot be reached): at least 4 hours.
  - At approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer.
  - With reverse pitch suitable for manoeuvring, see [3.5.5] for additional requirements in the case of a barred speed range.
- f) Engine(s) driving generator(s) for electrical propulsion and/or main power supply
  - At 100% power (rated electrical power of generator): at least 60 min.
  - At 110% power (rated electrical power of generator): at least 10 min.

Note 2: Each engine is to be tested 100% electrical power for at least 60 min and 110% of rated electrical power of the generator for at least 10 min. This may, if possible, be done during the electrical propulsion plant test, which is required to be tested with 100% propulsion power (i.e. total electric motor capacity for propulsion) by distributing the power on as few generators as possible. The duration of this test is to be sufficient to reach stable operating temperatures of all rotating machines or for at least 4 hours. When some of the gen. set(s) cannot be tested due to insufficient time during the propulsion system test mentioned above, those required tests are to be carried out separately.

- Demonstration of the generator prime movers' and governors' ability to handle load steps as described in Ch 1, Sec 2, [2.7].

- g) Propulsion engines also driving power take off (PTO) generator.
- 100% engine power (MCR) at corresponding speed  $n_0$ : at least 4 hours.
  - 100% propeller branch power at engine speed  $n_0$  (unless covered in previous bullet point): 2 hours.
  - 100% PTO branch power at engine speed  $n_0$ : at least 1 hour.
- h) Engines driving auxiliaries.
- 100% power (MCR) at corresponding speed  $n_0$ : at least 30 min.
  - Approved intermittent overload: testing for duration as approved.

### **3.5.5 Torsional vibration - barred speed range**

Where a barred speed range (bsr) is required, passages through this bsr, both accelerating and decelerating, are to be demonstrated. The times taken are to be recorded and are to be equal to or below those times stipulated in the approved documentation, if any. This also includes when passing through the bsr in reverse rotational direction, especially during the stopping test.

Note 1: Applies both for manual and automatic passing-through systems.

The ship's draft and speed during all these demonstrations is to be recorded. In the case of a controllable pitch propeller, the pitch is also to be recorded.

The engine is to be checked for stable running (steady fuel index) at both upper and lower borders of the bsr. Steady fuel index means an oscillation range less than 5% of the effective stroke (idle to full index).

## **3.6 Test of air starting system for main and auxiliary engines**

**3.6.1** The capability of the starting air system to charge the air receivers within one hour from atmospheric pressure to a pressure sufficient to ensure the number of starts required in Sec 10, [17.3.1] for main and auxiliaries engines is to be demonstrated.

## **3.7 Tests of steam turbines**

### **3.7.1 Main propulsion turbines**

Main turbines are to be subjected during dock trials and subsequent sea trials to the following tests:

- operation at rated rpm for at least 3 hours
- reversing manoeuvres
- astern revolutions equal to at least 70% of the rated ahead rpm.

During astern and subsequent forward operation, the steam pressures and temperatures and the relative expansion are not to assume magnitudes liable to endanger the safe operation of the plant.

During the trials all safety, alarm, shut-off and control systems associated to the turbine are to be tested or properly simulated.

Note 1: Note 1: The astern trial is to be limited to 30 minutes or in accordance with manufacturer's recommendation to avoid overheating of the turbine due to the effects of "windage" and friction.

### **3.7.2 Auxiliary turbines**

Turbines driving electric generators or auxiliary machines are to be run for at least 4 hours at their rated power and for 30 minutes at 110% of rated power.

During the trials all safety, alarm, shut-off and control systems associated to the turbine are to be tested or properly simulated.

## **3.8 Tests of gas turbines**

### **3.8.1 Main propulsion turbines**

Main turbines are to be subjected during dock trials and subsequent sea trials to the following tests:

- operation at rated rpm for at least 3 hours
- ship reversing manoeuvres.

During the various operations, the pressures, temperatures and relative expansion are not to assume magnitudes liable to endanger the safe operation of the plant.

During the trials all safety, alarm, shut-off and control systems associated to the turbine are to be tested or properly simulated.

### **3.8.2 Auxiliary turbines**

Turbines driving electric generators or auxiliary machines are to be run for at least 4 hours at their rated power and for 30 minutes at 110% of rated power.

During the trials all safety, alarm, shut-off and control systems associated to the turbine are to be tested or properly simulated.

### **3.9 Tests of electric propulsion system**

#### **3.9.1 Dock trials**

- a) The dock trials are to include the test of the electrical production system, the power management and the load limitation.
- b) A test of the propulsion plant at a reduced power, in accordance with dock trial facilities, is to be carried out. During this test, the following are to be checked:
  - electric motor rotation speed variation
  - functional test, as far as practicable (power limitation is to be tested with a reduced value)
  - protection devices
  - monitoring and alarm transmission including interlocking system.
- c) Prior to the sea trials, an insulation test of the electric propulsion plant is to be carried out.

#### **3.9.2 Sea trials**

Testing of the performance of the electric propulsion system is to be effected in accordance with an approved test program.

This test program is to include at least:

- Speed rate of rise
- Endurance test:
  - operation at normal continuous cruise power for at least 4 hours
  - 1 hour at 100% rated output power with winding temperature rise below 2°K per hour, according to IEC publication 60034-1
  - operation in reverse direction of propeller rotation at the maximum torque or thrust allowed by the propulsion system for 10 minutes.
- Check of the crash astern operation in accordance with the sequence provided to reverse the speed from full ahead to full astern, in case of emergency. During this test, all necessary data concerning any effects of the reversing of power on the generators are to be recorded, including the power and speed variation
- Test of functionality of electric propulsion, when manoeuvring and during the ship turning test
- Test of power management performance: reduction of power due to loss of one or several generators to check, in each case, the power limitation and propulsion availability.

### **3.10 Tests of gears**

#### **3.10.1 Tests during sea trials**

During the sea trials, the performance of reverse and/or reduction gearing is to be verified, both when running ahead and astern.

In addition, the following checks are to be carried out:

- check of the bearing and oil temperature
- detection of possible gear hammering, where required by Ch 1, Sec 9, [3.5.1]
- test of the monitoring, alarm and safety systems.

#### **3.10.2 Check of the tooth contact**

- a) Prior to the sea trials, the tooth surfaces of the pinions and wheels are to be coated with a thin layer of suitable coloured compound.

Upon completion of the trials, the tooth contact is to be inspected. The contact marking is to appear uniformly distributed without hard bearing at the ends of the teeth and without preferential contact lines.

The tooth contact is to comply with Tab 1.

- b) The verification of tooth contact at sea trials by methods other than that described above will be given special consideration by the Society.
- c) In the case of reverse and/or reduction gearing with several gear trains mounted on roller bearings, manufactured with a high standard of accuracy and having an input torque not exceeding 20000 N·m, the check of the tooth contact may be reduced at the Society's discretion.

Such a reduction may also be granted for gearing which has undergone long workshop testing at full load and for which the tooth contact has been checked positively.

In any case, the teeth of the gears are to be examined by the Surveyor after the sea trials. Subject to the results, additional inspections or re-examinations after a specified period of service may be required.

### 3.11 Tests of main propulsion shafting and propellers

#### 3.11.1 Shafting alignment

Where alignment calculations are required to be submitted in pursuance of Ch 1, Sec 7, [3.4.1], the alignment conditions are to be checked on board by the Shipyard, as follows:

- a) shafting installation and intermediate bearing position, before and during assembling of the shafts:
  - optical check of the relative position of bushes after fitting
  - check of the flanged coupling parameters (gap and sag)
  - check of the centring of the shaft sealing glands
- b) engine (or gearbox) installation, with floating ship:
  - check of the engine (or gearbox) flanged coupling parameters (gap and sag)
  - check of the crankshaft deflections before and after the connection of the engine with the shaft line, by measuring the variation in the distance between adjacent webs in the course of one complete revolution of the engine

Note 1: The ship is to be in the loading conditions defined in the alignment calculations.

- c) load on the bearings:
  - check of the intermediate bearing load by means of jack-up load measurements
  - check of the bearing contact area by means of coating with an appropriate compound.

**Table 1 : Tooth contact for gears**

Heat treatment and machining	Percentage of tooth contact	
	across the whole face width	of the tooth working depth
quenched and tempered, cut	70	40
<ul style="list-style-type: none"> <li>• quenched and tempered, shaved or ground</li> <li>• surface-hardened</li> </ul>	90	40

#### 3.11.2 Shafting vibrations

Torsional vibration measurements are to be carried out where required by Ch 1, Sec 9. The type of the measuring equipment and the location of the measurement points are to be specified.

#### 3.11.3 Bearings

The temperature of the bearings is to be checked under the machinery power conditions specified in [3.1.2].

#### 3.11.4 Stern tube sealing gland

The stern tube oil system is to be checked for possible oil leakage through the stern tube sealing gland.

#### 3.11.5 Propellers

- a) For controllable pitch propellers, the functioning of the system controlling the pitch from full ahead to full astern position is to be demonstrated. It is also to be checked that this system does not induce any overload of the engine.
- b) The proper functioning of the devices for emergency operations is to be tested during the sea trials.

### 3.12 Tests of piping systems

#### 3.12.1 Hydrostatic tests of piping after assembly on board

- a) When the hydrostatic tests of piping referred to in Ch 1, Sec 10, [20.5.2] are carried out on board, they may be carried out in conjunction with the leak tests required in [3.12.2].
- b) Low pressure pipes, such as bilge or ballast pipes are to be tested, after fitting on board, under a pressure at least equal to the maximum pressure to which they can be subjected in service. Moreover, the parts of such pipes which pass, outside pipe tunnels, through compartments for ballast water, fresh water, fuel or liquid cargo, are to be fitted before the hydraulic test of the corresponding compartments.
- c) Heating coils in oil fuel tanks or in liquid cargo tanks and fuel pipes are to be subjected, after fitting on board, to a hydraulic test under a pressure not less than 1,5 times the design pressure, with a minimum of 4 bars.
- d) For pressure tests of plastic pipes after assembly on board, see Ch 1, App 3, [4.9].

#### 3.12.2 Leak tests

Except otherwise permitted by the Society, all piping systems are to be leak tested under operational conditions after completion on board.

### **3.12.3 Functional tests**

During the sea trials, piping systems serving propulsion and auxiliary machinery, including the associated monitoring and control devices, are to be subjected to functional tests at the nominal power of the machinery. Operating parameters (pressure, temperature, consumption) are to comply with the values recommended by the equipment manufacturer.

### **3.12.4 Performance tests**

The Society reserves the right to require performance tests, such as flow rate measurements, should doubts arise from the functional tests.

## **3.13 Tests of steering gear**

### **3.13.1 General**

- a) The steering gear is to be tested during the sea trials under the conditions stated in [3.1] in order to demonstrate, to the Surveyor's satisfaction, that the applicable requirements of Ch 1, Sec 14 are fulfilled.
- b) For controllable pitch propellers, the propeller pitch is to be set at the maximum design pitch approved for the maximum continuous ahead rotational speed.
- c) If the ship cannot be tested at the deepest draught, alternative trial conditions will be given special consideration by the Society. In such case, the ship speed corresponding to the maximum continuous number of revolutions of the propulsion machinery may apply.

### **3.13.2 Tests to be performed**

Tests of the steering gear are to include at least:

- a) functional test of the main and auxiliary steering gear with demonstration of the performances required by Ch 1, Sec 14, [2.3]
- b) test of the steering gear power units, including transfer between steering gear power units
- c) test of the isolation of one power actuating system, checking the time for regaining steering capability
- d) test of the hydraulic fluid refilling system
- e) test of the alternative power supply required by Ch 1, Sec 14, [2.7.2], item e)
- f) test of the steering gear controls, including transfer of controls and local control
- g) test of the means of communication between the navigation bridge, the engine room and the steering gear compartment
- h) test of the alarms and indicators
- i) where the steering gear design is required to take into account the risk of hydraulic locking, a test is to be performed to demonstrate the efficiency of the devices intended to detect this.

Note 1: Tests d) to i) may be carried out either during the mooring trials or during the sea trials.

Note 2: For ships of less than 500 gross tonnage and for fishing vessels, the Society may accept departures from the above list, in particular to take into account the actual design features of their steering gear.

Note 3: Azimuth thrusters are to be subjected to the above tests, as far as applicable.

## **4 Inspection of machinery after sea trials**

### **4.1 General**

#### **4.1.1**

- a) For all types of propulsion machinery, those parts which have not operated satisfactorily in the course of the sea trials, or which have caused doubts to be expressed as to their proper operation, are to be disassembled or opened for inspection. Machinery or parts which are opened up or disassembled for other reasons are to be similarly inspected.
- b) Should the inspection reveal defects or damage of some importance, the Society may require other similar machinery or parts to be opened up for inspection.
- c) An exhaustive inspection report is to be submitted to the Society for information.

### **4.2 Diesel engines**

#### **4.2.1**

- a) In general, for all diesel engines, the following items are to be verified:
  - the deflection of the crankshafts
  - the cleanliness of the lubricating oil filters.
- b) In the case of propulsion engines for which power tests have not been carried out in the workshop, some parts, agreed upon by the interested parties, are to be disassembled for inspection after the sea trials.

# Appendix 1      Calculation for Internal Combustion Engine Crankshafts

## Symbols

- B** : Width of the web, in mm (see Fig 3)  
 In case of 2-stroke semi-built crankshafts, B is to be taken in way of crankpin fillet radius centre according to Fig 3
- D** : Crankpin diameter, in mm (see Fig 3 and Fig 4)
- D<sub>A</sub>** : Outside diameter of web, in mm, as defined in [1.2.1], item p)
- D<sub>BG</sub>** : Diameter of axial bore in journal, in mm (see Fig 3 and Fig 4)
- D<sub>BH</sub>** : Diameter of axial bore in crankpin, in mm (see Fig 3)
- D<sub>G</sub>** : Journal diameter, in mm (see Fig 3 and Fig 4)
- D<sub>O</sub>** : Diameter of oil bore in crankpin, in mm (see Fig 5)
- D<sub>S</sub>** : Shrink-fit diameter, in mm (see Fig 4)
- E** : Pin eccentricity, in mm (see Fig 3)
- F** : Area, in mm<sup>2</sup>, related to the reference cross-section of web, equal to:  
 $F = B W$
- K** : Crankshaft manufacturing process factor, as defined in [6.1.1], item a)
- K<sub>e</sub>** : Empirical factor considering to some extent the influence of adjacent crank and bearing restraint, and taken as follows:
- K<sub>e</sub> = 0,8 for 2-stroke engines
  - K<sub>e</sub> = 1,0 for 4-stroke engines
- L<sub>S</sub>** : Axial length of the shrink-fit, in mm (see Fig 4)
- M<sub>BO</sub>** : Bending moment calculated at the outlet of crankpin oil bore, in N·m, equal to:  
 $M_{BO} = M_{BTO} \cos \psi + M_{BRO} \sin \psi$
- M<sub>BOmax</sub>** : Maximum value of the bending moment M<sub>BO</sub> within one working cycle, in N·m
- M<sub>BOmin</sub>** : Minimum value of the bending moment M<sub>BO</sub> within one working cycle, in N·m
- M<sub>BON</sub>** : Alternating bending moment calculated at the outlet of crankpin oil bore, in N·m, defined in [2.1.2], item d)
- M<sub>BRF</sub>** : Bending moment acting in web, in N·m, as defined in [2.1.1], item c)
- M<sub>BRFmax</sub>** : Maximum value of the bending moment M<sub>BRF</sub> within one working cycle, in N·m
- M<sub>BRFmin</sub>** : Minimum value of the bending moment M<sub>BRF</sub> within one working cycle, in N·m
- M<sub>BRFN</sub>** : Alternating bending moment related to the centre of the web, in N·m, defined in [2.1.2], item b)
- M<sub>BRO</sub>** : Bending moment of the radial component of the connecting rod force, in N·m (see Fig 5)
- M<sub>BTO</sub>** : Bending moment of the tangential component of the connecting rod force, in N·m (see Fig 5)
- M<sub>T</sub>** : Torque, in N·m
- M<sub>Tmax</sub>** : Maximum value of the torque M<sub>T</sub> within one working cycle, in N·m
- M<sub>Tmin</sub>** : Minimum value of the torque M<sub>T</sub> within one working cycle, in N·m
- M<sub>TN</sub>** : Alternating torque, in N·m, as defined in [2.2.2]
- Q<sub>1</sub>** : Acceptability factor for the crankpin fillet, as defined in [7.1.1]
- Q<sub>2</sub>** : Acceptability factor for the journal fillet, as defined in [7.1.1]
- Q<sub>3</sub>** : Acceptability factor for the crankpin outlet of oil bore, as defined in [7.1.1]
- Q<sub>RF</sub>** : Radial force acting in web, in N, as defined in [2.1.1], item c)
- Q<sub>RFmax</sub>** : Maximum value of the radial force Q<sub>RF</sub> within one working cycle, in N
- Q<sub>RFmin</sub>** : Minimum value of the radial force Q<sub>RF</sub> within one working cycle, in N
- Q<sub>RFN</sub>** : Alternating radial force related to the web, in N, as defined in [2.1.2], item c)
- R<sub>G</sub>** : Fillet radius of journal, in mm (see Fig 3 and Fig 4)
- R<sub>H</sub>** : Fillet radius of crankpin, in mm (see Fig 3)
- R<sub>m</sub>** : Minimum specified tensile strength of crankshaft material, in N/mm<sup>2</sup>

S : Pin overlap, in mm, given by the following formula (see Fig 3):

$$S = \frac{D + D_G}{2} - E$$

Where pins do not overlap, the negative value of S calculated by the above formula is to be considered

$T_G$  : Recess of journal fillet, in mm (see Fig 3)

$T_H$  : Recess of crankpin fillet, in mm (see Fig 3)

W : Axial web thickness, in mm (see Fig 3)

$W_e$  : Section modulus related to the cross-section of axially bored crankpin, in mm<sup>3</sup>, equal to:

$$W_e = \frac{\pi}{32} \left( \frac{D^4 - D_{BH}^4}{D} \right)$$

$W_{eqw}$  : Section modulus related to the cross-section of web, in mm<sup>3</sup>, equal to:

$$W_{eqw} = \frac{B \cdot W^2}{6}$$

$W_{PG}$  : Polar section modulus related to cross-section of axially bored journal, in mm<sup>3</sup>, equal to:

$$W_{PG} = \frac{\pi}{16} \left( \frac{D_G^4 - D_{BG}^4}{D_G} \right)$$

$W_{PH}$  : Polar section modulus related to cross-section of axially bored crankpin, in mm<sup>3</sup>, equal to:

$$W_{PH} = \frac{\pi}{16} \left( \frac{D^4 - D_{BH}^4}{D} \right)$$

$W_{red}$  : Reduced axial web thickness, in mm, to be considered instead of W in the case of 2-stroke semi-built crankshafts with  $T_H > R_H$  and to be taken as equal to (see Fig 3):

$$W_{red} = W - (T_H - R_H)$$

$\alpha_B$  : Stress concentration factor for bending in crankpin fillet, as evaluated in [3.1.2], item a)

$\alpha_T$  : Stress concentration factor for torsion in crankpin fillet, as evaluated in [3.1.2], item b)

$\beta_B$  : Stress concentration factor for bending in journal fillet, as evaluated in [3.1.3], item a)

$\beta_Q$  : Stress concentration factor for compression due to radial force in journal fillet, as evaluated in [3.1.3], item b)

$\beta_T$  : Stress concentration factor for torsion in journal fillet, as evaluated in [3.1.3], item c)

$\gamma_B$  : Stress concentration factor for bending in crankpin oil bore, as evaluated in [3.1.4]

$\gamma_T$  : Stress concentration factor for torsion in outlet of crankpin oil bore, as evaluated in [3.1.4]

$\sigma_{add}$  : Additional bending stress, in N/mm<sup>2</sup>, due to misalignment, as defined in [4.1.1]

$\sigma_{BFN}$  : Nominal alternating bending stress related to the web, in N/mm<sup>2</sup>, as defined in [2.1.2], item b)

$\sigma_{BG}$  : Alternating bending stress in journal fillet, in N/mm<sup>2</sup>, as defined in [2.1.3], item b)

$\sigma_{BH}$  : Alternating bending stress in crankpin fillet, in N/mm<sup>2</sup>, as defined in [2.1.3], item a)

$\sigma_{BO}$  : Alternating bending stress in outlet of crankpin oil bore, in N/mm<sup>2</sup>, as defined in [2.1.4]

$\sigma_{BON}$  : Nominal alternating bending stress related to the crankpin diameter, in N/mm<sup>2</sup>, as defined in [2.1.2], item d)

$\sigma'_{DW}$  : Allowable alternating bending fatigue strength of crankshaft in the crankpin fillet area, in N/mm<sup>2</sup>, as defined in [6.1.1], item a)

$\sigma''_{DW}$  : Allowable alternating bending fatigue strength of crankshaft in the journal fillet area, in N/mm<sup>2</sup>, as defined in [6.1.1], item b)

$\sigma'''_{DW}$  : Allowable alternating bending fatigue strength of crankshaft in the crankpin oil bore area, in N/mm<sup>2</sup>, as defined in [6.1.1], item c)

$\sigma_{QFN}$  : Nominal alternating compressive stress due to radial force related to the web, in N/mm<sup>2</sup>, as defined in [2.1.2], item c)

$\sigma_{TO}$  : Alternating torsional stress in outlet of crankpin oil bore, in N/mm<sup>2</sup>, as defined in [2.2.3], item c)

$\sigma'_V$  : Equivalent alternating stress in way of crankpin fillet, in N/mm<sup>2</sup>, as defined in [5.2.1], item a)

$\sigma''_V$  : Equivalent alternating stress in way of journal fillet, in N/mm<sup>2</sup>, as defined in [5.2.1], item b)

$\sigma'''_V$  : Equivalent alternating stress in way of outlet of crankpin oil bore, in N/mm<sup>2</sup>, as defined in [5.2.1], item c)

$\tau_G$  : Alternating torsional stress in journal fillet, in N/mm<sup>2</sup>, as defined in [2.2.3], item b)

$\tau_H$  : Alternating torsional stress in way of crankpin fillet, in N/mm<sup>2</sup>, as defined in [2.2.3], item a)

$\tau_{NG}$  : Nominal alternating torsional stress related to journal diameter, in N/mm<sup>2</sup>, as defined in [2.2.2]

$\tau_{NH}$  : Nominal alternating torsional stress related to crankpin diameter, in N/mm<sup>2</sup>, as defined in [2.2.2]

$\psi$  : Angular position, in deg (see Fig 5).

# 1 General

## 1.1 Application

### 1.1.1

- a) These Rules for the design of crankshafts are to be applied to I.C. engines for propulsion and auxiliary purposes, where the engines are capable of continuous operation at their rated power when running at rated speed.  
Where a crankshaft design involves the use of surface treated fillets, or when fatigue parameter influences are tested, or when working stresses are measured, the relevant documents with calculations/analysis are to be submitted to the Society in order to demonstrate equivalence to the Rules.
- b) These Rules apply only to solid-forged and semi-built crankshafts of forged or cast steel, with one crank throw between main bearings.

## 1.2 Documentation to be submitted

**1.2.1** The following documents and particulars required for the calculation of crankshafts as indicated in Ch 1, Sec 2, Tab 1 and Ch 1, Sec 2, Tab 2 are to be submitted:

- a) engine builder
- b) crankshaft drawings containing all the data in respect of the geometrical configurations of the crankshaft
- c) engine type designation
- d) kind of engine:
  - in-line engine or V-type engine with adjacent connecting rods
  - V-type engine with forked/inner connecting rods
  - V-type engine with articulated-type connecting rods
  - crosshead engine or trunk piston engine
- e) operating method: 2-stroke or 4-stroke cycle
- f) combustion method: direct injection, precombustion chamber, etc
- g) number of cylinders  
diameter of cylinders, in mm  
length of piston stroke, in mm  
length of connecting rod (between bearing centers), in mm
- h) rated power, in kW  
rated engine speed, in rpm  
mean effective pressure, in bar  
mean indicated pressure, in bar  
maximum net cylinder pressure  $P_{max}$ , in bar  
charge air pressure (before inlet valves or scavenge ports, whichever applies), in bar  
nominal compression ratio
- i) direction of rotation: clockwise or counter clockwise (see Fig 1)
- j) firing order (corresponding to item i) with the respective ignition intervals, in deg
- k) oscillating mass of one cylinder (mass of piston, rings, pin, piston rod, crosshead, oscillating part of connecting rod), in kg  
mass of connecting rod, in kg, and position of gravity centre
- l) digitalized gas pressure curve presented at equidistant intervals, in bar versus crank angle (at least every 5° CA)
- m) for V-type engines: V-angle  $\alpha_v$ , in deg (see Fig 1)

**Figure 1 : Designation of the cylinders**

- n) data of crankshaft:
- drawing number
  - kind of crankshaft (e.g. solid-forged crankshaft, semi-built crankshaft, etc.)
  - method of manufacture (e.g. free form forged, continuous grain flow forged, drop-forged, etc.), with description of the forging process
  - heat treatment (e.g. tempered)
  - every surface treatment affecting fillets or oil holes
  - particulars of alternating torsional stress calculations (see [2.2])
- o) crank dimensions necessary for the calculation of stress concentration factors, in mm unless other specified (see Fig 2 and Fig 3):
- crankpin diameter  $D$
  - diameter of axial bore in crankpin  $D_{BH}$
  - fillet radius of crankpin  $R_H$
  - recess of crankpin fillet  $T_H$
  - journal diameter  $D_G$
  - diameter of axial bore in journal  $D_{BG}$
  - fillet radius of journal  $R_G$
  - recess of journal fillet  $T_G$
  - web thickness  $W$
  - web width  $B$
  - bending length  $L_1$
  - bending length  $L_2$
  - bending length  $L_3$
  - diameter of oil bore in crankpin  $D_O$
  - smallest edge radius of oil bore
  - surface roughness of oil bore fillet
  - inclination of oil bore axis related to shaft axis  $Y$ , in deg.
- p) additional data for shrink-fits of semi-built crankshafts, in mm unless other specified (see Fig 4):
- shrink diameter  $D_S$
  - length of shrink-fit  $L_S$
  - outside diameter of web  $D_A$  or twice the minimum distance  $x$  (see Fig 4) between centreline of journals and outer contour of web, whichever is less
  - distance  $y$  between the adjacent generating lines of journal and pin connected to the same web  
In general:  $y \geq 0,05 D_S$   
Where  $y$  is less than  $0,1 D_S$ , special consideration is to be given by the Society to the effect of the stress due to the shrink-fit on the fatigue strength at the crankpin fillet
  - amount of shrink-fit (upper and lower tolerances)
  - maximum torque, in N·m
  - maximum nominal alternating torsional stress (ascertained by means of a harmonic synthesis and related to cross-sectional area of bored crankpin), in N/mm<sup>2</sup>
  - engine speed (at which the maximum nominal alternating torsional stress occurs), in rpm
  - minimum engine speed (for which the harmonic synthesis was carried out), in rpm
- q) details of crankshaft material:
- material designation (according to ISO, EN, DIN, AISI, etc.)
  - mechanical properties of material (minimum values obtained from longitudinal test specimens):
    - tensile strength, in N/mm<sup>2</sup>
    - yield strength, in N/mm<sup>2</sup>
    - reduction in area at break, in %
    - elongation  $A_5$ , in %
    - impact energy – KV, in J
    - Young's modulus, in N/mm<sup>2</sup>
  - method of crankshaft material melting process (e.g. open-hearth furnace, electric furnace, etc.)

r) data of stress concentration factors (S.C.F.) to be given only when data for stress concentration factors and/or fatigue are furnished by the engine manufacturer on the basis of measurements (full supporting details are to be enclosed):

- S.C.F. for bending in crankpin fillet  $\alpha_B$
- S.C.F. for torsion in crankpin fillet  $\alpha_T$
- S.C.F. for bending in journal fillet  $\beta_B$
- S.C.F. for torsion in journal fillet  $\beta_T$
- S.C.F. for compression in journal fillet  $\beta_Q$

### 1.3 Principles of calculation

1.3.1 The design of crankshafts is based on an evaluation of safety against fatigue in the highly stressed areas.

The calculation is also based on the assumption that the areas exposed to highest stresses are:

- fillet transitions between the crankpin and web as well as between the journal and web
- outlets of crankpin oil bores.

When the journal diameter is equal to or larger than the crankpin one, the outlets of main journal oil bores are to be formed in a similar way to the crankpin oil bores, otherwise separate documentation of fatigue safety may be required.

Calculation of crankshaft strength consists initially in determining the nominal alternating bending (see [2.1]) and nominal alternating torsional stresses (see [2.2]) which, multiplied by the appropriate stress concentration factors using the theory of constant energy of distortion (von Mises' Criterion, see [3]), result in an equivalent alternating stress (uni-axial stress, see [5]). This equivalent alternating stress is then compared with the fatigue strength of the selected crankshaft material (see [6]). This comparison will show whether or not the crankshaft concerned is dimensioned adequately (see [7]).

## 2 Calculation of alternating stresses

### 2.1 Calculation of alternating stresses due to bending moments and radial forces

#### 2.1.1 Assumptions

a) The calculation is based on a statically determined system, composed of a single crank throw supported in the centre of adjacent main journals and subject to gas and inertia forces. The bending length is taken as the length between the two main bearing midpoints (distance  $L_3$ , see Fig 2 (a) and Fig 2 (b)).

b) The bending moments  $M_{BR}$  and  $M_{BT}$  are calculated in the relevant section based on triangular bending moment diagrams due to the radial component  $F_R$  and the tangential component  $F_T$  of the connecting rod force, respectively (see Fig 2 (a)).

For crank throws with two connecting rods acting upon one crankpin, the relevant bending moments are obtained by superposition of the two triangular bending moment diagrams according to phase (see Fig 2 (b)).

c) Bending moments and radial forces acting in web

The bending moment  $M_{BRF}$  and the radial force  $Q_{RF}$  are taken as acting in the centre of the solid web (distance  $L_1$  in Fig 2) and are derived from the radial component of the connecting rod force.

The alternating bending and compressive stresses due to bending moments and radial forces are to be related to the cross-section of the crank web:

- at the centre of the overlap  $S$  in cases of overlap of the pins (see Fig 3), and
- at the centre of the distance  $y$  between the adjacent generating lines of the two pins in cases of pins which do not overlap (see Fig 4).

This reference cross-section results from the web thickness  $W$  and the web width  $B$  (see Fig 3).

Mean stresses are neglected.

d) Bending acting in outlet of crankpin oil bore

The two relevant bending moments  $M_{BRO}$  and  $M_{BTO}$  (see Symbols and Fig 5) are taken in the crankpin cross-section through the oil bore.

The alternating stresses due to these bending moments are to be related to the cross-sectional area of the axially bored crankpin.

Mean bending stresses are neglected.

Figure 5 : Crankpin section through the oil bore

### 2.1.2 Calculation of nominal alternating bending and compressive stresses in web

- a) The radial and tangential forces due to gas and inertia loads acting upon the crankpin at each connecting rod position will be calculated over one working cycle.

A simplified calculation of the radial forces may be used at the discretion of the Society.

Using the forces calculated over one working cycle and taking into account of the distance from the main bearing midpoint, the time curve of the bending moments  $M_{BRF}$ ,  $M_{BRO}$ ,  $M_{BTO}$  and radial forces  $Q_{RF}$  (see Symbols) will be then calculated.

In case of V-type engines, the bending moments (progressively calculated from the gas and inertia forces and for the various crank angles) of the two cylinders acting on one crank throw are superposed according to phase. Different designs (forked connecting rod, articulated-type connecting rod or adjacent connecting rods) shall be taken into account.

Where there are cranks of different geometrical configurations (e.g. asymmetrical cranks) in one crankshaft, the calculation is to cover all crank variants.

- b) Nominal alternating bending stress in web cross-section

The nominal alternating bending stress  $\sigma_{BFN}$  related to the web is calculated, in N/mm<sup>2</sup>, as follows:

$$\sigma_{BFN} = \pm \frac{M_{BRFN}}{W_{eqw}} \cdot K_e \cdot 10^3$$

where:

$M_{BRFN}$  : Alternating bending moment related to the centre of the web, in N·m, equal to (see Fig 2 (a) and Fig 2 (b)):

$$M_{BRFN} = \pm 0,5 (M_{BRFmax} - M_{BRFmin})$$

$W_{eqw}$ ,  $K_e$ ,  $M_{BRFmax}$ ,  $M_{BRFmin}$  : As defined in Symbols.

- c) Nominal alternating compressive stress in web cross-section

The nominal alternating compressive stress  $\sigma_{QFN}$  due to radial force related to the web is calculated, in N/mm<sup>2</sup>, as follows:

$$\sigma_{QFN} = \pm \frac{Q_{RFN}}{F} \cdot K_e$$

where:

$Q_{RFN}$  : Alternating radial force related to the web, in N, equal to (see Fig 2 (a) and Fig 2 (b)):

$$Q_{RFN} = \pm 0,5 (Q_{RFmax} - Q_{RFmin})$$

$F$ ,  $K_e$ ,  $Q_{RFmax}$ ,  $Q_{RFmin}$  : As defined in Symbols.

- d) Nominal alternating bending stress in outlet of crankpin oil bore

The nominal alternating bending stress  $\sigma_{BON}$  related to the crankpin diameter is calculated, in N/mm<sup>2</sup>, as follows:

$$\sigma_{BON} = \pm \frac{M_{BON}}{W_e} \cdot 10^3$$

where:

$M_{BON}$  : Alternating bending moment calculated at the outlet of crankpin oil bore, in N·m, equal to:

$$M_{BON} = \pm 0,5 (M_{BOmax} - M_{BOmin})$$

$W_e$ ,  $M_{BOmax}$ ,  $M_{BOmin}$  : As defined in Symbols.

### 2.1.3 Calculation of alternating bending stresses in fillets

- a) The alternating bending stress  $\sigma_{BH}$  in crankpin fillet is calculated, in N/mm<sup>2</sup>, as follows:

$$\sigma_{BH} = \pm (\alpha_B \cdot \sigma_{BFN})$$

- b) The alternating bending stress  $\sigma_{BG}$  in journal fillet is calculated, in N/mm<sup>2</sup>, as follows (not applicable to semi-built crankshafts):

$$\sigma_{BG} = \pm (\beta_B \cdot \sigma_{BFN} + \beta_Q \cdot \sigma_{QFN})$$

where:

$\alpha_B$ ,  $\beta_B$ ,  $\beta_Q$  : Stress concentration factors as defined in [3.1]

$\sigma_{BFN}$ ,  $\sigma_{QFN}$  : Stresses as defined in [2.1.2], item b) and item c) respectively.

### 2.1.4 Calculation of alternating bending stress in outlet of crankpin oil bore

The alternating bending stress  $\sigma_{BO}$  in outlet of crankpin oil bore is calculated, in N/mm<sup>2</sup>, as follows:

$$\sigma_{BO} = \pm (\gamma_B \cdot \sigma_{BON})$$

where:

$\gamma_B$  : Stress concentration factor as defined in [3.1.4]

$\sigma_{BON}$  : Stress as defined in [2.1.2], item d).

## 2.2 Calculation of alternating torsional stresses

### 2.2.1 General

The calculation for nominal alternating torsional stresses is to be undertaken by the engine manufacturer according to the information contained in [2.2.2].

The maximum nominal alternating torsional stress is to be specified by the manufacturer.

The maximum value obtained from such calculations will be used by the Society when determining the equivalent alternating stress according to the provisions of Article [5].

In the absence of such a maximum value, the Society reserves the right to incorporate a fixed value in the calculation for the crankshaft dimensions, to be established at its discretion in each case.

In the event of the Society being entrusted to carry out a forced vibration calculation on behalf of the engine manufacturer to determine the torsional vibration stresses expected in the engine and where relevant in the shafting, the following data are to be submitted in addition to those required in [1.2.1]:

- a) equivalent dynamic system of the engine, comprising:
  - mass moment of inertia of every mass point, in  $\text{kg}\cdot\text{m}^2$
  - inertialess torsional stiffnesses, in  $\text{N}\cdot\text{m}/\text{rad}$ , of all crankshaft parts between two mass points
- b) vibration dampers, specifying:
  - type designation
  - mass moments of inertia, in  $\text{kg}\cdot\text{m}^2$
  - inertialess torsional stiffnesses, in  $\text{N}\cdot\text{m}/\text{rad}$
  - values of the damping coefficients, in  $\text{N}\cdot\text{m}\cdot\text{s}$
- c) flywheels, specifying:
  - mass moment of inertia, in  $\text{kg}\cdot\text{m}^2$ .

Where the whole propulsion system is to be considered, the following information is also to be submitted:

- a) elastic couplings, specifying:
  - dynamic characteristics and damping data, as well as the permissible value of alternating torque
- b) gearing and shafting, specifying:
  - shaft diameters of gear shafts, thrust shafts, intermediate shafts and propeller shafts, mass moments of inertia, in  $\text{kg}\cdot\text{m}^2$ , of gearing or important mass points, gear ratios and, for gearboxes of complex type, the schematic gearing arrangement
- c) propellers, specifying:
  - propeller diameter
  - number of blades
  - pitch and developed area ratio
  - mass moment of inertia of propeller in air and with entrained water, in  $\text{kg}\cdot\text{m}^2$  (for controllable pitch propellers both the values at full pitch and at zero pitch are to be specified)
  - damping characteristics, if available and documented
- d) natural frequencies with their relevant modes of vibration and the vector sums for the harmonics of the engine excitation
- e) estimated torsional vibration stresses in all important elements of the system with particular reference to clearly defined resonance speeds of rotation and continuous operating ranges.

### 2.2.2 Calculation of nominal alternating torsional stresses

The maximum and minimum values of the alternating torques are to be ascertained for every mass point of the complete dynamic system and for the entire speed range by means of a harmonic synthesis of the forced vibrations from the 1st order up to and including the 15<sup>th</sup> order for 2-stroke cycle engines and from the 0,5<sup>th</sup> order up to and including the 12<sup>th</sup> order for 4-stroke cycle engines.

In performing this calculation, allowance is to be made for the damping that exists in the system and for unfavourable conditions (e.g., misfiring in one of the cylinders).

Note 1: Misfiring is defined as cylinder condition when no combustion occurs but only compression cycle.

The speed step calculation shall be selected in such a way that any resonance found in the operational speed range of the engine shall be detected.

Where barred speed ranges are necessary, they shall be arranged so that satisfactory operation is possible despite their existence. There are to be no barred speed ranges above a speed ratio of  $\lambda \geq 0,8$  for normal firing conditions.

The values received from such calculation are to be submitted to the Society for consideration.

The nominal alternating torsional stresses referred to crankpin ( $\tau_{NH}$ ) and journal ( $\tau_{NG}$ ) in every mass point which is essential to the assessment result, in  $\text{N}/\text{mm}^2$ , from the following formulae:

$$\tau_{NH} = \pm \frac{M_{TN}}{W_{PH}} \cdot 10^3$$

$$\tau_{NG} = \pm \frac{M_{TN}}{W_{PG}} \cdot 10^3$$

where:

$M_{TN}$  : Maximum alternating torque, in N·m, equal to:

$$M_{TN} = \pm 0,5 (M_{Tmax} - M_{Tmin})$$

$W_{PH}$ ,  $W_{PG}$ ,  $M_{Tmax}$ ,  $M_{Tmin}$  : As defined in Symbols.

Bored crankpins and journals whose bore longitudinal axis does not coincide with the axis of the said crankpins and journals, will be considered by the Society in each case.

For the purpose of the crankshaft assessment, the nominal alternating torsional stress considered in further calculations is the highest calculated value, according to above method, occurring at the most torsionally loaded mass point of the crankshaft system.

Where barred speed ranges exist, the torsional stresses within these ranges are not to be considered for assessment calculations.

The approval of crankshaft will be based on the installation having the largest nominal alternating torsional stress (but not exceeding the maximum figure specified by the engine manufacturer).

Thus, for each installation, it is to be ensured by suitable calculation that this approved nominal alternating torsional stress is not exceeded. This calculation is to be submitted to the Society for assessment (see Ch 1, Sec 9).

### 2.2.3 Calculation of alternating torsional stresses in fillets and outlet of crankpin oil bore

The calculation of the alternating torsional stresses is to be carried out for the crankpin fillet, the journal fillet and the outlet of the crankpin oil bore, as follows:

a) the alternating torsional stress  $\tau_H$ , in N/mm<sup>2</sup>, in way of crankpin fillet is given by the following formula:

$$\tau_H = \pm (\alpha_T \cdot \tau_{NH})$$

b) the alternating torsional stress  $\tau_G$ , in N/mm<sup>2</sup>, in way of journal fillet is given by the following formula (not applicable to semi-built crankshafts):

$$\tau_G = \pm (\beta_T \cdot \tau_{NG})$$

c) the alternating torsional stress  $\sigma_{TO}$ , in N/mm<sup>2</sup>, in way of outlet of crankpin oil bore is given by the following formula:

$$\sigma_{TO} = \pm (\gamma_T \cdot \tau_{NH})$$

where:

$\alpha_T$ ,  $\beta_T$ ,  $\gamma_T$ ,  $\tau_{NG}$ ,  $\tau_{NH}$  : As defined in Symbols.

## 3 Evaluation of stress concentration factors (SCF)

### 3.1 General

**3.1.1** The stress concentration factors are evaluated by means of the formulae according to [3.1.2], [3.1.3] and [3.1.4] applicable to the fillets and crankpin oil bore of solid forged web-type crankshafts and to the crankpin fillets of semi-built crankshafts only. It is to be noticed that stress concentration factor formulae concerning the oil bore are only applicable to a radially drilled oil hole. All formulae are based on investigations of FVV (Forschungsvereinigung Verbrennungskraftmaschinen) for fillets and on investigations of ESDU (Engineering Science Data Unit) for oil holes.

Where the geometry of the crankshaft is outside the boundaries of the analytical stress concentration factors, the calculation method detailed in Article [9] may be undertaken.

All crank dimensions necessary for the calculation of stress concentration factors are shown in Fig 3.

The stress concentration factors for bending ( $\alpha_B$  and  $\beta_B$ ) are defined as the ratio of the maximum equivalent von Mises stress (occurring in the fillets under bending load) to the nominal bending stress related to the web cross-section.

The stress concentration factor for compression ( $\beta_Q$ ) in the journal fillet is defined as the ratio of the maximum equivalent von Mises stress (occurring in the fillet due to the radial force) to the nominal compressive stress related to the web cross-section.

The stress concentration factors for torsion ( $\alpha_T$  and  $\beta_T$ ) are defined as the ratio of the maximum equivalent shear stress (occurring in the fillets under torsional load) to the nominal torsional stress related to the axially bored crankpin or journal cross-section.

The stress concentration factors for bending ( $\gamma_B$ ) and torsion ( $\gamma_T$ ) are defined as the ratio of the maximum principal stress (occurring at the outlet of the crankpin oil hole under bending and torsional loads) to the corresponding nominal stress related to the axially bored crankpin cross-section.

When reliable measurements and/or calculations are available, which can allow direct assessment of stress concentration factors, the relevant documents and their analysis method have to be submitted to the Society in order to demonstrate their equivalence to the present rule evaluation. This is always to be performed when dimensions are outside of any of the validity ranges for the empirical formulae presented in [3.1.2] to [3.1.4].

Articles [9] and [12] describes how FE analyses can be used for the calculation of the stress concentration factors. Care should be taken to avoid mixing equivalent (von Mises) stresses and principal stresses.

For the calculation of stress concentration factors in crankpin and journal fillets, the related dimensions given in Tab 1 are to be applied.

Stress concentration factors are valid for the following ranges of related dimensions for which the investigations have been carried out:

$$0,03 \leq r_H \leq 0,13$$

$$0,03 \leq r_G \leq 0,13$$

$$s \leq 0,50$$

$$0,20 \leq w \leq 0,80$$

$$1,10 \leq b \leq 2,20$$

$$0 \leq d_o \leq 0,20$$

$$0 \leq d_H \leq 0,80$$

$$0 \leq d_G \leq 0,80$$

Low range of s can be extended down to large negative values provided that:

- if the value of calculated factor  $f(\text{recess})$  is less than 1, then  $f(\text{recess}) = 1$  is to be considered
- if  $s < -0,5$  then  $f(s,w)$  and  $f(r,s)$  are to be evaluated replacing the actual value of s by  $s = -0,5$ .

**Table 1 : Related dimensions for calculation of stress concentration factors**

Crankpin fillet	Journal fillet
$r_H = R_H / D$	$r_G = R_G / D$
$s = S / D$	
$w = W / D$ for crankshafts with overlap $w = W_{\text{red}} / D$ for crankshafts without overlap	
$b = B / D$	
$d_o = D_o / D$	
$d_H = d_{BH} / D$	$d_G = D_{BG} / D$
$t_H = T_H / D$	$t_G = T_G / D$

### 3.1.2 Crankpin fillet

a) The stress concentration factor for bending  $\alpha_B$  is equal to:

$$\alpha_B = 2,6914 \cdot f(s,w) \cdot f_1(w) \cdot f_1(b) \cdot f(r_H) \cdot f(d_G) \cdot f(d_H) \cdot f(\text{recess})$$

where:

$$f(s,w) = -4,1883 + 29,2004 w - 77,5925 w^2 + 91,9454 w^3 - 40,0416 w^4 + (1-s)(9,5440 - 58,3480 w + 159,3415 w^2 - 192,5846 w^3 + 85,2916 w^4) + (1-s)^2(-3,8399 + 25,0444 w - 70,5571 w^2 + 87,0328 w^3 - 39,1832 w^4)$$

$$f_1(w) = 2,1790 w^{0,7171}$$

$$f_1(b) = 0,6840 - 0,0077 b + 0,1473 b^2$$

$$f(r_H) = 0,2081 r_H^{-0,5231}$$

$$f(d_G) = 0,9993 + 0,27 d_G - 1,0211 d_G^2 + 0,5306 d_G^3$$

$$f(d_H) = 0,9978 + 0,3145 d_H - 1,5241 d_H^2 + 2,4147 d_H^3$$

$$f(\text{recess}) = 1 + (t_H + t_G)(1,8 + 3,2 s)$$

b) The stress concentration factor for torsion  $\alpha_T$  is equal to:

$$\alpha_T = 0,8 \cdot f(r_H,s) \cdot f_2(b) \cdot f_2(w)$$

where:

$$f(r_H,s) = r_H^x \text{ with } x = -0,322 + 0,1015(1-s)$$

$$f_2(b) = 7,8955 - 10,654 b + 5,3482 b^2 - 0,857 b^3$$

$$f_2(w) = w^{-0,145}$$

### 3.1.3 Journal fillet (not applicable to semi-built crankshaft)

a) The stress concentration factor for bending  $\beta_B$  is equal to:

$$\beta_B = 2,7146 \cdot f_B(s,w) \cdot f_B(w) \cdot f_B(b) \cdot f_B(r_G) \cdot f_B(d_G) \cdot f_B(d_H) \cdot f(\text{recess})$$

where:

$$f_B(s,w) = -1,7625 + 2,9821 w - 1,5276 w^2 + (1 - s) (5,1169 - 5,8089 w + 3,1391 w^2) + (1 - s)^2 (-2,1567 + 2,3297 w - 1,2952 w^2)$$

$$f_B(w) = 2,2422 w^{0,7548}$$

$$f_B(b) = 0,5616 + 0,1197 b + 0,1176 b^2$$

$$f_B(r_G) = 0,1908 r_G^{-0,5568}$$

$$f_B(d_G) = 1,0012 - 0,6441 d_G + 1,2265 d_G^2$$

$$f_B(d_H) = 1,0022 - 0,1903 d_H + 0,0073 d_H^2$$

f(recess) : As defined in [3.1.2], item a).

b) The stress concentration factor for compression  $\beta_Q$  due to the radial force is equal to:

$$\beta_Q = 3,0128 \cdot f_Q(s) \cdot f_Q(w) \cdot f_Q(b) \cdot f_Q(r_G) \cdot f_Q(d_H) \cdot f(\text{recess})$$

where:

$$f_Q(s) = 0,4368 + 2,1630 (1 - s) - 1,5212 (1 - s)^2$$

$$f_Q(w) = \frac{w}{0,0637 + 0,9369w}$$

$$f_Q(b) = -0,5 + b$$

$$f_Q(r_G) = 0,5331 r_G^{-0,2038}$$

$$f_Q(d_H) = 0,9937 - 1,1949 d_H + 1,7373 d_H^2$$

f(recess) : As defined in [3.1.2], item a).

c) The stress concentration factor for torsion  $\beta_T$  is equal to:

- if  $D = D_G$  and  $R_H = R_G$ :

$$\beta_T = \alpha_T$$

- if  $D \neq D_G$  and/or  $R_H \neq R_G$ :

$$\beta_T = 0,8 \cdot f(r_H,s) \cdot f_2(b) \cdot f_2(w)$$

with  $f(r_H,s)$ ,  $f_2(b)$  and  $f_2(w)$  determined in accordance with [3.1.2], item b), but taking  $r_H = R_G / D_G$  instead of  $r_H = R_H / D$  for the calculation of  $f(r_H,s)$ .

### 3.1.4 Outlet of crankpin oil bore

The stress concentration factors for bending  $\gamma_B$  and for torsion  $\gamma_T$  are equal to:

$$\gamma_B = 3 - 5,88 d_o + 34,6 d_o^2$$

$$\gamma_T = 4 - 6 d_o + 30 d_o^2$$

## 4 Additional bending stresses

### 4.1 General

**4.1.1** In addition to the alternating bending stresses in fillets (see [2.1.3]), further bending stresses due to misalignment and bedplate deformation as well as due to axial and bending vibrations are to be considered, applying  $\sigma_{add}$  as given in Tab 2.

It is recommended that a value of  $\pm 20$  N/mm<sup>2</sup> be used for the axial vibration component for assessment purposes where axial vibration calculation results of the complete dynamic system (engine/shafting/gearing/propeller) are not available. Where axial vibration calculation results of the complete dynamic system are available, the calculated values may be used instead.

**Table 2 : Additional bending stress  $\sigma_{add}$**

Type of engine	$\sigma_{add}$ , in N/mm <sup>2</sup>
Crosshead engine	$\pm 30$ <b>(1)</b>
Trunk piston engine	$\pm 10$
<b>(1)</b> The additional stress of $\pm 30$ N/mm <sup>2</sup> is composed of two components: <ul style="list-style-type: none"> <li>• an additional stress of <math>\pm 20</math> N/mm<sup>2</sup> resulting from axial vibration</li> <li>• an additional stress of <math>\pm 10</math> N/mm<sup>2</sup> resulting from misalignment/bedplate deformation.</li> </ul>	

## 5 Calculation of equivalent alternating stress

### 5.1 General

**5.1.1** In the fillets, bending and torsion lead to two different biaxial stress fields which can be represented by a von Mises equivalent stress with the additional assumptions that bending and torsion stresses are time-phased and the corresponding peak values occur at the same location.

As a result, the equivalent alternating stress is to be calculated for the crankpin fillet as well as for the journal fillet, using von Mises criterion.

At the oil hole outlet, bending and torsion lead to two different stress fields which can be represented by an equivalent principal stress equal to the maximum of principal stress resulting from combination of these two stress fields with the assumption that bending and torsion are time-phased.

The above two different ways of equivalent stress evaluation both lead to stresses which may be compared to the same fatigue strength value of crankshaft assessed according to von Mises criterion.

### 5.2 Equivalent alternating stresses

**5.2.1** The equivalent alternating stresses, in N/mm<sup>2</sup>, are calculated according to the following formulae:

a) equivalent alternating stress  $\sigma'_v$  in way of crankpin fillet:

$$\sigma'_v = \pm \sqrt{(\sigma_{BH} + \sigma_{add})^2 + 3\tau_H^2}$$

b) equivalent alternating stress  $\sigma''_v$  in way of journal fillet:

$$\sigma''_v = \pm \sqrt{(\sigma_{BG} + \sigma_{add})^2 + 3\tau_G^2}$$

c) equivalent alternating stress  $\sigma'''_v$  in way of outlet of crankpin oil bore:

$$\sigma'''_v = \pm \frac{1}{3} \sigma_{BO} \left[ 1 + 2 \sqrt{1 + \frac{9}{4} \left( \frac{\sigma_{TO}}{\sigma_{BO}} \right)^2} \right]$$

## 6 Calculation of fatigue strength

### 6.1 General

**6.1.1** The fatigue strength is to be understood as that value of von Mises equivalent alternating stress which a crankshaft can permanently withstand at the most highly stressed points.

The fatigue strength may be evaluated by means of the following formulae:

a) allowable alternating bending fatigue strength of crankshaft  $\sigma'_{DW}$ , in N/mm<sup>2</sup>, in the crankpin fillet area:

$$\sigma'_{DW} = \pm KR'_m \left( 0,264 + \frac{1,073}{D^{0,2}} + \frac{785 - R_m}{4900} + \frac{196}{R_m} \sqrt{\frac{1}{R_H}} \right)$$

b) allowable alternating bending fatigue strength of crankshaft  $\sigma''_{DW}$ , in N/mm<sup>2</sup>, in the journal fillet area:

$$\sigma''_{DW} = \pm KR'_m \left( 0,264 + \frac{1,073}{D_G^{0,2}} + \frac{785 - R_m}{4900} + \frac{196}{R_m} \sqrt{\frac{1}{R_G}} \right)$$

c) allowable alternating bending fatigue strength of crankshaft  $\sigma'''_{DW}$ , in N/mm<sup>2</sup>, in the crankpin oil bore area:

$$\sigma'''_{DW} = \pm KR'_m \left( 0,264 + \frac{1,073}{D^{0,2}} + \frac{785 - R_m}{4900} + \frac{196}{R_m} \sqrt{\frac{2}{D_O}} \right)$$

where:

K : Factor equal to:

- for different types of crankshafts without surface treatment (values greater than 1,00 are only applicable to fatigue strength in fillet area):
  - K = 1,05 for continuous grain flow forged or drop-forged crankshafts
  - K = 1,00 for free form forged crankshafts (without continuous grain flow)
- for cast steel crankshafts with cold rolling treatment in fillet area:
  - K = 0,93 for cast steel crankshafts manufactured by companies using a cold rolling process approved by the Society

$$R'_m = 0,42 R_m + 39,3$$

When a surface treatment process is applied, it is to be approved by the Society. Guidance for calculation of surface treated fillets and oil bore outlets is presented in Article [11].

These formulae are subject to the following conditions:

- surfaces of the fillet, the outlet of the oil bore and inside the oil bore (down to a minimum depth equal to 1,5 times the oil bore diameter) are to be smoothly finished
- for calculation of  $\sigma'_{DW}$ ,  $\sigma''_{DW}$  and  $\sigma'''_{DW}$ , the values of  $R_G$ ,  $R_H$  and  $D_C/2$  are to be taken as not less than 2 mm.

As an alternative, the fatigue strength of the crankshaft can be determined by experiment based either on full size crank throw (or crankshaft) or on specimens taken from a full size crank throw. For evaluation of test results, see Article [10].

## 7 Acceptability criteria

### 7.1

**7.1.1** The sufficient dimensioning of a crankshaft is confirmed by a comparison of the equivalent alternating stress and the fatigue strength. This comparison has to be carried out for the crankpin fillet, the journal fillet, the outlet of crankpin oil bore and is based on the following acceptability factors  $Q_i$ :

$$Q_1 = \frac{\sigma'_{DW}}{\sigma'_V}$$

$$Q_2 = \frac{\sigma''_{DW}}{\sigma''_V}$$

$$Q_3 = \frac{\sigma'''_{DW}}{\sigma'''_V}$$

Adequate dimensioning of the crankshaft is ensured if these acceptability factors satisfy the criterion:

$$Q_i \geq 1,15 \quad \text{with } i = 1 \text{ to } 3$$

## 8 Calculation of shrink-fits of semi-built crankshaft

### 8.1 General

**8.1.1** Respecting the radius of the transition  $R_G$  from the journal diameter  $D_C$  to the shrink diameter  $D_S$ , the following criterion is to be complied with:

$$R_G \geq \text{Max} (0,015 D_C ; 0,5 (D_S - D_C))$$

The actual oversize  $Z$  of the shrink-fit is to be within the limits  $Z_{\min}$  and  $Z_{\max}$  calculated in accordance with [8.3] and [8.4].

In the case where the condition in [8.2] cannot be fulfilled then calculation methods of  $Z_{\min}$  and  $Z_{\max}$  according to [8.3] and [8.4] are not applicable due to multizone-plasticity problems.

In such a case,  $Z_{\min}$  and  $Z_{\max}$  have to be established based on FEM calculations.

### 8.2 Maximum permissible hole in journal pin

**8.2.1** The hole diameter in the journal pin  $D_{BG}$ , in mm, is to satisfy the following criterion:

$$D_{BG} \leq D_S \sqrt{1 - \frac{4000 \cdot S_R \cdot M_{\max}}{\mu \cdot \pi \cdot D_S^2 \cdot L_S \cdot R_{SP}}}$$

where:

$D_S, L_S$  : As defined in Symbols

$S_R$  : Safety factor against slipping, however a value not less than 2 is to be taken unless documented by experiments

$M_{\max}$  : Absolute maximum value of the torque  $M_{T\max}$  (see Symbols), in N·m

$\mu$  : Coefficient for static friction, however a value not greater than 0,2 is to be taken unless documented by experiments

$R_{SP}$  : Minimum yield strength of material for journal pin, in N/mm<sup>2</sup>.

This condition serves to avoid plasticity in the hole of the journal pin.

### 8.3 Necessary minimum oversize of shrink-fit

**8.3.1** The necessary minimum oversize  $Z_{\min}$  of the shrink-fit, in mm, is determined by the greater value calculated according to:

$$Z_{\min} \geq \frac{R_{SW} \cdot D_S}{E_m}$$

and

$$Z_{\min} \geq \frac{4000 \cdot S_R \cdot M_{\max}}{\pi \cdot \mu \cdot E_m \cdot D_S \cdot L_S} \cdot \frac{1 - \left(\frac{D_S}{D_A}\right)^2 \cdot \left(\frac{D_{BG}}{D_S}\right)^2}{\left[1 - \left(\frac{D_S}{D_A}\right)^2\right] \cdot \left[1 - \left(\frac{D_{BG}}{D_S}\right)^2\right]}$$

where:

$R_{SW}$  : Minimum yield strength of material for crank web, in N/mm<sup>2</sup>

$E_m$  : Young's modulus of material for crank web, in N/mm<sup>2</sup>

$\mu, S_R, M_{max}$ : As defined in [8.2.1].

## 8.4 Maximum permissible oversize of shrink-fit

**8.4.1** The maximum permissible oversize  $Z_{max}$  of the shrink-fit, in mm, is calculated according to:

$$Z_{max} \leq \frac{R_{SW} \cdot D_s}{E_m} + \frac{0,8 D_s}{1000}$$

where:

$R_{SW}, D_s, E_m$ : As defined in [8.3.1].

This condition concerning the maximum permissible oversize serves to restrict the shrinkage induced mean stress in the journal fillet.

## 9 Guidance for calculation of stress concentration factors in the web fillet radii of crankshafts by utilizing FEM

### 9.1 General

**9.1.1** The objective of the analysis is to develop Finite Element Method (FEM) calculated figures as an alternative to the analytically calculated stress concentration factors (SCF) at the crankshaft fillets. The analytical method is based on empirical formulae developed from strain gauge measurements of various crank geometries and accordingly the application of these formulae is limited to those geometries.

The SCFs calculated according to this Appendix are defined as the ratio of stresses calculated by FEM to nominal stresses in both journal and pin fillets. When used in connection with the method of the present Article [9] or with the alternative methods, von Mises stresses shall be calculated for bending and principal stresses for torsion.

The procedure, as well as evaluation guidelines, are valid for both solid cranks and semi-built cranks (except journal fillets).

The analysis is to be conducted as linear elastic FE analysis, and unit loads of appropriate magnitude are to be applied for all load cases.

The calculation of SCF at the oil bores is not covered by this Appendix.

It is advised to check the element accuracy of the FE solver in use, e.g. by modeling a simple geometry and comparing the stresses obtained by FEM with the analytical solution for pure bending and torsion.

Boundary Element Method (BEM) may be used instead of FEM.

### 9.2 Model requirements

**9.2.1** The basic recommendations and perceptions for building the FE-model are presented in [9.2.2]. It is obligatory for the final FE-model to fulfill the requirement in [9.2.4].

#### 9.2.2 Element mesh recommendations

In order to fulfil the mesh quality criteria it is advised to construct the FE model for the evaluation of Stress Concentration Factors according to the following recommendations:

- a) The model consists of one complete crank, from the main bearing centreline to the opposite side main bearing centreline.
- b) Element types used in the vicinity of the fillets:

- 10 node tetrahedral elements
- 8 node hexahedral elements
- 20 node hexahedral elements.

- c) Mesh properties in fillet radii

The following applies to  $\pm 90$  degrees in circumferential direction from the crank plane:

- Maximum element size  $a = r / 4$  through the entire fillet as well as in the circumferential direction.

When using 20 node hexahedral elements, the element size in the circumferential direction may be extended up to 5 a.

In the case of multi-radii fillet, r is the local fillet radius.

If 8 node hexahedral elements are used even smaller element size is required to meet the quality criteria.

- Recommended manner for element size in fillet depth direction:
    - 1st layer thickness equal to element size of a
    - 2nd layer thickness equal to element size of 2 a
    - 3rd layer thickness equal to element size of 3 a
  - Minimum 6 elements across web thickness
- d) Generally the rest of the crank should be suitable for numeric stability of the solver
- e) Counterweights have to be modeled only when influencing the global stiffness of the crank significantly
- f) Modeling of oil drillings is not necessary as long as the influence on global stiffness is negligible and the proximity to the fillet is more than 2 r (see Fig 6)
- g) Drillings and holes for weight reduction have to be modeled
- h) Sub-modeling may be used as far as the software requirements are fulfilled.

Figure 6 : Oil bore proximity to fillet

### 9.2.3 Material

The present Appendix does not consider material properties such as Young's Modulus (E) and Poisson's ratio ( $\nu$ ). In FE analysis, those material parameters are required, as strain is primarily calculated and stress is derived from strain using the Young's Modulus and Poisson's ratio.

Reliable values for material parameters have to be used, either as quoted in literature or as measured on representative material samples.

For steel, the following values are advised:

$$E = 2,05 \cdot 10^5 \text{ MPa} \quad \text{and} \quad \nu = 0,3$$

### 9.2.4 Element mesh quality criteria

If the actual element mesh does not fulfil any of the following criteria at the examined area for SCF evaluation, then a second calculation with a refined mesh is to be performed:

- Principal stress criterion  
The quality of the mesh should be assured by checking the stress component normal to the surface of the fillet radius. Ideally, this stress should be zero. With principal stresses  $\sigma_1$ ,  $\sigma_2$  and  $\sigma_3$ , the following criterion is required:  
$$\text{Min} (|\sigma_1| ; |\sigma_2| ; |\sigma_3|) < 0,03 \text{ Max} (|\sigma_1| ; |\sigma_2| ; |\sigma_3|)$$
- Averaged / unaveraged stress criterion  
The criterion is based on observing the discontinuity of stress results over elements at the fillet for the calculation of SCF. Unaveraged nodal stress results calculated from each element connected to a node i should differ less than by 5% from the 100% averaged nodal stress results at this node i at the examined location.

## 9.3 Load cases

9.3.1 To substitute the analytically determined SCF in this Appendix, the following load cases have to be calculated.

### 9.3.2 Torsion

In analogy to the testing apparatus used for the investigations made by FVV, the structure is loaded in pure torsion. In the model, surface warp at the end faces is suppressed.

Torque is applied to the central node located at the crankshaft axis. This node acts as the master node with 6 degrees of freedom and is connected rigidly to all nodes of the end face.

Boundary and load conditions (see Fig 7) are valid for both in-line and V-type engines.

For all nodes in both the journal and crank pin fillets, principal stresses are extracted and the equivalent torsional stress  $\tau_{\text{equiv}}$  is calculated:

$$\tau_{\text{equiv}} = \text{Max} \left( \frac{|\sigma_1 - \sigma_2|}{2} ; \frac{|\sigma_2 - \sigma_3|}{2} ; \frac{|\sigma_1 - \sigma_3|}{2} \right)$$

The maximum value for crankpin fillet  $\tau_{equiv, \alpha}$  and for journal fillet  $\tau_{equiv, \beta}$  is used for the subsequent calculation of the SCF  $\alpha_T$  and  $\beta_T$ :

$$\alpha_T = \frac{\tau_{equiv, \alpha}}{\tau_{NH}}$$

$$\beta_T = \frac{\tau_{equiv, \beta}}{\tau_{NG}}$$

where:

$\tau_{NH}, \tau_{NG}$ : Nominal torsional stresses, in N/mm<sup>2</sup>, referred to the crankpin and the journal, respectively, and calculated as per [2.2.2] with the torsional torque T (see Fig 7):

$$\tau_{NH} = \pm \frac{T}{W_{PH}} \cdot 10^3$$

$$\tau_{NG} = \pm \frac{T}{W_{PG}} \cdot 10^3$$

Figure 7 : Boundary and load conditions for the torsion load case

### 9.3.3 Pure bending (4-point bending)

In analogy to the testing apparatus used for the investigations made by FVV, the structure is loaded in pure bending. In the model, surface warp at the end faces is suppressed.

The bending moment is applied to the central node located at the crankshaft axis. This node acts as the master node with 6 degrees of freedom and is connected rigidly to all nodes of the end face.

Boundary and load conditions (see Fig 8) are valid for both in-line- and V- type engines.

For all nodes in both the journal and crankpin fillets, von Mises equivalent stresses  $\sigma_{equiv}$  are extracted.

The maximum value for crankpin fillet  $\sigma_{equiv, \alpha}$  and for journal fillet  $\sigma_{equiv, \beta}$  is used for the subsequent calculation of the SCF  $\alpha_B$  and  $\beta_B$ :

$$\alpha_B = \frac{\sigma_{equiv, \alpha}}{\sigma_N}$$

$$\beta_B = \frac{\sigma_{equiv, \beta}}{\sigma_N}$$

where:

$\sigma_N$ : Nominal bending stress, in N/mm<sup>2</sup>, related to the web cross-section and calculated as per [2.1.2] item b) with the bending moment M (see Fig 8):

$$\tau_N = \pm \frac{M}{W_{eqw}} \cdot 10^3$$

Figure 8 : Boundary and load conditions for the pure bending load case

9.3.4 Bending with shear force (3-point bending)

This load case is calculated to determine the SCF for pure transverse force (radial force,  $\beta_Q$ ) for the journal fillet.

In analogy to the testing apparatus used for the investigations made by FVV, the structure is loaded in 3-point bending. In the model, surface warp at the both end faces is suppressed.

All nodes are connected rigidly to the central node; boundary conditions are applied to the central nodes. These nodes act as master nodes with 6 degrees of freedom.

The force is applied to the central node located at the pin centreline of the connecting rod. This node is connected to all nodes of the pin cross-sectional area. Warping of the sectional area is not suppressed.

Boundary and load conditions are valid for in-line engines (see Fig 9) and V-type engines. V-type engines can be modeled with one connecting rod force only. Using two connecting rod forces will make no significant change in the SCF.

Figure 9 : Boundary and load conditions for the 3-point bending load case of an in-line engine

The maximum equivalent von Mises stress  $\sigma_{3P}$  in the journal fillet is evaluated. The SCF in the journal fillet can be determined with one of the two following methods:

a) Method 1

This method is analogue to the FVV investigation. The results from 3-point and 4-point bending are combined as follows:

$$\sigma_{3P} = \sigma_{N3P} \beta_B + \sigma_{Q3P} \beta_Q$$

where:

$\sigma_{3P}$  : As found by the FE calculation

$\sigma_{N3P}$  : Nominal bending stress in the web centre due to the force  $F_{3P}$ , in N, applied to the centreline of the actual connecting rod (see Fig 10)

$\beta_B$  : SCF as determined in [9.3.3]

$$\sigma_{Q3P} = \frac{Q_{3P}}{BW}$$

with:

$Q_{3P}$  : Radial (shear) force in the web due to the force  $F_{3P}$ , in N, applied to the centreline of the actual connecting rod (see also Fig 2).

b) Method 2

This method is not analogous to the FVV investigation. In a statically determined system with one crank throw supported by two bearings, the bending moment and radial (shear) force are proportional. Therefore the SCF in the journal fillet can be found directly by the 3-point bending FE calculation.

The SCF is then calculated according to:

$$\beta_{BQ} = \frac{\sigma_{3P}}{\sigma_{N3P}}$$

where:

$\sigma_{3P}, \sigma_{N3P}$ : As defined in item a) above.

When using this method, the radial force and stress determination in this Appendix becomes superfluous. The alternating bending stress in the journal fillet as per [2.1.3] is then evaluated:

$$\sigma_{BG} = \pm |\beta_{BQ} \cdot \sigma_{BFN}|$$

Note 1: The use of this method does not apply to the crankpin fillet and this SCF must not be used in connection with calculation methods other than those assuming a statically determined system as in this Appendix.

**Figure 10 : Load applications for in-line and V-type engines**

## 10 Guidance for evaluation of fatigue tests

### 10.1 Introduction

**10.1.1** Fatigue testing can be divided into two main groups; testing of small specimens and full-size crank throws. Testing can be made using the staircase method or a modified version thereof which is presented in this document. Other statistical evaluation methods may also be applied.

#### 10.1.2 Small specimen testing

For crankshafts without any fillet surface treatment, the fatigue strength can be determined by testing small specimens taken from a full-size crank throw. When other areas in the vicinity of the fillets are surface treated introducing residual stresses in the fillets, this approach cannot be applied.

One advantage of this approach is the rather high number of specimens which can be then manufactured. Another advantage is that the tests can be made with different stress ratios (R-ratios) and/or different modes e.g. axial, bending and torsion, with or without a notch. This is required for evaluation of the material data to be used with critical plane criteria.

#### 10.1.3 Full-size crank throw testing

For crankshafts with surface treatment the fatigue strength can only be determined through testing of full size crank throws. For cost reasons, this usually means a low number of crank throws. The load can be applied by hydraulic actuators in a 3 or 4 point bending arrangement, or by an exciter in a resonance test rig. The latter is frequently used, although it usually limits the stress ratio to  $R = -1$ .

### 10.2 Evaluation of test results

#### 10.2.1 Principles

Prior to fatigue testing the crankshaft must be tested as required by quality control procedures, e.g. for chemical composition, mechanical properties, surface hardness, hardness depth and extension, fillet surface finish, etc.

The test samples should be prepared so as to represent the "lower end" of the acceptance range e.g. for induction hardened crankshafts this means the lower range of acceptable hardness depth, the shortest extension through a fillet, etc. Otherwise the mean value test results should be corrected with a confidence interval: a 90% confidence interval may be used both for the sample mean and the standard deviation.

The test results, when applied in this Appendix, shall be evaluated to represent the mean fatigue strength, with or without taking into consideration the 90% confidence interval as mentioned above. The standard deviation should be considered by taking the 90% confidence into account. Subsequently the result to be used as the fatigue strength is then the mean fatigue strength minus one standard deviation.

If the evaluation aims to find a relationship between (static) mechanical properties and the fatigue strength, the relation must be based on the real (measured) mechanical properties, not on the specified minimum properties.

The calculation technique presented in [10.2.4] was developed for the original staircase method. However, since there is no similar method dedicated to the modified staircase method the same is applied for both.

#### 10.2.2 Staircase method

In the original staircase method, the first specimen is subjected to a stress corresponding to the expected average fatigue strength. If the specimen survives  $10^7$  cycles, it is discarded and the next specimen is subjected to a stress that is one increment above the previous, i.e. a survivor is always followed by the next using a stress one increment above the previous. The increment should be selected to correspond to the expected level of the standard deviation.

When a specimen fails prior to reaching  $10^7$  cycles, the obtained number of cycles is noted and the next specimen is subjected to a stress that is one increment below the previous. With this approach, the sum of failures and run-outs is equal to the number of specimens.

This original staircase method is only suitable when a high number of specimens are available. Through simulations it has been found that the use of about 25 specimens in a staircase test leads to a sufficient accuracy in the result.

#### 10.2.3 Modified staircase method

When a limited number of specimens are available, it is advisable to apply the modified staircase method. Here the first specimen is subjected to a stress level that is most likely well below the average fatigue strength. When this specimen has survived  $10^7$  cycles, this same specimen is subjected to a stress level one increment above the previous. The increment should be selected to correspond to the expected level of the standard deviation. This is continued with the same specimen until failure.

Then the number of cycles is recorded and the next specimen is subjected to a stress that is at least 2 increments below the level where the previous specimen failed.

With this approach, the number of failures usually equals the number of specimens. The number of run-outs, counted as the highest level where  $10^7$  cycles were reached, also equals the number of specimens.

The acquired result of a modified staircase method should be used with care, since some results available indicate that testing a runout on a higher test level, especially at high mean stresses, tends to increase the fatigue limit. However, this “training effect” is less pronounced for high strength steels (e.g. UTS > 800 MPa).

If the confidence calculation is desired or necessary, the minimum number of test specimens is 3.

**10.2.4 Calculation of sample mean and standard deviation**

A hypothetical example of tests for 5 crank throws is presented further in the subsequent text. When using the modified staircase method and the evaluation method of Dixon and Mood, the number of samples will be 10, meaning 5 run-outs and 5 failures, i.e.:

- Number of samples:

$$n = 10$$

Furthermore, the method distinguishes between:

- Less frequent event is failures:

$$C = 1$$

- Less frequent event is run-outs:

$$C = 2$$

The method uses only the less frequent occurrence in the test results, i.e. if there are more failures than run-outs, then the number of run-outs is used, and vice versa.

In the modified staircase method, the number of run-outs and failures are usually equal. However, the testing can be unsuccessful, e.g. the number of run-outs can be less than the number of failures if a specimen with 2 increments below the previous failure level goes directly to failure. On the other hand, if this unexpected premature failure occurs after a rather high number of cycles, it is possible to define the level below this as a run-out.

Dixon and Mood’s approach, derived from the maximum likelihood theory, which also may be applied here, especially on tests with few samples, presented some simple approximate equations for calculating the sample mean and the standard deviation from the outcome of the staircase test. The sample mean can be calculated as follows:

$$\bar{S}_a = S_{a0} + d \left( \frac{A}{F} - \frac{1}{2} \right) \quad \text{when} \quad C = 1$$

$$\bar{S}_a = S_{a0} + d \left( \frac{A}{F} + \frac{1}{2} \right) \quad \text{when} \quad C = 2$$

The standard deviation can be found by:

$$s = 1,62 d \left( \frac{BF - A^2}{F^2} + 0,029 \right)$$

where:

$S_{a0}$  : Lowest stress level for the less frequent occurrence

$d$  : Stress increment

$$F = \sum f_i$$

$$A = \sum i f_i$$

$$B = \sum i^2 f_i$$

$i$  : Stress level numbering

$f_i$  : Number of samples at stress level  $i$ .

The formula for the standard deviation is an approximation and can be used when:

$$\frac{BF - A^2}{F^2} > 0,3 \quad \text{and} \quad 0,5s < d < 1,5s$$

If any of these two conditions are not fulfilled, a new staircase test should be considered or the standard deviation should be taken quite large in order to be on the safe side.

If increment  $d$  is greatly higher than the standard deviation  $s$ , the procedure leads to a lower standard deviation and a slightly higher sample mean, both compared to values calculated when the difference between the increment and the standard deviation is relatively small. Respectively, if increment  $d$  is much less than the standard deviation  $s$ , the procedure leads to a higher standard deviation and a slightly lower sample mean.

**10.2.5 Confidence interval for mean fatigue limit**

If the staircase fatigue test is repeated, the sample mean and the standard deviation will most likely be different from the previous test. Therefore, it is necessary to assure with a given confidence that the repeated test values will be above the chosen fatigue limit by using a confidence interval for the sample mean.

The confidence interval for the sample mean value with unknown variance is known to be distributed according to the t-distribution (also called student’s t-distribution) which is a distribution symmetric around the average.

Note 1: The confidence level normally used for the sample mean is 90%, meaning that 90% of sample means from repeated tests will be above the value calculated with the chosen confidence level. Fig 11 shows the t value for (1 – α) 100% confidence interval for the sample mean.

**Figure 11 : Student’s t-distribution**

If  $S_a$  is the empirical mean and  $s$  is the empirical standard deviation over a series of  $n$  samples, in which the variable values are normally distributed with an unknown sample mean and unknown variance, the (1 – α) 100% confidence interval for the mean is:

$$P\left(S_a - t_{\alpha, n-1} \frac{s}{\sqrt{n}} < S_{aX\%}\right) = 1 - \alpha$$

The resulting confidence interval is symmetric around the empirical mean of the sample values, and the lower endpoint can be found as:

$$S_{aX\%} = S_a - t_{\alpha, n-1} \frac{s}{\sqrt{n}}$$

which is the mean fatigue limit (population value) to be used to obtain the reduced fatigue limit where the limits for the probability of failure are taken into consideration.

**10.2.6 Confidence interval for standard deviation**

The confidence interval for the variance of a normal random variable is known to possess a chi-square distribution with  $n - 1$  degrees of freedom.

Note 1: The confidence level on the standard deviation is used to ensure that the standard deviations for repeated tests are below an upper limit obtained from the fatigue test standard deviation with a confidence level. Fig 12 shows the chi-square for (1 – α) 100% confidence interval for the variance.

**Figure 12 : Chi-square distribution**

An assumed fatigue test value from  $n$  samples is a normal random variable with a variance of  $\sigma^2$  and has an empirical variance  $\alpha^2$ . Then a (1 – α) 100% confidence interval for the variance is:

$$P\left(\frac{(n-1)s^2}{\sigma^2} < \chi^2_{\alpha, n-1}\right) = 1 - \alpha$$

A (1 – α) 100% confidence interval for the standard deviation is obtained by the square root of the upper limit of the confidence interval for the variance and can be found by:

$$S_{\chi\%} = \sqrt{\frac{n-1}{\chi^2_{\alpha, n-1}}} s$$

This standard deviation (population value) is to be used to obtain the fatigue limit, where the limits for the probability of failure are taken into consideration.

### 10.3 Small specimen testing

**10.3.1** In this connection, a small specimen is considered to be one of the specimens taken from a crank throw. Since the specimens shall be representative for the fillet fatigue strength, they should be taken out close to the fillets, as shown in Fig 13.

It should be made certain that the principal stress direction in the specimen testing is equivalent to the full-size crank throw. The verification is recommended to be done by utilizing the finite element method.

The (static) mechanical properties are to be determined as stipulated by the quality control procedures.

#### 10.3.2 Determination of bending fatigue strength

It is advisable to use un-notched specimens in order to avoid uncertainties related to the stress gradient influence. Push-pull testing method (stress ratio  $R = -1$ ) is preferred, but especially for the purpose of critical plane criteria other stress ratios and methods may be added.

In order to ensure principal stress direction in push-pull testing to represent the full-size crank throw principal stress direction and when no further information is available, the specimen shall be taken in 45 degrees angle as shown in Fig 13.

- If the objective of the testing is to document the influence of high cleanliness, test samples taken from positions approximately 120 degrees in a circumferential direction may be used. See Fig 13.
- If the objective of the testing is to document the influence of continuous grain flow (cgf) forging, the specimens should be restricted to the vicinity of the crank plane.

**Figure 13 : Specimen locations in a crank throw**

#### 10.3.3 Determination of torsional fatigue strength

- If the specimens are subjected to torsional testing, the selection of samples should follow the same guidelines as for bending above. The stress gradient influence has to be considered in the evaluation.
- If the specimens are tested in push-pull and no further information is available, the samples should be taken out at an angle of 45 degrees to the crank plane in order to ensure collinearity of the principal stress direction between the specimen and the full size crank throw. When taking the specimen at a distance from the (crank) middle plane of the crankshaft along the fillet, this plane rotates around the pin centre point making it possible to resample the fracture direction due to torsion (the results are to be converted into the pertinent torsional values).

#### 10.3.4 Other test positions

If the test purpose is to find fatigue properties and the crankshaft is forged in a manner likely to lead to cgf, the specimens may also be taken longitudinally from a prolonged shaft piece where specimens for mechanical testing are usually taken. The condition is that this prolonged shaft piece is heat treated as a part of the crankshaft and that the size is so as to result in a similar quenching rate as the crank throw.

When using test results from a prolonged shaft piece, it must be considered how well the grain flow in that shaft piece is representative for the crank fillets.

**10.3.5 Correlation of test results**

The fatigue strength achieved by specimen testing shall be converted to correspond to the full-size crankshaft fatigue strength with an appropriate method (size effect).

When using the bending fatigue properties from tests mentioned in this section, it should be kept in mind that successful continuous grain flow (cgf) forging leading to elevated values compared to other (non cgf) forging, will normally not lead to a torsional fatigue strength improvement of the same magnitude.

In such cases it is advised to either carry out also torsional testing or to make a conservative assessment of the torsional fatigue strength, e.g. by using no credit for cgf. This approach is applicable when using the Gough Pollard criterion. However, this approach is not recognized when using the von Mises or a multi-axial criterion such as Findley.

If the found ratio between bending and torsion fatigue differs significantly from  $3^{1/2}$ , one should consider replacing the use of the von Mises criterion with the Gough Pollard criterion. Also, if critical plane criteria are used, it must be kept in mind that cgf makes the material inhomogeneous in terms of fatigue strength, meaning that the material parameters differ with the directions of the planes.

Any addition of influence factors must be made with caution. If for example a certain addition for clean steel is documented, it may not necessarily be fully combined with a K-factor for cgf. Direct testing of samples from a clean and cgf forged crank is preferred.

**10.4 Full size testing**

**10.4.1 Hydraulic pulsation**

A hydraulic test rig can be arranged for testing a crankshaft in 3-point or 4-point bending as well as in torsion. This allows for testing with any R-ratio.

Although the applied load should be verified by strain gauge measurements on plain shaft sections for the initiation of the test, it is not necessarily used during the test for controlling load. It is also pertinent to check fillet stresses with strain gauge chains.

Furthermore, it is important that the test rig provides boundary conditions as defined in [9.3.2] to [9.3.4]).

The (static) mechanical properties are to be determined as stipulated by the quality control procedures.

**10.4.2 Resonance tester**

A rig for bending fatigue normally works with an R-ratio of  $-1$ . Due to operation close to resonance, the energy consumption is moderate. Moreover, the frequency is usually relatively high, meaning that  $10^7$  cycles can be reached within some days. Fig 14 shows a layout of the testing arrangement.

**Figure 14 : An example of testing arrangement of the resonance tester for bending loading**

The applied load should be verified by strain gauge measurements on plain shaft sections. It is also pertinent to check fillet stresses with strain gauge chains.

Clamping around the journals must be arranged in a way that prevents severe fretting which could lead to a failure under the edges of the clamps. If some distance between the clamps and the journal fillets is provided, the loading is consistent with 4-point bending and thus representative for the journal fillets also.

In an engine, the crankpin fillets normally operate with an R-ratio slightly above -1 and the journal fillets slightly below -1. If found necessary, it is possible to introduce a mean load (deviate from  $R = -1$ ) by means of a spring preload.

A rig for torsion fatigue can also be arranged as shown in Fig 15. When a crank throw is subjected to torsion, the twist of the crankpin makes the journals move sideways. If one single crank throw is tested in a torsion resonance test rig, the journals with their clamped-on weights will vibrate heavily sideways.

**Figure 15 : An example of testing arrangement of the resonance tester for torsion loading with double crank throw section**

This sideway movement of the clamped-on weights can be reduced by having two crank throws, especially if the cranks are almost in the same direction. However, the journal in the middle will move more.

Since sideway movements can cause some bending stresses, the plain portions of the crankpins should also be provided with strain gauge arranged to measure any possible bending that could have an influence on the test results.

Similarly, to the bending case the applied load shall be verified by strain gauge measurements on plain shaft sections. It is also pertinent to check fillet stresses with strain gauge chains as well.

### 10.4.3 Use of results and crankshaft acceptability

In order to combine tested bending and torsion fatigue strength results in calculation of crankshaft acceptability, (see Article [7]), the Gough-Pollard approach and the maximum principal equivalent stress formulation can be applied for the following cases:

- Related to the crankpin diameter:

$$Q = \left( \sqrt{\left( \frac{\sigma_{BH}}{\sigma_{DWCT}} \right)^2 + \left( \frac{\tau_{BH}}{\tau_{DWCT}} \right)^2} \right)^{-1}$$

where:

$\sigma_{DWCT}$  : Fatigue strength by bending testing

$\tau_{DWCT}$  : Fatigue strength by torsion testing.

- Related to the crankpin oil bore:

$$Q = \frac{\sigma_{DWOT}}{\sigma_v}$$

$$\sigma_v = \frac{1}{3} \sigma_{BO} \left[ 1 + 2 \sqrt{1 + \frac{9}{4} \left( \frac{\sigma_{TO}}{\sigma_{BO}} \right)^2} \right]$$

$\sigma_{DWOT}$  : Fatigue strength by means of largest principal strength from torsion testing.

- Related to the journal diameter:

$$Q = \left( \sqrt{\left( \frac{\sigma_{BG}}{\sigma_{DWJT}} \right)^2 + \left( \frac{\tau_G}{\tau_{DWJT}} \right)^2} \right)^{-1}$$

$\sigma_{DWJT}$  : Fatigue strength by bending testing

$\tau_{DWJT}$  : Fatigue strength by torsion testing.

In case increase in fatigue strength due to the surface treatment is considered to be similar between the above cases, it is sufficient to test only the most critical location according to the calculation where the surface treatment had not been taken into account.

## 10.5 Use of existing results for similar crankshafts

10.5.1 For fillets or oil bores without surface treatment, the fatigue properties found by testing may be used for similar crankshaft designs providing:

- Material:
  - Similar material type
  - Cleanliness on the same or better level
  - The same mechanical properties can be granted (size versus hardenability)
- Geometry:
  - Difference in the size effect of stress gradient is insignificant or it is considered
  - Principal stress direction is equivalent. See [10.3].
- Manufacturing:
  - Similar manufacturing process.

Induction hardened or gas nitrited crankshafts will suffer fatigue either at the surface or at the transition to the core. The surface fatigue strength as determined by fatigue tests of full size cranks, may be used on an equal or similar design as the tested crankshaft when the fatigue initiation occurred at the surface. With the similar design, it is meant that a similar material type and surface hardness are used and the fillet radius and hardening depth are within approximately  $\pm 30\%$  of the tested crankshaft.

Fatigue initiation in the transition zone can be either subsurface, i.e. below the hard layer, or at the surface where the hardening ends. The fatigue strength at the transition to the core can be determined by fatigue tests as described above, provided that the fatigue initiation occurred at the transition to the core. Tests made with the core material only will not be representative since the tension residual stresses at the transition are lacking.

Note 1: The fatigue limit can decrease in the very high cycle domain with subsurface crack initiation due to trapped hydrogen that accumulates through diffusion around some internal defect functioning as an initiation point. In these cases, it would be appropriate to reduce the fatigue limit by some percent per decade of cycles beyond  $10^7$ . Based on a publication by Yukitaka Murakami "Metal Fatigue: Effects of Small Defects and Non-metallic Inclusions" the reduction is suggested to be 5% per decade especially when the hydrogen content is considered to be high.

## 11 Guidance for calculation of surface treated fillets and oil bore outlets

### 11.1 Introduction

11.1.1 This Article deals with surface treated fillets and oil bore outlets. The various treatments are explained and some empirical formula are given for calculation purposes. Conservative empiricism has been applied intentionally, in order to be on the safe side from a calculation standpoint.

Note 1: Measurements or more specific knowledge should be used if available. However, in the case of a wide scatter (e.g. for residual stresses) the values should be chosen from the end of the range that would be on the safe side for calculation purposes.

### 11.2 Definition of surface treatment

11.2.1 "Surface treatment" is a term covering treatments such as thermal, chemical or mechanical operations, leading to inhomogeneous material properties such as hardness, chemistry or residual stresses from the surface to the core.

#### 11.2.2 Surface treatment methods

Tab 3 covers possible treatment methods and how they influence the properties that are decisive for the fatigue strength.

It is important to note that since only induction hardening, nitriding, cold rolling and stroke peening are considered relevant for marine engines, other methods as well as combination of two or more of the above are not dealt with in this document. In addition, die quenching can be considered in the same way as induction hardening.

**Table 3 : Surface treatment methods and the characteristics they affect.**

Treatment method	Affecting		
	chemistry	hardness	residual stresses
Induction hardening	-	X	X
Nitriding	X	X	X
Case hardening	X	X	X
Die quenching (no temper)	-	X	X
Cold rolling	-	-	X
Stroke peening	-	-	X
Shot peening	-	-	X
Laser peening	-	-	X
Ball coining	-	-	X

### 11.3 Calculation principles

**11.3.1** The basic principle is that the alternating working stresses shall be below the local fatigue strength (including the effect of surface treatment) wherein non-propagating cracks may occur, see also [11.6.2] for details. This is then divided by a certain safety factor. This applies through the entire fillet or oil bore contour as well as below the surface to a depth below the treatment-affected zone i.e. to cover the depth all the way to the core.

Consideration of the local fatigue strength shall include the influence of the local hardness, residual stress and mean working stress. The influence of the ‘giga-cycle effect’, especially for initiation of subsurface cracks, should be covered by the choice of safety margin.

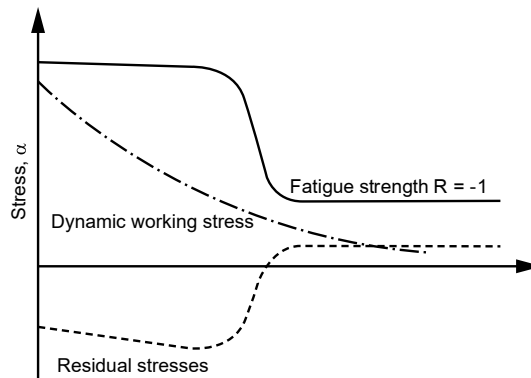

It is of vital importance that the extension of hardening/peening in an area with concentrated stresses be duly considered. Any transition where the hardening/peening is ended is likely to have considerable tensile residual stresses.

This forms a ‘weak spot’ and is important if it coincides with an area of high stresses.

Alternating and mean working stresses must be known for the entire area of the stress concentration as well as to a depth of about 1,2 times the depth of the treatment. Fig 16 indicates this principle in the case of induction hardening. The base axis is either the depth (perpendicular to the surface) or along the fillet contour.

The acceptability criterion should be applied stepwise from the surface to the core as well as from the point of maximum stress concentration along the fillet surface contour to the web.

**Figure 16 : Stresses as functions of depth, general principles**

#### 11.3.2 Evaluation of local fillet stresses

It is necessary to have knowledge of the stresses along the fillet contour as well as in the subsurface to a depth somewhat beyond the hardened layer. Normally this will be found via FEA as described in Article [9]. However, the element size in the subsurface range will have to be the same size as at the surface. For crankpin hardening only the small element size will have to be continued along the surface to the hard layer. If no FEA is available, a simplified approach may be used. This can be based on the empirically determined stress concentration factors (SCFs), as in Article [3] if within its validity range, and a relative stress gradient inversely proportional to the fillet radius. Bending and torsional stresses must be addressed separately. The combination of these is addressed by the acceptability criterion.

The subsurface transition-zone stresses, with the minimum hardening depth, can be determined by means of local stress concentration factors along an axis perpendicular to the fillet surface. These functions  $\alpha_{B-local}$  and  $\alpha_{T-local}$  have different shapes due to the different stress gradients.

The SCFs  $\alpha_B$  and  $\alpha_T$  are valid at the surface. The local  $\alpha_{B-local}$  and  $\alpha_{T-local}$  drop with increasing depth. The relative stress gradients at the surface depend on the kind of stress raiser, but for crankpin fillets they can be simplified to  $2/R_H$  in bending and  $1/R_H$  in torsion. The journal fillets are handled analogously by using  $R_G$  and  $D_G$ . The nominal stresses are assumed to be linear from the surface to a midpoint in the web between the crankpin fillet and the journal fillet for bending and to the crankpin or journal centre for torsion.

The local SCFs are then functions of depth t:

- for bending (see Fig 17):

$$\alpha_{B-local} = (\alpha_B - 1)e^{\frac{-2t}{R_H} + 1} - \left(\frac{2t}{\sqrt{W^2 + S^2}}\right)^{\frac{0,6}{\alpha_B}}$$

- for torsion (see Fig 18):

$$\alpha_{T-local} = (\alpha_T - 1)e^{\frac{-t}{R_H} + 1} - \left(\frac{2t}{D}\right)^{\frac{1}{\alpha_T}}$$

If the pin is hardened only and the end of the hardened zone is closer to the fillet than three times the maximum hardness depth, FEA should be used to determine the actual stresses in the transition zone.

Figure 17 : Bending SCF in the crankpin fillet as a function of depth.

The corresponding SCF for the journal fillet can be found by replacing  $R_H$  with  $R_G$ .

Figure 18 : Torsional SCF in the crankpin fillet as a function of depth.

The corresponding SCF for the journal fillet can be found by replacing  $R_H$  with  $R_G$  and  $D$  with  $D_G$ .

**11.3.3 Evaluation of oil bore stresses**

Stresses in the oil bores can be determined also by FEA. The element size should be less than 1/8 of the oil bore diameter  $D_0$  and the element mesh quality criteria should be followed as prescribed in Article [9]. The fine element mesh should continue well beyond a radial depth corresponding to the hardening depth.

The loads to be applied in the FEA are the torque, see [9.3.2] and the bending moment, with four-point bending as in [9.3.3]. If no FEA is available, a simplified approach may be used. This can be based on the empirically determined SCF from Article [3] if within its applicability range. Bending and torsional stresses at the point of peak stresses are combined as in Article [5].

Fig 19 indicates a local drop of the hardness in the transition zone between a hard and soft material. Whether this drop occurs depends also on the tempering temperature after quenching in the QT process.

The peak stress in the bore occurs at the end of the edge rounding. Within this zone the stress drops almost linearly to the centre of the pin. As can be seen from Fig 19, for shallow (A) and intermediate (B) hardening, the transition point practically coincides with the point of maximal stresses. For deep hardening the transition point comes outside of the point of peak stress and the local stress can be assessed as a portion  $(1-2tH/D)$  of the peak stresses where  $tH$  is the hardening depth.

The subsurface transition-zone stresses (using the minimum hardening depth) can be determined by means of local stress concentration factors along an axis perpendicular to the oil bore surface. These functions  $\gamma_{B-local}$  and  $\gamma_{T-local}$  have different shapes, because of the different stress gradients.

The stress concentration factors  $\gamma_B$  and  $\gamma_T$  are valid at the surface. The local SCFs  $\gamma_{B-local}$  and  $\gamma_{T-local}$  drop with increasing depth. The relative stress gradients at the surface depend on the kind of stress raiser, but for crankpin oil bores they can be simplified to  $4/D_0$  in bending and  $2/D_0$  in torsion. The local SCFs are then functions of the depth  $t$ :

$$\gamma_{B-local} = (\gamma_B - 1)e^{-\frac{4t}{D_0}} + 1$$

$$\gamma_{T-local} = (\gamma_T - 1)e^{-\frac{2t}{D_0}} + 1$$

Figure 19 : Stresses and hardness in induction hardened oil holes

11.3.4 Acceptability criteria

Acceptance of crankshafts is based on fatigue considerations; This Appendix compares the equivalent alternating stress and the fatigue strength ratio to an acceptability factor of  $Q \geq 1,15$  for oil bore outlets, crankpin fillets and journal fillets. This shall be extended to cover also surface treated areas independent of whether surface or transition zone is examined.

11.4 Introduction hardening

11.4.1 Generally, the hardness specification shall specify the surface hardness range i.e. minimum and maximum values, the minimum and maximum extension in or through the fillet and also the minimum and maximum depth along the fillet contour. The referenced Vickers hardness is considered to be HV0,5...HV5.

The induction hardening depth is defined as the depth where the hardness is 80% of the minimum specified surface hardness.

In the case of crankpin or journal hardening only, the minimum distance to the fillet shall be specified due to the tensile stress at the heat-affected zone as shown in Fig 20.

If the hardness-versus-depth profile and residual stresses are not known or specified, one may assume the following:

- the hardness profile consists of two layers (see Fig 21):
  - constant hardness from the surface to the transition zone
  - constant hardness from the transition zone to the core material
- residual stresses in the hard zone of 200 MPa (compression)
- transition-zone hardness as 90% of the core hardness unless the local hardness drop is avoided
- transition-zone maximum residual stresses (von Mises) of 300 MPa tension.

If the crankpin or journal hardening ends close to the fillet, the influence of tensile residual stresses has to be considered. If the minimum distance between the end of the hardening and the beginning of the fillet is more than 3 times the maximum hardening depth, the influence may be disregarded.

Figure 20 : Residual stresses along the surface of a pin and fillet

Figure 21 : Typical hardness as a function of depth.

The arrows indicate the defined hardening depth. Note the indicated potential hardness drop at the transition to the core. This can be a weak point as local strength may be reduced and tensile residual stresses may occur.

**11.4.2 Local fatigue strength**

Induction-hardened crankshafts will suffer fatigue either at the surface or at the transition to the core. The fatigue strengths, for both the surface and the transition zone, can be determined by fatigue testing of full size cranks as described in Article [10]. In the case of a transition zone, the initiation of the fatigue can be either subsurface (i.e. below the hard layer) or at the surface where the hardening ends. Tests made with the core material only will not be representative since the tensile residual stresses at the transition are lacking.

Alternatively, the surface fatigue strength can be determined empirically as follows where HV is the surface Vickers hardness. The following formula provides a conservative value, with which the fatigue strength is assumed to include the influence of the residual stress. The resulting value is valid for a working stress ratio of R = -1:

$$\sigma_{F\text{surface}} = 400 + 0,5 (HV - 400)$$

Note 1: It has to be noted also that the mean stress influence of induction-hardened steels may be significantly higher than that for QT steels.

The fatigue strength in the transition zone, without taking into account any possible local hardness drop, shall be determined by the equation introduced in Article [6].

For journal and respectively to crankpin fillet applies:

$$\sigma_{F\text{transition, cpin}} = \pm K(0,42R_m + 39,3) \left[ 0,264 + 1,073Y^{-0,2} + \frac{785 - R_m}{4900} + \frac{196}{R_m} \sqrt{\frac{1}{X}} \right]$$

where:

- for journal fillet: Y = D<sub>G</sub> and X = R<sub>G</sub>
- for crankpin fillet: Y = D and X = R<sub>H</sub>
- for oil bore outlet: Y = D and X = D<sub>o</sub>/2

The influence of the residual stress is not included in the above formula.

For the purpose of considering subsurface fatigue, below the hard layer, the disadvantage of tensile residual stresses has to be considered by subtracting 20% from the value determined above. This 20% is based on the mean stress influence of alloyed quenched and tempered steel having a residual tensile stress of 300 MPa.

When the residual stresses are known to be lower, also smaller value of subtraction shall be used. For low-strength steels the percentage chosen should be higher.

For the purpose of considering surface fatigue near the end of the hardened zone (i.e. in the heat-affected zone shown in the Fig 20) the influence of the tensile residual stresses can be considered by subtracting a certain percentage, in accordance with Tab 4, from the value determined by the above formula.

**Table 4 : The influence of tensile residual stresses at a given distance from the end of the hardening towards the fillet**

	Maximum hardening depth		%
		1	0 to 1,0
	2	1,0 to 2,0	12
	3	2,0 to 3,0	6
	4	3,0 or more	0

### 11.5 Nitriding

**11.5.1** The hardness specification shall include the surface hardness range (min and max) and the minimum and maximum depth. Only gas nitriding is considered. The referenced Vickers hardness is considered to be HV0,5.

The depth of the hardening is defined in different ways in the various standards and the literature. The most practical method to use in this context is to define the nitriding depth tN as the depth to a hardness of 50 HV above the core hardness.

The hardening profile should be specified all the way to the core. If this is not known, it may be determined empirically via the following formula:

$$HV(t) = HV_{core} + (HV_{surface} - HV_{core}) \left( \frac{50}{HV_{surface} - HV_{core}} \right)^{\left( \frac{t}{tN} \right)^2}$$

where:

- t : Local depth
- HV(t) : Hardness at depth t
- HV<sub>core</sub> : Core hardness (minimum)
- HV<sub>surface</sub> : Surface hardness (minimum)
- tN : Nitriding depth as defined above (minimum).

#### 11.5.2 Local fatigue strength

It is important to note that in nitrided crankshaft cases, fatigue is found either at the surface or at the transition to the core. This means that the fatigue strength can be determined by tests as described in Article [10].

Alternatively, the surface fatigue strength (principal stress) can be determined empirically and conservatively as follows. This is valid for a surface hardness of 600 HV or greater:

$$\sigma_{Fsurface} = 450 \text{ Mpa}$$

Note 1: This fatigue strength is assumed to include the influence of the surface residual stress and applies for a working stress ratio of R = -1.

The fatigue strength in the transition zone can be determined by the equation introduced in Article [6]. For crankpin and respectively to journal applies:

$$\sigma_{Ftransition, cpin} = \pm K(0, 42R_m + 39, 3) \left[ 0, 264 + 1, 073 Y^{-0,2} + \frac{785 - R_m}{4900} + \frac{196}{R_m} \sqrt{\frac{1}{X}} \right]$$

where:

- for journal fillet: Y = D<sub>G</sub> and X = R<sub>G</sub>
- for crankpin fillet: Y = D and X = R<sub>H</sub>
- for oil bore outlet: Y = D and X = D<sub>o</sub>/2

Note 2: This fatigue strength is not assumed to include the influence of the residual stresses.

In contrast to induction-hardening the nitrided components have no such distinct transition to the core. Although the compressive residual stresses at the surface are high, the balancing tensile stresses in the core are moderate because of the shallow depth. For the purpose of analysis of subsurface fatigue the disadvantage of tensile residual stresses in and below the transition zone may be even disregarded in view of this smooth contour of a nitriding hardness profile.

Although in principle the calculation should be carried out along the entire hardness profile, it can be limited to a simplified approach of examining the surface and an artificial transition point. This artificial transition point can be taken at the depth where the local hardness is approximately 20 HV above the core hardness. In such a case, the properties of the core material should be used. This means that the stresses at the transition to the core can be found by using the local SCF formula mentioned earlier when inserting t = 1,2tN.

**Figure 22 : Sketch of the location for the artificial transition point in the depth direction**

## 11.6 Cold forming

**11.6.1** The advantage of stroke peening or cold rolling of fillets is the compressive residual stresses introduced in the high-loaded area. Even though surface residual stresses can be determined by X-ray diffraction technique and subsurface residual stresses can be determined through neutron diffraction, the local fatigue strength is virtually non-assessable on that basis since suitable and reliable correlation formula are hardly known.

Therefore, the fatigue strength has to be determined by fatigue testing; see also Article [10]. Such testing is normally carried out as four-point bending, with a working stress ratio of  $R = -1$ . From these results, the bending fatigue strength, surface or subsurface-initiated depending on the manner of failure can be determined and expressed as the representative fatigue strength for applied bending in the fillet.

In comparison to bending, the torsion fatigue strength in the fillet may differ considerably from the ratio (utilized by the von Mises criterion)  $3^{1/2}$ . The forming-affected depth that is sufficient to prevent subsurface fatigue in bending, may still allow subsurface fatigue in torsion. Another possible reason for the difference in bending and torsion could be the extension of the highly stressed area.

The results obtained in a full-size crank test can be applied for another crank size provided that the base material (alloyed Q + T) is of the similar type and that the forming is done so as to obtain the similar level of compressive residual stresses at the surface as well as through the depth. This means that both the extension and the depth of the cold forming must be proportional to the fillet radius.

### 11.6.2 Stroke peening by means of a ball

The fatigue strength obtained can be documented by means of full size crank tests or by empirical methods if applied on the safe side. If both bending and torsion fatigue strengths have been investigated and differ from the ratio  $3^{1/2}$ , the von Mises criterion should be excluded.

If only bending fatigue strength has been investigated, the torsional fatigue strength should be assessed conservatively. If the bending fatigue strength is concluded to be  $x\%$  above the fatigue strength of the non-peened material, the torsional fatigue strength should not be assumed to be more than  $2/3$  of  $x\%$  above that of the non-peened material.

As a result of the stroke peening process the maximum of the compressive residual stress is found in the subsurface area. Therefore, depending on the fatigue testing load and the stress gradient, it is possible to have higher working stresses at the surface in comparison to the local fatigue strength of the surface. Because of this phenomenon small cracks may appear during the fatigue testing, which will not be able to propagate in further load cycles and/or with further slight increases of the testing load because of the profile of the compressive residual stress. Put simply, the high compressive residual stresses below the surface 'arrest' small surface cracks.

This is illustrated in Fig 23 as gradient load 2.

In fatigue testing with full-size crankshafts these small "hairline cracks" should not be considered to be the failure crack. The crack that is technically the fatigue crack leading to failure, and that therefore shuts off the test-bench, should be considered for determination of the failure load level. This also applies if induction-hardened fillets are stroke-peened.

In order to improve the fatigue strength of induction-hardened fillets it is possible to apply the stroke peening process in the crankshafts' fillets after they have been induction-hardened and tempered to the required surface hardness. If this is done, it might be necessary to adapt the stroke peening force to the hardness of the surface layer and not to the tensile strength of the base material. The effect on the fatigue strength of induction hardening and stroke peening the fillets shall be determined by a full-size crankshaft test.

### 11.6.3 Use of existing results for similar crankshafts

The increase in fatigue strength, which is achieved by applying stroke peening (see [11.6.2]), may be utilized in another similar crankshaft if all of the following criteria are fulfilled:

- ball size relative to fillet radius within  $\pm 10\%$  in comparison to the tested crankshaft
- at least the same circumferential extension of the stroke peening
- angular extension of the fillet contour relative to fillet radius within  $\pm 15\%$  in comparison to the tested crankshaft and located to cover the stress concentration during engine operation
- similar base material, e.g. alloyed quenched and tempered
- forward feed of ball of the same proportion of the radius
- force applied to ball proportional to base material hardness (if different)
- force applied to ball proportional to square of ball radius.

### 11.6.4 Cold rolling

The fatigue strength can be obtained by means of full size crank tests or by empirical methods, if these are applied so as to be on the safe side. If both, bending and torsion fatigue strengths have been investigated, and differ from the ratio  $3^{1/2}$ , the von Mises criterion should be excluded.

If only bending fatigue strength has been investigated, the torsional fatigue strength should be assessed conservatively. If the bending fatigue strength is concluded to be  $x\%$  above the fatigue strength of the non-rolled material, the torsional fatigue strength should not be assumed to be more than  $2/3$  of  $x\%$  above that of the non-rolled material.

11.6.5 Use of existing results for similar crankshafts

The increase in fatigue strength, which is achieved applying cold rolling (see [11.6.4]), may be utilized in another similar crankshaft if all of the following criteria are fulfilled:

- at least the same circumferential extension of cold rolling
- angular extension of the fillet contour relative to fillet radius within  $\pm 15\%$  in comparison to the tested crankshaft and located to cover the stress concentration during engine operation
- similar base material, e.g. alloyed quenched and tempered
- roller force to be calculated so as to achieve at least the same relative (to fillet radius) depth of treatment.

Figure 23 : Working and residual stresses below the stroke-peened surface

12 Calculation of stress concentration factors in the oil bore outlets of crankshafts through utilization of the finite element method

12.1 General

12.1.1 The objective of the analysis described in this Article is to substitute the analytical calculation of the stress concentration factor (SCF) at the oil bore outlet with suitable finite element method (FEM) calculated figures. The former method is based on empirical formula developed from strain gauge readings or photo-elasticity measurements of various round bars. Because use of these formula beyond any of the validity ranges can lead to erroneous results in either direction, the FEM-based method is highly recommended.

The SCF calculated according to the rules set forth in this document is defined as the ratio of FEM-calculated stresses to nominal stresses calculated analytically. In use in connection with the present method in this Appendix, principal stresses shall be calculated.

The analysis is to be conducted as linear elastic FE analysis, and unit loads of appropriate magnitude are to be applied for all load cases.

It is advisable to check the element accuracy of the FE solver in use, e.g. by modeling a simple geometry and comparing the FEM-obtained stresses with the analytical solution.

A boundary element method (BEM) approach may be used instead of FEM.

12.2 Model requirements

12.2.1 The basic recommendations and assumptions for building of the FE-model are presented in [12.2.2]. The final FE-model must meet one of the criteria in [12.2.4].

### 12.2.2 Element mesh recommendations

For the mesh quality criteria to be met, construction of the FE model for the evaluation of stress concentration factors according to the following recommendations is advised:

- a) the model consists of one complete crank, from the main bearing centre line to the opposite side's main bearing centre line.
- b) the following element types are used in the vicinity of the outlets:
  - 10 node tetrahedral elements
  - 8 node hexahedral elements
  - 20 node hexahedral elements
- c) the following mesh properties for the oil bore outlet are used:
  - maximum element size  $a = r / 4$  through the entire outlet fillet as well as in the bore direction (if 8-node hexahedral elements are used, even smaller elements are required for meeting of the quality criterion)
  - recommended manner for element size in the fillet depth direction
    - first layer's thickness equal to element size of  $a$
    - second layer's thickness equal to element size of  $2a$
    - third -layer thickness equal to element size of  $3a$
- d) in general, the rest of the crank should be suitable for numeric stability of the solver
- e) drillings and holes for weight reduction have to be modeled.

Submodeling may be used as long as the software requirements are fulfilled.

### 12.2.3 Material

This Appendix does not consider material properties such as Young's modulus (E) and Poisson's ratio ( $\nu$ ). In the FE analysis, these material parameters are required, as primarily strain is calculated and stress is derived from strain through the use of Young's modulus and Poisson's ratio. Reliable values for material parameters have to be used, either as quoted in the literature or measured from representative material samples.

For steel the following is advised:

$$E = 2,05 \cdot 10^5 \text{ MPa} \quad \text{and} \quad \nu = 0,3$$

### 12.2.4 Element mesh quality criteria

If the actual element mesh does not fulfill any of the following criteria in the area examined for SCF evaluation, a second calculation, with a finer mesh is to be performed.

- a) Principal stresses criterion

The quality of the mesh should be assured through checking of the stress component normal to the surface of the oil bore outlet radius. With principal stresses  $\sigma_1$ ,  $\sigma_2$  and  $\sigma_3$  the following criterion must be met:

$$\min(|\sigma_1||\sigma_2||\sigma_3|) < 0,03 \max(|\sigma_1||\sigma_2||\sigma_3|)$$

- b) Averaged/unaveraged stresses criterion

The averaged/unaveraged –stresses criterion is based on observation of the discontinuity of stress results over elements at the fillet for the calculation of the SCF:

Unaveraged nodal stress results calculated from each element connected to a node  $i$  should differ less than 5% from the 100% averaged nodal stress results at this node  $i$  at the location examined.

## 12.3 Load cases and assessment of stress

12.3.1 For substitution of the analytically determined SCF in this Appendix, calculation shall be performed for the following load cases.

### 12.3.2 Torsion

The structure is loaded in pure torsion. The surface warp at the end faces of the model is suppressed.

Torque is applied to the central node, on the crankshaft axis. This node acts as the master node with six degrees of freedom, and is connected rigidly to all nodes of the end face.

The boundary and load conditions are valid for both in-line- and V- type engines.

For all nodes in an oil bore outlet, the principal stresses are obtained and the maximum value is taken for subsequent calculation of the SCF:

$$\gamma_T = \frac{\max(|\sigma_1||\sigma_2||\sigma_3|)}{\tau_N}$$

where the nominal torsion stress  $\tau_N$  referred to the crankpin is evaluated per [2.2.2] with torque T:

$$\tau_N = \frac{T}{w_p}$$

### 12.3.3 Bending

The structure is loaded in pure bending. The surface warp at the end faces of the model is suppressed.

The bending moment is applied to the central node on the crankshaft axis. This node acts as the master node, with six degrees of freedom, and is connected rigidly to all nodes of the end face.

The boundary and load conditions are valid for both in-line- and V- type engines.

For all nodes in the oil bore outlet, principal stresses are obtained and the maximum value is taken for subsequent calculation of the SCF:

$$\gamma_B = \frac{\max(|\sigma_1|, |\sigma_2|, |\sigma_3|)}{\sigma_N}$$

where the nominal bending stress  $\sigma_N$  referred to the crankpin is calculated per [2.1.2], item d) with bending moment  $M$ :

$$\sigma_N = \frac{M}{W_e}$$

# Appendix 2      Safety of Internal Combustion Engines Supplied with Low Pressure Gas

## 1 General

### 1.1 Scope

#### 1.1.1 Type of engines

This appendix addresses the requirements for trunk piston internal combustion engines supplied with low pressure natural gas as fuel. It is to be applied in association with the requirements of Ch 1, Sec 2, as far as found applicable to the specific natural gas burning engine design.

Engines can be either dual fuel engines (hereinafter referred to as DF engines) or gas fuel only engines (hereinafter referred to as GF engines).

Gas can be introduced as follows:

- into the air inlet manifold, scavenge space, or cylinder air inlet channel port, or
- mixed with air before the turbo-charger (pre-mixed engines).

The gas / air mixture in the cylinder can be ignited by the combustion of a certain amount of fuel (pilot injection) or by extraneous ignition (sparking plug).

The scope of this appendix is limited to natural gas fuelled engines.

#### 1.1.2 Applications

This appendix covers, but is not limited to, the following applications:

- mechanical propulsion
- generating sets intended for main propulsion and auxiliary applications
- single engine or multi-engine installations.

## 1.2 Definitions

#### 1.2.1 Certified safe

Certified safe type equipment is to be as defined in Ch 2, Sec 1, [3.27]. The certification of electrical equipment is to correspond to the category and group for methane gas.

#### 1.2.2 Double block and bleed valves

Double block and bleed valves means the set of valves referred to in:

- Pt D, Ch 9, Sec 16, [4.5.1]
- NR529, 2.2.9 and NR529, 9.4.4 to 9.4.6.

#### 1.2.3 Gas

Gas means a fluid having a vapour pressure exceeding 2,8 bar absolute at a temperature of 37,8°C.

#### 1.2.4 Gas engine (DF engine or GF engine)

Gas engine means either a dual fuel engine (DF engine) or a gas fuel only engine (GF engine).

- DF engine means an engine that can burn natural gas as fuel simultaneously with liquid fuel, either as pilot oil or bigger amount of liquid fuel (gas mode), and also has the capability of running on liquid diesel fuel oil only (Diesel mode).
- GF engine means an engine capable of operating on gas fuel only and not able to switch over to oil fuel operation.

#### 1.2.5 Gas admission valve

Gas admission valve is a valve or injector on the engine, which controls gas supply to the cylinder(s) according to the cylinder(s) actual gas demand.

#### 1.2.6 Gas piping

Gas piping means piping containing gas or air / gas mixtures, including venting pipes.

#### 1.2.7 Gas valve unit (GVU)

Gas valve unit (GVU) is a set of manual shut-off valves, actuated shut-off and venting valves, gas pressure sensors and transmitters, gas temperature sensors and transmitters, gas pressure control valve and gas filter used to control the gas supply to each gas consumer. It also includes a connection for inert gas purging.

**1.2.8 Low pressure gas**

Low pressure gas means gas with a pressure up to 10 bar.

**1.2.9 Lower heating value (LHV)**

Lower heating value (LHV) means the amount of heat produced from the complete combustion of a specific amount of fuel, excluding latent heat of vaporization of water.

**1.2.10 Methane number**

Methane Number is a measure of resistance of a gas fuel to knock, which is assigned to a test fuel based upon operation in knock testing unit at the same standard knock intensity.

Note 1: Pure methane is used as the knock resistant reference fuel, that is, methane number of pure methane is 100, and pure hydrogen is used as the knock sensitive reference fuel, methane number of pure hydrogen is 0.

**1.2.11 Pilot fuel**

Pilot fuel means the fuel oil that is injected into the cylinder to ignite the main gas-air mixture on DF engines.

**1.2.12 Pre-mixed engine**

Pre-mixed engine means an engine where gas is supplied in a mixture with air before the turbocharger.

**1.2.13 Safety Concept**

Safety concept is a document describing the safety philosophy with regard to gas as fuel. It describes how risks associated with this type of fuel are controlled under reasonably foreseeable abnormal conditions as well as possible failure scenarios and their control measures.

Note 1: A detailed evaluation regarding the hazard potential of injury from a possible explosion is to be carried out and reflected in the safety concept of the engine.

**1.3 Document to be submitted**

**1.3.1** In addition to those required in Ch 1, Sec 2, Tab 1, Ch 1, Sec 2, Tab 2 and Ch 1, Sec 2, Tab 3, the documents and drawing listed in Tab 1 are to be submitted for approval of DF or GF engines.

Where considered necessary, the Society may request further documents to be submitted.

**Table 1 : Documents and drawings to be submitted**

No.	A/I (1)	Item
Documents to be submitted for both DF and GF engines		
1	A	Schematic layout or other equivalent documents of gas system on the engine
2	A	Gas piping system (including double-walled arrangement where applicable)
3	A	Parts for gas admission system (4)
4	A	Arrangement of explosion relief valves (crankcase (2), charge air manifold, exhaust gas manifold) as applicable
5	A	List of certified safe equipment and evidence of relevant certification
6	A	Hazardous area plan
7	I	Safety concept
8	I	Report of the risk analysis (3)
9	I	Gas specification
Documents to be submitted for DF engines only		
10	A	Schematic layout or other equivalent documents of fuel oil system (main and pilot fuel systems) on the engine
11	A	Shielding of high pressure fuel pipes for pilot fuel system, assembly
12	A	High pressure parts for pilot fuel oil injection system (4)
Documents to be submitted for GF engines only		
13	A	Ignition system
(1) A : for approval, I : for information		
(2) If required by Ch 1, Sec 2		
(3) See [1.4]		
(4) The documentation is to contain specification of pressures, pipe dimensions and materials.		

## **1.4 Risk analysis**

### **1.4.1 Scope of the risk analysis**

The risk analysis is to address:

- a failure or malfunction of any system or component involved in the gas operation of the engine
- a gas leakage downstream of the gas valve unit
- the safety of the engine in case of emergency shutdown or blackout, when running on gas
- the interactions between the gas fuel system and the engine.

Note 1: With regard to the scope of the risk analysis it shall be noted that failures in systems external to the engine, such as fuel storage or fuel gas supply systems, may require action from the engine control and monitoring system in the event of an alarm or fault condition. Conversely failures in these external systems may, from the vessel perspective, require additional safety actions from those required by the engine limited risk analysis required by this appendix.

### **1.4.2 Form of the risk analysis**

The risk analysis is to be carried out in accordance with international standard ISO 31010:2009: Risk management - Risk assessment techniques, or other recognized standards.

The required analysis is to be based on the single failure concept, which means that only one failure needs to be considered at the same time. Both detectable and non-detectable failures are to be considered. Consequences failures, i.e. failures of any component directly caused by a single failure of another component, are also to be considered.

### **1.4.3 Procedure for the risk analysis**

The risk analysis is to:

- a) Identify all the possible failures in the concerned equipment and systems which could lead:
  - to the presence of gas in components or locations not designed for such purpose, and/or
  - to ignition, fire or explosion.
- b) Evaluate the consequences
- c) Where necessary, identify the failure detection method
- d) Where the risk cannot be eliminated, identify the corrective measures:
  - 1) in the system design, such as:
    - redundancies
    - safety devices, monitoring or alarm provisions which permit restricted operation of the system
  - 2) in the system operation, such as:
    - initiation of the redundancy
    - activation of an alternative mode of operation.

The results of the risk analysis are to be documented.

### **1.4.4 Equipment and systems to be analysed**

The risk analysis required for engines is to cover at least the following aspects:

- a) failure of the gas-related systems or components, in particular:
  - gas piping and its enclosure, where provided
  - cylinder gas supply valves

Note 1: Failures of the gas supply components not located directly on the engine, such as block-and-bleed valves and other components of the GVU, are not to be considered in the analysis.

- b) failure of the ignition system (oil fuel pilot injection or sparking plugs)
- c) failure of the air to fuel ratio control system (charge air bypass, gas pressure control valve, etc.)
- d) for engines where gas is injected upstream of the turbocharger compressor, failure of a component likely to result in a source of ignition (hot spots)
- e) failure of the gas combustion or abnormal combustion (misfiring, knocking)
- f) failure of the engine monitoring, control and safety systems

Note 2: Where engines incorporate electronic control systems, a failure mode and effects analysis (FMEA) is to be carried out in accordance with Ch 1, Sec 2, Tab 1, Footnote (5).

- g) abnormal presence of gas in engine components (e.g. air inlet manifold and exhaust manifold of DF or GF engines) and in the external systems connected to the engines (e.g. exhaust duct).
- h) changes of operating modes for DF engines
- i) hazard potential for crankcase fuel gas accumulation, for engines where the space below the piston is in direct communication with the crankcase, refer to NR529, 10.3.1.2

## 2 Design Requirements

### 2.1 General Principles

**2.1.1** The manufacturer is to declare the allowable gas composition limits for the engine and the minimum and (if applicable) maximum methane number.

**2.1.2** Components containing or likely to contain gas are to be designed to:

- minimise the risk of fire and explosion so as to demonstrate an appropriate level of safety commensurate with that of an oil-fuelled engine;
- mitigate the consequences of a possible explosion to a level providing a tolerable degree of residual risk, due to the strength of the component(s) or the fitting of suitable pressure relief devices of an approved type.

Also refer to NR529, 10.2 and NR529, 10.3.

### 2.2 Gas piping

#### 2.2.1 General

The requirements of this section apply to engine-mounted gas piping. The piping is to be designed in accordance with the criteria for gas piping (design pressure, wall thickness, materials, piping fabrication and joining details etc.) as given in NR529, Part A-1, 7. For ships having the service notation **liquefied gas carrier**, Pt D, Ch 9, Sec 5, [1] to Pt D, Ch 9, Sec 5, [9] and Pt D, Ch 9, Sec 16 apply.

#### 2.2.2 Arrangement of the gas piping system on the engine

Pipes and equipment containing fuel gas are defined as hazardous area Zone 0 (refer to NR529, 12.5.1).

The space between the gas fuel piping and the wall of the outer pipe or duct is defined as hazardous area Zone 1 (refer to NR529, 12.5.2.6).

##### a) Normal "double wall" arrangement

The gas piping system on the engine is to be arranged according to the principles and requirements of NR529, 9.6. For ships having the service notation **liquefied gas carrier**, Pt D, Ch 9, Sec 16, [4.3.1] applies.

The design criteria for the double pipe or duct are given in NR529, 9.8 and NR529, 7.4.1.4.

In case of a ventilated double wall, the ventilation inlet is to be located in accordance with the provisions of NR529, 13.8.3. For ships having the service notation **liquefied gas carrier**, Pt D, Ch 9, Sec 16, [4.3.1], item b) applies.

The pipe or duct is to be pressure tested in accordance with Ch 1, Sec 10, [20.5.2] to ensure gas tight integrity and to show that it can withstand the expected maximum pressure at gas pipe rupture.

##### b) Alternative arrangement

Single walled gas piping is only acceptable:

- for engines installed in ESD protected machinery spaces, as defined in NR529, 5.4.1.2 and in compliance with other relevant parts of NR529 (e.g. NR529, 5.6)
- in the case as per NR529, 9.6.2, Note 18.

For ships having the service notation **liquefied gas carrier**, Part D, Chapter 9 applies.

In case of gas leakage in an ESD-protected machinery space, which would result in the shut-down of the engine(s) in that space, a sufficient propulsion and manoeuvring capability including essential and safety systems is to be maintained.

Therefore the safety concept of the engine is to clearly indicate application of the "double wall" or "alternative" arrangement.

Note 1: The minimum power to be maintained is to be assessed on a case-by-case basis from the operational characteristics of the ship.

#### 2.2.3 Engine charge air and exhaust systems

- a) The charge air and exhaust systems on the engine are to be designed in accordance with [2.1.2]. Relief devices are to be fitted with a flame arrester. Discharge from pressure relief devices is to prevent the passage of flame to the machinery space and be arranged such that the discharge does not endanger personnel or damage other engine components or systems.
- b) In case of a single engine installation, the engine is to be capable of operating at sufficient load to maintain power to essential consumers after opening of the pressure relief devices caused by an explosion event. Sufficient power for propulsion capability is to be maintained.
- c) Load reduction is to be considered on a case-by-case basis, depending on engine configuration (single or multiple) and charge air relief mechanism (self-closing valve or bursting disc).
- d) Continuous relief of exhaust gas (through open rupture disc) into the engine room or other enclosed spaces is not acceptable

#### 2.2.4 Engine crankcase

##### a) Crankcase explosion relief valves

Crankcase explosion relief valves are to be installed in accordance with Ch 1, Sec 2, [2.3.4]. Refer also to NR529, 10.3.1.2.

b) Inerting

For maintenance purposes, a connection, or other means, is to be provided for crankcase inerting and ventilating and gas concentration measuring.

**2.2.5 Gas ignition in the cylinder**

The requirements of NR529, 10.3 apply. For ships having the service notation **liquefied gas carrier**, Pt D, Ch 9, Sec 16, [7.1.1] applies.

**2.2.6 Control, monitoring, alarm and safety systems**

The engine control system is to be independent and separate from the safety system.

The gas supply valves are to be controlled by the engine control system or by the engine gas demand.

Combustion is to be monitored on an individual cylinder basis.

In the event that poor combustion is detected on an individual cylinder, gas operation may be allowed in the conditions specified in NR529, 10.3.1.6.

If monitoring of combustion for each individual cylinder is not practicable due to engine size and design, common combustion monitoring may be accepted.

Unless the risk analysis required by [1.4] proves otherwise, the monitoring and safety system functions for DF or GF engines are to be provided in accordance with Tab 2 in addition to the general monitoring and safety system functions required by the Rules.

Note 1: For DF engines, Tab 2 applies only to the gas mode.

**Table 2 : Monitoring and safety system functions for DF and GF engines**

Parameter	Alarm	Automatic activation of the double block-and-bleed valves	Automatic switching over to oil fuel mode (1)	Engine shutdown
Abnormal pressures in the gas fuel supply line	X	X	X	X (2)
Gas fuel supply systems - malfunction	X	X	X	X (2)
Pilot fuel injection or spark ignition systems - malfunction	X	X (3)	X	X (2) (3)
Exhaust gas temperature after each cylinder - high	X	X (3)	X	X (2) (3)
Exhaust gas temperature after each cylinder, deviation from average – low (4)	X	X (3)	X	X (2) (3)
Cylinder pressure or ignition - failure, including misfiring, knocking and unstable combustion	X	X (3) (5)	X (5)	X (2) (3) (5)
Oil mist concentration in crankcase or bearing temperature (6) - high	X	X		X
Pressure in the crankcase – high (5)	X	X	X	
Engine stops - any cause	X	X		
Failure of the control-actuating medium of the block and bleed valves	X	X	X	
<p>(1) DF engine only, when running in gas mode.                      (2) GF engine only.                      (3) For GF engines, the double block-and-bleed valves and the engine shut-down may not be activated in case of specific failures affecting only one cylinder, provided that the concerned cylinder can be individually shut-off and the safe operation of the engine in such conditions is demonstrated by the risk analysis.                      (4) Required only if necessary for the detection of misfiring.                      (5) In the case where the failure can be corrected by an automatic mitigation action, only the alarm may be activated. If the failure persists after a given time, the safety actions are to be activated.                      (6) Where required by Ch 1, Sec 2, [2.3.5].</p>				

**2.2.7 Gas admission valves**

Gas admission valves are to be certified safe as follows:

- The inside of the valve contains gas and is therefore to be certified for Zone 0.
- When the valve is located within a pipe or duct in accordance with the provisions of [2.2.2], item a), the outside of the valve is to be certified for Zone 1.
- When the valve is arranged without enclosure in accordance with the “ESD-protected machinery space” concept (see [2.2.2], item b)), no certification is required for the outside of the valve, provided that the valve is de-energized upon gas detection in the space.

However, if they are not rated for the zone they are intended for, it is to be documented that they are suitable for that zone. Documentation and analysis is to be based on IEC 60079-10-1 or IEC 60092-502.

## 3 Specific design requirements

### 3.1 DF Engines

#### 3.1.1 General

The maximum continuous power that a DF engine can develop in gas mode may be lower than the approved MCR of the engine (i.e. in oil fuel mode), depending in particular on the gas quality.

This maximum power available in gas mode and the corresponding conditions are to be stated by the engine manufacturer and demonstrated during the type test.

For the application of [4.1.4], [4.2.1] and [4.3], referring to Ch 1, Sec 2, [4.1.4], Ch 1, Sec 2, [4.3.3] item c) and Ch 1, Sec 18, [3.5.4], the 110% load tests are not required in the gas mode for DF engines.

#### 3.1.2 Starting, changeover and stopping

DF engines are to be arranged to use either oil fuel or gas fuel for the main fuel charge and with pilot oil fuel for ignition. The engines are to be arranged for rapid changeover from gas use to fuel oil use. In the case of changeover to either fuel supply, the engines are to be capable of continuous operation using the alternative fuel supply without interruption to the power supply.

Changeover to gas fuel operation is to be only possible at a power level and under conditions where it can be done with acceptable reliability and safety as demonstrated through testing.

Changeover from gas fuel operation mode to oil fuel operation mode is to be possible at all situations and power levels.

The changeover process itself from and to gas operation is to be automatic but manual interruption is to be possible in all cases.

In case of shut-off of the gas supply, the engines are to be capable of continuous operation by oil fuel only.

#### 3.1.3 Pilot injection

Gas supply to the combustion chamber is not to be possible without operation of the pilot oil injection.

Note 1: Pilot injection is to be monitored for example by fuel oil pressure and combustion parameters.

### 3.2 GF engines

#### 3.2.1 Spark ignition system

In case of failure of the spark ignition, the engine is to be shut down except if this failure is limited to one cylinder, subject to immediate shut off of the cylinder gas supply and provided that the safe operation of the engine is substantiated by the risk analysis and by tests.

### 3.3 Pre-mixed engines

#### 3.3.1 Charge air system

Inlet manifold, turbo-charger, charge air cooler, etc. are to be regarded as parts of the fuel gas supply system. Failures of those components likely to result in a gas leakage are to be considered in the risk analysis (see [1.4]).

Flame arresters are to be installed before each cylinder head, unless otherwise justified in the risk analysis, considering design parameters of the engine such as the gas concentration in the charge air system, the path length of the gas-air mixture in the charge air system, etc.

## 4 Type testing, factory acceptance tests and shipboard trials

### 4.1 Type Testing

#### 4.1.1 General

Type approval of DF and GF engines is to be carried out in accordance with the provisions of Ch 1, Sec 2, [4], taking into account the requirements of this sub-article.

#### 4.1.2 Type of engine

In addition to the criteria given in Ch 1, Sec 2, [4.1.2], item c), the type of engine is defined by the following:

- gas admission method (direct cylinder injection, charge air space or pre-mixed)
- gas supply valve operation (mechanical or electronically controlled)
- ignition system (pilot injection, spark ignition, glow plug or gas self-ignition)
- ignition system (mechanical or electronically controlled)

#### 4.1.3 Safety precautions

In addition to the safety precautions mentioned in Section 2, [4.1.3], measures to verify that gas fuel piping on engine is gas tight are to be carried out prior to start-up of the engine.

#### 4.1.4 Test programme

The type testing of the engine is to be carried out in accordance with Ch 1, Sec 2, [4.1.4].

For DF engines, the load tests referred to in Ch 1, Sec 2, [4.1.4] are to be carried out in gas mode at the different percentages of the maximum power available in gas mode (see [3.1.1]).

The influence of the methane number and LHV of the fuel gas is not required to be verified during the Stage B type tests. It is however to be justified by the engine designer through internal tests or calculations and documented in the type approval test report.

### 4.1.5 Measurements and records

In addition to the measurements and records required in Ch 1, Sec 2, [4.1.5], the following engine data are to be measured and recorded:

- each fuel index for gas and diesel as applicable (or equivalent reading)
- gas pressure and temperature at the inlet of the gas manifold
- gas concentration in the crankcase

Additional measurements may be required in connection with the design assessment.

### 4.1.6 Stage A - internal tests

In addition to tests required in Ch 1, Sec 2, [4.1.6], the following conditions are to be tested:

- DF engines are to run the load points defined in Ch 1, Sec 2, [4.1.6], in both gas and diesel modes (with and without pilot injection in service) as found applicable for the engine type.
- For DF engines with variable liquid / gas ratio, the load tests are to be carried out at different ratios between the minimum and the maximum allowable values.
- For DF engines, switch over between gas and diesel modes are to be tested at different loads.

### 4.1.7 Stage B - witnessed tests

Gas engines are to undergo the different tests required in Ch 1, Sec 2, [4.1.7].

In case of DF engine, all load points must be run in both gas and diesel modes that apply for the engine type as defined by the engine designer (see [4.1.4]). This also applies to the overspeed test.

In case of DF engines with variable liquid / gas ratio, the load tests are to be carried out at different ratios between the minimum and the maximum allowable values.

#### a) Functional tests

In addition to the functional tests required in Ch 1, Sec 2, [4.1.7], item c), the following tests are to be carried out:

- for DF engines, the lowest specified speed is to be verified in diesel mode and gas mode
- for DF engines, switch over between gas and diesel modes are to be tested at different loads
- the efficiency of the ventilation arrangement of the double walled gas piping system is to be verified
- simulation of a gas leakage in way of a cylinder gas supply valve.

Engines intended to produce electrical power are to be tested as follows:

- capability to take sudden load and loss of load in accordance with the provisions of Ch 1, Sec 2, [2.7.6], items c) and d)
- for GF and premixed engines, the influences of LHV, methane number and ambient conditions on the dynamic load response test results are to be theoretically determined and specified in the test report. Referring to the limitations as specified in [2.1.1], the margin for satisfying dynamic load response is to be determined.

Note 1: For DF engines, switchover to oil fuel during the test is acceptable.

Note 2: Application of electrical load in more than 2 load steps can be permitted in the conditions stated in Ch 1, Sec 2, [2.7.5], item d).

#### b) Integration tests

GF and DF engines are to undergo integration tests to verify that the response of the complete mechanical, hydraulic and electronic engine system is as predicted for all intended operational modes. The scope of these tests is to be agreed with the Society for selected cases based on the risk analysis required in [1.4], and is to include at least the following incidents:

- failure of ignition (spark ignition or pilot injection systems), both for one cylinder unit and common system failure
- failure of a cylinder gas supply valve
- failure of the combustion (to be detected by e.g. misfiring, knocking, exhaust temperature deviation, etc.)
- abnormal gas pressure
- abnormal gas temperature

Note 3: Abnormal gas temperature may be carried out using a simulation signal of the temperature.

### 4.1.8 Stage C - Component inspection

Component inspection is to be carried out in accordance with the provisions of Ch 1, Sec 2, [4.1.8]. The components to be inspected after the test run are to include also:

- gas supply valve including pre-chamber as found applicable
- spark igniter (for GF engines)
- pilot fuel injection valve (for DF engines)

## **4.2 Factory acceptance test**

### **4.2.1 General**

Factory acceptance tests of DF and GF engines are to be carried out in accordance with Ch 1, Sec 2, [4.3], taking into account [4.2.2] to [4.2.5].

For DF engines, the load tests referred to in Ch 1, Sec 2, [4.3.3], item c), are to be carried out in gas mode at the different percentages of the maximum power available in gas mode (see [3.1.1]).

### **4.2.2 Safety precautions**

In addition to the safety precautions mentioned in Ch 1, Sec 2, [4.3.1], measures to verify that gas fuel piping on engine is gas tight are to be carried out prior to start-up of the engine.

### **4.2.3 Records**

In addition to the records required in Ch 1, Sec 2, [4.3.3], item b), the following engine data are to be recorded:

- fuel index, both gas and diesel as applicable (or equivalent reading)
- gas pressure and temperature.

### **4.2.4 Test loads**

Test loads for various engine applications are given in Ch 1, Sec 2, [4.3.3], item c). DF engines are to be tested in both diesel and gas mode as found applicable. In addition the scope of the trials may be expanded depending on the engine application, service experience, or other relevant reasons.

### **4.2.5 Integration tests**

GF and DF engines are to undergo integration tests to verify that the response of the complete mechanical, hydraulic and electronic system is as predicted for all intended operational modes.

The scope of these tests is to be agreed with the Society for selected cases based on the risk analysis required in [1.4] and is to include at least the following incidents:

- failure of ignition (spark ignition or pilot injection systems), for one cylinder unit
- failure of a cylinder gas supply valve
- failure of the combustion (to be detected by e.g. misfiring, knocking, exhaust temperature deviation, etc.)
- abnormal gas pressure
- abnormal gas temperature

The above tests may be carried out using simulation or other alternative methods, subject to special consideration by the Society.

## **4.3 Shipboard trials**

**4.3.1** Shipboard trials are to be carried out in accordance with the provisions of Ch 1, Sec 18, [3.5].

For DF engines, the test loads required in Ch 1, Sec 18, [3.5.4] are to be carried out in all operating modes (gas mode, diesel mode, etc.).

For DF engines, the load tests referred to in Ch 1, Sec 18, [3.5.4] are to be carried out in gas mode at the different percentages of the maximum power available in gas mode (see [3.1.1]).

# Appendix 3 Plastic Pipes

## 1 General

### 1.1 Application

**1.1.1** These requirements are applicable to pipes / piping systems made of plastic or made predominantly of other material than metal.

**1.1.2** The use of mechanical joints approved for the use in metallic piping systems only is not permitted.

**1.1.3** Piping systems intended for non-essential services are only required to meet the requirements of recognized standards and [2.1.3], item b), [2.5.2], [3.1.2], [3.1.3], [3.1.4], [3.1.5], [3.1.6], [3.1.7] and Article [4].

### 1.2 Use of plastic pipes

**1.2.1** Plastic may be used in piping systems in accordance with the provisions of Ch 1, Sec 10, [2.1.3], provided the following requirements are complied with.

**1.2.2** Plastic pipes are to be type approved by the Society.

### 1.3 Specifications

**1.3.1** The specification of the plastic piping is to be submitted in accordance with the provisions of Ch 1, Sec 10, [1.2.2]. It is to comply with a recognised national or international standard approved by the Society. In addition, the requirements stated below are to be complied with.

### 1.4 Terms and conditions

#### 1.4.1 Plastic(s)

Plastic(s) includes both thermoplastic and thermosetting plastic materials with or without reinforcement, such as PVC and fibre reinforced plastic (FRP). Plastic includes synthetic rubber and materials of similar thermo/mechanical properties.

#### 1.4.2 Pipes / piping systems

Pipes / piping systems means those made of plastic(s) and include the pipes, fittings, system joints, method of joining and any internal or external liners, coverings and coatings required to comply with the performance criteria.

#### 1.4.3 Joint

Joint means the location at which two pieces of pipe or a pipe and a fitting are connected together. The joint may be made by adhesive bonding, laminating, welding, flanges and mechanical joints according to Ch 1, Sec 10, Fig 2.

#### 1.4.4 Fitting

Fittings means bends, elbows, fabricated branch pieces etc. of plastic materials.

#### 1.4.5 Nominal pressure

Nominal pressure means the maximum permissible working pressure which should be determined in accordance with the requirements in [2.1.3].

#### 1.4.6 Design pressure

Design pressure means the maximum working pressure which is expected under operation conditions or the highest set pressure of any safety valve or pressure relief device on the system, if fitted.

#### 1.4.7 Fire endurance

Fire endurance means the capability of piping to maintain its strength and integrity (i.e. capable of performing its intended function) for some predetermined period of time while exposed to fire.

#### 1.4.8 Essential to the safety of ships

Essential to the safety of ships means all piping systems that in the event of failure will pose a threat to personnel and the ship.

#### 1.4.9 Essential services

Essential services are those services essential to propulsion and steering and safety of the ship as specified in Ch 2, Sec 1, [3.2].

Note 1: Examples for piping systems essential to the safety are provided by Tab 1.

## 2 General requirements

### 2.1 Strength

**2.1.1** The strength of the pipes is to be determined by a hydrostatic test failure pressure of a pipe specimen under the standard conditions: atmospheric pressure equal to 100 kPa, relative humidity 30%, environmental and carried fluid temperature 298 kPa (25°C).

**2.1.2** The strength of fittings and joints is to be not less than that of the pipes.

**2.1.3** The nominal pressure  $P_N$  is to be determined from the following conditions:

a) Internal pressure

For an internal pressure  $P_{N\text{ intr}}$  the following is to be taken whichever is smaller:

- $P_{N\text{ intr}} \leq P_{\text{sth}} / 4$
- $P_{N\text{ intr}} \leq P_{\text{lth}} / 2,5$

where:

$P_{\text{sth}}$  : Short-term hydrostatic test pipe failure pressure

$P_{\text{lth}}$  : Long-term hydrostatic test pipe failure pressure (>100 000 hours)

b) External pressure  $P_{N\text{ extr}}$  (for any installation which may be subject to vacuum conditions inside the pipe or a head of liquid acting on the outside of the pipe; and for any pipe installation required to remain operational in case of flooding damage, as per SOLAS Chapter II-1, Regulation 8-1, as amended, or for any pipes that would allow progressive flooding to other compartments through damaged piping or through open ended pipes in the compartments)

$$P_{N\text{ ext}} \leq P_{\text{col}} / 3$$

where  $P_{\text{col}}$  is the collapse pressure.

In no case is the pipe collapse pressure to be less than 0,3 MPa

The maximum working external pressure is the sum of the vacuum inside the pipe and the static pressure head outside the pipe.

**2.1.4** Notwithstanding the requirements of items a) or b) as applicable, the pipe or pipe layer minimum wall thickness is to follow recognized standards. In the absence of standards for pipes not subject to external pressure, the requirements of item a) above are to be met.

**2.1.5** The maximum permissible working pressure is to be specified with due regard for maximum possible working temperatures in accordance with Manufacturer's recommendations.

### 2.2 Axial strength

**2.2.1** The sum of the longitudinal stresses due to pressure, weight and other loads is not to exceed the allowable stress in the longitudinal direction.

**2.2.2** In the case of fibre reinforced plastic pipes, the sum of the longitudinal stresses is not to exceed half of the nominal circumferential stress derived from the nominal internal pressure condition (see [2.1.3]).

### 2.3 Impact resistance

**2.3.1** Plastic pipes and joints are to have a minimum resistance to impact in accordance with a recognised national or international standard.

After the test the specimen is to be subjected to hydrostatic pressure equal to 2,5 times the design pressure for at least 1 hour.

### 2.4 Temperature

**2.4.1** The permissible working temperature depending on the working pressure is to be in accordance with Manufacturer's recommendations, but in each case it is to be at least 20°C lower than the minimum heat distortion/deflection temperature of the pipe material, determined according to ISO 75-2:2013 method A, or equivalent e.g. ASTM D648-18.

The minimum heat distortion/deflection temperature is to be not less than 80°C.

### 2.5 Requirements depending on service and/or location

#### 2.5.1 Fire endurance

Pipes and their associated joints and fittings whose integrity is essential to the safety of ships, including plastic piping required by SOLAS Chapter II-2, regulation 21.4, as amended, to remain operational after a fire casualty, are required to meet the minimum fire endurance requirements of Appendix 1 or 2, as applicable, of IMO Resolution A.753(18), as amended.

Unless instructed otherwise by the Flag Administration, fire endurance tests are to be carried out with specimen representative for pipes, joints and fittings:

### a) Pipes:

- for sizes with outer diameter < 200 mm: the minimum outer diameter and wall thickness
- for sizes with outer diameter  $\geq$  200 mm: one test specimen for each category of  $t/D$ , with:  
D = outer diameter  
t = structural wall thickness.

A scattering of  $\pm 10\%$  for  $t/D$  is regarded as the same group. Minimum size approved is equal to the diameter of specimen successfully tested.

### b) Joints:

Each type of joint applicable for applied fire endurance level tested on pipe to pipe specimen.

Note 1: A test specimen incorporating several components of a piping system may be tested in a single test.

Note 2: Test conditions are most demanding for minimum wall thickness and thus larger wall thickness is covered. A key factor determining the fire performance of a pipe component variant is the thickness-to-diameter ( $t/D$ ) ratio and whether it is larger or smaller than that of the variant which has been fire-tested.

If fire-protective coatings or layers are included in the variant used in the fire test, only variants with the same or greater thickness of protection, regardless of the ( $t/D$ ) ratio, are to be qualified by the fire test.

Means are to be provided to ensure a constant media pressure inside the test specimen during the fire test as specified in Ch 1, App 1 or Ch 1, App 2 of the IMO Res.A.753(18), as amended. During the test it is not permitted to replace media drained by fresh water or nitrogen.

Depending on the capability of a piping system to maintain its strength and integrity, there exist three different levels of fire endurance for piping systems:

- Level 1. Piping having passed the fire endurance test specified in Appendix 1 of IMO Resolution A.753(18), as amended, for a duration of a minimum of one hour without loss of integrity in the dry condition is considered to meet level 1 fire endurance standard (L1).  
Level 1W - Piping systems similar to Level 1 systems except these systems do not carry flammable fluid or any gas and a maximum 5% flow loss in the system after exposure is acceptable (L1W).
- Level 2. Piping having passed the fire endurance test specified in Appendix 1 of IMO Resolution A.753(18), as amended, for a duration of a minimum of 30 minutes in the dry condition is considered to meet level 2 fire endurance standard (L2).  
Level 2W - Piping systems similar to Level 2 systems except a maximum 5% flow loss in the system after exposure is acceptable (L2W).
- Level 3. Piping having passed the fire endurance test specified in Appendix 2 of IMO Resolution A.753(18) for a duration of a minimum of 30 minutes in the wet condition is considered to meet level 3 fire endurance standard (L3).

Permitted use of piping depending on fire endurance, location and piping system is given in Tab 1.

For Safe Return to Port purposes (SOLAS Chapter II-2, Regulation 21.4), plastic piping can be considered to remain operational after a fire casualty if the plastic pipes and fittings have been tested to L1 standard.

### 2.5.2 Flame spread

- All pipes, except those fitted on open decks and within tanks, cofferdams, pipe tunnels, and ducts if separated from accommodation, permanent manned areas and escape ways by means of an A class bulkhead are to have low surface flame spread characteristics not exceeding average values listed in Appendix 3 of IMO Resolution A.753(18), as amended.
- Surface flame spread characteristics are to be determined using the procedure given in the 2010 FTP Code, Annex 1, Part 5 with regard to the modifications due to the curvilinear pipe surfaces as also listed in Appendix 3 of IMO Resolution A.753(18), as amended.
- Surface flame spread characteristics may also be determined using the test procedures given in ASTM D635-18, or in other national equivalent standards. Under the procedure of ASTM D635-18 a maximum burning rate of 60 mm/min applies. In case of adoption of other national equivalent standards, the relevant acceptance criteria are to be defined.

### 2.5.3 Fire protection coating

Where a fire protective coating of pipes and fittings is necessary for achieving the fire endurance level required, it is to meet the following requirements:

- The pipes are generally to be delivered from the manufacturer with the protective coating on.
- The fire protection properties of the coating are not to be diminished when exposed to salt water, oil or bilge slops. It is to be demonstrated that the coating is resistant to products likely to come into contact with the piping.
- In considering fire protection coatings, such characteristics as thermal expansion, resistance against vibrations and elasticity are to be taken into account.
- The fire protection coatings are to have sufficient resistance to impact to retain their integrity.

### 2.5.4 Electrical conductivity

Where electrical conductivity is to be ensured, the resistance of the pipes and fittings is not to exceed  $1 \cdot 10^5$  Ohm/m.

Table 1 : Fire endurance of piping systems

PIPING SYSTEM	LOCATION (13)										
	Machinery spaces of category A (14)	Other machinery spaces and pump rooms (15)	Cargo pump rooms (16)	Ro-Ro cargo holds (17)	Other dry cargo holds (18)	Cargo tanks (19)	Fuel oil tanks (20)	Ballast water tanks (21)	Cofferdams, void spaces, pipe tunnels (22)	Accommodation, service and control spaces (23)	Open decks (24)

Urea transfer / supply system (SCR installations)	L1 (12)	L1 (12)	NA	NA	NA	NA	NA	NA	0	L3 (1) (11) NA	0

**Note 1:**

- L1 : Fire endurance test (appendix 1 of IMO Resolution A.753(18), as amended) in dry conditions, 60 min
  - L1W : Fire endurance test (see [2.5.1])
  - L2 : Fire endurance test (appendix 1 of IMO Resolution A.753(18), as amended) in dry conditions, 30 min
  - L2W : Fire endurance test (see [2.5.1])
  - L3 : Fire endurance test (appendix 2 of IMO Resolution A.753(18), as amended) in wet conditions, 30 min
  - 0 : No fire endurance test required
  - NA : Not applicable
  - X : Metallic materials having a melting point greater than 925°C
- (1) Where non-metallic piping is used, remote controlled valves to be provided at ship side (valve is to be controlled from outside space).
  - (2) Remote closing valves to be provided at the cargo tanks.
  - (3) When cargo tanks contain flammable liquids with flash point  $> 60$  °C, "0" may replace "NA" or "X".
  - (4) For drains serving only the space concerned, "0" may replace "L1W".
  - (5) When controlling functions are not required by the Rules, "0" may replace "L1".
  - (6) For pipes between machinery space and deck water seal, "0" may replace "L1".
  - (7) For passenger vessels, "X" is to replace "L1".
  - (8) Scuppers serving open decks in positions 1 and 2, as defined in Pt B, Ch 1, Sec 3, are to be "X" throughout unless fitted at the upper end with a means of closing capable of being operated from a position above the freeboard deck in order to prevent downflooding.
  - (9) For essential services, such as fuel oil tank heating and ship's whistle, "X" is to replace "0".
  - (10) For tankers required to comply with Pt D, Ch 7, Sec 4, [2.1.3], "NA" is to replace "0".
  - (11) L3 in service spaces, NA in accommodation and control spaces.
  - (12) Type Approved plastic piping without fire endurance test (0) is acceptable downstream of the tank valve, provided this valve is metal seated and arranged as fail-to-closed or with quick closing from a safe position outside the space in the event of fire.
  - (13) For passenger Ships subject to SOLAS Chapter II-2, Regulation 21.4 (Safe return to Port), plastic pipes for services required to remain operational in the part of the ship not affected by the casualty thresholds, such as systems intended to support safe areas, are to be considered essential services. In accordance with IMO Circular MSC.1/Circ.1369, interpretation 12, for Safe Return to Port purposes, plastic piping can be considered to remain operational after a fire casualty if the plastic pipes and fittings have been tested to L1 standard.
  - (14) Machinery spaces of category A are defined in Ch 4, Sec 1, [2.29.1].
  - (15) Spaces, other than category A machinery spaces and cargo pumps rooms, containing propulsion machinery, boilers, fuel oil units, steam and internal combustion engines, generators and major electrical machinery, oil filling stations, refrigerating, stabilizing, ventilation and air-conditioning machinery, and similar spaces, and trunks to such spaces.
  - (16) Spaces containing cargo pumps, and entrances and trunks to such spaces.
  - (17) Ro-ro cargo spaces and special category spaces are defined in Ch 4, Sec 1, [2].
  - (18) All spaces other than ro-ro cargo holds used for non-liquid cargo and trunks to such spaces.
  - (19) All spaces used for liquid cargo and trunks to such spaces.
  - (20) All spaces used for fuel oil (excluding cargo tanks) and trunks to such spaces.
  - (21) All spaces used for ballast water and trunks to such spaces.
  - (22) Cofferdams and voids are those empty spaces between two bulkheads separating two adjacent compartments.
  - (23) Accommodation spaces, service spaces and control stations are defined in Ch 4, Sec 1, [2].
  - (24) Open decks are defined in Ch 4, Sec 5, [1.3.3], item b), 2).

### 3 Material approval and quality control during manufacture

#### 3.1 General

**3.1.1** Except as required in [1.1.3], prototypes of pipes and fittings are to be tested to determine short-term and long-term design strength, fire endurance and low surface flame spread characteristics (if applicable), electrical resistance (for electrically conductive pipes), impact resistance in accordance with the requirements of this Appendix.

**3.1.2** For prototype testing representative samples of pipes and fittings are to be selected to the satisfaction of the Society.

**3.1.3** The Manufacturer is to have quality system that meets ISO 9001:2015 standards or equivalent. The quality system is to consist of elements necessary to ensure that pipes and fittings are produced with consistent and uniform mechanical and physical properties.

**3.1.4** Each pipe and fitting is to be tested by the Manufacturer at a hydrostatic pressure not less than 1,5 times the nominal pressure. Alternatively, for pipes and fittings not employing hand lay up techniques, the hydrostatic pressure test may be carried out in accordance with the hydrostatic testing requirements stipulated in the recognised national or international standard to which the pipe or fittings are manufactured, provided that there is an effective quality system in place.

**3.1.5** Piping and fittings are to be permanently marked with identification. Identification is to include pressure ratings, the design standards that the pipe or fitting is manufactured in accordance with, and the material of which the pipe or fitting is made.

**3.1.6** In case the Manufacturer does not have an approved quality system complying with ISO 9001:2015 or equivalent, pipes and fittings are to be tested in accordance with this Appendix to the satisfaction of the Surveyors for every batch of pipes.

**3.1.7** Depending upon the intended application a Society may require the pressure testing of each pipe and/or fitting.

### 4 Arrangement and installation of plastic pipes

#### 4.1 Supports

**4.1.1** Selection and spacing of pipe supports in shipboard systems are to be determined as a function of allowable stresses and maximum deflection criteria. Support spacing is not to be greater than the pipe Manufacturer's recommended spacing. The selection and spacing of pipe supports are to take into account pipe dimensions, length of the piping, mechanical and physical properties of the pipe material, mass of pipe and contained fluid, external pressure, operating temperature, thermal expansion effects, loads due to external forces, thrust forces, water hammer, vibrations, maximum accelerations to which the system may be subjected.

Combination of loads is to be considered.

**4.1.2** Each support is to evenly distribute the load of the pipe and its content over the full width of the support. Measures are to be taken to minimise wear of the pipes where they are in contact with the supports.

**4.1.3** Heavy components in the piping system such as valves and expansion joints are to be independently supported.

#### 4.2 Expansion

**4.2.1** Suitable provision is to be made in each pipeline to allow for relative movement between pipes made of plastic and the steel structure, having due regard to:

- the high difference in the coefficients of thermal expansion
- deformations of the ship's structure.

**4.2.2** Calculations of the thermal expansions are to take into account the system working temperature and the temperature at which the assembly is performed.

#### 4.3 External loads

**4.3.1** When installing the piping, allowance is to be made for temporary point loads, where applicable. Such allowance is to include at least the force exerted by a load (person) of 100 kg at mid-span on any pipe of more than 100 mm nominal outside diameter.

**4.3.2** Besides for providing adequate robustness for all piping including open-ended piping a minimum wall thickness, complying with [2.1], may be increased taking into account the conditions encountered during service on board ships.

**4.3.3** Pipes are to be protected from mechanical damage where necessary.

## **4.4 Strength of connections**

### **4.4.1 General**

- a) The strength of connections is not to be less than that of the piping system in which they are installed.
- b) Pipes and fittings may be assembled using adhesive-bonded, welded, flanged or other joints.
- c) When used for joint assembly, adhesives are to be suitable for providing a permanent seal between the pipes and fittings throughout the temperature and pressure range of the intended application.
- d) Tightening of joints, where required, is to be performed in accordance with the manufacturer's instructions.

## **4.5 Installation of conductive pipes**

**4.5.1** In piping systems for fluids with conductivity less than 1000 pico siemens per metre (pS/m) such as refined products and distillates use is to be made of conductive pipes.

Regardless of the fluid being conveyed, plastic piping is to be electrically conductive if the piping passes through a hazardous area. The resistance to earth from any point in the piping system is not to exceed  $1 \times 10^6$  Ohm. It is preferred that pipes and fittings be homogeneously conductive. Pipes and fittings having conductive layers are to be protected against a possibility of spark damage to the pipe wall. Satisfactory earthing is to be provided.

After completion of the installation, the resistance to earth is to be verified. Earthing wires are to be accessible for inspection

## **4.6 Application of fire protection coatings**

**4.6.1** Where necessary for the required fire endurance as stated in [2.5.3], fire protection coatings are to be applied on the joints, after performing hydrostatic pressure tests of the piping system.

**4.6.2** The fire protection coatings are to be applied in accordance with the manufacturer's recommendations, using a procedure approved in each case.

## **4.7 Penetration of fire divisions and watertight bulkheads or decks**

**4.7.1** Where plastic pipes pass through "A" or "B" class divisions, arrangements are to be made to ensure that fire endurance is not impaired. These arrangements are to be tested in accordance with 'Recommendations for Fire Test Procedures for "A", "B" and "F" Bulkheads' 2010 FTP Code, annex 1, part 3, as amended.

**4.7.2** When plastic pipes pass through watertight bulkheads or decks, the watertight integrity of the bulkhead or deck is to be maintained. For pipes not able to satisfy the requirements in [2.1.3] item b), a metallic shut-off valve operable from above the freeboard deck should be fitted at the bulkhead or deck.

**4.7.3** If the bulkhead or deck is also a fire division and destruction by fire of plastic pipes may cause the inflow of liquid from tanks, a metallic shut-off valve operable from above the freeboard deck is to be fitted at the bulkhead or deck.

## **4.8 Control during installation**

### **4.8.1 General**

- a) Installation is to be in accordance with the Manufacturer's guidelines.
- b) Prior to commencing the work, joining techniques are to be approved by the Society.
- c) The tests and explanations specified in the present Appendix are to be completed before shipboard piping installation commences.
- d) The personnel performing this work are to be properly qualified and certified to the satisfaction of the Society.
- e) The procedure for making bonds is to be submitted to the Society for qualification. It is to include the following:
  - materials used
  - tools and fixtures
  - joint preparation requirements
  - cure temperature
  - dimensional requirements and tolerances
  - acceptance criteria for the test of the completed assembly
- f) Any change in the bonding procedure which will affect the physical and mechanical properties of the joint is to require the procedure to be requalified.

#### **4.8.2 Bonding qualification test**

- a) A test assembly is to be fabricated in accordance with the procedure to be qualified. It is to consist of at least one pipe-to-pipe joint and one pipe-to-fitting joint.
- b) When the test assembly has been cured, it is to be subjected to a hydrostatic test pressure at a safety factor of 2,5 times the design pressure of the test assembly, for not less than one hour. No leakage or separation of joints is allowed. The test is to be conducted so that the joint is loaded in both longitudinal and circumferential directions.
- c) Selection of the pipes used for the test assembly is to be in accordance with the following:
  - when the largest size to be joined is 200 mm nominal outside diameter or smaller, the test assembly is to be the largest piping size to be joined.
  - when the largest size to be joined is greater than 200 mm nominal outside diameter, the size of the test assembly is to be either 200 mm or 25% of the largest piping size to be joined, whichever is the greater.
- d) When conducting performance qualifications, each bonder and each bonding operator are to make up test assemblies, the size and number of which are to be as required above.

#### **4.9 Testing after installation on board**

**4.9.1** Piping systems for essential services are to be subjected to a test pressure not less than 1,5 times the design pressure or 4 bar whichever is greater. Notwithstanding the requirement above, the requirement in [4.9.2] may be applied to open ended pipes (drains, effluent, etc.).

**4.9.2** Piping systems for non-essential services are to be checked for leakage under operational conditions.

**4.9.3** For piping required to be electrically conductive, earthing is to be checked, and random resistance testing is to be conducted.

### **5 Test specification for plastic pipes**

#### **5.1 Scope**

**5.1.1** This Article contains requirements for the type approval of plastic pipes. It is applicable to piping systems, including pipe joints and fittings, made predominately of other material than metal.

#### **5.2 Documentation**

**5.2.1** The following information for the plastic pipes, fittings and joints is to be submitted for consideration and approval:

- a) General information
  - pipe and fitting dimensions
  - maximum internal and external working pressure
  - working temperature range
  - intended services and installation locations
  - the level of fire endurance
  - electrically conductive
  - intended fluids
  - limits on flow rates
  - serviceable life
  - installation instructions
  - details of marking.
- b) Drawings and supporting documentation
  - certificates and reports for relevant tests previously carried out
  - details of relevant standards
  - all relevant design drawings, catalogues, data sheets, calculations and functional descriptions
  - fully detailed sectional assembly drawings showing pipe, fittings and pipe connections.

c) Materials (as applicable)

- the resin type
- catalyst and accelerator types, and concentration employed in the case of reinforced polyester resin pipes or hardeners where epoxide resins are employed
- a statement of all reinforcements employed where the reference number does not identify the mass per unit area or the tex number of a roving used in a filament winding process, these are to be detailed
- full information regarding the type of gel-coat or thermoplastic liner employed during construction, as appropriate
- cure/post-cure conditions. The cure and post-cure temperatures and times employ resin/reinforcement ratio
- winding angle and orientation
- Joint bonding procedures and qualification tests results, see [4.8.1], item e).

**5.3 Testing**

**5.3.1** Testing is to demonstrate compliance of the pipes, fittings and joints for which type approval is sought with the present Appendix.

Pipes, joints and fittings are to be tested for compliance with the requirements of recognized standards acceptable to the Society. In that order, recommended standards are given in Tab 2 and Tab 3.

**Table 2 : Typical requirements for all systems**

No.	Test	Typical standard	Notes
1	Internal pressure (1)	<ul style="list-style-type: none"> <li>• the present [2.1.3], item a)</li> <li>• ASTM D 1599-18</li> <li>• ASTM D 2992-18</li> <li>• ISO 15493:2003</li> </ul> or equivalent	Top, middle, bottom (of range) Tests are to be carried out on pipe spools made of different pipe sizes, fittings and pipe connections
2	External pressure (1)	<ul style="list-style-type: none"> <li>• the present [2.1.3], item b)</li> <li>• ISO 15493:2003</li> </ul> or equivalent	As above, for straight pipes only
3	Axial strength	the present [2.2]	As above
4	Load deformation	ASTM D 2412-21 or equivalent	Top, middle, bottom (of each pressure range)

# Appendix 4 Type Testing Procedure for Crankcase Explosion Relief Valves

## 1 General

### 1.1 Scope

**1.1.1** This appendix specifies type tests and identifies standard test conditions using methane gas and air mixture to demonstrate the Society requirements are satisfied for crankcase explosion relief valves intended to be fitted to engines and gear cases.

**1.1.2** This test procedure is only applicable to explosion relief valves fitted with flame arresters.

Note 1: Where internal oil wetting of a flame arrester is a design feature of an explosion relief valve, alternative testing arrangements that demonstrate compliance with this appendix may be proposed by the manufacturer. The alternative testing arrangements are to be agreed by the Society.

### 1.2 Recognised standards

**1.2.1** The following standards are considered as recognised standards:

- ISO 16852:2016
- ISO/IEC 17025:2017
- ISO 12100:2010
- VDI 3673-1:2002
- IMO MSC/Circ.677 as amended by MSC/Circ.1009 and MSC.1/Circ.1324.

### 1.3 Purpose

**1.3.1** The purpose of type testing crankcase explosion relief valves is fourfold:

- To verify the effectiveness of the flame arrester
- To verify that the valve closes after an explosion
- To verify that the valve is gas/air tight after an explosion
- To establish the level of over pressure protection provided by the valve.

### 1.4 Approval

**1.4.1** The approval of explosion relief valves is at the discretion of the Society based on the appraisal of plans and particulars and the test facility's report of the results of type testing.

## 2 Type testing procedure

### 2.1 Test facilities

**2.1.1** Test houses carrying out type testing of crankcase explosion relief valves are to meet the following requirements:

- a) The test houses where testing is carried out are to be accredited to a National or International Standard, e.g. ISO/IEC 17025:2017, and are to be acceptable to the Society.
- b) The test facilities are to be equipped so that they can perform and record explosion testing in accordance with this procedure
- c) The test facilities are to have equipment for controlling and measuring a methane gas in air concentration within a test vessel to an accuracy of  $\pm 0.1\%$
- d) The test facilities are to be capable of effective point-located ignition of a methane gas in air mixture
- e) The pressure measuring equipment is to be capable of measuring the pressure in the test vessel in at least two positions, one at the valve and the other at the test vessel centre. The measuring arrangements are to be capable of measuring and recording the pressure changes throughout an explosion test at a frequency recognising the speed of events during an explosion. The result of each test is to be documented by video recording and by recording with a heat sensitive camera
- f) The test vessel for explosion testing is to have documented dimensions. The dimensions are to be such that the vessel is not "pipe like" with the distance between dished ends being not more than 2.5 times its diameter. The internal volume of the test vessel is to include any standpipe arrangements

- g) The test vessel is to be provided with a flange, located centrally at one end perpendicular to the vessel longitudinal axis, for mounting the explosion relief valve.  
The test vessel is to be arranged in an orientation consistent with how the valve will be installed in service, i.e., in the vertical plane or the horizontal plane
- h) A circular plate is to be provided for fitting between the pressure vessel flange and valve to be tested with the following dimensions:
- 1) Outside diameter of 2 times the outer diameter of the valve top cover
  - 2) Internal bore having the same internal diameter as the valve to be tested
- i) The test vessel is to have connections for measuring the methane in air mixture at the top and bottom
- j) The test vessel is to be provided with a means of fitting an ignition source at a position specified in [2.2.3].
- k) The test vessel volume is to be as far as practicable, related to the size and capability of the relief valve to be tested. In general, the volume is to correspond to the requirement in Ch 1, Sec 2, [2.3.4], d) for the free area of explosion relief valve to be not less than  $115 \text{ cm}^2/\text{m}^3$  of crankcase gross volume.

Note 1: This means that the testing of a valve having  $1150 \text{ cm}^2$  of free area, would require a test vessel with a volume of  $10 \text{ m}^3$ .

Note 2: Where the free area of relief valves is greater than  $115 \text{ cm}^2/\text{m}^3$  of the crankcase gross volume, the volume of the test vessel is to be consistent with the design ratio.

Note 3: In no case is the volume of the test vessel to vary by more than +15% to -15% from the design  $\text{cm}^2/\text{m}^3$  volume ratio.

## 2.2 Explosion test process

**2.2.1** All explosion tests to verify the functionality of crankcase explosion relief valves are to be carried out using an air and methane mixture with a volumetric methane concentration of  $9.5\% \pm 0.5\%$ . The pressure in the test vessel is to be not less than atmospheric and is not to exceed the opening pressure of the relief valve.

**2.2.2** The concentration of methane in the test vessel is to be measured at the top and bottom of the vessel and these concentrations are not to differ by more than 0.5%.

**2.2.3** The ignition of the methane and air mixture is to be made at the centreline of the test vessel at a position approximately one third of the height or length of the test vessel opposite to where the valve is mounted.

**2.2.4** The ignition is to be made using a maximum 100 joule explosive charge.

## 2.3 Valves to be tested

**2.3.1** The valves used for type testing (including testing specified in [2.3.3]) are to be selected from the manufacturer's normal production line for such valves by the classification society witnessing the tests.

**2.3.2** For approval of a specific valve size, three valves are to be tested in accordance with [2.3.3] and [2.4]. For a series of valves see [2.6].

**2.3.3** The valves selected for type testing are to have been previously tested at the manufacturer's works to demonstrate that the opening pressure is in accordance with the specification within a tolerance of  $\pm 20\%$  and that the valve is air tight at a pressure below the opening pressure for at least 30 seconds.

Note 1: This test is to verify that the valve is air tight following assembly at the manufacturer's works and that the valve begins to open at the required pressure demonstrating that the correct spring has been fitted.

**2.3.4** The type testing of valves is to recognise the orientation in which they are intended to be installed on the engine or gear case. Three valves of each size are to be tested for each intended installation orientation, i.e. in the vertical and/or horizontal positions.

## 2.4 Method

**2.4.1** The following requirements are to be satisfied at explosion testing:

- a) The explosion testing is to be witnessed by a classification society surveyor
- b) Where valves are to be installed on an engine or gear case with shielding arrangements to deflect the emission of explosion combustion products, the valves are to be tested with the shielding arrangements fitted
- c) Successive explosion testing to establish a valve's functionality is to be carried out as quickly as possible during stable weather conditions
- d) The pressure rise and decay during all explosion testing is to be recorded
- e) The external condition of the valves is to be monitored during each test for indication of any flame release by video and heat sensitive camera

**2.4.2** The explosion testing is to be in three stages for each valve that is required to be approved as being type tested.

a) Stage 1:

Two explosion tests are to be carried out in the test vessel with the circular plate described in [2.1.1] h) fitted and the opening in the plate covered by a 0.05 mm thick polythene film

Note 1: These tests establish a reference pressure level for determination of the capability of a relief valve in terms of pressure rise in the test vessel, see [2.5.1] f).

b) Stage 2:

- 1) Two explosion tests are to be carried out on three different valves of the same size. Each valve is to be mounted in the orientation for which approval is sought i.e., in the vertical or horizontal position with the circular plate described in [2.1.1] h) located between the valve and pressure vessel mounting flange
- 2) The first of the two tests on each valve is to be carried out with a 0.05mm thick polythene bag, having a minimum diameter of three times the diameter of the circular plate and volume not less than 30% of the test vessel, enclosing the valve and circular plate. Before carrying out the explosion test the polythene bag is to be empty of air. The polythene bag is required to provide a readily visible means of assessing whether there is flame transmission through the relief valve following an explosion consistent with the requirements of the standards identified in [1.2]

Note 2: During the test, the explosion pressure will open the valve and some unburned methane/air mixture will be collected in the polythene bag. When the flame reaches the flame arrester and if there is flame transmission through the flame arrester, the methane/air mixture in the bag will be ignited and this will be visible.

- 3) Provided that the first explosion test successfully demonstrated that there was no indication of combustion outside the flame arrester and there are no visible signs of damage to the flame arrester or valve, a second explosion test without the polythene bag arrangement is to be carried out as quickly as possible after the first test. During the second explosion test, the valve is to be visually monitored for any indication of combustion outside the flame arrester and video records are to be kept for subsequent analysis. The second test is required to demonstrate that the valve can still function in the event of a secondary crankcase explosion
- 4) After each explosion, the test vessel is to be maintained in the closed condition for at least 10 seconds to enable the tightness of the valve to be ascertained. The tightness of the valve can be verified during the test from the pressure/time records or by a separate test after completing the second explosion test

c) Stage 3:

Carry out two further explosion tests as described in Stage 1. These further tests are required to provide an average baseline value for assessment of pressure rise, recognising that the test vessel ambient conditions may have changed during the testing of the explosion relief valves in Stage 2.

## **2.5 Assessment and records**

**2.5.1** For the purposes of verifying compliance with the requirements of this Section, the assessment and records of the valves used for explosion testing is to address the following:

- a) The valves to be tested are to have evidence of design appraisal/approval by the classification society witnessing tests
- b) The designation, dimensions and characteristics of the valves to be tested are to be recorded. This is to include the free area of the valve and of the flame arrester and the amount of valve lift at 0.2bar
- c) The test vessel volume is to be determined and recorded
- d) For acceptance of the functioning of the flame arrester there is not to be any indication of flame or combustion outside the valve during an explosion test. This should be confirmed by the test laboratory taking into account measurements from the heat sensitive camera
- e) The pressure rise and decay during an explosion is to be recorded, with indication of the pressure variation showing the maximum overpressure and steady underpressure in the test vessel during testing. The pressure variation is to be recorded at two points in the pressure vessel
- f) The effect of an explosion relief valve in terms of pressure rise following an explosion is ascertained from maximum pressures recorded at the centre of the test vessel during the three stages. The pressure rise within the test vessel due to the installation of a relief valve is the difference between average pressure of the four explosions from Stages 1 and 3 and the average of the first tests on the three valves in Stage 2. The pressure rise is not to exceed the limit specified by the manufacturer
- g) The valve tightness is to be ascertained by verifying from the records at the time of testing that an underpressure of at least 0.3bar is held by the test vessel for at least 10 seconds following an explosion. This test is to verify that the valve has effectively closed and is reasonably gas-tight following dynamic operation during an explosion
- h) After each explosion test in Stage 2, the external condition of the flame arrester is to be examined for signs of serious damage and/or deformation that may affect the operation of the valve
- i) After completing the explosion tests, the valves are to be dismantled and the condition of all components ascertained and documented. In particular, any indication of valve sticking or uneven opening that may affect operation of the valve is to be noted. Photographic records of the valve condition are to be taken and included in the report.

## 2.6 Design series qualification

**2.6.1** The qualification of quenching devices to prevent the passage of flame can be evaluated for other similar devices of identical type where one device has been tested and found satisfactory.

**2.6.2** The quenching ability of a flame arrester depends on the total mass of quenching lamellas/mesh. Provided the materials, thickness of materials, depth of lamellas/thickness of mesh layer and the quenching gaps are the same, then the same quenching ability can be qualified for different sizes of flame arresters satisfying:

$$\frac{n_1}{n_2} = \sqrt{\frac{S_1}{S_2}}$$

and

$$\frac{A_1}{A_2} = \frac{S_1}{S_2}$$

where:

- $n_1$  : total depth of flame arrester corresponding to the number of lamellas of size 1 quenching device for a valve with a relief area equal to  $S_1$
- $n_2$  : total depth of flame arrester corresponding to the number of lamellas of size 2 quenching device for a valve with a relief area equal to  $S_2$
- $A_1$  : free area of quenching device for a valve with a relief area equal to  $S_1$
- $A_2$  : free area of quenching device for a valve with a relief area equal to  $S_2$

**2.6.3** The qualification of explosion relief valves of larger sizes than that which has been previously satisfactorily tested in accordance with [2.4] and [2.5] can be evaluated where valves are of identical type and have identical features of construction subject to the following:

- a) The free area of a larger valve does not exceed three times + 5% that of the valve that has been satisfactorily tested
- b) One valve of the largest size, see a), requiring qualification is subject to satisfactory testing required by [2.3.3] and [2.4.2], b) except that a single valve will be accepted in [2.4.2], b), 1) and the volume of the test vessel is not to be less than one third of the volume required by [2.1.1], k)
- c) The assessment and records are to be in accordance with [2.5] noting that [2.5.1], f) will only be applicable to Stage 2 (see [2.4.2]) for a single valve.

**2.6.4** The qualification of explosion relief valves of smaller sizes than that which has been previously satisfactorily tested in accordance with [2.4] and [2.5] can be evaluated where valves are of identical type and have identical features of construction subject to the following:

- a) The free area of a smaller valve is not less than one third of the valve that has been satisfactorily tested
- b) One valve of the smallest size, subject to a), requiring qualification is subject to satisfactory testing required by [2.3.3] and [2.4.2], b) except that a single valve will be accepted in [2.4.2], b), 1) and the volume of the test vessel is not to be more than the volume required by [2.1.1], k)
- c) The assessment and records are to be in accordance with article [2.5] noting that [2.5.1], f) will only be applicable to Stage 2 for a single valve.

## 2.7 Report

**2.7.1** The test facility is to deliver a full report that includes the following information and documents:

- Test specification
- Details of test pressure vessel and valves tested
- The orientation in which the valve was tested, (vertical or horizontal position).
- Methane in air concentration for each test
- Ignition source
- Pressure curves for each test
- Video recordings of each valve test
- The assessment and records stated in [2.5].

# Appendix 5 Type Approval of Mechanical Joints

## 1 General

### 1.1 Scope

**1.1.1** This specification describes the type testing condition for type approval of mechanical joints intended for use in marine piping systems. Conditions outlined in these requirements are to be fulfilled before Type Approval Certificates are issued.

**1.1.2** The Society may accept alternative testing in accordance with national or international standards where applicable to the intended use and application.

**1.1.3** This specification is applicable to mechanical joints defined in Ch 1, Sec 10, [2.4.5] including compression couplings and slip-on joints of different types for marine use.

### 1.2 Documentation

**1.2.1** Following documents and information are to be submitted by Manufacturer for assessment and/or approval:

- product quality assurance system implemented
- complete description of the product
- typical sectional drawings with all dimensions necessary for evaluation of joint design
- complete specification of materials used for all components of the assembly
- proposed test procedure as required in [2] and corresponding test reports or other previous relevant tests
- initial information:
  - maximum design pressures (pressure and vacuum)
  - maximum and minimum design temperatures
  - conveyed media
  - intended services
  - maximum axial, lateral and angular deviation, allowed by manufacturer
  - installation details.

### 1.3 Materials

**1.3.1** The materials used for mechanical joints are to comply with the requirements of Ch 1, Sec 10, [2.4.5].

The manufacturer has to submit evidence to substantiate that all components are adequately resistant to working the media at design pressure and temperature specified.

## 2 Testing, procedures and requirements

### 2.1 Aim of the tests

**2.1.1** The aim of tests is to demonstrate ability of the pipe joints to operate satisfactory under intended service conditions. The scope and type of tests to be conducted e.g. applicable tests, sequence of testing, and the number of specimen, is subject to approval and will depend on joint design and its intended service in accordance with the requirements of Ch 1, Sec 10.

### 2.2 Test fluid

**2.2.1** Unless otherwise specified, the water or oil as test fluid is to be used.

### 2.3 Test program

**2.3.1** Testing requirements for mechanical joints are to be as indicated in Tab 1.

### 2.4 Selection of test specimen

**2.4.1** Test specimens are to be selected from production line or at random from stock.

Where there is a variety of size of joints requiring approval, a minimum of three separate sizes, representative of the range, from each type of joint to be tested in accordance with in Tab 1.

## 2.5 Mechanical joint assembly

**2.5.1** Assembly of mechanical joints is to consist of components selected in accordance with [2.4.1] and the pipe sizes appropriate to the design of the joints.

**2.5.2** Where pipe material would affect the performance of mechanical joints, the selection of joints for testing is to take the pipe material into consideration.

**2.5.3** Where not specified, the length of pipes to be connected by means of the joint to be tested is to be at least five times the pipe diameter. Before assembling the joint, conformity of components to the design requirements is to be verified. In all cases the assembly of the joint is to be carried out only according to the manufacturer's instructions. No adjustment operations on the joint assembly, other than that specified by the manufacturer, are permitted during the test.

## 2.6 Test results acceptance criteria

**2.6.1** Where a mechanical joint assembly does not pass all or any part of the tests in Tab 1, two assemblies of the same size and type that failed are to be tested and only those tests which the mechanical joint assembly failed in the first instance, are to be repeated. In the event where one of the assemblies fails the second test, that size and type of assembly is to be considered unacceptable.

**2.6.2** The methods and results of each test are to be recorded and reproduced as and when required.

**Table 1 : Tests for mechanical joints**

Tests	Type of mechanical joint			Notes and references
	Compression couplings and pipes unions	Slip on joints		
		Grid type and machine grooved type	Slip type	
1 Tightness test	+	+	+	[2.7.1]
2 Vibration (fatigue) test	+	+	-	[2.7.2]
3 Pressure pulsation test (1)	+	+	-	[2.7.3]
4 Burst pressure test	+	+	+	[2.7.4]
5 Pull-out test	+	+	-	[2.7.5]
6 Fire endurance test	+	+	+	[2.7.6] if required by Ch 1, Sec 10, Tab 17
7 Vacuum test	+ (3)	+	+	[2.7.7] for suction line only
8 Repeated assembly test	+ (2)	+	-	[2.7.8]

+ : test is required  
 - : test is not required  
 (1) for use in those systems where pressure pulsation other than water hammer is expected  
 (2) except press type and swage type  
 (3) except joints with metal-to-metal tightening surfaces

## 2.7 Methods of tests

### 2.7.1 Tightness test

In order to ensure correct assembly and tightness of the joints, all mechanical joints are to be subjected to a tightness test, as follows:

- The mechanical joint assembly test specimen is to be connected to the pipe or tubing in accordance with the requirements of [2.5] and the manufacturers instructions, filled with test fluid and de-aerated.  
 Mechanical joints assemblies intended for use in rigid connections of pipe lengths, are not to be longitudinally restrained. The pressure inside the joint assembly is to be slowly increased to 1,5 times of design pressure. This test pressure is to be retained for a minimum period of 5 minutes.  
 In the event of a drop in pressure or visible leakage, the test (including fire test) is to be repeated for two further specimens. If during the repeat test one test piece fails, the coupling is regarded as having failed.  
 Other alternative tightness test procedure, such as pneumatic test, may be accepted.
- For compression couplings a static gas pressure test is to be carried out to demonstrate the integrity of the mechanical joints assembly for tightness under the influence of gaseous media. The pressure is to be raised to maximum pressure or 70 bar whichever is less.
- Where the tightness test is carried out using gaseous media as permitted in a) above, then the static pressure test mentioned in b) above need not be carried out.

2.7.2 Vibration (fatigue) test

In order to establish the capability of the mechanical joint assembly to withstand fatigue, which is likely to occur due to vibrations under service conditions, mechanical joints assemblies are to be subject to the following vibration test.

Conclusions of the vibration tests should show no leakage or damage.

a) Testing of compression couplings and pipe unions

Compression couplings and pipe unions intended for use in rigid pipe connections are to be tested as follows. Rigid connections are joints, connecting pipe length without free angular or axial movement.

Two lengths of pipe are to be connected by means of the joint to be tested. One end of the pipe is to be rigidly fixed while the other end is to be fitted to the vibration rig. The test rig and the joint assembly specimen being tested are to be arranged as shown in Fig 1.

Figure 1 : Testing of compression couplings and pipe unions

The joint assembly is to be filled with test fluid, de-aerated and pressurised to the design pressure of the joint.

Pressure during the test is to be monitored. In the event of a drop in the pressure and visible leakage, the test is to be repeated as described in [2.6].

Visual examination of the joint assembly is to be carried out.

Re-tightening may be accepted once during the first 1000 cycles.

Vibration amplitude is to be within 5% of the value calculated from the following formula:

$$A = \frac{2SL^2}{3ED}$$

where:

- A : Single amplitude, in mm
- L : Length of the pipe, in mm
- S : Allowable bending stress, in N/mm<sup>2</sup>, based on 0,25 of the yield stress
- E : Modulus of elasticity of tube material (for mild steel, E = 210 kN/mm<sup>2</sup>)
- D : Outside diameter of tube, in mm.

Test specimen is to withstand not less than 10<sup>7</sup> cycles with frequency 20 - 50 Hz without leakage or damage.

b) Grip type and machine grooved type joints

Grip type joints and other similar joints containing elastic elements are to be tested in accordance with the following method.

A test rig of cantilever type used for testing fatigue strength of components may be used. The test specimen being tested is to be arranged in the test rig as shown in Fig 2.

Figure 2 : Grip type and machine grooved type joints

Two lengths of pipes are to be connected by means of joint assembly specimen to be tested. One end of the pipe is to be rigidly fixed while the other end is to be fitted to the vibrating element on the rig. The length of pipe connected to the fixed end should be kept as short as possible and in no case exceed 200 mm.

Mechanical joint assemblies are not to be longitudinally restrained.

The assembly is to be filled with test fluid, de-aerated and pressurized to the design pressure of the joint. Preliminary angle of deflection of pipe axis is to be equal to the maximum angle of deflection, recommended by the manufacturer. The amplitude is to be measured at 1 m distance from the center line of the joint assembly at free pipe end connected to the rotating element of the rig (see Fig 2).

Parameters of testing are to be as indicated as per Tab 2 and to be carried out on the same assembly.

Pressure during the test is to be monitored. In the event of a drop in the pressure and visual signs of leakage the test is to be repeated as described in [2.6]. Visual examination of the joint assembly is to be carried out for signs of damage which may eventually cause leakage.

**Table 2 : Parameters of testing**

Number of cycles	Amplitude, mm	Frequency, Hz
3·10 <sup>6</sup>	± 0,06	100
3·10 <sup>6</sup>	± 0,50	45
3·10 <sup>6</sup>	± 1,50	10

**2.7.3 Pressure pulsation test**

In order to determine capability of mechanical joint assembly to withstand pressure pulsation likely to occur during working conditions, joint assemblies intended for use in rigid connections of pipe lengths, are to be tested in accordance with the following method.

The mechanical joint test specimen for carrying out this test may be the same as that used in the test in [2.7.1], item a), provided it passed that test.

The vibration test in [2.7.2] and the pressure pulsation test are to be carried out simultaneously for compression couplings and pipe unions.

The mechanical joint test specimen is to be connected to a pressure source capable of generating pressure pulses of magnitude as shown in Fig 3.

Impulse pressure is to be raised from 0 to 1,5 times the design pressure of the joint with a frequency equal to 30-100 cycles per minute. The number of cycles is not to be less than 5 x 10<sup>5</sup>.

The mechanical joint is to be examined visually for sign of leakage or damage during the test.

**Figure 3 : Impulse pressure diagram**

### **2.7.4 Burst pressure test**

In order to determine the capability of the mechanical joint assembly to withstand a pressure as stated by Ch 1, Sec 10, [2.4.5], item d), the following burst test is to be carried out.

Mechanical joint test specimen is to be connected to the pipe or tubing in accordance with the requirements of [2.5] filled with test fluid, de-aerated and pressurized to test pressure with an increasing rate of 10% per minute of test pressure. The mechanical joint assembly intended for use in rigid connections of pipe lengths is not to be longitudinally restrained.

Duration of this test is not to be less than 5 minutes at the maximum pressure.

Where considered convenient, the mechanical joint test specimen used in the tightness test in [2.7.1], may be used for the burst test provided it passed the tightness test.

The specimen may exhibit a small deformation whilst under test pressure, but no leakage or visible cracks are permitted.

### **2.7.5 Pull-out test**

In order to determine the ability of a mechanical joint assembly to withstand the axial loading likely to be encountered in service without the connecting pipe becoming detached, following pullout test is to be carried out.

Pipes of suitable length are to be fitted to each end of the mechanical joints assembly test specimen. The test specimen is to be pressurized to design pressure. When pressure is attained, an external axial load is to be imposed with a value calculated using the following formula:

$$L = \frac{\pi}{4} D^2 p$$

where:

- D : Pipe outside diameter, in mm
- p : Design pressure, in N/mm<sup>2</sup>
- L : Applied axial load, in N.

The pressure and axial load are to be maintained for a period of 5 minutes.

During the test, pressure is to be monitored and relative movement between the joint assembly and the pipe measured.

The mechanical joint assembly is to be visually examined for drop in pressure and signs of leakage or damage.

There is to be no movement between the mechanical joint assembly and the connecting pipes.

### **2.7.6 Fire endurance test**

In order to establish capability of the mechanical joints to withstand effects of fire which may be encountered in service, mechanical joints are to be subjected to a fire endurance test. The fire endurance test is to be conducted on the selected test specimens as per the following standards.

- ISO19921:2005 - Ships and marine technology – Fire resistance of metallic pipe components with resilient and elastomeric seals – Test methods
- ISO19922:2005 - Ships and marine technology – Fire resistance of metallic pipe components with resilient and elastomeric seals – Requirements imposed on the test bench.

Clarifications to the standard requirements in ISO19921:2005, paragraphs 7.2, 7.4, 7.6 and 7.7:

- a) If the fire test is conducted with circulating water at a pressure different from the design pressure of the joint (however of at least 5 bar) the subsequent pressure test is to be carried out to 1,5 times the design pressure.
- b) If the fire test is required in Ch 1, Sec 10, Tab 17 to be “8 min dry + 22 min wet” or “30 min dry”, i.e. conducted for a period of time without circulating of water, the following test conditions apply:
  - Test condition “8 min dry + 22 min wet”: The test piece is not required to be rinsed with the test medium (water) in preparation for the test as required in Paragraph 7.2 of ISO19921:2005. The exposure to fire is to be started and continued for 8 minutes with the sample dry; after 8 minutes of dry test condition the piping system is to be filled with water and test pressure is to be increased up to at least 5 bar within 2 minutes, then maintained to at least 5 bar. After further 22 minutes (i.e. 30 minutes from initial exposure to fire) the exposure to fire is to be stopped and a hydrostatic pressure test as specified in item a) is to be carried out.
  - Test condition “30 min dry”: The exposure to fire is to be started and continued for 30 minutes with the sample dry. After 30 minutes the exposure to fire is to be stopped and a hydrostatic pressure test as specified in item a) is to be carried out.

For fire tests in dry condition the pressure inside the test specimen is to be monitored for a rise due to heating of the enclosed air. Means of pressure relief are to be provided where deemed necessary.

High pressures created during this test can result in failure of the test specimen. Precautions are to be taken to protect personnel and facilities.

Paragraph 7.5 of ISO 19921:2005 does not apply to the dry tests and no forced air circulation is to be arranged.

For fire endurance test requiring exposure time greater than 30 minutes test conditions are adjusted to meet the extended required total exposure time. In all cases for dry-wet test the minimum dry test exposure time is 8 minutes.

- c) A selection of representative nominal bores may be tested in order to evaluate the fire resistance of a series or range of mechanical joints of the same design. When a mechanical joint of a given nominal bore ( $D_n$ ) is so tested then other mechanical joints falling in the range  $D_n$  to  $2 \cdot D_n$  (both inclusive) are considered accepted.
- d) Alternative test methods and/or test procedures considered to be at least equivalent may be accepted at the discretion of the Society in cases where the test pieces are too large for the test bench and cannot be completely enclosed by the flames.
- e) Where thermal insulation is acceptable as a means of providing fire resistance, the following requirements apply:
  - Thermal insulation materials applied on couplings are to be non-combustible according to ISO1182:2010 as required by the Fire Test Procedures Code as defined in Ch 4, Sec 1, [2.21]. Precautions are to be taken to protect the insulation from being impregnated with flammable oils.
  - At least the fire endurance and the vibration testing in Tab 1 are to be carried out with thermal insulation in place.
  - A service restriction is to be stated on the type approval certificate that the mechanical joints are to be fitted with thermal insulation during the installation in cases where the mechanical joints are used where fire resistance is required, unless mechanical joints are delivered already fitted with thermal insulation before installation.

### **2.7.7 Vacuum test**

In order to establish the capability of the mechanical joint assembly to withstand internal pressures below atmospheric, similar to the conditions likely to be encountered under service conditions, the following vacuum test is to be carried out.

The mechanical joint assembly is to be connected to a vacuum pump and subjected to a pressure of 170 mbar absolute. Once this pressure is stabilized, the specimen under test is to be isolated from the vacuum pump and the pressure is to be maintained for a period of 5 minutes.

No internal pressure rise is permitted.

### **2.7.8 Repeated assembly test**

The mechanical joint test specimen is to be dismantled and reassembled 10 times in accordance with manufacturers instructions and then subjected to a tightness test as defined in [2.7.1].

# Appendix 6 Special Approval of Alloy Steel used for Intermediate Shaft Material

## 1 General

### 1.1 Application

**1.1.1** This Appendix applies to the approval of alloy steel which has a minimum specified tensile strength greater than 800 N/mm<sup>2</sup>, but less than 950 N/mm<sup>2</sup> intended for use as intermediate shaft material.

### 1.2 Torsional fatigue test

**1.2.1** A torsional fatigue test is to be performed to verify that the material exhibits similar fatigue life as conventional steels. The torsional fatigue strength of said material is to be equal to or greater than the permissible torsional vibration stress  $\tau_c$  given by the formula of  $\tau_1$  in Ch 1, Sec 9, [3.4.2], item b).

The test is to be carried out with notched and unnotched specimens respectively. For calculation of the stress concentration factor of the notched specimen, fatigue strength reduction factor  $\beta$  should be evaluated in consideration of the severest torsional stress concentration in the design criteria.

Note 1: The stress concentration factor (scf) at the end of slots can be determined by means of the following empirical formulae:

$$scf = \alpha_{t(hole)} + 0,8 \frac{(1-e)/d}{\sqrt{\left(1 - \frac{d_i}{d}\right) \frac{e}{d}}}$$

This formula applies to:

- slots at 120 or 180 or 360 degrees apart
- slots with semicircular ends. A multi-radii slot end can reduce the local stresses, but this is not included in this empirical formula
- slots with no edge rounding (except chamfering), as any edge rounding increases the scf slightly.

where:

l : Slot length

e : Slot width

d : Shaft outside diameter

$d_i$  : Shaft inside diameter

$\alpha_{t(hole)}$  : Stress concentration of radial holes (in this context e = hole diameter) and can be determined as:

$$\alpha_{t(hole)} = 2,3 - 3 \frac{e}{d} + 15 \left(\frac{e}{d}\right)^2 + 10 \left(\frac{e}{d}\right)^2 \left(\frac{d_i}{d}\right)^2$$

or simplified to  $\alpha_{t(hole)} = 2,3$

For unnotched specimen, scf = 1

### 1.2.2 Test conditions

Test conditions are to be in accordance with Tab 1. Mean surface roughness, in  $\mu\text{m}$ , is to be less than 0,2 Ra with the absence of localised machining marks verified by visual examination at low magnification (x20) as required by Section 8.4 of ISO 1352:2011.

Test procedures are to be in accordance with Section 10 of ISO 1352:2011.

**Table 1 : Test condition**

Loading type	Torsion
Stress ratio	R = -1
Load waveform	Constant-amplitude sinusoidal
Evaluation	S-N curve
Number of cycles for test termination	1 x 10 <sup>7</sup> cycles

**1.2.3 Acceptance criteria**

Measured high-cycle torsional fatigue strength  $\tau_{C1}$  and low-cycle torsional fatigue strength  $\tau_{C2}$  are to be equal to or greater than the values given by the following formulae:

$$\tau_{C1} \geq \tau_{C,\lambda=0} = \frac{\sigma_B + 160}{6} C_K C_D$$

$$\tau_{C2} \geq 1,7 \frac{1}{\sqrt{C_K}} \tau_{C1}$$

where:

$C_K$  : Factor for the particular shaft design features, see Ch 1, Sec 9, Tab 1

$C_D$  : Size factor, see Ch 1, Sec 9, [3.2.2]

$\sigma_B$  : Specified minimum tensile strength in N/mm<sup>2</sup> of the shaft material.

**1.3 Cleanliness requirements**

**1.3.1** The steels are to have a degree of cleanliness as shown in Tab 2 when tested according to ISO 4967:2013 method A. Representative samples are to be obtained from each heat of forged or rolled products.

The steels are generally to comply with the minimum requirements of NR216, Ch 5, Sec 3, Tab 1, with particular attention given to minimising the concentrations of sulphur, phosphorus and oxygen in order to achieve the cleanliness requirements. The specific steel composition is required to be approved by the Society.

**1.4 Inspection**

**1.4.1** The ultrasonic testing required by NR216, Ch 5, Sec 1, [10.3.1] is to be carried out prior to acceptance. The acceptance criteria are to be in accordance with IACS Recommendation No. 68 or a recognized national or international standard.

**Table 2 : Cleanliness requirements**

Inclusion group	Series	Limiting chart diagram index I
Type A	Fine	1,0
	Thick	1,0
Type B	Fine	1,5
	Thick	1,0
Type C	Fine	1,0
	Thick	1,0
Type D	Fine	1,0
	Thick	1,0
Type DS	–	1,0

# Appendix 7 Exhaust Gas Back Pressure Analysis

## 1 General

### 1.1 Scope

**1.1.1** This Appendix provides guidance regarding the exhaust gas back pressure analysis to be submitted to justify exhaust systems connections without forced ventilation as per Ch 1, Sec 11, [2.4.1], when an exhaust gas pollution prevention system is installed.

### 1.2 Required analysis

#### 1.2.1 Calculation cases

A dedicated exhaust gas back pressure analysis is to be submitted for each exhaust gas pollution prevention system installation on-board.

#### 1.2.2 Conclusion of the back pressure assessment

The back pressure created by the exhaust gas pollution prevention system is to be determined for each case, with a view to ensure that the specific equipment is compatible with an interconnected exhaust gas piping system without forced ventilation (spray, packing, etc.).

The back pressure calculation is to demonstrate that the diesel engines associated with the exhaust gas pollution prevention system are capable of being operated within the limits specified by the engine manufacturer.

Note 1: Particular attention is to be paid to the part of the piping system between isolating valves and exhaust gas pollution prevention system line outlet due to the fact that there is a reduction of flow circulation and altered temperature conditions. Moisture issues are to be taken into account during material selection of the exhaust piping, in order to avoid any premature corrosion.

### 1.3 Input data

**1.3.1** The particulars of each engine type are to be documented and explained:

- Engine type
- Number of turbochargers
- Exhaust gas temperature at turbocharger outlet
- Exhaust gas temperature after boiler / SCR / silencer and/or any equipment in the exhaust gas line (as applicable)
- Total exhaust gas quantity
- Engine manufacturer maximum permissible pressure drop
- Exhaust gas pipe diameter and length after turbocharger
- Exhaust gas pipe diameter and length at manifold
- Exhaust gas pipe diameter and length after manifold
- Exhaust gas pipe diameter and length before boiler / SCR / silencer and/or any equipment in the exhaust gas line (as applicable)
- Exhaust gas pipe diameter and length after Boiler / SCR / silencer and/or any equipment in the exhaust gas line (as applicable)
- Exhaust gas pipe diameter and length after exhaust gas pollution prevention system

#### 1.3.2 Ambient conditions

Ambient conditions corresponding to the ship operation, in particular summer and winter conditions as well as area of navigation are to be taken into consideration for the back pressure calculation.

**1.3.3** A general description of the exhaust gas piping and exhaust gas pollution prevention system with the applicable limitations and ambient conditions is to be detailed in each case.

### 1.4 Exhaust gas back pressure assessment

#### 1.4.1 General

The analysis is to detail the pressure losses along the exhaust lines. The total pressure loss is to be calculated for each possible exhaust line configuration depending on the number of engines connected to the exhaust gas pollution prevention system.

In addition, the following pressure losses are to be detailed individually:

- pressure losses along the exhaust gas pollution prevention system line
- pressure losses along lines with components other than exhaust gas pollution prevention system such as silencer, exhaust gas boiler, SCR etc

**1.4.2** The calculation methodology is to be described with detailed formulas and related assumptions and/or approximations.

### **1.4.3 CFD simulation**

The Society reserves the right to require a CFD simulation for each case near the limit of engine manufacturer maximum permissible pressure drop to validate the installation of such design on board.

Appendix 2	Indirect Test Method for Induction Machines (Static Torque Method)

# Section 1 General

## 1 Application

### 1.1 General

**1.1.1** The requirements of this Chapter apply to electrical installations on ships. In particular, they apply to the components of electrical installations for:

- primary essential services
- secondary essential services
- essential services for special purposes connected with ships specifically intended for such purposes (e.g. cargo pumps on tankers, cargo refrigerating systems, air conditioning systems on passenger ships)
- services for habitability.

The other parts of the installation are to be so designed as not to introduce any risks or malfunctions to the above services.

**1.1.2** The Society may consider modified requirements for installations not exceeding either 50 V or 50 kW total generator capacity (and for ships assigned with a restricted navigation notation).

### 1.2 References to other regulations and standards

**1.2.1** The Society may refer to other regulations and standards when deemed necessary. These include the IEC publications, notably the IEC 60092 series.

It is to be noted however that, where the prescriptive requirements in the present Rules and such standards are not aligned, the prescriptive requirements in the present Rules take precedence and are to be applied.

**1.2.2** When referred to by the Society, publications by the International Electrotechnical Commission (IEC) or other internationally recognised standards defined in this Chapter, are in principle those currently in force at the date of the contract for construction.

Note 1: The use of previous versions of these standards will be considered on case by case basis.

## 2 Documentation to be submitted

### 2.1

**2.1.1** The documents listed in Tab 1 are to be submitted.

**Table 1 : Documents to be submitted**

No.	I/A (1)	Documents to be submitted
1	A	General arrangement of electrical installation.
2	A	Single line diagram of main and emergency power and lighting systems.
3	I	Electrical power balance (main and emergency supply).
4	A	Calculation of short-circuit currents for each installation in which the sum of rated power of the energy sources which may be connected contemporaneously to the network is greater than 500 kVA (kW).
5	A	Where the maximal short-circuit current on the main bus-bar is expected to exceed 50 kA for the main and emergency switchboards, justification of the main bus-bar and bracket strength related to induced electromagnetic forces (except junction bars to the interrupting and protective devices).
6	A	List of circuits including, for each supply and distribution circuit, data concerning the nominal current, the cable type, length and cross-section, nominal and setting values of the protective and control devices.
7	A	Single line diagram and detailed diagram of the main switchboard.
8	A	Single line diagram and detailed diagram of the emergency switchboard.
9	A	Diagram of the most important section boards or motor control centres (above 100 kW).
10	A	Diagram of the supply for monitoring and control systems of propulsion motors and generator prime movers.
11	A	Diagram of the supply, monitoring and control systems of the rudder propellers.
<p>(1) A : To be submitted for approval I : To be submitted for information.</p> <p>(2) For high voltage installations.</p> <p>(3) For electric propulsion installations.</p>		

No.	I/A (1)	Documents to be submitted
12	A	Diagram of the supply, monitoring and control systems of controllable pitch propellers.
13	A	Diagram of the general emergency alarm system, of the public address system and other intercommunication systems.
14	A	Detailed diagram of the navigation-light switchboard.
15	A	Diagram of the remote stop system (ventilation, fuel pump, fuel valves, etc.).
16	A	List of batteries including type and manufacturer, voltage and capacity, location and equipment and/or system(s) served, maintenance and replacement schedule (when used for essential and emergency services).
17	A (2)	Selectivity and coordination of the electrical protection.
18	A (3)	Single line diagram.
19	A (3)	Principles of control system and its power supply.
20	A (3)	Alarm and monitoring system including: <ul style="list-style-type: none"> <li>• list of alarms and monitoring points</li> <li>• power supply diagram.</li> </ul>
21	A (3)	Safety system including: <ul style="list-style-type: none"> <li>• list of monitored parameters for safety system</li> <li>• power supply diagram.</li> </ul>
22	I (3)	Arrangements and details of the propulsion control consoles and panels.
23	I (3)	Arrangements and details of electrical coupling.
24	I (3)	Arrangements and details of the frequency converters together with the justification of their characteristics.
25	I (3)	Arrangements of the cooling system provided for the frequency converter and motor enclosure.
26	A (3)	Test program for converters and rotating machines having rated power > 3 MW, dock and sea trials.
<p>(1) A : To be submitted for approval I : To be submitted for information.</p> <p>(2) For high voltage installations.</p> <p>(3) For electric propulsion installations.</p>		

### 3 Definitions

#### 3.1 General

**3.1.1** Unless otherwise stated, the terms used in this Chapter have the definitions laid down by the IEC standards. The definitions given in the following requirements also apply.

#### 3.2 Essential services

**3.2.1** Essential services are defined in Pt A, Ch 1, Sec 1, [1.2.1]. They are subdivided in primary and secondary essential services defined in [3.3] and [3.4].

#### 3.3 Primary essential services

**3.3.1** Primary essential services are those which need to be maintained in continuous operation.

Examples of equipment for primary essential services are the following:

- steering gear
- actuating systems of controllable pitch propellers
- scavenging air blowers, fuel oil supply pumps, fuel valve cooling pumps, lubricating oil pumps and cooling water pumps for main and auxiliary engines and turbines necessary for the propulsion
- forced draught fans, feed water pumps, water circulating pumps, condensate pumps, oil burning installations, for steam plants or steam turbines ship, and also for auxiliary boilers on ship where steam is used for equipment supplying primary essential services
- azimuth thrusters which are the sole means for propulsion/steering with lubricating oil pumps, cooling water pumps
- electrical equipment for electric propulsion plant with lubricating oil pumps and cooling water pumps
- electric generators and associated power sources supplying the above equipment
- hydraulic pumps supplying the above equipment
- viscosity control equipment for heavy fuel oil

- control, monitoring and safety devices/systems for equipment for primary essential services
- speed regulators dependent on electrical energy for main or auxiliary engines necessary for propulsion
- starting equipment of diesel engines and gas turbines.

The main lighting system for those parts of the ship normally accessible to and used by personnel and passengers is also considered as a primary essential service.

### **3.4 Secondary essential services**

**3.4.1** Secondary essential services are those services which need not necessarily be in continuous operation.

Examples of equipment for secondary essential services are the following:

- windlasses
- thrusters
- fuel oil transfer pumps and fuel oil treatment equipment
- lubrication oil transfer pumps and lubrication oil treatment equipment
- preheaters for heavy fuel oil
- sea water pumps
- starting air and control air compressors
- bilge, ballast and heeling pumps
- fire pumps and other fire-extinguishing medium pumps
- ventilation fans for engine and boiler rooms
- services considered necessary to maintain dangerous cargo in a safe condition
- navigation lights, aids and signals
- internal safety communication equipment
- fire detection and alarm systems
- electrical equipment for watertight closing appliances
- electric generators and associated power supplying the above equipment
- hydraulic pumps supplying the above mentioned equipment
- control, monitoring and safety for cargo containment systems
- control, monitoring and safety devices/systems for equipment for secondary essential services.
- cooling system of environmentally controlled spaces.

### **3.5 Services for habitability**

**3.5.1** Services for habitability are those intended for minimum comfort conditions for people on board.

Examples of equipment for maintaining conditions of habitability:

- cooking
- heating
- domestic refrigeration
- mechanical ventilation
- sanitary and fresh water
- electric generators and associated power sources supplying the above equipment.

### **3.6 Safety voltage**

**3.6.1** A voltage which does not exceed 50 V a.c. r.m.s. between conductors, or between any conductor and earth, in a circuit isolated from the supply by means such as a safety isolating transformer.

**3.6.2** A voltage which does not exceed 50 V d.c. between conductors or between any conductor and earth in a circuit isolated from higher voltage circuits.

### **3.7 Low-voltage systems**

**3.7.1** Alternating current systems with rated voltages greater than 50 V r.m.s. up to 1000 V r.m.s. inclusive and direct current systems with a maximum instantaneous value of the voltage under rated operating conditions greater than 50 V up to 1500 V inclusive.

### **3.8 High-voltage systems**

**3.8.1** Alternating current systems with rated voltages greater than 1000 V r.m.s. and direct current systems with a maximum instantaneous value of the voltage under rated operating conditions greater than 1500 V.

### 3.9 Basic insulation

**3.9.1** Insulation applied to live parts to provide basic protection against electric shock.

Note 1: Basic insulation does not necessarily include insulation used exclusively for functional purposes.

### 3.10 Supplementary insulation

**3.10.1** Independent insulation applied in addition to basic insulation in order to provide protection against electric shock in the event of a failure of basic insulation.

### 3.11 Double insulation

**3.11.1** Insulation comprising both basic insulation and supplementary insulation.

### 3.12 Reinforced insulation

**3.12.1** A single insulation system applied to live parts, which provides a degree of protection against electric shock equivalent to double insulation.

Note 1: The term "insulation system" does not imply that the insulation must be one homogeneous piece. It may comprise several layers which cannot be tested singly as supplementary or basic insulation.

### 3.13 Earthing

**3.13.1** The earth connection to the general mass of the hull of the ship in such a manner as will ensure at all times an immediate discharge of electrical energy without danger.

### 3.14 Normal operational and habitable condition

**3.14.1** *A condition under which the ship as a whole, the machinery, services, means and aids ensuring propulsion, ability to steer, safe navigation, fire and flooding safety, internal and external communications and signals, means of escape, and emergency boat winches, as well as the designed comfortable conditions of habitability are in working order and functioning normally.*

### 3.15 Emergency condition

**3.15.1** *A condition under which any services needed for normal operational and habitable conditions are not in working order due to failure of the main source of electrical power.*

### 3.16 Main source of electrical power

**3.16.1** *A source intended to supply electrical power to the main switchboard for distribution to all services necessary for maintaining the ship in normal operational and habitable condition.*

### 3.17 Dead ship condition

**3.17.1** *The condition under which the main propulsion plant, boilers and auxiliaries are not in operation due to the absence of power.*

Note 1: Dead ship condition is a condition in which the entire machinery installation, including the power supply, is out of operation and the auxiliary services such as compressed air, starting current from batteries etc., for bringing the main propulsion into operation and for the restoration of the main power supply are not available.

### 3.18 Main generating station

**3.18.1** *The space in which the main source of electrical power is situated.*

### 3.19 Main switchboard

**3.19.1** *A switchboard which is directly supplied by the main source of electrical power and is intended to distribute electrical energy to the ship's services.*

### 3.20 Emergency switchboard

**3.20.1** *A switchboard which in the event of failure of the main electrical power supply system is directly supplied by the emergency source of electrical power or the transitional source of emergency and is intended to distribute electrical energy to the emergency services.*

### **3.21 Emergency source of electrical power**

**3.21.1** *A source of electrical power, intended to supply the emergency switchboard in the event of failure of the supply from the main source of electrical power.*

### **3.22 Section boards**

**3.22.1** A switchgear and controlgear assembly which is supplied by another assembly and arranged for the distribution of electrical energy to other section boards or distribution boards.

### **3.23 Distribution board**

**3.23.1** A switchgear and controlgear assembly arranged for the distribution of electrical energy to final sub-circuits.

### **3.24 Final sub-circuit**

**3.24.1** That portion of a wiring system extending beyond the final required overcurrent protective device of a board.

### **3.25 Hazardous areas**

**3.25.1** Areas in which an explosive atmosphere is or may be expected to be present in quantities such as to require special precautions for the construction, installation and use of electrical apparatus.

Note 1: An explosive gas atmosphere is a mixture with air, under atmospheric conditions, of flammable substances in the form of gas, vapour or mist, in which, after ignition, combustion spreads throughout the unconsumed mixture.

**3.25.2** Hazardous areas are classified in zones based upon the frequency and the duration of the occurrence of explosive atmosphere.

**3.25.3** Hazardous areas for explosive gas atmosphere are classified in the following zones:

- Zone 0: an area in which an explosive gas atmosphere is present continuously or is present for long periods
- Zone 1: an area in which an explosive gas atmosphere is likely to occur in normal operation
- Zone 2: an area in which an explosive gas atmosphere is not likely to occur in normal operation and if it does occur, is likely to do only infrequently and will exist for a short period only.

### **3.26 High fire risk areas**

**3.26.1** The high fire risk areas are defined as follows:

- a) machinery spaces as defined in Ch 4, Sec 1, [2.29], except spaces having little or no fire risk as defined by category (10) of Ch 4, Sec 5, [1.3.3], item b) 2)
- b) spaces containing fuel treatment equipment and other highly flammable substances
- c) galleys and pantries containing cooking appliances
- d) laundry with drying equipment
- e) spaces as defined in Ch 4, Sec 5, [1.3.3] for ships carrying more than 36 passengers, as:
  - (8) accommodation spaces of greater fire risk
  - (12) machinery spaces and main galleys
  - (14) other spaces in which flammable liquids are stowed

### **3.27 Certified safe-type equipment**

**3.27.1** Certified safe-type equipment is electrical equipment of a type for which a national or other appropriate authority has carried out the type verifications and tests necessary to certify the safety of the equipment with regard to explosion hazard when used in an explosive gas atmosphere.

### **3.28 Voltage and frequency transient**

#### **3.28.1 Voltage transient**

Sudden change in voltage (excluding spikes) which goes outside the nominal voltage tolerance limits and returns to and remains inside these limits within a specified recovery time after the initiation of the disturbance (time range: seconds).

#### **3.28.2 Frequency transient**

Sudden change in frequency which goes outside the frequency tolerance limits and returns to and remains inside these limits within a specified recovery time after initiation of the disturbance (time range: seconds).

### 3.29 Environmental categories

**3.29.1** Electrical equipment is classified into environmental categories according to the temperature range, vibration levels, and resistance to chemically active substances, to humidity, and to EMC required for installation in bridge and deck zone.

The designation of the environmental categories is indicated by the EC Code in Tab 2.

The first characteristic numeral indicates the temperature range in which the electrical equipment operates satisfactorily, as specified in Tab 3.

The second characteristic numeral indicates the vibration level in which the electrical equipment operates satisfactorily, as specified in Tab 4.

**3.29.2** The tests for verifying the additional letters and the characteristic numeral of the environmental categories are defined in Ch 3, Sec 6.

### 3.30 Black out situation

**3.30.1** A “blackout situation” means that the main and auxiliary machinery installations, including the main power supply, are out of operation but the services for bringing them into operation (e.g. compressed air, starting current from batteries, etc.) are available.

**Table 2 : EC Code**

Code letter	First characteristic numeral	Second characteristic numeral	Additional letter
EC	(numerals 1 to 4)	(numerals 1 to 3)	S (1) C (2) B (3)

(1) The additional letter S indicates the resistance to salt mist (exposed decks, masts) of the electrical equipment.  
 (2) The supplementary letter C indicates the relative humidity up to 80% (air conditioned areas) in which the electrical equipment operates satisfactorily.  
 (3) The additional letter B indicates the compliance for installing on the bridge and deck zone or in the vicinity of the bridge, with regards to EMC requirements specified in IEC 60533.

**Table 3 : First characteristic numeral**

First characteristic numeral	Brief description of location	Temperature range, in °C	
1	Air conditioned areas	+ 5	+ 40
2	Enclosed spaces	+ 5	+ 45
3	Inside consoles or close to combustion engines and similar	+ 5	+ 55
4	Exposed decks, masts	- 25	+ 45

**Table 4 : Second characteristic numeral**

Second characteristic numeral	Brief description of location	Frequency range, in Hz	Displacement amplitude, in mm	Acceleration amplitude g
1	Machinery spaces, command and control stations, accommodation spaces, exposed decks, cargo spaces	from 2,0 to 13,2	1,0	-
		from 13,2 to 100	-	0,7
2	Masts	from 2,0 to 13,2	3,0	-
		from 13,2 to 50	-	2,1
3	On air compressors, on diesel engines and similar	from 2,0 to 25,0	1,6	-
		from 25,0 to 100	-	4,0

## Section 2 General Design Requirements

### 1 Environmental conditions

#### 1.1 General

**1.1.1** The electrical components of installations are to be designed and constructed to operate satisfactorily under the environmental conditions on board.

In particular, the conditions shown in the tables in this Article are to be taken into account.

Note 1: The environmental conditions are characterised by:

- one set of variables including climatic conditions (e.g. ambient air temperature and humidity), conditions dependent upon chemically active substances (e.g. salt mist) or mechanically active substances (e.g. dust or oil), mechanical conditions (e.g. vibrations or inclinations) and conditions dependent upon electromagnetic noise and interference, and
- another set of variables dependent mainly upon location on vessels, operational patterns and transient conditions.

#### 1.2 Ambient air temperatures

**1.2.1** For ships classed for unrestricted navigation, the ambient air temperature ranges shown in Tab 1 are applicable in relation to the various locations of installation.

**Table 1 : Ambient air temperature**

Location	Temperature range, in °C	
Enclosed spaces	+ 5	+ 45
Inside consoles or fitted on combustion engines and similar	+ 5	+ 55
Air conditioned areas	+ 5	+ 40
Exposed decks	- 25	+ 45

**1.2.2** For ships classed for service in specific zones, the Society may accept different ranges for the ambient air temperature (e.g. for ships operating outside the tropical belt, the maximum ambient air temperature may be assumed as equal to + 40°C instead of + 45°C).

#### 1.3 Humidity

**1.3.1** For ships classed for unrestricted service, the humidity ranges shown in Tab 2 are applicable in relation to the various locations of installation.

**Table 2 : Humidity**

Location	Humidity
General	95% up to 45°C 70% above 45°C
Air conditioned areas	Different values may be considered on a case-by-case basis

#### 1.4 Sea water temperatures

**1.4.1** The temperatures shown in Tab 3 are applicable to ships classed for unrestricted service.

**1.4.2** For ships classed for service in specific zones, the Society may accept different values for the sea water temperature (e.g. for ships operating outside the tropical belt, the maximum sea water temperature may be assumed as equal to + 25°C instead of + 32°C).

**Table 3 : Water temperature**

Coolant	Temperature range, in °C	
Sea water	0	+ 32

#### 1.5 Salt mist

**1.5.1** The applicable salt mist content in the air is to be 1mg/m<sup>3</sup>.

## 1.6 Inclinations

1.6.1 The inclinations applicable are those shown in Tab 4.

The Society may consider deviations from these angles of inclination taking into consideration the type, size and service conditions of the ships.

**Table 4 : Inclination of ship**

Type of machinery, equipment or component	Angles of inclination, in degrees (1)			
	Athwartship		Fore-and-aft	
	static	dynamic (4)	static	dynamic (5)
Machinery and equipment relative to main electrical power installation	15	22,5	5	7,5
Machinery and equipment relative to the emergency power installation and crew and passenger safety systems of the ship (e.g. emergency source of power, emergency fire pumps, etc.)	22,5 (2)	22,5 (2)	10	10
Switchgear and associated electrical and electronic components and remote control systems (3)	22,5	22,5	10	10

(1) Athwartship and fore-and-aft angles may occur simultaneously in their most unfavourable combination.  
 (2) In the case of gas carriers or chemical tankers, the emergency power supply must also remain operable with the ship flooded to a final athwartship inclination up to a maximum of 30°.  
 (3) No undesired switching operations or functional changes may occur up to an angle of inclination of 45°.  
 (4) The period of dynamic inclination may be assumed equal to 10 s.  
 (5) The period of dynamic inclination may be assumed equal to 5 s.

## 1.7 Vibrations

1.7.1 In relation to the location of the electrical components, the vibration levels given in Tab 5 are to be assumed.

1.7.2 The natural frequencies of the equipment, their suspensions and their supports are to be outside the frequency ranges specified.

Where this is not possible using a suitable constructional technique, the equipment vibrations are to be dumped so as to avoid unacceptable amplifications.

**Table 5 : Vibration levels**

Location	Frequency range, in Hz	Displacement amplitude, in mm	Acceleration amplitude g
Machinery spaces, command and control stations, accommodation spaces, exposed decks, cargo spaces	from 2,0 to 13,2	1,0	–
	from 13,2 to 100	–	0,7
On air compressors, on diesel engines and similar	from 2,0 to 25,0	1,6	–
	from 25,0 to 100	–	4,0
Masts	from 2,0 to 13,2	3,0	–
	from 13,2 to 50	–	2,1

## 2 Quality of power supply

### 2.1 General

2.1.1 All electrical components supplied from the main and emergency systems are to be so designed and manufactured that they are capable of operating satisfactorily under the normally occurring variations in voltage and frequency specified from [2.2] to [2.4].

### 2.2 a.c. distribution systems

2.2.1 For alternating current components the voltage and frequency variations of power supply shown in Tab 6 are to be assumed.

**Table 6 : Voltage and frequency variations of power supply in a.c.**

Parameter	Variations	
	Continuous	Transient
Voltage	+ 6% - 10%	± 20% (recovery time: 1,5 s)
Frequency	± 5%	± 10% (recovery time: 5 s)
<b>Note 1:</b> For alternating current components supplied by emergency generating sets, different variations may be considered.		

**2.3 d.c. distribution systems**

**2.3.1** For direct current components the power supply variations shown in Tab 7 are to be assumed.

**Table 7 : Voltage variations in d.c.**

Parameters	Variations
Voltage tolerance (continuous)	± 10%
Voltage cyclic variation	5%
Voltage ripple (a.c. r.m.s. over steady d.c. voltage)	10%

**2.3.2** For direct current components supplied by electrical battery the following voltage variations are to be assumed:

- +30% to -25% for components connected to the battery during charging (see Note 1)
- +20% to -25% for components not connected to the battery during charging.

Note 1: Different voltage variations as determined by the charging/discharging characteristics, including ripple voltage from the charging device, may be considered.

**2.3.3** Any special system, e.g. electronic circuits, whose function cannot operate satisfactorily within the limits shown in the tables should not be supplied directly from the system but by alternative means, e.g. through stabilized supply.

**2.4 Harmonic distortions**

**2.4.1** For components intended for systems without substantially static converter loads and supplied by synchronous generators, it is assumed that the total voltage harmonic distortion does not exceed 5%, and the single harmonic does not exceed 3% of the nominal voltage.

**2.4.2** For components intended for systems fed by static converters, and/or systems in which the static converter load predominates, it is assumed that:

- the single harmonics distortion does not exceed 5% of the nominal voltage up to the 15th harmonic of the nominal frequency, decreasing to 1% at the 100th harmonic (see Fig 1), and that
- the total harmonic distortion does not exceed 8%.

**Figure 1 :**

**2.4.3** Higher values for the harmonic content (e.g. in electric propulsion plant systems) may be accepted where all installed equipment and systems have been designed for a higher specified limit. This relaxation on limits is to be documented (harmonic distortion calculation report).

### 3 Electromagnetic susceptibility

#### 3.1

**3.1.1** For electronic type components such as sensors, alarm panels, automatic and remote control equipment, protective devices and speed regulators, the conducted and radiated disturbance levels to be assumed are those given in Part C, Chapter 3.

Note 1: See also IEC Publication 60533 - "Electromagnetic Compatibility of Electrical and Electronic Installations in Ships and of Mobile and Fixed Offshore Units".

**3.1.2** Electrical and electronic equipment on the bridge and in the vicinity of the bridge, not required neither by classification rules nor by International Conventions and liable to cause electromagnetic disturbance, shall be of type which fulfil the test requirements of test specification Ch 3, Sec 6, Tab 1, tests 19 and 20.

Note 1: Bridge and vicinity of the bridge covers deck and bridge zone, such as:

- the wheelhouse including bridge wings
- control rooms, characterized by equipment for inter-communication, signal processing, radio communication and navigation, auxiliary equipment
- area in close proximity (within a 5 meters distance) to receiving and/or transmitting antennas and large openings in the metallic structure.

### 4 Materials

#### 4.1 General

**4.1.1** In general, and unless it is adequately protected, all electrical equipment is to be constructed of durable, flame-retardant, moisture-resistant materials which are not subject to deterioration in the atmosphere and at the temperatures to which they are likely to be exposed. Particular consideration is to be given to sea air and oil vapour contamination.

Note 1: The flame-retardant and moisture-resistant characteristics may be verified by means of the tests cited in IEC Publication 60092-101 or in other recognised standards.

**4.1.2** Where the use of incombustible materials or lining with such materials is required, the incombustibility characteristics may be verified by means of the test cited in IEC Publication 60092-101 or in other recognised standards.

#### 4.2 Insulating materials for windings

**4.2.1** Insulated windings are to be resistant to moisture, sea air and oil vapour unless special precautions are taken to protect insulants against such agents.

**4.2.2** The insulation classes given in Tab 8 may be used in accordance with IEC Publication 60085.

**Table 8 : Insulation Classes**

Class	Maximum continuous operating temperature, in °C
A	105
E	120
B	130
F	155
H	180

#### 4.3 Insulating materials for cables

**4.3.1** See Ch 2, Sec 9, [2.3].

### 5 Construction

#### 5.1 General

**5.1.1** All electrical apparatus is to be so constructed as not to cause injury when handled or touched in the normal manner.

**5.1.2** The design of electrical equipment is to allow accessibility to each part that needs inspection or adjustment, also taking into account its arrangement on board.

**5.1.3** Enclosures are to be of adequate mechanical strength and rigidity.

**5.1.4** Enclosures for electrical equipment are generally to be of metal; other materials may be accepted for accessories such as connection boxes, socket-outlets, switches and luminaires. Other exemptions for enclosures or parts of enclosures not made of metal will be specially considered by the Society.

**5.1.5** Cable entrance are not to impair the degree of protection of the relevant enclosure (see Ch 2, Sec 3, Tab 2).

**5.1.6** All nuts and screws used in connection with current-carrying parts and working parts are to be effectively locked.

**5.1.7** All equipment is generally to be provided with suitable, fixed terminal connectors in an accessible position for convenient connection of the external cables.

## **5.2 Degree of protection of enclosures**

**5.2.1** Electrical equipment is to be protected against the ingress of foreign bodies and water.

The minimum required degree of protection, in relation to the place of installation, is generally that specified in Ch 2, Sec 3, Tab 2.

**5.2.2** The degrees of protection are to be in accordance with:

- IEC Publication No. 60529 for equipment in general
- IEC Publication No. 60034-5 for rotating machines.

**5.2.3** For cable entries see [5.1.5].

## **6 Protection against explosion hazard**

### **6.1 Protection against explosive gas or vapour atmosphere hazard**

**6.1.1** Electrical equipment intended for use in areas where explosive gas or vapour atmospheres may occur (e.g. oil tankers, liquefied gas carriers, chemical tankers, ro-ro spaces, paint stores, ballast water management systems etc.), is to be of a "safe type" suitable for the relevant flammable atmosphere and for shipboard use.

**6.1.2** The following "certified safe type" equipment is considered:

- intrinsically-safe: Ex(ia) - Ex(ib)
- flameproof: Ex(d)
- increased safety: Ex(e)
- pressurised enclosure: Ex(p)
- encapsulated: Ex(m)
- sand filled: Ex(q)
- special protection: Ex(s) (apparatus not conforming with IEC 60079 may be considered safe by a national or other authorised body for use in potentially explosive atmospheres. In such cases, the apparatus is identified with the symbol "s")
- oil-immersed apparatus (only when required by the application): Ex(o).

**6.1.3** Other equipment complying with types of protection other than those in [6.1.2] may be considered by the Society, such as:

- simple electrical apparatus and components (e.g. thermocouples, photocells, strain gauges, junction boxes, switching devices), included in intrinsically-safe circuits not capable of storing or generating electrical power or energy in excess of limits stated in the relevant rules
- electrical apparatus specifically designed and certified by the appropriate authority for use in Zone 0 or specially tested for Zone 2 (e.g. type "n" protection)
- equipment the type of which ensures the absence of sparks and arcs and of "hot spots" during its normal operation
- pressurised equipment
- equipment having an enclosure filled with a liquid dielectric, or encapsulated.

### **6.2 Protection against combustible dust hazard**

**6.2.1** Electrical appliances intended for use in areas where a combustible dust hazard may be present are to be arranged with enclosures having a degree of protection and maximum surface temperature suitable for the dust to which they may be exposed.

Note 1: Where the characteristics of the dust are unknown, the appliances are to have a degree of protection IP6X. For most dusts a maximum surface temperature of 200°C is considered adequate.

# Section 3 System Design

## 1 Supply systems and characteristics of the supply

### 1.1 Supply systems

1.1.1 The following distribution systems may be used:

- a) on d.c. installations:
  - two-wire insulated
  - two-wire with one pole earthed
- b) on a.c. installations:
  - three-phase three-wire with neutral insulated
  - three-phase three-wire with neutral directly earthed or earthed through an impedance
  - three-phase four-wire with neutral directly earthed or earthed through an impedance
  - single-phase two-wire insulated
  - single-phase two-wire with one phase earthed.

1.1.2 Distribution systems other than those listed in [1.1.1] will be considered by the Society on a case by case basis.

1.1.3 The hull return system of distribution is not to be used for power, heating or lighting in any ship of 1600 gross tonnage and upwards.

1.1.4 The requirement of [1.1.3] does not preclude under conditions approved by the Society the use of:

- a) impressed current cathodic protective systems
- b) limited and locally earthed systems, or
- c) insulation level monitoring devices provided the circulation current does not exceed 30 mA under the most unfavourable conditions.

Note 1: Limited and locally earthed systems such as starting and ignition systems of internal combustion engines are accepted provided that any possible resulting current does not flow directly through any dangerous spaces.

1.1.5 For the supply systems of ships carrying liquid developing combustible gases or vapours, see Pt D, Ch 7, Sec 5, Pt D, Ch 8, Sec 10 or Pt D, Ch 9, Sec 10.

1.1.6 For the supply systems in HV Installations, see Ch 2, Sec 13.

### 1.2 Maximum voltages

1.2.1 The maximum voltages for both alternating current and direct current low-voltage systems of supply for the ship's services are given in Tab 1.

1.2.2 Voltages exceeding those shown will be specially considered in the case of specific systems.

1.2.3 For high voltage systems, see Ch 2, Sec 13.

**Table 1 : Maximum voltages for various ship services**

Use		Maximum voltage V
For permanently installed and connected to fixed wiring	Power equipment	1000
	Heating equipment (except in accommodation spaces)	500
	Cooking equipment	500
	Lighting	250
	Space heaters in accommodation spaces	250
	Control <b>(1)</b> , communication (including signal lamps) and instrumentation equipment	250
<b>(1)</b> For control equipment which is part of a power and heating installation (e.g. pressure or temperature switches for start/stop motors), the same maximum voltage as allowed for the power and heating equipment may be used provided that all components are constructed for such voltage. However, the control voltage to external equipment is not to exceed 500 V.		
<b>(2)</b> Both conductors in such systems are to be insulated from earth.		

Use		Maximum voltage V
For permanently installed and connected by flexible cable	Power and heating equipment, where such connection is necessary because of the application (e.g. for moveable cranes or other hoisting gear)	1000
For socket-outlets supplying	Portable appliances which are not hand-held during operation (e.g. refrigerated containers) by flexible cables	1000
	Portable appliances and other consumers by flexible cables	250
	Equipment requiring extra precaution against electric shock where a isolating transformer is used to supply one appliance (2)	250
	Equipment requiring extra precaution against electric shock with or without a safety transformer (2)	50
<p>(1) For control equipment which is part of a power and heating installation (e.g. pressure or temperature switches for start/stop motors), the same maximum voltage as allowed for the power and heating equipment may be used provided that all components are constructed for such voltage. However, the control voltage to external equipment is not to exceed 500 V.</p> <p>(2) Both conductors in such systems are to be insulated from earth.</p>		

## 2 Sources of electrical power

### 2.1 General

2.1.1 *Electrical installations are to be such that:*

- a) *All electrical auxiliary services necessary for maintaining the ship in normal operational and habitable conditions and for the preservation of the cargo will be assured without recourse to the emergency source of electrical power.*
- b) *Electrical services essential for safety will be assured under various emergency conditions.*
- c) *When a.c. generators are involved, attention is to be given to the starting of squirrel-cage motors connected to the system, particularly with regard to the effect of the magnitude and duration of the transient voltage change produced due to the maximum starting current and the power factor. The voltage drop due to such starting current is not to cause any motor already operating to stall or have any adverse effect on other equipment in use.*

### 2.2 Main source of electrical power

2.2.1 *A main source of electrical power is to be provided, of sufficient capability to supply all electrical auxiliary services necessary for maintaining the ship in normal operational and habitable conditions and for the preservation of the cargo without recourse to the emergency source of electrical power.*

2.2.2 For vessels propelled by electrical power and having two or more constant voltage propulsion generating sets which constitute the source of electrical energy for the ship's auxiliary services, see Ch 2, Sec 14.

2.2.3 *The main source of electrical power is to consist of at least two generating sets.*

*The capacity of these generating sets is to be such that in the event of any one generating set being stopped it will still be possible to supply those services necessary to provide:*

- a) *normal operational conditions of propulsion and safety (see [2.2.4])*
- b) *minimum comfortable conditions of habitability (see Ch 2, Sec 1, [3.5])*
- c) *preservation of the cargo, i. e. all the equipment which are needed for refrigerated cargo or operation of any safety device, such as inert gas generator.*

Such capacity is, in addition, to be sufficient to start the largest motor without causing any other motor to stop or having any adverse effect on other equipment in operation.

2.2.4 Those services necessary to provide normal operational conditions of propulsion and safety include primary and secondary essential services.

For the purpose of calculating the capacity necessary for such services, it is essential to consider which of them can be expected to be in use simultaneously.

For a duplicated service, one being supplied electrically and the other non-electrically (e.g. driven by the main engine), the electrical capacity is not included in the above calculation.

2.2.5 The services in [2.2.4] do not include:

- thrusters not forming part of the main propulsion (except in manoeuvring conditions)
- cargo handling gear
- cargo pumps
- refrigerators for air conditioning.

**2.2.6** Further to the provisions above, the generating sets shall be such as to ensure that with any one generator or its primary source of power out of operation, the remaining generating sets shall be capable of providing the electrical services necessary to start the main propulsion plant from a "dead ship" condition.

**2.2.7** Where the electrical power is normally supplied by more than one generator set simultaneously in parallel operation, provision of protection, including automatic disconnection of sufficient non-essential services and, if necessary, secondary essential services and those provided for habitability, should be made to ensure that, in case of loss of any of these generating sets, the remaining ones are kept in operation to permit propulsion and steering and to ensure safety.

**2.2.8** Where the electrical power is normally supplied by one generator, provision is to be made, upon loss of power, for automatic starting and connecting to the main switchboard of stand-by generator(s) of sufficient capacity to supply the primary essential services and to ensure the safety of the ship, with automatic restarting of the essential auxiliaries, in sequential operation if required. Starting and connection to the main switchboard of the stand-by generator is to be preferably within 30 seconds, but in any case not more than 45 seconds after loss of power.

Where prime movers with longer starting time are used, this starting and connection time may be exceeded upon approval from the Society

**2.2.9** Load shedding or other equivalent arrangements should be provided to protect the generators required in the present Article against sustained overload.

The load shedding should be automatic.

The non-essential services, services for habitability and, if necessary, the secondary essential services may be shed in order to make sure that the connected generator set(s) is/are not overloaded.

**2.2.10** The emergency source of electrical power may be used for the purpose of starting from a "dead ship" condition if its capability either alone or combined with that of any other source of electrical power is sufficient to provide at the same time those services required to be supplied in accordance with the provisions of [3.6.3], items a), b), c) and d), or Pt D, Ch 11, Sec 5 for passenger ships.

**2.2.11** The arrangement of the ship's main source of electrical power shall be such that essential services can be maintained regardless of the speed and direction of rotation of the main propulsion machinery or shafting.

**2.2.12** Generators driven by the propulsion plant (shaft generators) which are intended to operate at constant speed (e.g. a system where vessel speed and direction are controlled by varying propeller pitch) may be accepted as forming part of the main source of electrical power if, in all sailing and manoeuvring conditions including the propeller being stopped, the capacity of these generators is sufficient to provide the electrical power to comply with [2.2.3] and all further requirements, especially those of [2.2.6]. They are to be not less effective and reliable than the independent generating sets.

**2.2.13** Shaft generator installations which do not comply with the provisions of [2.2.12] may be used as additional sources of electrical power with respect to the power balance provided that:

- a) in the event of a loss of power from the shaft generator(s), e.g. due to a sudden stopping of the propulsion plant, or upon frequency variations exceeding  $\pm 10\%$ , a standby generating set is started automatically
- b) the capacity of the standby set is sufficient for the loads necessary for propulsion and safety of the vessel
- c) the time required to restore these services is not longer than 45 s.

**2.2.14** Where transformers, converters or similar appliances constitute an essential part of the electrical supply system, the system is to be so arranged as to ensure the same continuity of supply as stated in this sub-article.

This may be achieved by arranging at least two three-phase or three single-phase transformers supplied, protected and installed as indicated in Fig 1, so that with any one transformer not in operation, the remaining transformer(s) is (are) sufficient to ensure the supply to the services stated in [2.2.3].

Each transformer required is to be located as a separate unit with separate enclosure or equivalent, and is to be served by separate circuits on the primary and secondary sides.

Each primary circuit is to be provided with switchgear and protection devices in each phase.

Each of the secondary circuits is to be provided with a multipole isolating switch.

Suitable interlocks or a warning label are to be provided in order to prevent maintenance or repair of one single-phase transformer unless both switchgears are opened on their primary and secondary sides.

**2.2.15** For ships intended for operation with periodically unattended machinery spaces, see Part F, Chapter 3.

**2.2.16** For starting arrangements for main generating sets, see Ch 1, Sec 2, [3.1].

**2.2.17** Where single phase transformers are used, only one spare element is required if special precautions are taken to rapidly replace the faulty one.

**2.2.18** Generators and generator systems, having the ship propulsion machinery as their prime mover but not forming part of the ship main source of electrical power, may be used whilst the ship is at sea to supply electrical services required for normal operational and habitable conditions provided that:

- a) there are sufficient and adequately rated additional generators fitted, which constitute the main source of electrical power required by [2.2.1]
- b) arrangements are fitted to automatically start one or more of the generators, constituting the main source of electrical power required by [2.2.1], upon the frequency variations exceeding  $\pm 10\%$  of the limits specified below
- c) within the declared operating range of the generators and/or generator systems the specified limits for the voltage variations and the frequency variations in Ch 2, Sec 2 can be met
- d) the short circuit current of the generator and/or generator system is sufficient to trip the generator/generator system circuit-breaker taking into account the selectivity of the protective devices for the distribution system
- e) where considered appropriate, load shedding arrangements are to be fitted
- f) on ships having remote control of the ship's propulsion machinery from the navigating bridge, means are provided, or procedures be in place, so as to ensure that supplies to essential services are maintained during manoeuvring conditions in order to avoid a blackout situation.

**Figure 1 :**

- (a) switchgear and protection devices
- (b) multipole isolating switch

### 2.3 Emergency source of electrical power

**2.3.1** A self-contained emergency source of electrical power shall be provided.

**2.3.2** Provided that suitable measures are taken for safeguarding independent emergency operation under all circumstances, the emergency generator may be used, exceptionally, and for short periods, to supply non-emergency circuits.

Exceptionally is understood to mean conditions, while the vessel is at sea, such as:

- a) blackout situation
- b) dead ship situation
- c) routine use for testing
- d) short-term parallel operation with the main source of electrical power for the purpose of load transfer.

Unless otherwise instructed by the Society, the emergency generator may be used during lay time in port for the supply of the ship mains, provided the requirements of [2.4] are complied with.

**2.3.3** The electrical power available shall be sufficient to supply all those services that are essential for safety in an emergency, due regard being paid to such services as may have to be operated simultaneously.

**2.3.4** *The emergency source of electrical power shall be capable, having regard to starting currents and the transitory nature of certain loads, of supplying simultaneously at least the services stated in [3.6.3] for the period specified, if they depend upon an electrical source for their operation.*

**2.3.5** *The transitional source of emergency electrical power, where required, is to be of sufficient capacity to supply at least the services stated in [3.6.7] for half an hour, if they depend upon an electrical source for their operation.*

**2.3.6** *An indicator shall be mounted in a suitable place on the main switchboard or in the machinery control room to indicate when the batteries constituting either the emergency source of electrical power or the transitional source of emergency electrical power referred to in [2.3.15] and [2.3.16] are being discharged.*

**2.3.7** *If the services which are to be supplied by the transitional source receive power from an accumulator battery by means of semiconductor converters, means are to be provided for supplying such services also in the event of failure of the converter (e.g. providing a bypass feeder or a duplication of converter).*

**2.3.8** *Where electrical power is necessary to restore propulsion, the capacity of the emergency source shall be sufficient to restore propulsion to the ship in conjunction to other machinery as appropriate, from a dead ship condition within 30 min. after blackout.*

For the purpose of this requirement only, the dead ship condition and blackout are both understood to mean a condition under which the main propulsion plant, boilers and auxiliaries are not in operation and in restoring the propulsion, no stored energy for starting the propulsion plant, the main source of electrical power and other essential auxiliaries is to be assumed available. It is assumed that means are available to start the emergency generator at all times.

The emergency generator and other means needed to restore the propulsion are to have a capacity such that the necessary propulsion starting energy is available within 30 minutes of blackout/dead ship condition as defined above. Emergency generator stored starting energy is not to be directly used for starting the propulsion plant, the main source of electrical power and/or other essential auxiliaries (emergency generator excluded).

For steam ships, the 30 minute time limit given in SOLAS can be interpreted as time from blackout/dead ship condition defined above to light-off the first boiler.

**2.3.9** *Where the emergency source of power is necessary to restore the main source of electrical power, provisions are to be made to allow a manual restart of a main generating set in case of failure of the emergency source.*

**2.3.10** *Provision shall be made for the periodic testing of the complete emergency system and shall include the testing of automatic starting arrangements, where provided.*

**2.3.11** *For starting arrangements for emergency generating sets, see Ch 1, Sec 2, [3.1].*

**2.3.12** *The emergency source of electrical power may be either a generator or an accumulator battery which shall comply with the requirements of [2.3.13] or [2.3.15], respectively.*

**2.3.13** *Where the emergency source of electrical power is a generator, it shall be:*

- a) *driven by a suitable prime mover with an independent supply of fuel, having a flashpoint (closed cup test) of not less than 43°C*
- b) *started automatically upon failure of the main source of electrical power supply to the emergency switchboard unless a transitional source of emergency electrical power in accordance with c) below is provided; where the emergency generator is automatically started, it shall be automatically connected to the emergency switchboard; those services referred to in [3.6.7] shall then be connected automatically to the emergency generator, and*
- c) *provided with a transitional source of emergency electrical power as specified in [2.3.16] unless an emergency generator is provided capable both of supplying the services mentioned in that paragraph and of being automatically started and supplying the required load as quickly as is safe and practicable subject to a maximum of 45 s.*

**2.3.14** *It is accepted to apply the total consumer load in steps providing that:*

- *the total load is supplied within 45 seconds since power failure on the main switchboard*
- *the power distribution system is designed such that the declared maximum step loading is not exceeded*
- *the compliance of time delays and loading sequence with the above is demonstrated at ship's trials.*

**2.3.15** *Where the emergency source of electrical power is an accumulator battery it shall be capable of:*

- a) *carrying the emergency electrical load without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage*
- b) *automatically connecting to the emergency switchboard in the event of failure of the main source of electrical power, and*
- c) *immediately supplying at least those services specified in [3.6.7].*

**2.3.16** *The transitional source of emergency electrical power where required by [2.3.13] item c), shall consist of an accumulator battery which shall operate without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage and be so arranged as to supply automatically in the event of failure of either the main or the emergency source of electrical power for half an hour at least the services in [3.6.7] if they depend upon an electrical source for their operation.*

**2.3.17** Where the emergency and/or transitional source of power is an uninterruptible power system (UPS), it is to comply with the requirement of Ch 2, Sec 6, [3].

**2.3.18** Where the emergency and/or transitional emergency loads are supplied from a battery via an electronic converter or inverter, the maximum permitted d.c. voltage variations are to be taken as those on the load side of the converter or inverter. Where the d.c. is converted into a.c. the maximum variations are not exceed those given in Ch 2, Sec 2, Tab 6.

**2.3.19** If the emergency generator is fitted with control, alarm and safety systems based on electronic equipment, these systems are to be so arranged that, when in failure, there is still a possibility to operate the emergency generator manually. A failure of the electronic governor is not considered.

**2.3.20** For the emergency source of electrical power in passenger ships, see Pt D, Ch 11, Sec 5.

**2.3.21** Ships having the additional service feature **SPxxx** or **SPxxx-capable** with xxx greater than 60 are to comply, in addition to the requirements of this article, with the provisions of Pt D, Ch 11, Sec 5, [2].

## **2.4 Use of emergency generator in port**

**2.4.1** To prevent the generator or its prime mover from becoming overloaded when used in port, arrangements are to be provided to shed sufficient non-emergency loads to ensure its continued safe operation.

**2.4.2** The prime mover is to be arranged with fuel oil filters and lubrication oil filters, monitoring equipment and protection devices as requested for the prime mover for main power generation and for unattended operation.

Note 1: Pt F, Ch 3, Sec 1, Tab 28 applies.

**2.4.3** The fuel oil supply tank to the prime mover is to be provided with a low level alarm, arranged at a level ensuring sufficient fuel oil capacity for the emergency services for the period of time as required in [3.6].

**2.4.4** The prime mover is to be designed and built for continuous operation and should be subjected to a planned maintenance scheme ensuring that it is always available and capable of fulfilling its role in the event of an emergency at sea.

**2.4.5** Fire detectors are to be installed in the location where the emergency generator set and emergency switchboard are installed.

**2.4.6** Means are to be provided to readily change over to emergency operation.

**2.4.7** Control, monitoring and supply circuits for the purpose of the use of the emergency generator in port are to be so arranged and protected that any electrical fault will not influence the operation of the main and emergency services.

When necessary for safe operation, the emergency switchboard is to be fitted with switches to isolate the circuits.

**2.4.8** Instructions are to be provided on board to ensure that, even when the vessel is underway, all control devices (e.g. valves, switches) are in a correct position for the independent emergency operation of the emergency generator set and emergency switchboard.

These instructions are also to contain information on the required fuel oil tank level, position of harbour/sea mode switch, if fitted, ventilation openings, etc.

## **3 Distribution**

### **3.1 Earthed distribution systems**

**3.1.1** System earthing is to be effected by means independent of any earthing arrangements of the non-current-carrying parts.

**3.1.2** Means of disconnection are to be fitted in the neutral earthing connection of each generator so that the generator may be disconnected for maintenance or insulation resistance measurements.

**3.1.3** Generator neutrals may be connected in common, provided that the third harmonic content of the voltage wave form of each generator does not exceed 5%.

**3.1.4** Where a switchboard is split into sections operated independently or where there are separate switchboards, neutral earthing is to be provided for each section or for each switchboard. Means are to be provided to ensure that the earth connection is not removed when generators are isolated.

**3.1.5** Where for final sub-circuits it is necessary to locally connect a pole (or phase) of the sub-circuits to earth after the protective devices (e.g. in automation systems or to avoid electromagnetic disturbances), provision (e.g. d.c./d.c. converters or transformers) is to be made such that current unbalances do not occur in the individual poles or phases.

**3.1.6** For high voltage systems see Ch 2, Sec 13.

### **3.2 Insulated distribution systems**

**3.2.1** Every insulated distribution system, *whether primary or secondary* (see Note 1), *for power, heating or lighting, shall be provided with a device capable of continuously monitoring the insulation level to earth* (i.e. the values of electrical insulation to earth) *and of giving an audible and visual indication of abnormally low insulation values* (see Ch 2, Sec 15).

Note 1: A primary system is one supplied directly by generators. Secondary systems are those supplied by transformers or converters.

**3.2.2** For high voltage systems see Ch 2, Sec 13.

### **3.3 Distribution systems with hull return**

**3.3.1** *Where the hull return system is used, if permitted, all final sub-circuits, i.e. all circuits fitted after the last protective device, shall be two-wire.*

The hull return is to be achieved by connecting to the hull one of the busbars of the distribution board from which the final sub-circuits originate.

### **3.4 General requirements for distribution systems**

**3.4.1** The distribution system is to be such that the failure of any single circuit will not endanger or impair primary essential services and will not render secondary essential services inoperative for longer periods.

**3.4.2** No common switchgear (e.g. contactors for emergency stop) is to be used between the switchboard's busbars and two primary non duplicated essential services.

**3.4.3** *Where the main source of electrical power is necessary for propulsion and steering of the ship, the system shall be so arranged that the electrical supply to equipment necessary for propulsion and steering and to ensure safety of the ship will be maintained or immediately restored in the case of loss of any one of the generators in service.*

**3.4.4** Ships having the additional service feature **SPxxx** or **SPxxx-capable** with xxx greater than 60 are to comply, in addition to the requirements of this article, with the provisions of Pt D, Ch 11, Sec 5, [1.2.1].

### **3.5 Main distribution of electrical power**

**3.5.1** Where the main source of electrical power is necessary for propulsion of the ship, the main busbar is to be divided into at least two parts which are normally to be connected by circuit breakers or other approved means such as circuit breakers without tripping mechanisms or disconnecting links or switches by means of which busbars can be split safely and easily.

Bolted links, for example bolted bus bar sections, are not accepted.

The connection of generating sets and associated auxiliaries and other duplicated equipment is to be equally divided between the parts as far as practicable, so that in the event of damage to one section of the switchboard the remaining parts are still supplied.

**3.5.2** Two or more units serving the same consumer (e.g. main and standby lubricating oil pumps) are to be supplied by individual separate circuits without the use of common feeders, protective devices or control circuits.

This requirement is satisfied when such units are supplied by separate cables from the main switchboard or from two independent section boards.

**3.5.3** *A main electric lighting system which shall provide illumination throughout those parts of the ship normally accessible to and used by (passengers or) crew shall be supplied from the main source of electrical power.*

### **3.6 Emergency distribution of electrical power**

**3.6.1** *The emergency switchboard shall be supplied during normal operation from the main switchboard by an interconnector feeder which shall be adequately protected at the main switchboard against overload and short-circuit and which is to be disconnected automatically at the emergency switchboard upon failure of the main source of electrical power.*

*Where the system is arranged for feedback operation, the interconnector feeder is also to be protected at the emergency switchboard at least against short-circuit.*

**3.6.2** *In order to ensure ready availability of the emergency source of electrical power, arrangements shall be made where necessary to disconnect automatically non-emergency circuits from the emergency switchboard to ensure that power shall be available to the emergency circuits.*

**3.6.3** *The emergency source of electrical power shall be capable of supplying simultaneously at least the following services for the periods specified hereafter, if they depend upon an electrical source for their operation:*

- a) *for a period of 3 hours, emergency lighting at every muster and embarkation station and over the sides*
- b) *for a period of 18 hours, emergency lighting:*
  - 1) *in all service and accommodation alleyways, stairways and exits, personnel lift cars and personnel lift trunks*
  - 2) *in the machinery spaces and main generating stations including their control positions*
  - 3) *in all control stations, machinery control rooms, and at each main and emergency switchboard*
  - 4) *at all stowage positions for fire-fighter's outfits*
  - 5) *at the steering gear, and*
  - 6) *at the fire pump referred to in e) below, at the sprinkler pump, if any, at the emergency bilge pump, if any, and at the starting positions of their motors*
- c) *for a period of 18 hours:*
  - 1) *the navigation lights and other lights required by the International Regulations for Preventing Collisions at Sea in force*
  - 2) *the VHF radio installation required by Regulation IV/7.1.1 and IV/7.1.2 of SOLAS 1974 as amended, and, if applicable:*
    - *the MF radio installation required by Regulations IV/9.1.1, IV/9.1.2, IV/10.1.2 and IV/10.1.3*
    - *the ship earth station required by Regulation IV/10.1.1, and*
    - *the MF/HF radio installation required by Regulations IV/11.1.1 and IV/11.1.2.*
- d) *for a period of 18 hours:*
  - 1) *all internal communication equipment as required in an emergency [3.6.4]*
  - 2) *the shipborne navigational equipment as required by Regulation V/19 where such provision is unreasonable or impracticable the Society may waive this requirement for ships of less than 5 000 gross tonnage*
  - 3) *the fire detection and fire alarm systems, and*
  - 4) *intermittent operation of the daylight signalling lamp, the ship's whistle, the manually operated call points and all internal signals (see [3.6.5]) that are required in an emergency unless such services have an independent supply for the period of 18 hours from an accumulator battery suitably located for use in an emergency*
- e) *for a period of 18 hours: one of the fire pumps required by the relevant provisions of Part C, Chapter 4, if dependent upon the emergency generator for its source of power*
- f) *for the period of time required in Ch 1, Sec 14, [2], the steering gear where it is required to be so supplied.*
- g) *On ships having the additional service feature **SPxxx** or **SPxxx-capable** with length greater than or equal to 50m, for a period of half an hour, any watertight door required by Pt D, Ch 11, Sec 2 to be power-operated together with their indicators and warning signals.*

**3.6.4** Internal communication equipment required in an emergency generally includes:

- a) the means of communication between the navigating bridge and the steering gear compartment
- b) the means of communication between the navigating bridge and the position in the machinery space or control room from which the engines are normally controlled
- c) the means of communication which is provided between the bridge and the radio communication station, if any
- d) the public address system.

**3.6.5** Internal signals required in an emergency generally include:

- a) general alarm
- b) watertight door indication.

**3.6.6** In a ship engaged regularly in voyages of short duration, i.e. voyages where the route is no greater than 20 nautical miles offshore or where the vessel has a class notation "Coastal Navigation", the Society may, if satisfied that an adequate standard of safety would be attained, accept a lesser period than the 18-hour period specified in [3.6.3], items b) to e), but not less than 12 hours.

Note 1: In ships for which Solas is not applicable, a reduced period of time may be accepted.

Note 2: For passenger ships see Pt D, Ch 11, Sec 5.

**3.6.7** *The transitional source of emergency electrical power, where required, shall supply for half an hour at least the following services if they depend upon an electrical source for their operation:*

- a) *the lighting required by [3.6.3], items a), b) and c) 1) for this transitional phase, the required emergency electric lighting, in respect of the machinery space and the accommodation and service spaces may be provided by permanently fixed, individual, automatically charged, relay operated accumulator lamps, and*
- b) *all services required by [3.6.3], items d) 1), d) 3) and d) 4), unless such services have an independent supply for the period specified from an accumulator battery suitably located for use in an emergency.*

### **3.7 Shore supply**

**3.7.1** Where arrangements are made for supplying the electrical installation from a source on shore or elsewhere, a suitable connection box is to be installed on the ship in a convenient location to receive the flexible cable from the external source.

**3.7.2** Permanently fixed cables of adequate rating are to be provided for connecting the box to the main switchboard.

**3.7.3** Where necessary for systems with earthed neutrals, the box is to be provided with an earthed terminal for connection between the shore's and ship's neutrals or for connection of a protective conductor.

**3.7.4** The connection box is to contain a circuit-breaker or a switch-disconnector and fuses.

The shore connection is to be protected against short-circuit and overload however, the overload protection may be omitted in the connection box if provided on the main switchboard.

**3.7.5** Means are to be provided for checking the phase sequence of the incoming supply in relation to the ship's system.

**3.7.6** The cable connection to the box is to be provided with at least one switch-disconnector on the main switchboard.

**3.7.7** The shore connection is to be provided with an indicator at the main switchboard in order to show when the cable is energised.

**3.7.8** At the connection box a notice is to be provided giving full information on the nominal voltage and frequency of the installation.

**3.7.9** The switch-disconnector on the main switchboard is to be interlocked with the main generator circuit-breakers in order to prevent its closure when any generator is supplying the main switchboard.

**3.7.10** Adequate means are to be provided to equalise the potential between the hull and the shore when the electrical installation of the ship is supplied from shore.

### **3.8 Supply of motors**

**3.8.1** A separate final sub-circuit is to be provided for every motor required for an essential service (and for every motor rated at 1 kW or more).

**3.8.2** Each motor is to be provided with controlgear ensuring its satisfactory starting.

Direct on line starters are accepted if the voltage drop does not exceed 15% of the network voltage.

**3.8.3** Efficient means are to be provided for the isolation of the motor and its associated control gear from all live poles of the supply.

Where the control gear is mounted on or adjacent to a switchboard, a disconnecting switch in the switchboard may be used for this purpose.

Otherwise, a disconnecting switch within the control gear enclosure or a separate enclosed disconnecting switch is to be provided.

**3.8.4** Where the starter or any other apparatus for disconnecting the motor is remote from the motor itself, one of the following is to be arranged:

- a) provision for locking the circuit disconnecting switch in the OFF position
- b) an additional disconnecting switch fitted near the motor
- c) provision such that the fuses in each live pole or phase can be readily removed and retained by persons authorised to have access to the motor.

**3.8.5** Unless automatic restarting is required, motor control circuits are to be designed so as to prevent any motor from unintentional automatic restarting after a stoppage due to over-current tripping or a fall in or loss of voltage, if such starting is liable to cause danger. Where reverse-current braking of a motor is provided, provision is to be made for the avoidance of reversal of the direction of rotation at the end of braking, if such reversal may cause danger.

### **3.9 Specific requirements for special power services**

**3.9.1** For the supply and characteristics of the distribution of the following services see the requirements listed:

- steering gear: Ch 1, Sec 14, [2]
- fire-extinguishing and detecting systems: Ch 4, Sec 15
- permanently installed submersible bilge pump: Ch 1, Sec 10, [6.7.7]
- ventilation fans, fuel pumps: Ch 4, Sec 2, [2.1]
- pumps discharging overboard above the lightest waterline and in way of the area of lifeboat and liferaft launching: Ch 1, Sec 10, [5.2.4].

**3.9.2** All power circuits terminating in a bunker or cargo space are to be provided with a multiple-pole switch outside the space for disconnecting such circuits.

### **3.10 Power supply to heaters**

**3.10.1** Each heater rated more than 16 A is to be connected to a separate final circuit.

### **3.11 Reefer containers**

**3.11.1** Where the ship is intended to carry a large number of refrigerated containers, provision of suitable means for preventing earth faults on containers from affecting the main distribution system is to be made (galvanic isolation, tripping of the faulty circuit).

### **3.12 Power supply to final sub-circuits: socket outlet and lighting**

**3.12.1** Final sub-circuits for lighting supplying more than one lighting point and for socket-outlets are to be fitted with protective devices having a current rating not exceeding 16 A.

**3.12.2** In spaces such as:

- main and large machinery spaces
- large galleys
- passageways
- stairways leading to boat-decks
- public spaces

there is to be more than one final sub-circuit for lighting such that failure of any one circuit does not reduce the lighting to an insufficient level.

**3.12.3** Where the emergency installation is required, one of the circuits in [3.12.2] may be supplied from the emergency source of power.

**3.12.4** All lighting circuits terminating in a bunker or cargo space are to be provided with a multiple-pole switch outside the space for disconnecting such circuits.

**3.12.5** The number of lighting points (lamps) supplied by a final sub-circuit having a current rating not exceeding 16 A is not to exceed the following maxima:

- 10 lamps for voltage up to 55 V
- 14 lamps for voltage from 56 V up to 120 V
- 24 lamps for voltage from 121 V to 250 V.

**3.12.6** Final sub-circuits for lighting in accommodation spaces may include socket-outlets. In that case, each socket-outlet counts for two lighting points.

### **3.13 Navigation lights**

**3.13.1** Navigation lights are to be connected separately to a distribution board specially reserved for this purpose.

**3.13.2** The distribution board in [3.13] is to be supplied from two alternative circuits, one from the main source of power and one from the emergency source of power (see also [3.6]).

The transfer of supply is to be practicable from the bridge, for example by means of a switch.

**3.13.3** Each navigation light is to be controlled and protected in each insulated pole by a double-pole switch and a fuse or, alternatively, by a double-pole circuit-breaker, fitted on the distribution board referred to in [3.13].

**3.13.4** Where there are double navigation lights, i.e. lights with two lamps or where for every navigation light a spare is also fitted, the connections to such lights may run in a single cable provided that means are foreseen in the distribution board to ensure that only one lamp or light may be supplied at any one time.

**3.13.5** Each navigation light is to be provided with an automatic indicator giving audible and/or visual warning in the event of failure of the light. If an audible device alone is fitted, it is to be connected to a separate source of supply from that of the navigation lights, for example an accumulator (storage) battery.

If a visual signal is used connected in series with the navigation light, means are to be provided to prevent the extinction of the navigation light due to the failure of the visual signal.

A minimum level of visibility is to be assured in the case of use of dimmer devices.

### **3.14 General emergency alarm system**

**3.14.1** An electrically operated bell or klaxon or other equivalent warning system installed in addition to the ship's whistle or siren, for sounding the general emergency alarm signal, is to comply with the requirements of this sub-article.

**3.14.2** The general emergency alarm system is to be supplemented by either a public address system complying with the requirements in [3.15] or other suitable means of communication.

**3.14.3** Entertainment sound system is to be automatically turned off when the general alarm system is activated.

**3.14.4** The system is to be continuously powered and is to have an automatic change-over to a standby power supply in case of loss of normal power supply.

An alarm is to be given in the event of failure of the normal power supply.

**3.14.5** The system is to be powered by means of two circuits, one from the ship's main supply and the other from the emergency source of electrical power required by [2.3] and [3.6].

**3.14.6** The system is to be capable of operation from the navigation bridge and, except for the ship's whistle, also from other strategic points.

Note 1: Other strategic points are taken to mean those locations, other than the navigation bridge, from where emergency situations are intended to be controlled and the general alarm system can be activated. A fire control station or a cargo control station should normally be regarded as strategic points.

**3.14.7** The alarm is to continue to function after it has been triggered until it is manually turned off or is temporarily interrupted by a message on the public address system.

**3.14.8** The alarm system is to be audible throughout all the accommodation and normal crew working spaces.

**3.14.9** The minimum sound pressure level for the emergency alarm tone in interior and exterior spaces is to be 80 dB (A) and at least 10 dB (A) above ambient noise levels occurring during normal equipment operation with the ship underway in moderate weather.

**3.14.10** In cabins without a loudspeaker installation, an electronic alarm transducer, e.g. a buzzer or similar, is to be installed.

**3.14.11** The sound pressure level at the sleeping position in cabins and in cabin bathrooms is to be at least 75 dB (A) and at least 10 dB (A) above ambient noise levels.

**3.14.12** For cables used for the general emergency alarm system, see [9.6.1].

### **3.15 Public address system**

**3.15.1** The public address system is to be a loudspeaker installation enabling the broadcast of messages into all spaces where people on board are normally present.

In spaces such as under deck passageways, bosun's locker, hospital and pump rooms, the public address system may not be required.

**3.15.2** Where the public address system is used to supplement the general emergency alarm system as per [3.14.2], it is to be continuously powered from the emergency source of electrical power required by [2.3] and [3.6].

**3.15.3** The system is to allow for the broadcast of messages from the navigation bridge and from other places on board the ship as deemed necessary.

**3.15.4** The system is to be protected against unauthorised use.

**3.15.5** The system is to be installed with regard to acoustically marginal conditions and not require any action from the addressee.

**3.15.6** Where an individual loudspeaker has a device for local silencing, an override arrangement from the control station(s), including the navigating bridge, is to be in place.

**3.15.7** With the ship underway in normal conditions, the minimum sound pressure level for broadcasting emergency announcements is to be:

- a) in interior spaces, 75 dB (A) and at least 20 dB (A) above the speech interference level
- b) in exterior spaces, 80 dB (A) and at least 15 dB (A) above the speech interference level.

With respect to cabin/state rooms, the sound pressure level is to be attained as required inside such spaces during sea trials.

### **3.16 Combined general emergency alarm-public address system**

**3.16.1** Where the public address system is the only means for sounding the general emergency alarm signal and the fire alarm, in addition to the requirements of [3.14] and [3.15], the following are to be satisfied:

- the system automatically overrides any other non emergency input system when an emergency alarm is required
- the system automatically overrides any volume control provided to give the required output for the emergency mode when an emergency alarm is required
- the system is arranged to prevent feedback or other interference
- the system is arranged to minimise the effect of a single failure so that the alarm signal is still audible (above ambient noise levels) also in the case of failure of any one circuit or component, by means of the use of:
  - multiple amplifiers
  - segregated cable routes to public rooms, alleyways, stairways and control stations
  - more than one device for generating electronic sound signal
  - electrical protection for individual loudspeakers against short-circuits.

### **3.17 Control and indication circuits**

**3.17.1** For the supply of automation systems, comprising control, alarm and safety system, see the requirements of Part C, Chapter 3.

**3.17.2** Control and indicating circuits relative to primary essential services are to be branched off from the main circuit in which the relevant equipment is installed. Equivalent arrangements may be accepted by the Society.

**3.17.3** Control and indicating circuits relative to secondary essential services and to non-essential services may be supplied by distribution systems reserved for the purpose to the satisfaction of the Society.

### **3.18 Power supply to the speed control systems of main propulsion engines**

**3.18.1** Electrically operated speed control systems of main engines are to be fed from the main source of electrical power.

**3.18.2** Where more than one main propulsion engine is foreseen, each speed control system is to be provided with an individual supply by means of separate wiring from the main switchboard or from two independent section boards.

Where the main busbars are divided into two sections, the governors are, as far as practicable, to be supplied equally from the two sections.

**3.18.3** In the case of propulsion engines which do not depend for their operation on electrical power, i.e. pumps driven from the main engine, the speed control systems are to be fed both from the main source of electrical power and from an accumulator battery for at least 15 minutes or from a similar supply source.

Such battery may also be used for other services such as automation systems, where foreseen.

### **3.19 Power supply to the speed control systems of generator sets**

**3.19.1** Each electrically operated control and/or speed control system of generator sets is to be provided with a separate supply from the main source of electric power and from an accumulator battery for at least 15 minutes or from a similar supply source.

**3.19.2** The speed control system of generator sets is to be supplied from the main switchboard or from independent section boards.

Where the main busbars are divided into two sections, the governors are, as far as practicable, to be supplied from the sections to which the relevant generators are connected.

### **3.20 Installation of water-based local application fire-fighting systems (FWBLAFFS)**

**3.20.1** The system is to be capable of manual release.

**3.20.2** The activation of the fire-fighting system is not to result in loss of electrical power or reduction of the manoeuvrability of the ship.

**3.20.3** The system and its components are to be designed to withstand ambient temperature changes, vibration, humidity, shock, impact, clogging and corrosion normally encountered in machinery spaces. Components within the protected spaces are to be designed to withstand the elevated temperatures which could occur during a fire.

**3.20.4** Degrees of protection are to be in accordance with [4.2].

**3.20.5** Systems requiring an external power source are to be supplied by the main power source.

**3.20.6** In case of activation of the system, an alarm in accordance with Ch 4, Sec 6, [4.7.4] is to be activated.

### 3.21 Integrated cargo and ballast systems on tankers

**3.21.1** Integrated electric systems used to drive both cargo and ballast pumps on tankers, including control and safety systems, are to comply with the provisions of Pt D, Ch 7, Sec 4, [3.6].

### 3.22 Harmonic distortion for ship electrical distribution system including harmonics filters

**3.22.1** Where harmonic filters are installed on main busbars of electrical distribution system, other than those installed for single application frequency drives such as pump motors, the ships are to be fitted with facilities to continuously monitor the levels of harmonic distortion experienced on the main busbar. The crew is to be alerted when the level of harmonic distortion exceeded the acceptable limits.

**3.22.2** Where the electrical distribution system on board a ship includes harmonic filters the system integrator of the distribution system is to show, by calculation, the effect of a failure of a harmonic filter on the level of harmonic distortion experienced.

**3.22.3** The system integrator of the distribution system is to provide the Society, for information, with guidance documenting permitted modes of operation of the electrical distribution system while maintaining harmonic distortion levels within acceptable limits during normal operation as well as following the failure of any combination of harmonic filters

**3.22.4** Arrangements are to be provided to alert the crew in the event of activation of the protection of a harmonic filter circuit.

**3.22.5** A harmonic filter is to be arranged as a three phase unit with individual protection of each phase. The activation of the protection arrangement in a single phase is to result in automatic disconnection of the complete filter.

**3.22.6** A current unbalance detection system, independent of the overcurrent protection, is to be provided in order to alert the crew in case of current unbalance.

**3.22.7** Additional protection for the individual capacitor element as e.g. relief valve or overpressure disconnecter in order to protect against damage from rupturing may be considered, depending on the type of capacitors used.

## 4 Degrees of protection of the enclosures

### 4.1 General

**4.1.1** The minimum required degree of protection for electrical equipment, in relation to the place of installation, is generally that specified in Tab 2.

**4.1.2** Equipment supplied at nominal voltages in excess of 500 V and accessible to non-authorized personnel (e.g. equipment not located in machinery spaces or in locked compartments under the responsibility of the ship's officers) is to have a degree of protection against touching live parts of at least IP 4X.

**4.1.3** In addition to the requirements of this paragraph, equipment installed in spaces with an explosion hazard is also subject to the provisions of Ch 2, Sec 2, [6].

**4.1.4** The enclosures of electrical equipment for the monitoring and control of watertight doors which are situated below the bulkhead deck are to provide suitable protection against the ingress of water.

In particular, the minimum required degree of protection is to be:

- IP X7 for electric motors, associated circuits and control components
- IP X8 for door position indicators and associated circuit components
- IP X6 for door movement warning signals.

Note 1: The water pressure testing of the enclosures protected to IP X8 is to be based on the pressure that may occur at the location of the component during flooding for a period of 36 hours.

**4.1.5** This requirement applies to ships with service notation **bulk carrier, ore carrier or combination carrier**, as described in Pt A, Ch 1, Sec 2, [4.3] and provided with a dewatering system (see Ch 1, Sec 10, [6.6.7]). The enclosures of electrical equipment for the dewatering system installed in any of the forward dry spaces are to provide protection to IPX8 standard for a water head equal to the height of the space in which the electrical equipment is installed for a time duration of at least 24 hours.

Table 2 : Minimum required degrees of protection

Condition in location	Example of location	Switchboard, control gear, motorstarters	Generators	Motors	Transformers	Luminaires	Heating appliances	Cooking appliances	Socket outlets	Accessories (e.g. switches, connection boxes)
Danger of touching live parts only	Dry accommodation spaces, dry control rooms	IP 20	X (1)	IP 20	IP 20	IP 20	IP 20	IP 20	IP 20	IP 20
Danger of dripping liquid and/or moderate mechanical damage	Control rooms, wheel-house, radio room	IP 22	X	IP 22	IP 22	IP 22	IP 22	IP 22	IP 22	IP 22
	Engine and boiler rooms above floor	IP 22	IP 22	IP 22	IP 22	IP 22	IP 22	IP 22	IP 44	IP 44
	Steering gear rooms	IP 22	IP 22	IP 22	IP 22	IP 22	IP 22	X	IP 44	IP 44
	Emergency machinery rooms	IP 22	IP 22	IP 22	IP 22	IP 22	IP 22	X	IP 44	IP 44
	General storerooms	IP 22	X	IP 22	IP 22	IP 22	IP 22	X	IP 22	IP 44
	Pantries	IP 22	X	IP 22	IP 22	IP 22	IP 22	IP 22	IP 44	IP 44
	Provision rooms	IP 22	X	IP 22	IP 22	IP 22	IP 22	X	IP 44	IP 44
Ventilation ducts	X	X	IP 22	X	X	X	X	X	X	
Increased danger of liquid and/or mechanical damage	Bathrooms and / or showers	X	X	X	X	IP 34	IP 44	X	IP 55	IP 55
	Engine and boiler rooms below floor	X	X	IP 44	X	IP 34	IP 44	X	X	IP 55
	Closed fuel oil separator rooms	IP 44	X	IP 44	IP 44	IP 34	IP 44	X	X	IP 55
	Closed lubricating oil separator rooms	IP 44	X	IP 44	IP 44	IP 34	IP 44	X	X	IP 55
Increased danger of liquid and mechanical damage	Ballast pump rooms	IP 44	X	IP 44 (2)	IP 44 (2)	IP 34	IP 44	X	IP 55	IP 55
	Refrigerated rooms	X	X	IP 44	X	IP 34	IP 44	X	IP 55	IP 55
	Galleys and laundries	IP 44	X	IP 44	IP 44	IP 34	IP 44	IP 44	IP 44	IP 44
	Public bathrooms and shower	X	X	IP 44	IP 44	IP 34	IP 44	X	IP 44	IP 44
Danger of liquid spraying, presence of cargo dust, serious mechanical damage, aggressive fumes	Shaft or pipe tunnels in double bottom	IP 55	X	IP 55	IP 55	IP 55	IP 55	X	IP 56	IP 56
	Holds for general cargo	X	X	IP 55	X	IP 55	IP 55	X	IP 56	IP 56

Danger of liquid in massive quantities	Open decks	IP 56	X	IP 56	X	IP 55	IP 56	X	IP 56	IP 56
<p>(1) The symbol "X" denotes equipment which it is not advised to install.</p> <p>(2) Electric motors and starting transformers for lateral thrust propellers located in spaces similar to ballast pump rooms may have degree of protection IP 22.</p>										

## 4.2 Installation of electrical and electronic equipment in engine rooms protected by fixed water-based local application fire-fighting systems (FWBLAFFS)

4.2.1 Unless it is essential for safety or operational purposes, electrical and electronic equipment is not to be located within areas protected by FWBLAFFS and in adjacent areas where water may extend.

The electrical and electronic equipment located within areas protected by FWBLAFFS and those within adjacent exposed to direct spray are to have a degree of protection not less than IP44.

Electrical and electronic equipment within adjacent areas not exposed to direct spray may have a lower degree of protection provided evidence of suitability for use in these areas is submitted taking into account the design and equipment layout, e.g. position of inlet ventilation openings, filters, baffles, etc. to prevent or restrict the ingress mist/spray into the equipment. The cooling airflow for the equipment is to be assured.

Note 1: Definitions (see Fig 2):

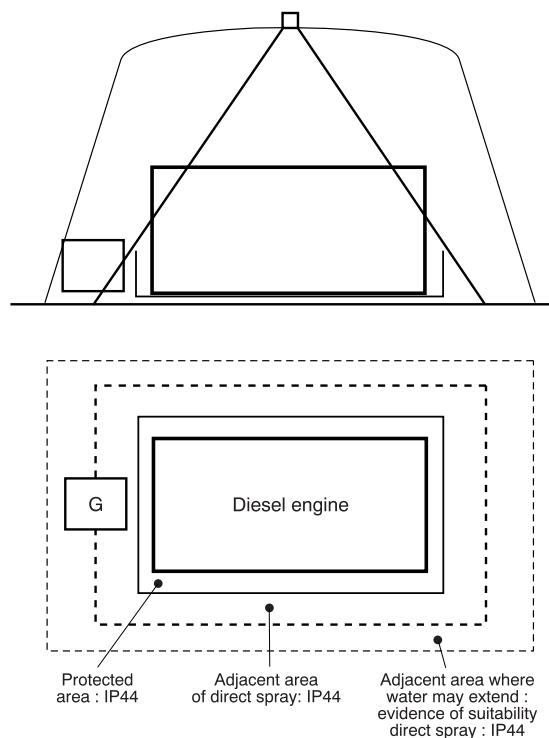

- protected space is a machinery space where a FWBLAFFS is installed
- protected areas: areas within a protected space which is required to be protected by FWBLAFFS
- adjacent areas:
  - areas other those protected areas, exposed
  - areas other those defined above, where water may extend.

Note 2: Additional precautions may be required to be taken in respect of:

- tracking as the result of water entering the equipment
- potential damage as the result of residual salts from sea water systems
- high voltage installations
- personnel protection against electric shock

Equipment may require maintenance after being subjected to water mist/spray.

**Figure 2 : Definitions of areas**

## 5 Diversity (demand) factors

### 5.1 General

**5.1.1** The cables and protective devices of final sub-circuits are to be rated in accordance with their connected load.

**5.1.2** Circuits supplying two or more final sub-circuits are to be rated in accordance with the total connected load subject, where justifiable, to the application of a diversity (demand) factor.

**5.1.3** A diversity (demand) factor may be applied provided that the known or anticipated operating conditions in a particular part of an installation are suitable for the application of diversity.

## 6 Environmental categories of the equipment

### 6.1 Environmental categories

**6.1.1** The environmental categories of the electrical equipment, in relation to the place of installation, are generally to be those specified in Tab 3.

**6.1.2** For ships operating outside the tropical belt, the maximum ambient air temperature may be assumed as equal to + 40°C instead of + 45°C, so that the first characteristic numeral changes from 1 to 3.

Table 3 : Required environmental categories

Main areas on board	Location within main area			
	General	Inside cubicles, desks, etc.	On machinery such as internal combustion engines, compressors	Masts
Machinery spaces, steering gear	EC21	EC31	EC23	X (1)
Control room, accommodation	EC21 EC11C	EC31	X	X
Bridge	EC21B EC11BC	EC31B	X	X
Pump room, holds, rooms without heating	EC41	X	X	X
Exposed decks	EC41S EC41BS	X	X	EC42S EC42BS

(1) The symbol "X" denotes locations which are generally not applicable.

## 7 Electrical protection

### 7.1 General requirements for overcurrent protection

**7.1.1** Electrical installations are to be protected against accidental overcurrents including short-circuit.

The choice, arrangement and performance of the various protective devices are to provide complete and coordinated automatic protection in order to ensure as far as possible:

- continuity of service in the event of a fault, through coordinated and discriminative action of the protective devices
- elimination of the effects of faults to reduce damage to the system and the hazard of fire as far as possible.

Note 1: An overcurrent is a current exceeding the nominal current.

Note 2: A short-circuit is the accidental connection by a relatively low resistance or impedance of two or more points in a circuit which are normally at different voltages.

**7.1.2** Devices provided for overcurrent protection are to be chosen according to the requirements, especially with regard to overload and short-circuit.

Note 1: Overload is an operating condition in an electrically undamaged circuit which causes an overcurrent.

**7.1.3** Systems are to be such as to withstand the thermal and electrodynamic stresses caused by the possible overcurrent, including short-circuit, for the admissible duration.

### 7.2 Short-circuit currents

**7.2.1** In calculating the maximum prospective short-circuit current, the source of current is to include the most powerful configuration of generators which can be simultaneously connected (as far as permitted by any interlocking arrangements), and the maximum number of motors which are normally simultaneously connected in the system.

The maximum number of generators or transformers is to be evaluated without taking into consideration short-term parallel operation (e.g. for load transfer) provided that suitable interlock is foreseen.

**7.2.2** Short-circuit current calculations are to be performed in accordance with a method recognised by the Society, such as that given in IEC Publication 61363-1.

**7.2.3** In the absence of precise data concerning the characteristics of generators, accumulator batteries and motors, the maximum short-circuit currents on the main busbars may be calculated as follows:

- for alternating current systems:

$$I_{ac} = 10 I_{TG} + 3,5 I_{TM}$$

$$I_{pk} = 2,4 I_{ac}$$

- for direct current systems supplied by batteries:

$$I_p = K C_{10} + 6 I_{TM}$$

where:

$I_p$  : Maximum short-circuit current

$I_{ac}$  : r.m.s. value of the symmetrical component (at the instant T/2)

$I_{pk}$  : Maximum peak value

$I_{TG}$  : Rated current of all generators which can be connected simultaneously

- $C_{10}$  : Battery capacity in Ah for a discharge duration of 10 hours  
 $K$  : Ratio of the short-circuit current of the batteries to  $C_{10}$  (see Note 1)  
 $I_{TM}$  : Rated current of all motors which are normally simultaneously connected in the system.

Note 1: For stationary batteries the following values may be assumed for guidance:

- vented lead-acid batteries:  $K = 8$
- vented alkaline type batteries intended for discharge at low rates corresponding to a battery duration exceeding three hours:  $K = 15$
- sealed lead-acid batteries having a capacity of 100 Ah or more or alkaline type batteries intended for discharge at high rates corresponding to a battery duration not exceeding three hours:  $K = 30$ .

**7.2.4** Converters used for power supply are to supply a short-circuit current sufficient for selective tripping of downstream protective devices without sustaining any internal damage. An automatic bypass may be used to achieve such a selective tripping.

### 7.3 Selection of equipment

**7.3.1** Circuit-breakers of withdrawable type are required where they are not suitable for isolation.

**7.3.2** Equipment is to be chosen on the basis of its rated current and its making/breaking capacity.

**7.3.3** In the selection of circuit-breakers with intentional short-time delay for short-circuit release, those of utilisation category B are to be used and they are to be selected also taking into account their rated short-time withstand current capacity ( $I_{cw}$ ).

For circuit-breakers without intentional short-time delay for short-circuit release, circuit breakers of utilisation category A may be used and they are to be selected according to their rated service short-circuit breaking capacity ( $I_{cs}$ ).

Note 1: For the purpose of these Rules, utilisation categories A and B are defined as follows:

- utilisation category A: circuit-breakers not specifically intended for selectivity under short-circuit conditions with respect to other short-circuit protective devices in series on the load side, i.e. without an intentional short-time delay provided for selectivity under short-circuit conditions
- utilisation category B: circuit-breakers specifically intended for selectivity under short-circuit conditions with respect to other short-circuit protective devices in series on the load side, i.e. with an intentional short-time delay (which may be adjustable) provided for selectivity under short-circuit conditions.

**7.3.4** For duplicated essential services and non-essential services, circuit-breakers may be selected according to their ultimate short-circuit breaking capacity ( $I_{cu}$ ).

**7.3.5** For switches, the making/breaking capacity is to be in accordance with utilisation category AC-22 A or DC-22 A (in compliance with IEC Publication 60947-3).

**7.3.6** For fuse-switch disconnectors or switch-disconnector fuse units, the making/breaking capacity is to be in accordance with utilisation categories AC-23 A or DC-23 A (in compliance with IEC Publication 60947-3).

### 7.4 Protection against short-circuit

**7.4.1** Protection against short-circuit currents is to be provided by circuit-breakers or fuses.

**7.4.2** The rated short-circuit breaking capacity of every protective device is to be not less than the maximum prospective value of the short-circuit current at the point of installation at the instant of contact separation.

**7.4.3** The rated short-circuit making capacity of every mechanical switching device intended to be capable of being closed on short-circuit is to be not less than the maximum value of the short-circuit current at the point of installation. On alternating current this maximum value corresponds to the peak value allowing for maximum asymmetry.

**7.4.4** Every protective device or contactor not intended for short-circuit interruption is to be adequate for the maximum short-circuit current liable to occur at the point of installation having regard to the time required for the short-circuit to be removed.

**7.4.5** The use of a protective device not having a short-circuit breaking or making capacity at least equal to the maximum prospective short-circuit current at the point where it is installed is permitted, provided that it is backed up on the generator side by a fuse or by a circuit-breaker having at least the necessary short-circuit rating and not being the generator circuit-breaker.

**7.4.6** The same fuse or circuit-breaker may back up more than one circuit-breaker where the circuits concerned do not involve essential services.

**7.4.7** The short-circuit performance of the back-up arrangement is to be equal to the requirements of IEC Publication 60947-2 for a single circuit-breaker having the same short-circuit performance category as the backed-up circuit-breaker and rated for the maximum prospective short-circuit level at the supply terminals of the arrangement.

**7.4.8** Circuit-breakers with fuses connected to the load side may be used, provided the back-up fuses and the circuit-breakers are of coordinated design, in order to ensure that the operation of the fuses takes place in due time so as to prevent arcing between poles or against metal parts of the circuit-breakers when they are submitted to overcurrents involving the operation of the fuse.

**7.4.9** When determining the performance requirements for the above-mentioned back-up protection arrangement, it is permissible to take into account the impedance of the various circuit elements of the arrangement, such as the impedance of a cable connection when the backed-up circuit-breaker is located away from the back-up breaker or fuse.

**7.5 Continuity of supply and continuity of service**

**7.5.1** The protection of circuits is to be such that a fault in one service does not cause the loss of any essential services.

**7.5.2** The protection of the emergency circuit is to be such that a failure in one circuit does not cause a loss of other emergency services.

Note 1: The continuity of supply for the primary essential services and the continuity of service for the secondary essential services are to be ensured.

The continuity of supply is the condition for which during and after a fault in a circuit, the supply to the healthy circuits (see circuit 3 in Fig 3) is permanently ensured.

The continuity of service is the condition for which after a fault in a circuit has been cleared, the supply to the healthy circuits (see circuit 3 in Fig 3) is re-established.

**Figure 3 : Continuity of supply and continuity of service**

**7.6 Protection against overload**

**7.6.1** Devices provided for overload protection are to have a tripping characteristic (overcurrent-trip time) adequate for the overload ability of the elements of the system to be protected and for any discrimination requirements.

**7.6.2** The use of fuses up to 320 A for overload protection is permitted.

**7.7 Localisation of overcurrent protection**

**7.7.1** Short-circuit protection is to be provided for every non-earthed conductor.

**7.7.2** Overload protection is to be provided for every non-earthed conductor nevertheless, in insulated single-phase circuits or insulated three-phase circuits having substantially balanced loads, the overload protection may be omitted on one conductor.

**7.7.3** Short-circuit and overload protective devices are not to interrupt earthed conductors, except in the case of multiple disconnection devices which simultaneously interrupt all the conductors, whether earthed or not.

**7.7.4** Electrical protection is to be located as close as possible to the origin of the protected circuit.

## **7.8 Protection of generators**

**7.8.1** Generators are to be protected against short-circuits and overloads by multipole circuit-breakers.

For generators not arranged to operate in parallel with a rated output equal to or less than 50 kVA, a multipole switch with a fuse in each insulated phase on the generator side may be accepted.

**7.8.2** When multipole switch and fuses are used, the fuse rating is to be maximum 110% of the generator rated current.

**7.8.3** Where a circuit-breaker is used:

- a) The overload protection is to trip the generator circuit-breaker at an overload between 10% and 50%. For an overload of 50% of the rated current of the generator, the time delay is not to exceed 2 minutes. However, the figure of 50% or the time delay of 2 minutes may be exceeded if the construction of the generator permits this.
- b) the setting of the short-circuit protection is to instantaneously trip the generator circuit-breaker at an overcurrent less than the steady short-circuit current of the generator. Short time delays (e.g. from 0,5 s to 1 s) may be introduced for discrimination requirements in "instantaneous" tripping devices.

**7.8.4** For emergency generators the overload protection may, instead of disconnecting the generator automatically, give a visual and audible alarm in a permanently attended space.

**7.8.5** After disconnection of a generator due to overload, the circuit-breaker is to be ready for immediate reclosure.

**7.8.6** Generator circuit-breakers are to be provided with a reclosing inhibitor which prevents their automatic reclosure after tripping due to a short-circuit.

**7.8.7** Generators having a capacity of 1500 kVA or above are to be equipped with a suitable protective device or system which, in the event of a short-circuit in the generator or in the supply cable between the generator and its circuit-breaker, will de-excite the generator and open the circuit-breaker (e.g. by means of differential protection).

**7.8.8** *Where the main source of electrical power is necessary for the propulsion of the ship, load shedding or other equivalent arrangements are to be provided to protect the generators against sustained overload.*

**7.8.9** Arrangements are to be made to disconnect or reduce automatically the excess load when the generators are overloaded in such a way as to prevent a sustained loss of speed and/or voltage (see Ch 2, Sec 2, Tab 6). The operation of such device is to activate a visual and audible alarm. A time delay of 5-20 s is considered acceptable.

**7.8.10** When an overload is detected the load shedding system is to disconnect automatically, after an appropriate time delay, the circuits supplying the non-essential services and, if necessary, the secondary essential services in a second stage.

**7.8.11** Alternating current generators arranged to operate in parallel are to be provided with reverse-power protection.

The protection is to be selected in accordance with the characteristics of the prime mover.

The following values are recommended:

- 2-6% of the rated power for turbogenerators
- 8-15% of the rated power for diesel generators.

The reverse-power protection may be replaced by other devices ensuring adequate protection of the prime movers.

**7.8.12** Generators are to be provided with an undervoltage protection which trips the breaker if the voltage falls to 70%-35% of the rated voltage.

The undervoltage release also prevents the closing of the circuit-breaker if the generator voltage does not reach a minimum of 85% of the rated voltage.

The operation of the undervoltage release is to be instantaneous when preventing closure of the breaker, but it is to be delayed for selectivity purposes when tripping the breaker.

**7.8.13** Generators are to be provided with overvoltage protection to avoid damage to the connected equipment.

## **7.9 Protection of circuits**

**7.9.1** *Each separate circuit shall be protected against short-circuit and against overload, unless otherwise specified in these Rules or where the Society may exceptionally otherwise permit.*

**7.9.2** Each circuit is to be protected by a multipole circuit-breaker or switch and fuses against overloads and short-circuits.

**7.9.3** Circuits for lighting are to be disconnected on both non-earthed conductors. Single-pole disconnection of final sub-circuits with both poles insulated is permitted only in accommodation spaces, when a differential protection is provided.

**7.9.4** The protective devices of the circuits supplying motors are to allow excess current to pass during transient starting of motors.

**7.9.5** Final sub-circuits which supply one consumer with its own overload protection (for example motors), or consumers which cannot be overloaded (for example permanently wired heating circuits and lighting circuits), may be provided with short-circuit protection only.

**7.9.6** Steering gear circuits are to be provided with short-circuit protection only (see Ch 1, Sec 14, [2]).

### **7.10 Protection of motors**

**7.10.1** Motors of rating exceeding 1 kW and all motors for essential services are to be protected individually against overload and short-circuit. The short-circuit protection may be provided by the same protective device for the motor and its supply cable (see [7.9.5]).

**7.10.2** For motors intended for essential services, the overload protection may be replaced by an overload alarm (for steering gear motors see Ch 1, Sec 14, [2]).

**7.10.3** The protective devices are to be designed so as to allow excess current to pass during the normal accelerating period of motors according to the conditions corresponding to normal use.

If the current/time characteristic of the overload protection device does not correspond to the starting conditions of a motor (e.g. for motors with extra-long starting period), provision may be made to suppress operation of the device during the acceleration period on condition that the short-circuit protection remains operational and the suppression of overload protection is only temporary.

**7.10.4** For continuous duty motors the protective gear is to have a time delay characteristic which ensures reliable thermal protection against overload.

**7.10.5** The protective devices are to be adjusted so as to limit the maximum continuous current to a value within the range 105% - 120% of the motor's rated full load current.

**7.10.6** For intermittent duty motors the current setting and the delay (as a function of time) of the protective devices are to be chosen in relation to the actual service conditions of the motor.

**7.10.7** Where fuses are used to protect polyphase motor circuits, means are to be provided to protect the motor against unacceptable overload in the case of single phasing.

**7.10.8** Motors rated above 1 kW are to be provided with:

- undervoltage protection, operating on the reduction or failure of voltage, to cause and maintain the interruption of power in the circuit until the motor is deliberately restarted or
- undervoltage release, operating on the reduction or failure of voltage, so arranged that the motor restarts automatically when power is restored after a power failure.

**7.10.9** The automatic restart of a motor is not to produce a starting current such as to cause excessive voltage drop.

In the case of several motors required to restart automatically, the total starting current is not to cause an excessive voltage drop or sudden surge current to this end, it may be necessary to achieve a sequence start.

**7.10.10** The undervoltage protective devices are to allow the motor to be started when the voltage exceeds 85% of the rated voltage and are to intervene without fail when the voltage drops to less than approximately 20% of the rated voltage, at the rated frequency and with a time delay as necessary.

### **7.11 Protection of storage batteries**

**7.11.1** Batteries are to be protected against overload and short-circuit by means of fuses or multipole circuit-breakers at a position adjacent to the battery compartment.

Note 1: Overcurrent protection may be omitted for the circuit to the starter motors when the current drawn is so large that is impracticable to obtain short-circuit protection.

Note 2: When conductors from the batteries are not protected against short-circuiting and overload, they are to be installed so as to be adequately protected against short-circuits and earth faults and as short as possible, e.g., starting batteries for emergency generator or fire pumps engines in the same skid or very near.

**7.11.2** Emergency batteries supplying essential services are to have short-circuit protection only.

### **7.12 Protection of shore power connection**

**7.12.1** Permanently fixed cables connecting the shore connection box to the main switchboard are to be protected by fuses or circuit-breakers (see [3.7.4]).

### **7.13 Protection of measuring instruments, pilot lamps and control circuits**

**7.13.1** Measuring circuits and devices (voltage transformers, voltmeters, voltage coils of measuring instruments, insulation monitoring devices etc.) and pilot lamps are to be protected against short-circuit by means of multipole circuit-breakers or fuses. The protective devices are to be placed as near as possible to the tapping from the supply.

The secondary side of current transformers is not to be protected.

**7.13.2** Control circuits and control transformers are to be protected against overload and short-circuit by means of multipole circuit-breakers or fuses on each pole not connected to earth.

Overload protection may be omitted for transformers with a rated current of less than 2 A on the secondary side.

The short-circuit protection on the secondary side may be omitted if the transformer is designed to sustain permanent short-circuit current.

**7.13.3** Where a fault in a pilot lamp would impair the operation of essential services, such lamps are to be protected separately from other circuits such as control circuits.

Note 1: Pilot lamps connected via short-circuit-proof transformers may be protected in common with control circuits.

**7.13.4** Circuits whose failure could endanger operation, such as steering gear control feeder circuits, are to be protected only against short-circuit.

**7.13.5** The protection is to be adequate for the minimum cross-section of the protected circuits.

### **7.14 Protection of transformers**

**7.14.1** The primary winding side of power transformers is to be protected against short-circuit and overload by means of multipole circuit-breakers or switches and fuses.

Overload protection on the primary side may be dispensed with where it is provided on the secondary side or when the total possible load cannot reach the rated power of the transformer.

**7.14.2** The protection against short-circuit is to be such as to ensure the selectivity between the circuits supplied by the secondary side of the transformer and the feeder circuit of the transformer.

**7.14.3** When transformers are arranged to operate in parallel, means are to be provided so as to trip the switch on the secondary winding side when the corresponding switch on the primary side is open.

## **8 System components**

### **8.1 General**

**8.1.1** The components of the electrical system are to be dimensioned such as to withstand the currents that can pass through them during normal service without their rating being exceeded.

**8.1.2** The components of the electrical system are to be designed and constructed so as to withstand for the admissible duration the thermal and electrodynamic stresses caused by possible overcurrents, including short-circuit.

## **9 Electrical cables**

### **9.1 General**

**9.1.1** *All electrical cables and wiring external to equipment shall be at least of a flame-retardant type, in accordance with Ch 2, Sec 9, [2.1.6].*

**9.1.2** When cables are laid in bunches, cable types are to be chosen in compliance with Ch 2, Sec 9, [2.1.7].

**9.1.3** Cables which are required to have fire-resisting characteristics are to comply with the requirements stipulated in Ch 2, Sec 9, [2.1.9].

**9.1.4** Cables and insulated wiring are generally to be chosen and installed in accordance with IEC Publications 60092-352, as well with the provisions of this Chapter.

### **9.2 Choice of insulation**

**9.2.1** The maximum rated operating temperature of the insulating material is to be at least 10°C higher than the maximum ambient temperature liable to occur or to be produced in the space where the cable is installed.

**9.2.2** The maximum rated conductor temperature for normal and short-circuit operation, for the type of insulating compounds normally used for shipboard cables, is not to exceed the values stated in Tab 4. Special consideration will be given to other insulating materials.

**9.2.3** PVC-ST2 insulated cables are not to be used either in refrigerated spaces, or on decks exposed to the weather of ships classed for unrestricted service.

**9.2.4** Mineral insulated cables will be considered on a case by case basis.

**Table 4 : Maximum rated conductor temperature**

Type of insulating compound	Abbreviated designation	Maximum rated conductor temperature, in °C	
		Normal operation	Short-circuit
a) Thermoplastic: - based upon polyvinyl chloride or copolymer of vinyl chloride and vinyl acetate	PVC	70	150
b) Elastomeric or thermoset: - based upon ethylene-propylene rubber or similar (EPM or EPDM)	EPR	90	250
- based upon high modulus or hard grade ethylene propylene rubber	HEPR	90	250
- based upon cross-linked polyethylene	XLPE	90	250
- based upon silicone rubber	S 95	95	350 (1)
- based upon ethylene-propylene rubber or similar (EPM or EPDM) halogen-free	HF EPR	90	250
- based upon high modulus or hard grade halogen-free ethylene propylene rubber	HF HEPR	90	250
- based upon halogen-free cross-linked polyethylene	HF XLPE	90	250
- based upon halogen-free silicone rubber	HF S 95	95	350 (1)
- based upon cross-linked polyolefin material for halogen-free cables	HF 90	90	250

(1) This temperature is applicable only to power cables and not appropriate for tinned copper conductors.

**9.3 Choice of protective covering**

**9.3.1** The conductor insulating materials are to be enclosed in an impervious sheath of material appropriate to the expected ambient conditions where cables are installed in the following locations:

- on decks exposed to the weather
- in damp or wet spaces (e.g. in bathrooms)
- in refrigerated spaces
- in machinery spaces and, in general
- where condensation water or harmful vapour may be present.

**9.3.2** Where cables are provided with armour or metallic braid (e.g. for cables installed in hazardous areas), an overall impervious sheath or other means to protect the metallic elements against corrosion is to be provided (see Ch 2, Sec 9, [2.5]).

**9.3.3** An impervious sheath is not required for single-core cables installed in tubes or ducts inside accommodation spaces, in circuits with maximum system voltage 250 V.

**9.3.4** In choosing different types of protective coverings, due consideration is to be given to the mechanical action to which each cable may be subjected during installation and in service.

If the mechanical strength of the protective covering is considered insufficient, the cables are to be mechanically protected (e.g. by an armour or by installation inside pipes or conduits).

**9.3.5** Single-core cables for a.c. circuits with rated current exceeding 20 A are to be either non-armoured or armoured with non-magnetic material.

**9.4 Cables in refrigerated spaces**

**9.4.1** Cables installed in refrigerated spaces are to have a watertight or impervious sheath and are to be protected against mechanical damage. If an armour is applied on the sheath, the armour is to be protected against corrosion by a further moisture-resisting covering.

**9.5 Cables in areas with a risk of explosion**

**9.5.1** For cables in areas with a risk of explosion, see [10.3].

### 9.6 Cables in circuits required to be operable under fire condition

9.6.1 Electrical services required to be operable under fire conditions are as follows:

- control and power systems to power-operated fire doors and status indication for all fire doors
- control and power systems to power-operated watertight doors and their status indication
- emergency fire pump
- emergency lighting
- fire and general alarms
- fire detection systems
- fire-extinguishing systems and fire-extinguishing media release alarms
- low location lighting
- public address systems
- remote emergency stop/shutdown arrangements for systems which may support the propagation of fire and/or explosion.

9.6.2 Where cables for services specified in [9.6.1] including their power supplies pass through high fire risk areas, and, in addition for passenger ships, through main vertical fire zones other than those which they serve, they are to be so arranged that a fire in any of these areas or zones does not affect the operation of the service in any other area or zone. This may be achieved by either of the following measures:

- Cables being of a fire resistant type complying with Ch 2, Sec 9, [2.1.9] are installed and run continuous to keep the fire integrity within the high fire risk area (see Fig 4)

Note 1: The application of this requirement for public spaces containing furniture and furnishings of other than restricted fire risk and having a deck area of 50 m<sup>2</sup> or more will be considered on the case by case basis.

- At least two-loops/radial distributions run as widely apart as is practicable and so arranged that in the event of damage by fire at least one of the loops/radial distributions remains operational.

Systems that are self monitoring, fail safe or duplicated with cable runs as widely separated as is practicable may be exempted.

9.6.3 Cables connecting fire pumps to the emergency switchboard shall be of a fire-resistant type where they pass through high fire risk areas.

Figure 4 : Routing of cables in high fire risk area

### 9.7 Cables for submerged bilge pumps

9.7.1 Cables and their connections to such pumps are to be capable of operating under a head of water equal to their distance below the bulkhead deck. The cable is to be impervious-sheathed and armoured, is to be installed in continuous lengths from above the bulkhead deck to the motor terminals and is to enter the air bell from the bottom.

### 9.8 Internal wiring of switchboards and other enclosures for equipment

9.8.1 For installation in switchboards and other enclosures for equipment, single-core cables may be used without further protection (sheath).

Other types of flame-retardant switchboard wiring may be accepted at the discretion of the Society.

**9.9 Current carrying capacity of cables**

**9.9.1** The current carrying capacity for continuous service of cables given in Tab 5 to Tab 9 is based on the maximum permissible service temperature of the conductor also indicated therein and on an ambient temperature of 45°C.

**9.9.2** The current carrying capacity cited in [9.9.1] is applicable, with rough approximation, to all types of protective covering (e.g. both armoured and non-armoured cables).

**9.9.3** Values other than those shown in Tab 5 to Tab 9 may be accepted provided they are determined on the basis of calculation methods or experimental values approved by the Society.

**9.9.4** When the actual ambient temperature obviously differs from 45°C, the correction factors shown in Tab 10 may be applied to the current carrying capacity in Tab 5 to Tab 9.

**9.9.5** Where more than six cables are bunched together in such a way that there is an absence of free air circulating around them, and the cables can be expected to be under full load simultaneously, a correction factor of 0,85 is to be applied.

**9.9.6** Where a cable is intended to supply a short-time load for 1/2-hour or 1-hour service (e.g. mooring winches or bow thruster propellers), the current carrying capacity obtained from Tab 5 to Tab 9 may be increased by applying the corresponding correction factors given in Tab 11.

In no case is a period shorter than 1/2-hour to be used, whatever the effective period of operation.

**9.9.7** For supply cables to single services for intermittent loads (e.g. cargo winches or machinery space cranes), the current carrying capacity obtained from Tab 5 to Tab 9 may be increased by applying the correction factors given in Tab 12.

The correction factors are calculated with rough approximation for periods of 10 minutes, of which 4 minutes with a constant load and 6 minutes without load.

**9.9.8** The current carrying capacity of cables connected in parallel is the sum of the current ratings of all parallel conductors but the cables must have equal impedance, equal cross-section, equal maximum permissible conductor temperatures and follow substantially identical routing or be installed in close proximity. Connections in parallel are only permitted for cross-sections of 10 mm<sup>2</sup> or above. When equal impedance can not be assumed, a correction factor of 0,9 is to be applied to the current carrying capacity.

**Table 5 : Current carrying capacity, in A, in continuous service for cables based on maximum conductor operating temperature of 60°C (ambient temperature 45°C)**

$110 < S$	–	1,50

**9.10 Minimum nominal cross-sectional area of conductors**

**9.10.1** In general the minimum allowable conductor cross-sectional areas are those given in Tab 13.

**9.10.2** The nominal cross-sectional area of the neutral conductor in three-phase distribution systems is to be equal to at least 50% of the cross-sectional area of the phases, unless the latter is less than or equal to 16 mm<sup>2</sup>. In such case the cross-sectional area of the neutral conductor is to be equal to that of the phase.

**9.10.3** For the nominal cross-sectional area of:

- earthing conductors, see Ch 2, Sec 12, [2.3]
- earthing connections for distribution systems, see Ch 2, Sec 12, [2.5]
- neutral connections for three-phase systems, see Ch 2, Sec 8, [1.2.4].

**Table 13 : Minimum nominal cross-sectional areas**

Service	Nominal cross-sectional area, in mm <sup>2</sup>	
	External wiring	Internal wiring
Power, heating and lighting systems	1,0	1,0
Control circuits for power plant	1,0	1,0
Control circuits other than those for power plant	0,75	0,5
Control circuits for telecommunications, measurement, alarms	0,5	0,2
Telephone and bell equipment, not required for the safety of the ship or crew calls	0,2	0,1
Bus and data cables	0,2	0,1

**9.11 Choice of cables**

**9.11.1** The rated voltage of any cable is to be not lower than the nominal voltage of the circuit for which it is used.

**9.11.2** The nominal cross-sectional area of each cable is to be sufficient to satisfy the following conditions with reference to the maximum anticipated ambient temperature:

- the current carrying capacity is to be not less than the highest continuous load carried by the cable
- the voltage drop in the circuit, by full load on this circuit, is not to exceed the specified limits
- the cross-sectional area calculated on the basis of the above is to be such that the temperature increases which may be caused by overcurrents or starting transients do not damage the insulation.

**9.11.3** The highest continuous load carried by a cable is to be calculated on the basis of the power requirements and of the diversity factor of the loads and machines supplied through that cable.

**9.11.4** When the conductors are carrying the maximum nominal service current, the voltage drop from the main or emergency switchboard busbars to any point in the installation is not to exceed 6% of the nominal voltage.

For battery circuits with supply voltage less than 55 V, this value may be increased to 10%.

For the circuits of navigation lights, the voltage drop is not to exceed 5% of the rated voltage under normal conditions.

**10 Electrical installations in hazardous areas**

**10.1 Electrical equipment**

**10.1.1** No electrical equipment is to be installed in hazardous areas unless the Society is satisfied that such equipment is:

- essential for operational purposes
- of a type which will not ignite the mixture concerned
- appropriate to the space concerned, and
- appropriately certified for safe usage in the dusts, vapours or gases likely to be encountered.

**10.1.2** Where electrical equipment of a safe type is permitted in hazardous areas it is to be selected with due consideration to the following:

- a) risk of explosive dust concentration (see Ch 2, Sec 2, [6.2]):
  - degree of protection of the enclosure
  - maximum surface temperature
- b) risk of explosive gas atmosphere (see Ch 2, Sec 2, [6.1]):
  - explosion group
  - temperature class.

**10.1.3** Where electrical equipment is permitted in hazardous areas, all switches and protective devices are to interrupt all poles or phases and, where practicable, to be located in a non-hazardous area unless specifically permitted otherwise. Such switches and equipment located in hazardous areas are to be suitably labelled for identification purposes.

**10.1.4** Electrical installations in hazardous areas are to be inspected by skilled personnel at their initial installation. The requirements of IEC 60079-17 apply.

**10.1.5** For electrical equipment installed in Zone 0 hazardous areas, only the following types are permitted:

- certified intrinsically-safe apparatus Ex(ia)
- simple electrical apparatus and components (e.g. thermocouples, photocells, strain gauges, junction boxes, switching devices), included in intrinsically-safe circuits of category “ia” not capable of storing or generating electrical power or energy in excess of limits stated in the relevant rules, and accepted by the appropriate authority
- equipment specifically designed and certified by the appropriate authority for use in Zone 0.

**10.1.6** For electrical equipment installed in Zone 1 hazardous areas, only the following types are permitted:

- any type that may be considered for Zone 0
- certified intrinsically-safe apparatus Ex(ib)
- simple electrical apparatus and components (e.g. thermocouples, photocells, strain gauges, junction boxes, switching devices), included in intrinsically-safe circuits of category “ib” not capable of storing or generating electrical power or energy in excess of limits stated in the relevant rules, and accepted by the appropriate authority
- certified flameproof Ex(d)
- certified pressurised Ex(p)
- certified increased safety Ex(e)
- certified encapsulated Ex(m)
- certified sand filled Ex(q)
- certified specially Ex(s)
- through runs of cable.

**10.1.7** For electrical equipment installed in Zone 2 hazardous areas, only the following types are permitted:

- any type that may be considered for Zone 1
- tested specially for Zone 2 (e.g. type “n” protection)
- pressurised, and accepted by the appropriate authority
- encapsulated, and accepted by the appropriate authority
- the type which ensures the absence of sparks and arcs and of “hot spots” during its normal operation.

**10.1.8** When apparatus incorporates a number of types of protection, it is to be ensured that all are suitable for use in the zone in which it is located.

## **10.2 Certified safe type documentation**

**10.2.1** Safe type certificates or equivalent documentation issued by an accredited or recognized certification body and established on a basis at least equivalent to the IEC 60079 series publication are to be submitted for each electrical equipment located in hazardous areas.

**10.2.2** For intrinsically safe circuits, a document describing the system is to be submitted to the Society, specifying the items of electrical equipment and the electrical parameters of the system, including those of inter-connecting wiring. This document is not required in case a certificate defining the parameters for the complete intrinsically safe system is available. The requirements of IEC 60079-14 apply.

## **10.3 Electrical cables**

**10.3.1** Electrical cables are not to be installed in hazardous areas except as specifically permitted or when associated with intrinsically safe circuits.

**10.3.2** All cables installed in Zone 0 or in Zone 1 are to be sheathed with at least one of the following:

- a) a non-metallic impervious sheath in combination with braiding or other metallic covering
- b) a copper or stainless steel sheath (for mineral insulated cables only).

**10.3.3** All cables installed in non-weather exposed Zone 2 areas are to be provided with at least a non-metallic external impervious sheath.

**10.3.4** Cables of intrinsically safe circuits are to have a metallic shielding with at least a non-metallic external impervious sheath.

**10.3.5** The circuits of a category “ib” intrinsically safe system are not to be contained in a cable associated with a category “ia” intrinsically safe system required for a hazardous area in which only category “ia” systems are permitted.

## **10.4 Electrical installations in battery rooms**

**10.4.1** Only lighting fittings may be installed in compartments assigned solely to large vented storage batteries (see Ch 2, Sec 11, [6.2.1]).

The associated switches are to be installed outside such spaces.

Overcurrent protective devices are to be installed as close as possible to, but outside of, battery rooms.

Electrical cables other than those pertaining to the equipment arranged in battery rooms are not permitted.

**10.4.2** Electrical equipment for use in battery rooms is to have minimum explosion group IIC and temperature class T1.

**10.4.3** Standard marine electrical equipment may be installed in compartments assigned solely to valve-regulated sealed storage batteries.

## **10.5 Electrical installations in paint stores or enclosed spaces leading to paint stores**

### **10.5.1 General**

Electrical equipment is to be installed in paint stores and in ventilation ducts serving such spaces only when it is essential for operational services.

Certified safe type equipment of the following type is acceptable:

- certified intrinsically-safe apparatus Ex(i)
- certified flameproof Ex(d)
- certified pressurised Ex(p)
- certified increased safety Ex(e)
- certified specially Ex(s).

Cables (through runs or termination cables) of armoured type or installed in metallic conduits are to be used.

**10.5.2** In the areas on open deck within 1 m of inlet and exhaust ventilation openings of paint stores or 3 m of exhaust mechanical ventilation outlets of such spaces, the following electrical equipment may be installed:

- electrical equipment with the type of protection as permitted in paint stores
- equipment of protection class Ex(n)
- appliances which do not generate arcs in service and whose surface does not reach unacceptably high temperature
- appliances with simplified pressurised enclosures or vapour-proof enclosures (minimum class of protection IP55) whose surface does not reach unacceptably high temperature; or
- cables as specified in [10.5.1].

### **10.5.3 Minimum requirements**

The minimum requirements for the certified safe type equipment are as follows:

- explosion group II B
- temperature class T3.

**10.5.4** Switches, protective devices and motor control gear of electrical equipment installed in a paint store are to interrupt all poles or phases and are preferably to be located in a non hazardous space.

### **10.5.5 Hazardous area classification**

- a) The paint stores and supply and exhaust ventilation ducts serving such spaces are to be classified as Zone 1, as defined in Ch 2, Sec 1, [3.25].
- b) Areas on open deck within 1 m of inlet and exhaust ventilation openings of paint stores or within 3 m of exhaust mechanical ventilation outlets of such spaces are to be classified as Zone 2, as defined in Ch 2, Sec 1, [3.25].
- c) Enclosed spaces giving access to paint stores may be considered as non-hazardous, provided that:
  - the door to the paint store is a gastight door with self-closing devices without holding back arrangements. A watertight door may be considered as being gastight
  - the paint store is provided with an acceptable, independent, natural ventilation system ventilated from a safe area, and
  - warning notices are fitted adjacent to the paint store entrance stating that the store contains flammable liquids

## **10.6 Electrical installations in stores for welding gas (acetylene) bottles**

**10.6.1** The following equipment may be installed in stores for welding gas bottles provided that it is of a safe type appropriate for Zone 1 area installation:

- lighting fittings
- ventilator motors where provided.

**10.6.2** Electrical cables other than those pertaining to the equipment arranged in stores for welding gas bottles are not permitted.

**10.6.3** Electrical equipment for use in stores for welding gas bottles is to have minimum explosion group IIC and temperature class T2.

## **10.7 Specific ships or installations**

**10.7.1** For installations in hazardous areas in:

- oil tankers, chemical tankers and liquefied gas carriers, see Pt D, Ch 7, Sec 5, Pt D, Ch 8, Sec 10 or Pt D, Ch 9, Sec 10
- ships arranged with spaces for the carriage of vehicles, see Pt D, Ch 1, Sec 4 or Pt D, Ch 12, Sec 4
- ships arranged with fuel storage and refuelling facilities for auxiliary vehicles, see Ch 4, Sec 11, [4]
- ships intended for the carriage of dangerous goods, see Ch 4, Sec 12, [2.3]
- ships arranged with tanks used for the storage and use of chemical treatment fluids for exhaust gas pollution prevention system, see Ch 1, Sec 11, [5.2.2]
- ships arranged with ballast water management systems, see Ch 1, Sec 13, [2.6].

## Section 4 Rotating Machines

### 1 Constructional requirements for generators and motors

#### 1.1 Mechanical construction

**1.1.1** Materials and construction of electrical machines are to conform to the relevant requirements of Ch 2, Sec 2, [4] and Ch 2, Sec 2, [5].

**1.1.2** Shafts are to be made of material complying with the provisions of NR216 Materials and Welding, Chapter 5 or, where rolled products are allowed in place of forgings, with those of NR216 Materials and Welding, Chapter 3.

**1.1.3** Where welded parts are foreseen on shafts and rotors, the provisions of NR216 Materials and Welding, Chapter 12 are to apply.

**1.1.4** Sleeve bearings are to be efficiently and automatically lubricated at all running speeds.

Provision is to be made for preventing the lubricant from gaining access to windings or other insulated or bare current carrying parts.

**1.1.5** Means are to be provided to prevent bearings from being damaged by the flow of currents circulating between them and the shaft. According to the manufacturer's requirements, electrical insulation of at least one bearing is to be considered.

**1.1.6** For surface-cooled machines with an external fan installed on the open deck, adequate protection of the fan against icing is to be provided.

**1.1.7** When liquid cooling is used, the coolers are to be so arranged as to avoid entry of water into the machine, whether by leakage or condensation in the heat exchanger, and provision is to be made for the detection of leakage.

**1.1.8** Rotating machines whose ventilation or lubrication system efficiency depends on the direction of rotation are to be provided with a warning plate.

#### 1.2 Sliprings, commutators and brushes

**1.2.1** Sliprings and commutators with their brushgear are to be so constructed that undue arcing is avoided under all normal load conditions.

**1.2.2** The working position of brushgear is to be clearly and permanently marked.

**1.2.3** Sliprings, commutators and brushgear are to be readily accessible for inspection, repairs and maintenance.

#### 1.3 Terminal connectors

**1.3.1** Suitable, fixed terminal connectors are to be provided in an accessible position for connection of the external cables.

**1.3.2** All terminal connectors are to be clearly identified with reference to a diagram.

**1.3.3** The degree of protection of terminal boxes is to be adequate to that of the machine.

#### 1.4 Electrical insulation

**1.4.1** Insulating materials for windings and other current carrying parts are to comply with the requirements of Ch 2, Sec 2, [4.2] and Ch 2, Sec 2, [4.3].

### 2 Special requirements for generators

#### 2.1 Prime movers, speed governors and overspeed protection

**2.1.1** Prime movers for generators are to comply with the relevant requirements of Ch 1, Sec 2, [2.7].

**2.1.2** When generators are to operate in parallel, the characteristics of speed governors are to comply with the provisions of [2.2].

## **2.2 A.c. generators**

**2.2.1** Alternators are to be so constructed that, when started up, they take up the voltage without the aid of an external electrical power source.

Where these provisions are not complied with, the external electrical power source is to be constituted by a battery installation in accordance with the requirements for electrical starting systems of auxiliary machinery (see Ch 1, Sec 2).

**2.2.2** The voltage wave form is to be approximately sinusoidal, with a maximum deviation from the sinusoidal fundamental curve of 5% of the peak value.

**2.2.3** Each alternator is to be provided with automatic means of voltage regulation.

**2.2.4** For a.c. generating sets operating in parallel, the governing characteristics regarding the load are to comply with requirement of Ch 1, Sec 2, [2.7.6].

**2.2.5** When a.c. generators are operated in parallel, the reactive loads of the individual generating sets are not to differ from their proportionate share of the total reactive load by more than 10% of the rated reactive power of the largest machine, or 25% of that of the smallest machine, whichever is the lesser.

## **2.3 Approval of generating sets**

**2.3.1** A generating set is considered as a whole system including:

- a prime mover engine and its auxiliaries (for fuel oil, turbo compressor, lubricating oil, cooling circuits...)
- an alternator, and its auxiliaries, if any (lubricating and cooling system...)
- engine control system, speed governor and associated sensors
- an automatic voltage regulator
- a coupling system
- cabling

**2.3.2** Components are to be type approved. Case by case approvals may be admitted at the discretion of the Society.

**2.3.3** Documentation for system assembly is to be provided:

- List of components
- General electrical diagram
- Coupling system
- Torsional Vibration Calculation, when required in Ch 1, Sec 9, [1.1]

**2.3.4** The rated power of the generating set is to be appropriate for its actual use. See also Ch 1, Sec 2, [1.3.2].

**2.3.5** The entity responsible of assembling the generating set is to install a rating plate marked with at least the following information:

- a) the generating set manufacturer's name or mark
- b) the set serial number
- c) the set date of manufacture (month/year)
- d) the rated power (both in kW and KVA) with one of the prefixes COP, PRP (or, only for emergency generating sets, LTP) as defined in ISO 8528-1:2018
- e) the rated power factor
- f) the set rated frequency, in Hz
- g) the set rated voltage, in V
- h) the set rated current, in A
- i) the mass, in kg.

## **3 Testing of rotating machines**

### **3.1 General**

**3.1.1** All machines are to be tested by the manufacturers.

**3.1.2** All tests are to be carried out according to IEC 60092-301.

**3.1.3** The manufacturer is to issue a test report giving, inter alia, information concerning the construction, type, serial number, insulation class and all other technical data relevant to the machine, as well as the results of the tests required.

**3.1.4** All electric motors rated at or above 100 kW and alternators rated at or above 100 kVA intended for essential services are to be type approved or case-by-case approved and surveyed by the Society during testing and, if appropriate, during manufacturing. Tested machines are to be individually certified by the Society.

In addition for rotating machines intended for propulsion developing a power of more than 1 MW, requirements given in [5] apply.

Note 1: An alternative inspection scheme may be agreed by the Society with the manufacturer whereby the attendance of the Surveyor will not be required as indicated above.

**3.1.5** All electric motors rated below 100 kW and alternators rated below 100 kVA intended for essential services are to be type approved or case-by-case approved. Individual works' certificate is to be issued by the manufacturer and detailed test report submitted to the Society.

**3.1.6** For rotating machines intended for non essential services, individual works' certificate is to be issued by the manufacturer and detailed test report made available and submitted upon request.

**3.1.7** Case-by-case approval, mentioned in [3.1.4] and [3.1.5], is to be in line with requirement given in Ch 2, Sec 15, [2.1.2].

### 3.2 Shaft material

**3.2.1** Shaft material for electric propulsion motors and for main engine driven generators where the shaft is part of the propulsion shafting is to be certified by the Society.

**3.2.2** Shaft material for other machines is to be in accordance with recognized international or national standard.

### 3.3 Tests

**3.3.1** Type test are to be carried out on a prototype machine or on the first batch of machines, and routine tests carried out on subsequent machines in accordance with Tab 1.

**3.3.2** Where the test procedure is not specified, the requirements of IEC 60034-1 apply.

**Table 1 : Tests to be carried out on electrical rotating machines**

No	Tests	a.c. Generators		Motors	
		Type test (1)	Routine test (2)	Type test (1)	Routine test (2)
1	Examination of the technical documentation (3), visual inspection in compliance with design drawings	X	X	X	X
2	Insulation resistance measurement (stator and rotor windings)	X	X	X	X
3	Winding resistance measurement (stator and rotor)	X	X	X	X
4	Verification of the voltage regulation system	X	X (4)		
5	Rated load test and temperature rise measurement	X		X	
6	Overcurrent test	X			
7	Overtorque test			X	
8	Verification of steady short-circuit conditions (5)	X			
9	Overspeed test	X	X	X	
10	Dielectric strength test (stator and rotor windings)	X	X	X	X
11	No load test	X	X	X	X
12	Verification of degree of protection	X		X	
13	Verification of bearings	X	X	X	X

(1) Type test on prototype machine or test on at least the first batch of machines.  
 (2) The reports of machines routine tested are to contain the manufacturer's serial number of the machine which has been type tested and the test result.  
 (3) For a.c. Generators, documentation showing the transient behavior of the short circuit current is to be submitted for information.  
 (4) Only functional test of the voltage regulator system.  
 (5) Verification of steady short-circuit condition applies to synchronous machines only.

**3.3.3 Testing of generating sets**

Generating sets are to be submitted to the following tests:

- Load impact tests on whole assembled system are to be performed, as described in Ch 1, Sec 2, [4.3.3] item c)3) and c)4)
- Test of alarms and safeties, as per applicable requirements
- Test of voltage regulation, as described in [4.4]

Assembled generating sets of an electrical power of 100 kVA and over are to be tested at manufacturer premises with BV attendance prior installation on board.

When the whole assembled generating set cannot be tested at the Manufacturer’s premises, those tests are to be carried out after installation and assembly on board.

**4 Description of test**

**4.1 Technical documentation and visual inspection**

**4.1.1** Technical documentation of machines rated at 100 kW (kVA) and over are to be available for examination by the Surveyor.

**4.1.2** A visual inspection of the machine is to be made to ensure, as far as practicable, that it complies with the technical documentation.

**4.2 Insulation resistance measurement**

**4.2.1** Immediately after the high voltage tests the insulation resistances are to be measured using a direct current insulation tester between:

- a) all current carrying parts connected together and earth
- b) all current carrying parts of different polarity or phase, where both ends of each polarity or phase are individually accessible.

The minimum values of test voltages and corresponding insulation resistances are given in Tab 2. The insulation resistance is to be measured close to the operating temperature, or an appropriate method of calculation is to be used.

**Table 2 : Minimum insulation resistance**

Rated voltage $U_n$ V	Minimum test voltage V	Minimum insulation resistance $M\Omega$
$U_n = 250$	$2 U_n$	1
$250 < U_n \leq 1000$	500	1
$1000 < U_n \leq 7200$	1000	$U_n/1000 + 1$
$7200 < U_n \leq 15000$	5000	$U_n/1000 + 1$

**4.3 Winding resistance measurement**

**4.3.1** The resistances of the machine windings are to be measured and recorded using an appropriate bridge method or voltage and current method.

**4.4 Verification of the voltage regulation**

**4.4.1** The alternating current generator, together with its voltage regulation system, is to be verified in such a way that, at all loads from no load running to full load, the rated voltage at the rated power factor is maintained under steady conditions within  $\pm 2,5\%$ . These limits may be increased to  $\pm 3,5\%$  for emergency sets.

**4.4.2** When the generator is driven at rated speed, giving its rated voltage, and is subjected to a sudden change of symmetrical load within the limits of specified current and power factor, the voltage is not to fall below 85% nor exceed 120% of the rated voltage.

**4.4.3** The voltage of the generator is then to be restored to within plus or minus 3% of the rated voltage for the main generator sets in not more than 1.5 s. For emergency sets, these values may be increased to plus or minus 4% in not more than 5 s, respectively.

**4.4.4** In the absence of precise information concerning the maximum values of the sudden loads, the following conditions may be assumed: 60% of the rated current with a power factor of between 0,4 lagging and zero to be suddenly switched on with the generator running at no load, and then switched off after steady-state conditions have been reached.

Subject to the Society’s agreement, such voltage regulation during transient conditions may be calculated values based on the previous type test records, and need not to be tested during factory testing of a generator.

**4.5 Rated load test and temperature rise measurements**

**4.5.1** The temperature rises are to be measured at the rated out-put, voltage and frequency and for the duty for which the machine is rated and marked in accordance with the testing methods specified in IEC 60034-1, or by means of a combination of other tests (see indirect methods in Ch 2, App 1 for synchronous machines and in Ch 2, App 2 for induction machines).

**4.5.2** The limits of temperature rise above ambient air temperature of 45°C for air-cooled machines are those given in Tab 3.

**Table 3 : Temperature rise limits for air-cooled machines based on an ambient temperature of 45°C**

No	Part of machines	Method of measurement of temperature (1)	Temperature rise, in °C, by class of insulation				
			A	E	B	F	H
1	a) a.c. windings of machines having outputs of 5000 kW (or kVA) or more	R ETD	55 60	– –	75 80	95 100	120 125
	b) a.c. windings of machines having outputs of less than 5000 kW (or kVA)	R ETD	55 60	70 –	75 85	100 105	120 125
2	Windings of armatures with commutators	T	45	60	65	80	100
		R	55	70	75	100	120
3	Field windings of a.c. and d.c machines having d.c. excitation other than those in item 4	T	45	60	65	80	100
		R	55	70	75	100	120
4	a) Field windings of synchronous machines with cylindrical rotors having d.c. excitation	R	–	–	85	105	130
	b) Stationary field windings of d.c. machines having more than one layer	T	45	60	65	80	100
		R ETD	55 –	70 –	75 85	100 105	120 130
	c) Low resistance field windings of more than one layer, and compensating windings	T, R (2)	55	70	75	95	120
d) Single-layer windings with exposed bare surfaces	T, R (2)	60	75	85	105	130	
5	Permanently short-circuited, insulated windings	T	55	70	75	95	120
6	Permanently short-circuited uninsulated windings	The temperature rise of these parts is in no case to reach such a value that there is a risk of damage to any insulating or other material on adjacent parts					
7	Magnetic core and other parts not in contact with windings						
8	Magnetic core and other parts in contact with windings	T	55	70	75	95	120
9	Commutators and sliprings, open or enclosed (3)	T	55	65	75	85	95
(1) T		: Measurement by the thermometer method					
R		: Measurement by the resistance method					
ETD		: Measurement by embedded temperature detectors.					
(2)		Temperature rise measurement is to use the resistance method R whenever practicable.					
(3)		If commutators and sliprings are adjacent to windings with a lower insulation class, the temperature rises for this class apply.					

**4.6 Overcurrent/overtorque test**

**4.6.1** Overcurrent test is to be carried out as a type test for generators, as required in IEC 60034-1. The overcurrent test is the proof of current capability of the windings, wires, connections etc. of each machine.

AC generators are to be capable of withstanding a current equal to 1,5 times the rated current for not less than 30 s.

Note 1: This test may be performed in conjunction with the short-circuit testing, provided the electrical input energy to the machine is not less than that required for the above overload capability.

**4.6.2** Overtorque test is to be carried out as a type test for motors, as required in IEC 60034-1. The overtorque test is a proof of momentary excess torque capability of the machine.

General purpose rotating machines are to be designed to withstand the following excess torque:

- AC induction motors and DC motors: 60% in excess of the torque that corresponds to the rating, for 15 s, without stalling or abrupt change in speed (under gradual increase of torque), the voltage and frequency being maintained at their rated value
- AC synchronous motors with salient poles: 50% in excess of the torque that corresponds to the rating, for 15 s, without falling out of synchronism, the voltage, frequency and excitation current being maintained at their rated values

- AC synchronous motors with wound (induction) or cylindrical rotors: 35% in excess of the torque that corresponds to the rating, for 15 s, without losing synchronism, the voltage and frequency being maintained at their rated value.

Note 1: The overtorque test can be replaced at a routine test by an overcurrent test.

Note 2: The overtorque test may be omitted for electrical propulsion motor supplied by converter if an overload protection/limitation is provided inside the converter. Justifications are to be transmitted by the converter manufacturer.

**4.6.3** In the case of machines for special uses (e.g. for wind-lasses), overload values other than the above may be considered.

#### **4.7 Verification of the steady short circuit current**

**4.7.1** It is to be verified that under steady state short-circuit conditions, the generator with its voltage regulating system is capable of maintaining, without sustaining any damage, a current of at least three times the rated current for a duration of at least 2 s or, where precise data is available, for a duration of any time delay which may be fitted in a tripping device for discrimination purposes.

In order to provide sufficient information for determining the discrimination settings in the distribution system where the generator is going to be used, the generator manufacturer is to provide the Society, for information, with documentation showing the transient behavior of the short circuit current upon a sudden short-circuit occurring when excited, and running at nominal speed. The influence of the automatic voltage regulator is to be taken into account, and the setting parameters for the voltage regulator are to be noted together with the decrement curve. Such a decrement curve is to be available when the setting of the distribution system's short-circuit protection is calculated. The decrement curve need not be based on physical testing. The manufacturer's simulation model for the generator and the voltage regulator may be used where this has been validated through the previous type test on the same model.

#### **4.8 Overspeed test**

**4.8.1** Machines are to withstand the overspeed test as specified in IEC 60034-1.

#### **4.9 Dielectric strength test**

**4.9.1** New and completed rotating machines are to withstand a dielectric test as specified in IEC 60034-1.

**4.9.2** For high voltage machines an impulse test is to be carried out on the coils according to Ch 2, Sec 13.

**4.9.3** When it is necessary to perform an additional high voltage test, this is to be carried out after any further drying, with a test voltage of 80% of that specified in IEC 60034-1.

**4.9.4** Completely rewound windings of used machines are to be tested with the full test voltage applied in the case of new machines.

**4.9.5** Partially rewound windings are to be tested at 75% of the test voltage required for new machines. Prior to the test, the old part of the winding is to be carefully cleaned and dried.

**4.9.6** Following cleaning and drying, overhauled machines are to be subjected to a test at a voltage equal to 1,5 times the rated voltage, with a minimum of 500 V if the rated voltage is less than 100 V, and with a minimum of 1000 V if the rated voltage is equal to or greater than 100 V.

**4.9.7** A repetition of the high voltage test for groups of machines and apparatus is to be avoided if possible, but if a test on an assembled group of several pieces of new apparatus, each of which has previously passed its high voltage test, is performed, the test voltage to be applied to such assembled group is 80% of the lowest test voltage appropriate for any part of the group.

Note 1: For windings of one or more machines connected together electrically, the voltage to be considered is the maximum voltage that occurs in relation to earth.

#### **4.10 No load test**

**4.10.1** Machines are to be operated at no load and rated speed whilst being supplied at rated voltage and frequency as a motor while generators are to be driven by a suitable means and excited to give rated terminal voltage.

During the running test, the vibration of the machine and operation of the bearing lubrication system, if appropriate, are to be checked.

#### **4.11 Verification of degree of protection**

**4.11.1** As specified in IEC 60034-5.

#### **4.12 Verification of bearings**

**4.12.1** Upon completion of the above tests, machines which have sleeve bearings are to be opened upon request for examination by the Surveyor, to establish that the shaft is correctly seated in the bearing shells.

## **5 Additional tests for rotating machines used as propulsion motor or thruster**

### **5.1 General**

**5.1.1** In addition to the tests defined in Tab 1, rotating machines used as propulsion motor or thruster and developing a power of more than 1 MW are to be subjected to the following requirements and tests during their assembly:

- a) Shaft line
  - requirements of Ch 1, Sec 7 apply
- b) Rotor winding assembly
  - dynamic balancing
- c) Stator winding assembly
  - dielectric test (after impregnation)
  - insulation resistance measurement (after impregnation)
- d) Frame
  - visual examination in compliance with design drawings
  - liquid penetrant test of 10% of the structure welds and 100% of the handling points.
- e) Watercooler
  - visual examination in compliance with design drawings
  - performance test (see temperature rise measurement test in Tab 1)
- f) Hydrostatic jacking unit
  - pressure test
  - working test under nominal conditions.

## Section 5 Transformers

### 1 Constructional requirements

#### 1.1 Construction

**1.1.1** Transformers, except those for motor starting, are to be double wound (two or more separate windings).

**1.1.2** Transformers are normally to be of the dry, air-cooled type.

**1.1.3** When a forced air cooling system is used, an alarm is to be activated in the event of its failure.

**1.1.4** Liquid-cooled transformers may be used provided that:

- the liquid is non-toxic and of a type which does not readily support combustion
- the construction is such that the liquid is not spilled in inclined position
- temperature and pressure relief devices with an alarm are installed
- drip trays or other suitable arrangements for collecting the liquid from leakages are provided
- a liquid gauge indicating the normal liquid level range is fitted.

**1.1.5** Transformers are to have enclosures with a degree of protection in accordance with Ch 2, Sec 3, Tab 2.

#### 1.2 Terminals

**1.2.1** Suitable fixed terminal connections are to be provided in an accessible position with sufficient space for convenient connection of the external cables.

**1.2.2** Terminals are to be clearly identified.

#### 1.3 Voltage variation, short-circuit conditions and parallel operation

**1.3.1** Under resistive load ( $\cos \Phi = 1$ ), the voltage drop from no load to full load is not to exceed 2,5%.

For transformers with a power lower than 5 kVA per phase, this voltage drop is not to exceed 5%.

An exception is made for special transformers, such as starting and instrument transformers, for which a different voltage variation may be considered.

**1.3.2** In determining the voltage ratio and the impedance voltage of transformers, account is to be taken of the total permitted voltage drop from the main switchboard's busbars to the consumers (see Ch 2, Sec 3, [9.11.4]).

**1.3.3** Transformers are to be constructed to withstand, without damage, the thermal and mechanical effects of a secondary terminal short-circuit for 2 s, with rated primary voltage and frequency.

For transformers of 1 MVA and over, this is to be justified with appropriate tests or documentation.

**1.3.4** When transformers are so arranged that their secondary windings may be connected in parallel, their winding connections are to be compatible, their rated voltage ratios are to be equal (with tolerances allowed) and their short-circuit impedance values, expressed as a percentage, are to have a ratio within 0,9 to 1,1.

When transformers are intended for operation in parallel, the rated power of the smallest transformer in the group is to be not less than half of the rated power of the largest transformer in the group.

#### 1.4 Electrical insulation and temperature rise

**1.4.1** Insulating materials for windings and other current carrying parts are to comply with the requirements of Ch 2, Sec 2.

**1.4.2** All windings of air-cooled transformers are to be suitably treated to resist moisture, air salt mist and oil vapours.

**1.4.3** The permissible limits of temperature rise with an ambient air temperature of 45°C for (natural or forced) air-cooled transformers are given in Tab 1. The temperature rises shown for windings refer to measurement by the resistance method while those for the core refer to the thermometer method.

**1.4.4** For dry-type transformers cooled with an external liquid cooling system, the permissible limits of temperature rise with a sea water temperature of 32°C are 13°C higher than those specified in Tab 1.

**1.4.5** For liquid-cooled transformers, the following temperature rises measured by the resistance method apply:

- 55°C where the fluid is cooled by air
- 68°C where the fluid is cooled by water.

**Table 1 : Temperature rise limits for transformers**

No	Part of machine	Temperature rise by class of insulation, in °C				
		A	E	B	F	H
1	Windings	55	70	75	95	120
2	Cores and other parts: a) in contact with the windings b) not in contact with the windings	a) the same values as for the windings b) in no case is the temperature to reach values such as to damage either the core itself or other adjacent parts or materials				

## 2 Testing

### 2.1 General

**2.1.1** Transformers intended for essential services are to be subjected to the test stated in [2.2].

**2.1.2** The manufacturer is to issue a test report giving, inter alia, information concerning the construction, type, serial number, insulation class and all other technical data relevant to the transformer, as well as the results of the tests required.

Such test reports are to be made available to the Society.

**2.1.3** In the case of transformers which are completely identical in rating and in all other constructional details, it will be acceptable for the temperature rise test to be performed on only one transformer.

The results of this test and the serial number of the tested transformer are to be inserted in the test reports for the other transformers.

**2.1.4** Where the test procedure is not specified, the requirements of IEC 60076 apply.

**2.1.5** The tests and, if appropriate, manufacture of transformers of 100 kVA and over (60 kVA when single phase) intended for essential services are to be attended by a Surveyor of the Society.

Transformers of 5 kVA up to the limit specified above are approved on a case by case basis, at the discretion of the Society, subject to the submission of adequate documentation and routine tests.

### 2.2 Tests on transformers

**2.2.1** Tests to be carried out on transformers are specified in Tab 2.

**Table 2 : Tests to be carried out on transformers**

No	Tests	Type test (1)	Routine test (2)
1	Examination of the technical documentation, as appropriate, and visual inspection (3)	X	X
2	Insulation resistance measurement	X	X
3	Measurement of winding resistance	X	X
4	Measurement of voltage ratio and check of phase displacement	X	X
5	Measurement of short-circuit impedance and load loss	X	X
6	Measurements of no-load loss and no load current	X	X
7	High voltage test	X	X
8	Induced voltage test	X	X
9	Temperature-rise measurement	X (4)	

(1) Type test on prototype transformer or test on at least the first batch of transformers.  
 (2) The certificates of transformers routine tested are to contain the manufacturer's serial number of the transformer which has been type tested and the test result.  
 (3) A visual examination is to be made of the transformer to ensure, as far as practicable, that it complies with technical documentation; inspection of enclosure, terminations, instrumentation or protection.  
 (4) Temperature rise test may be omitted for starting transformer.

### **2.3 Insulation tests**

**2.3.1** Transformers are to be subjected to a high voltage test in accordance with the procedure defined in IEC publication 60076-3.

**2.3.2** The test voltage is to be applied between each winding under test and the other windings not under test, core and enclosure all connected together.

Single-phase transformers for use in a polyphase group are to be tested in accordance with the requirements applicable to that group.

**2.3.3** The r.m.s. value of the test voltage is to be equal to  $2 U + 1000$  V, with a minimum of 2500 V, where U is the rated voltage of the winding. The full voltage is to be maintained for 1 minute.

**2.3.4** Partially rewound windings are to be tested at 80% of the test voltage required for new machines.

**2.3.5** The insulation resistance of a new, clean and dry transformer, measured after the temperature rise test has been carried out (at or near operating temperature) at a voltage equal to 500 V d.c., is to be not less than 5 M $\Omega$ .

**2.3.6** Transformers are to be subjected to an induced voltage insulation test by applying to the terminals of the winding under test a voltage equal to twice the rated voltage. The duration of the test is to be 60 s for any test frequency  $f_p$  up to and including twice the rated frequency  $f_n$ .

If the test frequency exceeds twice the rated frequency, the test time in seconds will be  $120 f_n/f_p$  with a minimum of 15s.

## Section 6 Semiconductor Converters

### 1 Constructional requirements

#### 1.1 Construction

**1.1.1** Semiconductor converters are to comply with the relevant requirements for switchgear assemblies (see Ch 2, Sec 8).

**1.1.2** The design of semi-conductor converters is to comply with the requirements of IEC Publication 60146-1-1 with applicable requirements modified to suit marine installations like e.g. environmental requirements stated in Ch 2, Sec 2.

**1.1.3** The design of semi-conductor converters for power supply is to comply with the requirements of IEC 62040 serie (see Article [2]).

**1.1.4** The design of semi-conductor converters for motor drives is to comply with the requirements of IEC 61800 serie.

**1.1.5** The monitoring and control circuits are generally to comply with the requirements of Part C, Chapter 3.

**1.1.6** For liquid-cooled converters the following provisions are to be satisfied:

- liquid is to be non-toxic and of low flammability
- drip trays or other suitable means are to be provided to contain any liquid leakages
- the resistivity of the cooling fluid in direct contact with semiconductor or other current carrying parts is to be monitored and an alarm initiated if the resistivity is outside the specified limits.

**1.1.7** Where forced cooling is used, the temperature of the heated cooling medium is to be monitored.

If the temperature exceeds a preset value an alarm is to be given and the shutdown of the converter is to be activated.

**1.1.8** Where forced (air or liquid) cooling is provided, it is to be so arranged that the converter cannot be or remain loaded unless effective cooling is maintained.

Alternatively, other effective means of protection against overtemperature may be provided.

**1.1.9** Stacks of semiconductor elements, and other equipment such as fuses, or control and firing circuit boards etc., are to be so arranged that they can be removed from equipment without dismantling the complete unit.

**1.1.10** Semiconductor converters are to be rated for the required duty having regard to the peak loads, system transient and overvoltage and to be dimensioned so as to withstand the maximum short-circuit currents foreseen at the point of installation for the time necessary to trip the protection of the circuits they supply.

#### 1.2 Protection

**1.2.1** Semiconductor elements are to be protected against short-circuit by means of devices suitable for the point of installation in the network.

**1.2.2** Overcurrent or overvoltage protection is to be installed to protect the converter. When the semiconductor converter is designed to work as an inverter supplying the network in transient periods, precautions necessary to limit the current are to be taken.

**1.2.3** Semiconductor converters are not to cause distortion in the voltage wave form of the power supply at levels exceeding the voltage wave form tolerances at the other user input terminals (see Ch 2, Sec 2, [2.4]).

**1.2.4** An alarm is to be provided for tripping of protective devices against overvoltages and overcurrents in electric propulsion converters and for converters for the emergency source of power.

#### 1.3 Parallel operation with other power sources

**1.3.1** For converters arranged to operate in parallel with other power sources, load sharing is to be such that under normal operating conditions overloading of any unit does not occur and the combination of paralleled equipment is stable.

#### 1.4 Temperature rise

**1.4.1** The permissible limit of temperature rise of the enclosure of the semiconductors is to be assessed on the basis of an ambient air temperature of 45°C or sea water temperature of 32°C for water-cooled elements, taking into account its specified maximum permissible temperature value.

**1.4.2** The value of the maximum permissible temperature of the elements at the point where this can be measured (point of reference) is to be stated by the manufacturer.

**1.4.3** The value of the mean rated current of the semiconductor element is to be stated by the manufacturer.

## **1.5 Creepage and clearance distances**

**1.5.1** Creepage and clearance distances are to comply with the requirements specified in IEC 61800-5-1. An interpolation of the specified values is permitted for high voltage semi-conductor converters.

## **2 Requirements for uninterruptible power system (UPS) units as alternative and/or transitional power**

### **2.1 Definitions**

#### **2.1.1 Uninterruptible power system (UPS)**

Combination of converters, switches and energy storage means, for example batteries, constituting a power system for maintaining continuity of load power in case of input power failure (see IEC Publication 62040-3).

#### **2.1.2 Off line UPS unit**

A UPS unit where under normal operation the output load is powered from the bypass line (raw mains) and only transferred to the inverter if the bypass supply fails or goes outside preset limits. This transition will invariably result in a brief (typically 2 to 10 ms) break in the load supply.

#### **2.1.3 Line interactive UPS unit**

An off-line UPS unit where the bypass line switch to stored energy power when the input power goes outside the preset voltage and frequency limits.

#### **2.1.4 On line UPS unit**

A UPS unit where under normal operation the output load is powered from the inverter, and will therefore continue to operate without break in the event of the supply input failing or going outside preset limits.

### **2.2 Design and construction**

**2.2.1** UPS units are to be constructed in accordance with IEC 62040-1, IEC 62040-2, IEC 62040-3, IEC 62040-4 and/or IEC 62040-5-3, as applicable, or an acceptable and relevant national or international standard.

**2.2.2** The operation of the UPS is not to depend upon external services.

**2.2.3** The type of UPS unit employed, whether off-line, line interactive or on-line, is to be appropriate to the power supply requirements of the connected load equipment.

**2.2.4** An external bypass is to be provided.

**2.2.5** The UPS unit is to be monitored and audible and visual alarm is to be given in a normally attended location for:

- power supply failure (voltage and frequency) to the connected load
- earth fault
- operation of battery protective device
- when the battery is being discharged
- when the bypass is in operation for on-line UPS units.

### **2.3 Location**

**2.3.1** The UPS unit is to be suitably located for use in an emergency.

**2.3.2** UPS units utilising valve regulated sealed batteries may be located in compartments with normal electrical equipment, provided the ventilation arrangements are in accordance with the requirements of IEC 62040-1, IEC 62040-2, IEC 62040-3, IEC 62040-4 and/or IEC 62040-5-3, as applicable, or an acceptable and relevant national or international standard.

### **2.4 Performance**

**2.4.1** The output power is to be maintained for the duration required for the connected equipment as stated in Ch 2, Sec 3, [3.6.3] and Pt D, Ch 11, Sec 5, [2.2.3].

**2.4.2** No additional circuits are to be connected to the UPS unit without verification that the UPS unit has adequate capacity.

**2.4.3** The UPS battery capacity is, at all times, to be capable of supplying the designated loads for the time specified in the regulations.

**2.4.4** On restoration of the input power, the rating of the charge unit shall be sufficient to recharge the batteries while maintaining the output supply to the load equipment.

### 3 Testing

#### 3.1 General

**3.1.1** Converters intended for essential services are to be subjected to the tests stated in [3.2].

**3.1.2** The manufacturer is to issue a test report giving information on the construction, type, serial number and all technical data relevant to the converter, as well as the results of the tests required.

**3.1.3** In the case of converters which are completely identical in rating and in all other constructional details, it will be acceptable for the rated current test and temperature rise measurement stipulated in [3.2] not to be repeated.

**3.1.4** The tests and, if appropriate, manufacture of converters of 50 kVA and over intended for essential services are to be attended by a Surveyor of the Society.

#### 3.2 Tests on converters

**3.2.1** Converters are to be subjected to tests in accordance with Tab 1.

Type tests are the tests to be carried out on a prototype converter or the first of a batch of converters, and routine tests are the tests to be carried out on subsequent converters of a particular type.

**3.2.2** The tests listed in Tab 1 are to be performed in accordance with IEC 60146-1-1. The relevant requirements of IEC 61800-5-1 and of IEC 62040-3 based on the equipment type also apply.

**3.2.3** The electronic components of the converters are to be constructed to withstand the tests required in Ch 3, Sec 6.

**3.2.4** Final approval of converters is to include complete function tests after installation on board, performed with all ship's systems in operation and in all characteristic load conditions.

**Table 1 : Tests to be carried out on static converters**

No	Tests	Type test (1)	Routine test (2)
1	Examination of the technical documentation, as appropriate, and visual inspection (3) including check of earth continuity	X	X
2	Light load function test to verify all basic and auxiliary functions	X	X
3	Rated current test	X	
4	Temperature rise measurement	X	
5	Insulation test (dielectric strength test and insulation resistance measurement)	X	X
6	Protection of the converters in case of failure of forced cooling system	X	X
(1) Type test on prototype converter or test on at least the first batch of converters. (2) The certificates of converters routine tested are to contain the manufacturer's serial number of the converter which has been type tested and the test result. (3) A visual examination is to be made of the converter to ensure, as far as practicable, that it complies with technical documentation.			

#### 3.3 Additional testing and survey for uninterruptible power system (UPS) units as alternative and/or transitional power

**3.3.1** UPS units of 50 kVA and over are to be surveyed by the Society during manufacturing and testing.

**3.3.2** Appropriate testing is to be carried out to demonstrate that the UPS unit is suitable for its intended environment. This is expected to include as a minimum the following tests:

- functionality, including operation of alarms
- ventilation rate
- battery capacity.

**3.3.3** Where the supply is to be maintained without a break following a power input failure, this is to be verified after installation by practical test.

**3.4 Insulation test**

**3.4.1** The test procedure is that specified in IEC Publication 60146.

**3.4.2** The effective value of the test voltage for the insulation test is to be as shown in Tab 2.

**Table 2 : Test voltages for high voltage test on static converters**

$\frac{U_m}{\sqrt{2}} = U$ in V (1)	Test voltage, in V
$U \leq 60$	600
$60 < U \leq 90$	900
$90 < U$	$2 U + 1000$ (at least 2000)

(1)  $U_m$ : highest crest value to be expected between any pair of terminals.

# Section 7 Storage Batteries and Chargers

## 1 Batteries

### 1.1 General

1.1.1 The requirements of this Section apply to permanently installed storage batteries (not to portable batteries).

1.1.2 Storage batteries may be of the lead-acid, nickel-alkaline or lithium type, due consideration being given to the suitability for any specific application.

Other types of storage batteries may be considered by the Society.

1.1.3 Cells are to be assembled in suitable crates or trays equipped with handles for convenient lifting.

### 1.2 Definitions

#### 1.2.1 Valve-regulated battery

A valve-regulated battery is one in which cells are closed but have an arrangement (valve) which allows the escape of gas if the internal pressure exceeds a predetermined value.

Note 1: The cells of batteries which are marketed as "sealed" or "maintenance free" are fitted with a pressure relief valve as a safety precaution to enable uncombined gas to be vented to the atmosphere; they should more properly be referred to as valve-regulated sealed batteries. In some circumstances the quantity of gas vented can be up to 25% of the equivalent vented design. The design is to take into consideration provision for proper ventilation.

#### 1.2.2 Vented battery

A vented battery is one in which the cells have a cover provided with an opening through which products of electrolysis and evaporation are allowed to escape freely from the cells to atmosphere.

#### 1.2.3 Shelf life

Shelf life is the duration of storage under specified conditions at the end of which a battery retains the ability to give a specified performance.

### 1.3 Vented batteries

1.3.1 Vented batteries are to be constructed to withstand the movement of the ship and the atmosphere (salt mist, oil etc.) to which they may be exposed.

1.3.2 Battery cells are to be so constructed as to prevent spilling of electrolyte at any inclination of the battery up to 40° from the vertical.

1.3.3 It is to be possible to check the electrolyte level and the pH.

### 1.4 Valve-regulated sealed batteries

1.4.1 Cell design is to minimise risks of release of gas under normal and abnormal conditions.

### 1.5 Li Ion batteries

1.5.1 For Li Ion batteries of capacity above 20kWh, the requirements specified in Pt F, Ch 14, Sec 1, [3] and Pt F, Ch 14, Sec 1, [5] apply.

For Li Ion batteries used as emergency source or transitional source, the requirements specified in Pt F, Ch 14, Sec 1, [5] apply.

1.5.2 For Li Ion batteries of capacity below 20 kWh, a risk analysis is to be conducted and submitted to the Society for review.

### 1.6 Testing

1.6.1 The battery autonomy is to be verified on board in accordance with the operating conditions.

### 1.7 Battery maintenance

1.7.1 Where batteries are fitted for use for essential and emergency services, a schedule of such batteries is to be compiled and maintained. The schedule, which is to be reviewed by the Society, is to include at least the following information regarding the battery(ies):

- Type and manufacturer’s type designation
- Voltage and ampere-hour rating
- Location
- Equipment and/or system(s) served
- maintenance/replacement cycle dates
- date(s) of last maintenance and/or replacement
- for replacement batteries in storage, the date of manufacture and shelf life.

**1.7.2** Procedures are to be put in place to ensure that, where batteries are replaced, they are of an equivalent performance type.

**1.7.3** Where vented type batteries replace valve-regulated sealed types, it is to be ensured that there is adequate ventilation and that the Society’s requirements relevant to the location and installation of vented types batteries are complied with.

**1.7.4** Details of the schedule and of the procedures are to be included in the ship’s safety management system and be integrated into the ship’s operational maintenance routine, as appropriate, to be verified by the Society’s surveyor.

## 2 Chargers

### 2.1 General

**2.1.1** Chargers are to be adequate for the batteries for which they are intended and provided with a voltage regulator.

**2.1.2** In the absence of indications regarding its operation, the battery charger is to be such that the completely discharged battery can be recharged to 80% capacity within a period of 10 hours without exceeding the maximum permissible charging current. A charging rate other than the above (e.g. fully charged within 6 hours for batteries for starting of motors) may be required in relation to the use of the battery.

**2.1.3** For floating service or for any other condition where the load is connected to the battery while it is on charge, the maximum battery voltage is not to exceed the safe value of any connected apparatus.

Note 1: Consideration is to be given to the temperature variation of the batteries.

**2.1.4** The battery charger is to be designed so that the charging current is set within the maximum current allowed by the manufacturer when the battery is discharged and the floating current to keep the battery fully charged.

**2.1.5** Trickle charging to neutralise internal losses is to be provided. An indication is to be provided to indicate a charging voltage being present at the charging unit.

**2.1.6** Protection against reversal of the charging current is to be provided.

**2.1.7** Battery chargers are to be constructed to simplify maintenance operation. Indications are to be provided to visualise the proper operation of the charger and for troubleshooting.

### 2.2 Testing

**2.2.1** Battery chargers are to be subjected to tests in accordance with Tab 1.

Type tests are the tests to be carried out on a prototype charger or the first of a batch of chargers, and routine tests are the tests to be carried out on subsequent chargers of a particular type.

**2.2.2** The electronic components of the battery chargers are to be constructed to withstand the tests required in Ch 3, Sec 6.

**2.2.3** The tests of battery chargers of 5 kW and over intended for essential services are to be attended by a Surveyor of the Society.

**Table 1 : Tests to be carried out on battery chargers**

No.	Tests	Type test (1)	Routine test (2)
1	Examination of the technical documentation, as appropriate, and visual inspection (3) including check of earth continuity	X	X
2	Functional tests (current and voltage regulation, quick, slow, floating charge, alarms)	X	X
3	Temperature rise measurement	X	
4	Insulation test (dielectric strength test and insulation resistance measurement)	X	X

(1) Type test on prototype battery charger or test on at least the first batch of battery chargers.

(2) The certificates of battery chargers routine tested are to contain the manufacturer’s serial number of the battery charger which has been type tested and the test result.

(3) A visual examination is to be made of the battery charger to ensure, as far as practicable, that it complies with technical documentation.

## Section 8 Switchgear and Controlgear Assemblies

### 1 Constructional requirements for main and emergency switchboards

#### 1.1 Construction

1.1.1 Construction is to be in accordance with IEC Publication 60092-302.

1.1.2 Where the framework, panels and doors of the enclosure are of steel, suitable measures are to be taken to prevent overheating due to the possible circulation of eddy currents.

1.1.3 Insulating material for panels and other elements of the switchboard is at least to be moisture-resistant and flame-retardant.

1.1.4 Switchboards are to be of dead front type, with enclosure protection according to Ch 2, Sec 3, Tab 2.

1.1.5 Switchboards are to be provided with insulated handrails or handles fitted in an appropriate position at the front of the switchboard. Where access to the rear is necessary for operational or maintenance purposes, an insulated handrail or insulated handles are to be fitted.

1.1.6 Where the aggregate capacity of generators connected to the main busbars exceeds 100 kVA, a separate cubicle for each generator is to be arranged with flame-retardant partitions between the different cubicles. Similar partitions are to be provided between the generator cubicles and outgoing circuits.

1.1.7 Instruments, handles or push-buttons for switchgear operation are to be placed on the front of the switchboard. All other parts which require operation are to be accessible and so placed that the risk of accidental touching of live parts, or accidental making of short-circuits and earthings, is reduced as far as practicable.

1.1.8 Where it is necessary to make provision for the opening of the doors of the switchboard, this is to be in accordance with one of the following requirements:

- a) opening is to necessitate the use of a key or tool (e.g. when it is necessary to replace a lamp or a fuse-link)
- b) all live parts which can be accidentally touched after the door has been opened are to be disconnected before the door can be opened
- c) the switchboard is to include an internal barrier or shutter with a degree of protection not less than IP2X shielding all live parts such that they cannot accidentally be touched when the door is open. It is not to be possible to remove this barrier or shutter except by the use of a key or tool.

1.1.9 All parts of the switchboard are to be readily accessible for maintenance, repair or replacement. In particular, fuses are to be able to be safely inserted and withdrawn from their fuse-bases.

1.1.10 Hinged doors which are to be opened for operation of equipment on the door or inside are to be provided with fixing devices for keeping them in open position.

1.1.11 Means of isolation of the circuit-breakers of generators and other important parts of the installation are to be provided so as to permit safe maintenance while the main busbars are alive.

1.1.12 Where components with voltage exceeding the safety voltage are mounted on hinged doors, the latter are to be electrically connected to the switchboard by means of a separate, flexible protective conductor.

1.1.13 All measuring instruments and all monitoring and control devices are to be clearly identified with indelible labels of durable, flame-retardant material.

1.1.14 The rating of each circuit, together with the rating of the fuse or the appropriate setting of the overload protective device (circuit-breaker, thermal relay etc.) for each circuit is to be permanently indicated at the location of the fuse or protective device.

1.1.15 When Busbar Trunking systems are used outside switchboards, IACS Recommendation No.67: Test and Installation of busbar trunking systems may be taken as reference for design, installation and testing.

#### 1.2 Busbars and bare conductors

1.2.1 Busbars are to be of copper or of copper-surrounded aluminium alloy if suitable for use in the marine environment and if precautions are taken to avoid galvanic corrosion.

1.2.2 All connections are to be so made as to inhibit corrosion.

**1.2.3** Busbars are to be dimensioned in accordance with IEC Publication 60092-302.

The mean temperature rise of busbars is not to exceed 45°C under rated current condition with an ambient air temperature of 45°C (see Ch 2, Sec 2, [1.2.2]) and is not to have any harmful effect on adjacent components. Higher values of temperature rise may be accepted to the satisfaction of the Society.

**1.2.4** The cross-section of neutral connection on an a.c. three-phase, four-wire system is to be at least 50% of the cross-section for the corresponding phases.

**1.2.5** Bare main busbars, excluding the conductors between the main busbars and the supply side of outgoing units, are to have the minimum clearances and creepage distances given in Tab 1. The values shown apply to clearances and creepage distances between live parts as well as between live parts and exposed conductive parts.

Note 1: Clearance is the distance between two conductive parts along a string stretched the shortest way between such parts. Creepage distance is the shortest distance along the surface of an insulating material between two conductive parts.

**Table 1 : Clearance and creepage distances**

Rated insulation voltage a.c. r.m.s. or d.c., in V	Minimum clearance, in mm	Minimum creepage distance, in mm
≤ 250	15	20
> 250 to ≤ 690	20	25
> 690	25	35

**1.2.6** Reduced values as specified in IEC Publication 60092-302 may be accepted for type tested and partially type tested assemblies.

The reference values for the evaluation of the minimum clearances and creepage distances for these assemblies are based on the following:

- pollution degree 3 (conductive pollution occurs, or dry non-conductive pollution occurs which becomes conductive due to condensation which is expected)
- overvoltage category III (distribution circuit level)
- unhomogenous field conditions (case A)
- rated operational voltage 1000 V a.c., 1500 V d.c.
- group of insulating material IIIa.

Special consideration is to be given to equipment located in spaces where a pollution degree higher than 3 is applicable, e.g. in diesel engine rooms.

**1.2.7** Busbars and other bare conductors with their supports are to be mechanically dimensioned and fixed such that they can withstand the stresses caused by short-circuits.

Where maximum symmetrical short-circuit currents are expected to exceed 50 kA, calculation is to be submitted to the Society.

**1.2.8** Busbars and bare conductors are to be protected, where necessary, against falling objects (e.g. tools, fuses or other objects).

### 1.3 Internal wiring

**1.3.1** Insulated conductors for internal wiring of auxiliary circuits of switchboards are to be constructed in accordance with Ch 2, Sec 9, [2.1.1].

**1.3.2** All insulated conductors provided for in [1.3.1] are to be of flexible construction and of the stranded type.

**1.3.3** Connections from busbars to protective devices are to be as short as possible. They are to be laid and secured in such a way to minimise the risk of a short-circuit.

**1.3.4** All conductors are to be secured to prevent vibration and are to be kept away from sharp edges.

**1.3.5** Connections leading to indicating and control instruments or apparatus mounted in doors are to be installed such that they cannot be mechanically damaged due to movement of the doors.

**1.3.6** Non-metallic trays for internal wiring of switchboards are to be of flame-retardant material.

**1.3.7** Control circuits are to be installed and protected such that they cannot be damaged by arcs from the protective devices.

**1.3.8** Where foreseen, fixed terminal connectors for connection of the external cables are to be arranged in readily accessible positions.

## **1.4 Switchgear and controlgear**

**1.4.1** Switchgear and controlgear are to comply with IEC Publication 60947 series and to be chosen from among that type approved by the Society.

**1.4.2** The characteristics of switchgear, controlgear and protective devices for the various consumers are to be in compliance with Ch 2, Sec 3, [7].

## **1.5 Auxiliary circuits**

**1.5.1** Auxiliary circuits are to be designed in such a manner that, as far as practicable, faults in such circuits do not impair the safety of the system. In particular, control circuits are to be designed so as to limit the dangers resulting from a fault between the control circuit and earth (e.g. inadvertent operation or malfunction of a component in the installation), also taking account of the earthing system of their supply.

**1.5.2** Auxiliary circuits of essential systems are to be independent of other auxiliary circuits.

**1.5.3** Common auxiliary circuits for groups of consumers are permitted only when the failure of one consumer jeopardises the operation of the entire system to which it belongs.

**1.5.4** Auxiliary circuits are to be branched off from the main circuit in which the relevant switchgear is used.

**1.5.5** The supply of auxiliary circuits by specifically arranged control distribution systems will be specially considered by the Society.

**1.5.6** Means are to be provided for isolating the auxiliary circuits as well when the main circuit is isolated (e.g. for maintenance purposes).

**1.5.7** For the protection of auxiliary circuits see Ch 2, Sec 3, [7.13].

## **1.6 Instruments**

**1.6.1** The upper limit of the scale of every voltmeter is to be not less than 120% of the rated voltage of the circuit in which it is installed.

**1.6.2** The upper limit of the scale of every ammeter is to be not less than 130% of the normal rating of the circuit in which it is installed.

**1.6.3** The upper limit of the scale of every wattmeter is to be not less than 120% of the rated voltage of the circuit in which it is installed.

**1.6.4** Ammeters or wattmeters for use with a.c. generators which may be operated in parallel are to be capable of indicating 15% reverse-current or reverse power, respectively.

**1.6.5** For wattmeters using one current circuit only, the measurement of the current of all generators is to be made in the same phase.

**1.6.6** The rated value of the measure read, at full load, is to be clearly indicated on the scales of instruments.

**1.6.7** Frequency meters are to have a scale at least  $\pm 5\%$  of the nominal frequency.

**1.6.8** The secondary windings of instrument transformers are to be earthed.

**1.6.9** Each a.c. generator not operated in parallel is to be provided with:

- 1 voltmeter
- 1 frequency meter
- 1 ammeter in each phase or 1 ammeter with a selector switch to enable the current in each phase to be read
- 1 three-phase wattmeter in the case of generators rated more than 50 kVA.

**1.6.10** Each a.c. generator operated in parallel is to be provided with:

- 1 three-phase wattmeter
- 1 ammeter in each phase or 1 ammeter with a selector switch to enable the current in each phase to be read.

**1.6.11** For paralleling purposes the following are to be provided:

- 2 voltmeters (voltage measurements of each alternator and busbar)
- 2 frequency meters (frequency measurements of each alternator and busbar).

Note 1: As an alternative, a switch may be provided to enable one voltmeter and one frequency meter to be connected to each generator before the latter is connected to the busbars.

The other voltmeter and frequency meter are to be permanently connected to the busbars.

Note 2: Voltmeter and frequency meter with dual display may be considered.

**1.6.12** Each secondary distribution system is to be provided with one voltmeter.

**1.6.13** Switchboards are to be fitted with means for monitoring the insulation level of insulated distribution systems as stipulated in Ch 2, Sec 3, [3.2.1].

**1.6.14** The main switchboard is to be fitted with a voltmeter or signal lamp indicating that the cable between the shore-connection box and the main switchboard is energised (see Ch 2, Sec 3, [3.7.7]).

**1.6.15** For each d.c. power source (e.g. converters, rectifiers and batteries), one voltmeter and one ammeter are to be provided, except for d.c. power sources for starting devices (e.g. starting motor for emergency generator).

## **1.7 Synchronisation of generators**

**1.7.1** It is to be possible to synchronise each generator intended for parallel operation with two independent synchronizing devices. At least, one of these synchronizing devices is to be manual.

**1.7.2** Provisions are to be made for manual speed control of the prime mover and manual voltage control of the generators at the place where the manual synchronization is carried out.

## **2 Constructional requirements for section boards and distribution boards**

### **2.1 Construction**

**2.1.1** Section boards and distribution boards are to be constructed, insofar as applicable, as specified for main and emergency switchboards.

**2.1.2** All parts which require operation in normal use are to be placed on the front.

**2.1.3** Distribution switchboards which are provided with two or more supply circuits arranged for automatic standby connection are to be provided with positive indication of which of the circuits is feeding the switchboard.

**2.1.4** Where switchboard supplying essential services is provided with a forced air cooling system, the air temperature is to be monitored. An alarm is to be activated when temperature exceeds a preset value.

## **3 Testing**

### **3.1 General**

**3.1.1** Switchboards are to be subjected to the tests specified from [3.2] to [3.4].

**3.1.2** The manufacturer is to issue the relative test reports providing information concerning the construction, serial number and technical data relevant to the switchboard, as well as the results of the tests required.

**3.1.3** The tests are to be carried out prior to installation on board.

**3.1.4** The test procedures are as specified in IEC Publication 60092-302.

**3.1.5** The tests of main switchboards, emergency switchboards or switchboards rated above 100 kW are to be attended by a surveyor of the Society.

### **3.2 Inspection of equipment, check of wiring and electrical operation test**

**3.2.1** It is to be verified that the switchboard:

- complies with the approved drawings
- maintains the prescribed degree of protection
- is constructed in accordance with the relevant constructional requirements, in particular as regards creepage and clearance distances.

**3.2.2** The connections, especially screwed or bolted connections, are to be checked for adequate contact, possibly by random tests.

**3.2.3** Depending on the complexity of the switchboard it may be necessary to carry out an electrical functioning test. The test procedure and the number of tests depend on whether or not the switchboard includes complicated interlocks, sequence control facilities, etc. In some cases it may be necessary to conduct or repeat this test following installation on board.

**3.3 High voltage test**

**3.3.1** The test is to be performed with alternating voltage at the assembly’s rated frequency with a ± 25% tolerance.

**3.3.2** The test voltage is to be applied:

- between all live parts connected together and exposed conductive parts
- between each polarity and, all other polarities and exposed conductive parts connected together.

During the high voltage test, measuring instruments, ancillary apparatus and electronic devices may be disconnected and tested separately in accordance with the appropriate requirements.

**3.3.3** The test voltage is to have a substantially sinusoidal waveform, and is not to exceed half of the full test value at the moment of application. It is then to be increased gradually within a few seconds to this full value and maintained for 60 seconds.

**3.3.4** The value of the test voltage for main and auxiliary circuits is given in Tab 2 and Tab 3.

**Table 2 : Test voltage for main circuits**

Rated insulation voltage $U_i$ , (line to line a.c. or d.c.), in V	Dielectric test voltage a.c. (r.m.s.), in V	Dielectric test voltage d.c., in V
$U_i \leq 60$	1000	1415
$60 < U_i \leq 300$	1500	2120
$300 < U_i \leq 690$	1890	2670
$690 < U_i \leq 800$	2000	2830
$800 < U_i \leq 1000$	2200	3110
$1000 < U_i \leq 1500$	–	3820

**Table 3 : Test voltage for auxiliary circuits**

Rated insulation voltage $U_i$ , (line to line), in V	Dielectric test voltage a.c. (r.m.s.), in V	Dielectric test voltage d.c., in V
$U_i \leq 12$	250	355
$12 < U_i \leq 60$	500	710
$U_i > 60$	see Tab 2	see Tab 2

**3.4 Measurement of insulation resistance**

**3.4.1** Immediately after the high voltage test, the insulation resistance is to be measured using a device with a direct current voltage of at least 500 V.

**3.4.2** The insulation resistance between all current carrying parts and earth (and between each polarity and the other polarities) is to be at least equal to 1 MΩ.

# Section 9 Cables

## 1 General

### 1.1 Type approval

1.1.1 Cables are to be of a type approved by the Society.

## 2 Constructional requirements

### 2.1 Construction

2.1.1 Cables and insulated wiring are generally to be constructed in accordance with the relevant recommendations of IEC Publications 60092-350, 60092-352, 60092-353, 60092-354, 60092-360, 60092-370 and 60092-376, as well as with the provisions of this Chapter.

2.1.2 Mineral-insulated cables are to be constructed according to IEC Publication 60702.

2.1.3 Optical fibre cables are to be constructed in accordance with IEC Publication 60794.

2.1.4 Cables and insulated wires manufactured and tested in accordance to standards other than those specified in [2.1.1] will be accepted provided they are in accordance with an acceptable and relevant international or national standard and are of an equivalent or higher safety level than those listed in [2.1.1].

However, cables such as flexible cable, fibre-optic cable, etc. used for special purposes may be accepted provided they are manufactured and tested in accordance with the relevant standards accepted by the Society.

2.1.5 Insulated wiring for auxiliary circuits of switchboards may be constituted by cables with a single conductor of the stranded type for all sections, PVC-ST2 or rubber-insulated in accordance with the standards cited in [2.1.1] and without further protection.

2.1.6 The insulated wiring is to be at least of the flame-retardant type according to IEC Publication 60332-1-2. Switchboard wires, of an equivalent flame-retardant type, will be specially considered by the Society.

2.1.7 In addition to the provisions of Ch 2, Sec 3, [9.1.1], when cables are laid in bunches, cable types are to be chosen in compliance with IEC Publication 60332-3-22 Category A, or other means (see Ch 2, Sec 12, [7.1.4], items b) and c)) are to be provided such as not to impair their original flame-retarding properties.

2.1.8 Where necessary for specific applications such as radio frequency or digital communication systems, which require the use of particular types of cables, the Society may permit the use of cables which do not comply with the provisions of Ch 2, Sec 3, [9.1.1] and with [2.1.7].

2.1.9 Fire resistant cables are to be designed and tested in accordance with the relevant IEC Publication 60092-series standards. They are to comply with the requirements of:

- IEC Standard 60331-1 for cables with an overall diameter exceeding 20 mm, or
- IEC Standard 60331-2 for cables with an overall diameter not exceeding 20 mm,
- otherwise IEC 60331-21.

The minimum flame application time is to be at least 90 minutes.

Fire resistant type cables are to be easily distinguishable.

Note 1: For special cables, requirements in the following standards may be used:

- IEC 60331-23: Procedures and requirements - Electric data cables
- IEC 60331-25: Procedures and requirements - Optical fibre cables

### 2.2 Conductors

2.2.1 Conductors are to be of annealed electrolytic copper with a resistivity not exceeding  $17,241 \Omega \text{ mm}^2/\text{km}$  at  $20^\circ\text{C}$  according to IEC 60228.

2.2.2 Individual conductor wires of rubber-insulated cables are to be tinned or coated with a suitable alloy.

2.2.3 All conductors are to be stranded, except for cables of nominal cross-sectional area  $2,5 \text{ mm}^2$  and less (provided that adequate flexibility of the finished cable is assured).

**2.2.4** For the minimum nominal cross-sectional areas permitted, see Ch 2, Sec 3, [9.10].

### **2.3 Insulating materials**

**2.3.1** The materials used for insulation are to comply with IEC Publication 60092-360 and to have the thicknesses specified for each type of cable in the relevant standard. The maximum permissible rated temperature is specified for the various materials.

**2.3.2** Materials and thicknesses other than those in [2.3.1] will be specially considered by the Society.

### **2.4 Inner covering, fillers and binders**

**2.4.1** The cores of a multicore cable are to be laid up. The spaces between the cores are to be filled so as to obtain an assembly having an essentially circular cross-section. The filling may be omitted in multicore cables having a conductor cross-sectional area not exceeding 4 mm<sup>2</sup>.

**2.4.2** When a non-metallic sheath is applied directly over the inner covering or the fillers, it may substitute partially for the inner covering or fillers.

### **2.5 Protective coverings (armour and sheath)**

**2.5.1** Metallic armour, if not otherwise protected against corrosion, is to be protected by means of a coating of protective paint (see Ch 2, Sec 3, [9.3]).

**2.5.2** The paint is to be non-flammable and of adequate viscosity. When dry, it is not to flake off.

**2.5.3** The materials used for sheaths are to be in accordance with IEC Publication 60092-360 and are to have the thicknesses specified for each type of cable in the relevant standard.

The quality of the materials is to be adequate to the service temperature of the cable.

**2.5.4** Materials other than those in [2.5.3] will be specially considered by the Society.

### **2.6 Identification**

**2.6.1** Each cable is to have clear means of identification so that the manufacturer can be determined.

**2.6.2** Fire non propagating cables are to be clearly labelled with indication of the standard according to which this characteristic has been verified and, if applicable, of the category to which they correspond.

## **3 Testing**

### **3.1 Type tests**

**3.1.1** Type tests are to be in accordance with the relevant IEC 60092-3. Series Publications and IEC 60332-1, IEC 60332-3 Category A, IEC 60331-1, IEC 60331-2, and IEC 60331-21 where applicable.

### **3.2 Routine tests**

**3.2.1** Every length of finished cable is to be subjected to the tests specified in [3.2.2].

**3.2.2** The following routine tests are to be carried out:

- a) visual inspection
- b) check of conductor cross-sectional area by measuring electrical resistance
- c) high voltage test
- d) insulation resistance measurement
- e) dimensional checks (as necessary).

**3.2.3** The manufacturer is to issue a statement providing information on the type and characteristics of the cable, as well as the results of the tests required and the Type Approval Certificates.

**3.2.4** The test procedure is as specified in IEC Publication 60092-350.

**3.2.5** Where an alternative scheme, e.g. a certified quality assurance system, is recognised by the Society, attendance of the Surveyor may not be required.

## Section 10 Miscellaneous Equipment

### 1 Switchgear and controlgear, protective devices

#### 1.1 General

1.1.1 Switchgear and controlgear are to comply with IEC Publication 60947.

1.1.2 For materials and construction see Ch 2, Sec 2, [4] and Ch 2, Sec 2, [5].

#### 1.2 Circuit-breakers

1.2.1 Power-driven circuit-breakers are to be equipped with an additional separate drive operated by hand.

1.2.2 Power circuit-breakers with a making capacity exceeding 10 kA are to be equipped with a drive which performs the make operation independently of the actuating force and speed.

1.2.3 Where the conditions for closing the circuit-breaker are not satisfied (e.g. if the undervoltage trip is not energised), the closing mechanism is not to cause the closing of the contacts.

1.2.4 All circuit-breakers rated more than 16 A are to be of the trip-free type, i.e. the breaking action initiated by overcurrent or undervoltage releases is to be fulfilled independently of the position of the manual handle or other closing devices.

#### 1.3 Protection devices

1.3.1 Short-circuit releases are generally to be independent of energy supplied from circuits other than that to be protected. Tripping due to short-circuit is to be reliable even in the event of a total loss of voltage in the protected circuit.

1.3.2 Short-circuit releases for generators are to be equipped with reclosing inhibitors and are to be delayed for selective tripping.

1.3.3 Overload releases or relays are to operate reliably at any voltage variation of the supply voltage in the protected circuit.

1.3.4 Undervoltage relays or releases are to cause the circuit-breaker to open if the voltage drops to 70%-35% of the rated voltage.

1.3.5 Shunt releases are to ensure the disconnection of the circuit-breaker even when the supply voltage of the release drops to 85% of the rated supply voltage.

1.3.6 The reverse power protection device is to respond to the active power regardless of the power factor, and is to operate only in the event of reverse power.

1.3.7 Single-phase failure devices in three-phase circuits are to operate without a time lag.

1.3.8 Insulation monitoring devices are to continuously monitor the insulation resistance to earth and trigger an alarm should the insulation resistance fall below a predetermined value.

The measuring current of such devices is not to exceed 30 mA in the event of a total short to earth.

### 2 Electrical slip ring assemblies

#### 2.1 General requirements

2.1.1 The purpose of the electrical slip ring is to form a continuous electrical connection between a fixed part and a rotating part. The electrical slip rings may transfer power or control/automation signals.

2.1.2 High voltage electrical slip rings are to be segregated from slip rings operating at different voltage ratings.

2.1.3 Slip rings fitted with forced cooling system are to be capable of restricted operation in case of loss of the cooling system. The cooling system failure is to be alarmed.

2.1.4 Where data transmission is carried out via a bus system, transmission paths are to be duplicated. Failure of each single system is to be alarmed.

**2.2 Construction**

- 2.2.1** It is to be taken into account that the mechanical and electrical characteristics of the slip rings can be degraded by contamination or by oxidation.
- 2.2.2** Enclosures for slip ring assemblies is to ensure at least a degree of protection IP23.
- 2.2.3** The suitability of used materials at maximum permitted temperature values is to be proven. The permitted conductor temperature values of the connected cables is not to be exceeded.
- 2.2.4** The maximum temperature rise of external surface parts which can easily be touched in service is not to exceed 15°C.
- 2.2.5** The enclosure is to be protected against internal condensation.
- 2.2.6** Clearance and creepage distances between non-insulated parts of low voltage slip rings are to be in accordance with Ch 2, Sec 8, [1.2.5] and Ch 2, Sec 8, [1.2.6]
- 2.2.7** Clearance and creepage distances between non-insulated parts of high voltage slip rings are to be in accordance with Ch 2, Sec 13, [2.3].
- 2.2.8** Power slip rings are to be capable to withstand without damage the maximum prospective value of the short-circuit current which can occur at its terminals.
- 2.2.9** High voltage slip rings are to be able to withstand an internal short circuit arcing failure with the maximum duration and magnitude which can occur at this particular point of the installation, without harmful effect to operators. They are to be internal arc classified (IAC). Where they are accessible by authorized personnel only, Accessibility Type A is sufficient (IEC 62271-200 Annex AA 2.2). Installation and location of the slip rings is to correspond with its internal arc classification and classified sides.

**2.3 Testing**

**2.3.1 General**

All slip rings are to be type approved or case-by-case approved and surveyed by the Society during testing and, if appropriate, during manufacturing. Tested slip rings are to be individually certified by the Society.

Electric slip ring assemblies are to be subjected to the tests stated in Tab 1. Where the test procedure is not specified, the requirements of IEC 61439-1 and IEC 61439-2 or IEC 62271-200 apply.

Tests procedure is to be submitted to the Society for approval.

Type tests are to be carried out, unless the manufacturer can produce evidence based on previous experience indicating the satisfactory performance of such equipment.

**Table 1 : Tests to be carried out on electrical slip rings**

No	Tests	Type test (1)	Routine test (2)
1	Examination of the technical documentation, as appropriate, and visual inspection (3) including check of protection index, clearances and creepage distances	X	X
2	Mechanical tests	X	X
3	Electric contact resistance test	X	X
4	Insulation resistance measurement	X	X
5	Dielectric strength test	X	X
6	Signal attenuation (for fibre optic swivel)	X	X
7	Functional test of auxiliaries (e.g. sensors, data transfer)	X	X
8	Endurance test	X	–
9	Temperature rise test	X	–
10	Impulse voltage withstand test	X	–
11	Short-circuit withstand test	X	–
12	Verification degree of protection	X	–
13	Environmental tests	X	–
<p>(1) Type test on prototype slip ring or test on at least the first batch of slip rings</p> <p>(2) The certificates of slip rings routine tested are to contain the manufacturer’s serial number of the slip ring which has been type tested and the test result</p> <p>(3) A visual examination is to be made of the slip ring, as far as practicable, that it complies with technical documentation.</p>			

## **2.4 Description of tests**

### **2.4.1 Visual inspection**

An inspection and checks are carried out with a view to establish that the electrical slip ring assembly:

- complies with approved technical documentation
- maintains the prescribed degree of protection
- is constructed in accordance with the relevant constructional requirements, in particular as regards to creepage and clearance distances

### **2.4.2 Mechanical tests**

The electrical slip ring is to be subjected to the following mechanical tests:

- Free rotation test on the full 360° in both clockwise and counter-clockwise. No hard point is to be encountered.
- Free rotation test on the full 360° in clockwise and counter-clockwise to measure and record the breakout torque and the steady running torque.
- Free rotation test on the full 360° in clockwise and counter-clockwise when the slip ring is inclined at an angle of 22,5° (roll) to measure and record the breakout torque and the steady running torque.

Tests are to be carried out at the specified rotation speed and the measured values are not to exceed data given by Manufacturer.

### **2.4.3 Electric contact resistance test**

The electrical slip ring is to be subjected to a resistance test to measure and record the contact resistance across all paths on the full 360° in clockwise and counter-clockwise. Test is to be carried out at the specified rotation speed. The measured values are not to exceed the values given by the Manufacturer.

### **2.4.4 Insulation resistance measurement**

Immediately after the high voltage test, the insulation resistance between all current carrying parts and earth (and between each polarity and the other polarities) is to be measured using a direct current insulation tester. The minimum values of test voltages and corresponding insulation resistances are as given in Ch 2, Sec 4, Tab 2.

### **2.4.5 Dielectric strength test**

Low voltage slip ring assemblies are to be subjected to a high voltage test as given in Ch 2, Sec 8, [3.3].

High voltage slip ring assemblies are to be subjected to a high voltage test:

- between all live parts connected together and exposed conductive parts
- between each polarity and, all other polarities and exposed conductive parts connected together

The test voltage is to be applied for at least 1 minute and is to be as given in Ch 2, Sec 13, Tab 2.

### **2.4.6 Signal attenuation test (for fibre optic swivel)**

The fibre optic swivel is to be subjected to signal attenuation test to measure and record the signal attenuation across all paths on the full 360° in clockwise and counter-clockwise. Test is to be carried out at the specified rotation speed. The measured values are not to exceed the values given by the Manufacturer.

### **2.4.7 Endurance test**

An endurance test at a rotation speed of 1 rpm is to be carried out as follows:

- 100 rotations with 10% rated current (I<sub>n</sub>)
- 100 rotations with 90% rated current (I<sub>n</sub>)
- 1 rotation with 150% rated current (I<sub>n</sub>)
- 100 rotations without current.

After the test, the slip rings electric contact resistance measurement is to be repeated.

### **2.4.8 Temperature rise test**

A temperature rise test is to be carried out to measure the temperature rise of the active parts and the slip ring enclosure when all paths are loaded at their rated current and with normal cooling capability. Test may be performed in static condition. The measured values are not to exceed the values given by the Manufacturer.

### **2.4.9 Short-circuit withstand test**

A short-circuit withstand test is to be performed to demonstrate that active parts with their supports are mechanically dimensioned and fixed to withstand the stresses caused by sudden short-circuit current without damage. The test value is not to be lower than the maximum prospective value of the short-circuit current on the slip ring. A calculation note is admitted as alternative to the test.

### **2.4.10 Impulse voltage withstand test**

An impulse voltage withstand test in accordance with requirements of IEC 61439-1 or IEC 62271-200 is to be carried out in case the air clearance does not satisfy the requirements of [2.2.6] and [2.2.7].

#### **2.4.11 Verification of degree of protection**

The degree of protection is to be as specified in IEC 60529.

#### **2.4.12 Environmental tests**

To validate that the slip rings assemblies are designed and constructed to operate satisfactorily under the environmental conditions expected on board they are to be subjected to the following environmental tests. During testing the slip rings are to be in normal operating conditions. For large slip rings, a case-by-case evaluation based on calculations and/or documented measures is admitted as an alternative to the vibration test.

- a) Ambient temperature test in compliance with IEC 60068-2-2, at temperatures specified in Ch 2, Sec 2, [1.2.1]
- b) Humidity resistance test in compliance with IEC 60068-2-30 Test Db, at a relative humidity specified in Ch 2, Sec 2, [1.3.1]
- c) Inclination test at inclination angles specified in Ch 2, Sec 2, [1.6.1]
- d) Vibration test in compliance with IEC 60068-2-6 Test Fc, at vibration levels specified in Ch 2, Sec 2, [1.7.1].

### **3 Lighting fittings**

#### **3.1 Applicable requirements**

**3.1.1** Lighting fittings are to comply with IEC Publications 60598 and 60092-306.

Lighting fittings complying with other standards will be specially considered by the Society.

#### **3.2 Construction**

**3.2.1** The temperature of terminals for connection of supplying cables is not to exceed the maximum conductor temperature permitted for the cable (see Ch 2, Sec 3, [9.9]).

Where necessary, luminaires are to be fitted with terminal boxes which are thermally insulated from the light source.

**3.2.2** Wires used for internal connections are to be of a temperature class which corresponds to the maximum temperature within the luminaire.

**3.2.3** The temperature rise of parts of luminaires which are in contact with the support is not to exceed 50°C. The rise is not to exceed 40°C for parts in contact with flammable materials.

**3.2.4** The temperature rise of surface parts which can easily be touched in service is not to exceed 15°C.

**3.2.5** High-power lights with higher surface temperatures than those in [3.2.2] and [3.2.3] are to be adequately protected against accidental contact.

### **4 Accessories**

#### **4.1 Applicable requirements**

**4.1.1** Accessories are to be constructed in accordance with the relevant IEC Publications, and in particular with Publication 60092-306.

#### **4.2 Construction**

**4.2.1** Enclosures of accessories are to be of metal having characteristics suitable for the intended use on board, or of flame-retardant insulating material.

**4.2.2** Terminals are to be suitable for the connection of stranded conductors, except in the case of rigid conductors for mineral-insulated cables.

### **5 Plug-and-socket connections**

#### **5.1 Applicable requirements**

**5.1.1** Plug-and-socket connections are to comply with IEC Publication 60092-306 and with the following additional standards in relation to their use:

- in accommodation spaces, day rooms and service rooms (up to 16 A, 250 V a.c.): IEC Publication 60083 or 60320, as applicable
- for power circuits (up to 250 A, 690 V a.c.): IEC Publication 60309
- for electronic switchgear: IEC Publications, e.g. 60512 and 60603
- for refrigerated containers: ISO 1496-2.

## **6 Heating and cooking appliances**

### **6.1 Applicable requirements**

**6.1.1** Heating and cooking appliances are to comply with the relevant IEC Publications (e.g. those of series 60335), with particular attention to IEC 60092-307.

### **6.2 General**

**6.2.1** Heating elements are to be enclosed and protected with metal or refractory material.

**6.2.2** The terminals of the power supply cable are not to be subjected to a higher temperature than that permitted for the conductor of the connection cable.

**6.2.3** The temperature of parts which are to be handled in service (switch knobs, operating handles and the like) is not to exceed the following values:

- 55°C for metal parts
- 65°C for vitreous or moulded material.

### **6.3 Space heaters**

**6.3.1** The casing or enclosure of heaters is to be so designed that clothing or other flammable material cannot be placed on them.

**6.3.2** The temperature of the external surface of space heaters is not to exceed 60°C.

**6.3.3** Space heaters are to be provided with a temperature limiting device without automatic reconnection which automatically trips all poles or phases not connected to earth when the temperature exceeds the maximum permissible value.

### **6.4 Cooking appliances**

**6.4.1** Live parts of cooking appliances are to be protected such that any foods or liquids which boil over or spill do not cause short-circuits or loss of insulation.

### **6.5 Fuel oil and lube oil heaters**

**6.5.1** In continuous-flow fuel oil and lube oil heaters, the maximum temperature of the heating elements is to be below the boiling point of the oil.

**6.5.2** Each oil heater is to be provided with a thermostat maintaining the oil temperature at the correct level.

**6.5.3** In addition to the thermostat in [6.5.2], each oil heater is to be provided with a temperature limiting device without automatic reconnection, and with the sensing device installed as close as possible to the heating elements and permanently submerged in the liquid.

### **6.6 Water heaters**

**6.6.1** Water heaters are to be provided with a thermostat and safety temperature limiter.

# Section 11      Location

## 1 General

### 1.1 Location

**1.1.1** The degree of protection of the enclosures and the environmental categories of the equipment are to be appropriate to the spaces or areas in which they are located; see Ch 2, Sec 3, Tab 2, Ch 2, Sec 3, Tab 3 and Ch 2, Sec 2, [5.2.2].

### 1.2 Areas with a risk of explosion

**1.2.1** Except where the installation of equipment for explosive gas atmosphere is provided for by the Rules, electrical equipment is not to be installed where flammable gases or vapours are liable to accumulate; see Ch 2, Sec 3, [10].

## 2 Main electrical system

### 2.1 Location in relation to the emergency system

**2.1.1** The arrangement of the emergency electrical system is to be such that a fire or other casualty in spaces containing the emergency source of electrical power, associated converting equipment, if any, the emergency switchboard and the emergency lighting switchboard will not render inoperative the main electric lighting system and the other primary essential services.

### 2.2 Main switchboard

**2.2.1** *The main switchboard shall be so placed relative to one main generating station that, as far as is practicable, the integrity of the normal electrical supply may be affected only by a fire or other casualty in one space.*

**2.2.2** *An environmental enclosure for the main switchboard, such as may be provided by a machinery control room situated within the main boundaries of the space, is not to be considered as separating switchboards from generators.*

**2.2.3** The main generating station is to be situated within the machinery space, i.e. within the extreme main transverse watertight bulkheads.

**2.2.4** Any bulkhead between the extreme main transverse watertight bulkheads is not regarded as separating the equipment in the main generating station provided that there is access between the spaces.

**2.2.5** The main switchboard is to be located as close as practicable to the main generating station, within the same machinery space and the same vertical and horizontal A60 fire boundaries.

**2.2.6** Where essential services for steering and propulsion are supplied from section boards, these and any transformers, converters and similar appliances constituting an essential part of the electrical supply system are also to satisfy the above provisions.

**2.2.7** A non-required subdivision bulkhead, with sufficient access, located between the switchboard and generators, or between two or more generators, is not to be considered as separating the equipment.

## 3 Emergency electrical system

### 3.1 Spaces for the emergency source

**3.1.1** *The emergency source of electrical power, associated transforming equipment, if any, transitional source of emergency power, emergency switchboard and emergency lighting switchboard shall be located above the uppermost continuous deck and shall be readily accessible from the open deck.*

*They shall not be located forward of the collision bulkhead.*

**3.1.2** *The spaces containing the emergency source of electrical power, associated transforming equipment, if any, the transitional source of emergency electrical power and the emergency switchboard are not to be contiguous to the boundaries of machinery spaces of Category A or those spaces containing the main source of electrical power, associated transforming equipment, if any, and the main switchboard.*

Where this is not practicable, the contiguous boundaries are to be Class A60.

### **3.2 Location in relation to the main electrical system**

**3.2.1** *The location of the emergency source of electrical power, associated transforming equipment, if any, the transitional source of emergency power, the emergency switchboard and the emergency lighting switchboard in relation to the main source of electrical power, associated transforming equipment, if any, and the main switchboard shall be such as to ensure to the satisfaction of the Society that a fire or other casualty in the space containing the main source of electrical power, associated transforming equipment, if any, and the main switchboard or in any machinery space of Category A will not interfere with the supply, control and distribution of emergency electrical power.*

**3.2.2** The arrangement of the main electrical system is to be such that a fire or other casualty in spaces containing the main source of electrical power, associated converting equipment, if any, the main switchboard and the main lighting switchboard will not render inoperative the emergency electric lighting system and the other emergency services other than those located within the spaces where the fire or casualty has occurred.

### **3.3 Emergency switchboard**

**3.3.1** *The emergency switchboard shall be installed as near as is practicable to the emergency source of electrical power.*

**3.3.2** *Where the emergency source of electrical power is a generator, the emergency switchboard shall be located in the same space unless the operation of the emergency switchboard would thereby be impaired.*

### **3.4 Emergency battery**

**3.4.1** *No accumulator battery fitted in accordance with the provisions of Ch 2, Sec 3, [2.3] shall be installed in the same space as the emergency switchboard.*

**3.4.2** For ships not subject to Solas, accumulator batteries fitted in accordance with the provisions of Ch 2, Sec 3, [2.3] and connected to a charging device of power of 2 kW or less may be accepted in the same space as the emergency switchboard but outside the emergency switchboard to the satisfaction of the Society.

## **4 Distribution boards**

### **4.1 Distribution boards for cargo spaces and similar spaces**

**4.1.1** Distribution boards containing multipole switches for the control of power and lighting circuits in bunkers and cargo spaces are to be situated outside such spaces.

### **4.2 Distribution board for navigation lights**

**4.2.1** The distribution board for navigation lights is to be placed in an accessible position on the bridge.

## **5 Cable runs**

### **5.1 General**

**5.1.1** Cable runs are to be selected so as to be as far as practicable accessible, with the exception of single cables, situated behind walls or ceilings constructed of incombustible materials, supplying lighting fittings and socket-outlets in accommodation spaces, or cables enclosed in pipes or conduits for installation purposes.

**5.1.2** Cable runs are to be selected so as to avoid action from condensed moisture and from dripping of liquids.

**5.1.3** Connection and draw boxes are to be accessible.

**5.1.4** Cables are generally not to be installed across expansion joints.

Where this is unavoidable, however, a loop of cable of length proportional to the expansion of the joint is to be provided (see Ch 2, Sec 12, [7.2.2]).

### **5.2 Location of cables in relation to the risk of fire and overheating**

**5.2.1** Cables and wiring serving essential or emergency power, lighting, internal communications or signals are, so far as is practicable, to be routed clear of galleys, laundries, machinery spaces of Category A and their casings and other high fire risk areas, except for supplying equipment in those spaces.

**5.2.2** When it is essential that a circuit functions for some time during a fire and it is unavoidable to carry the cable for such a circuit through a high fire risk area (e.g. cables connecting fire pumps to the emergency switchboard), the cable is to be of a fire-resistant type or adequately protected against direct exposure to fire.

**5.2.3** The electrical cables to the emergency fire pump are not to pass through the machinery spaces containing the main fire pumps and their source(s) of power and prime mover(s).

They are to be of a fire resistant type, in accordance with Ch 2, Sec 9, [2.1.9], where they pass through other high fire risk areas.

**5.2.4** Main cable runs (see Note 1) and cables for the supply and control of essential services are, as far as is practicable, to be kept away from machinery parts having an increased fire risk (see Note 2) unless:

- the cables have to be connected to the subject equipment
- the cables are protected by a steel bulkhead or deck, or
- the cables in that area are of the fire-resisting type.

Note 1: Main cable runs are for example:

- cable runs from generators and propulsion motors to main and emergency switchboards
- cable runs directly above or below main and emergency switchboards, centralised motor starter panels, section boards and centralised control panels for propulsion and essential auxiliaries.

Note 2: Machinery, machinery parts or equipment handling combustibles are considered to present an increased fire risk.

**5.2.5** Cables and wiring serving essential or emergency power, lighting, internal communications or signals are to be arranged, as far as practicable, in such a manner as to preclude their being rendered unserviceable by heating of the bulkheads that may be caused by a fire in an adjacent space.

**5.2.6** Cables are to be arranged as remote as possible from sources of heat such as hot pipes, resistors, etc. Where installation of cables near heat sources cannot be avoided, and where there is consequently a risk of damage to the cables by heat, suitable shields are to be installed, or other precautions to avoid overheating are to be taken, for example use of ventilation, heat insulation materials or special heat-resisting cables.

### **5.3 Location of cables in relation to electromagnetic interference**

**5.3.1** For the installation of cables in the vicinity of radio equipment or of cables belonging to electronic control and monitoring systems, steps are to be taken in order to limit the effects of unwanted electromagnetic interference (see Ch 3, Sec 5).

### **5.4 Services with a duplicate feeder**

**5.4.1** In the case of essential services requiring a duplicate supply (e.g. steering gear circuits), the supply and associated control cables are to follow different routes which are to be as far apart as practicable, separated both vertically and horizontally.

### **5.5 Emergency circuits**

**5.5.1** Cables supplying emergency circuits are not to run through spaces containing the main source of electrical power, associated transforming equipment, if any, the main switchboard and the main lighting switchboard, except for cables supplying emergency equipment located within such spaces (see [3.2.2]).

### **5.6 Electrical distribution in passenger ships**

**5.6.1** For the electrical distribution in passenger ships, see Pt D, Ch 11, Sec 5, [1.2].

## **6 Storage batteries**

### **6.1 General**

**6.1.1** Batteries are to be located where they are not exposed to excessive heat, extreme cold, spray, steam or other conditions which would impair performance or accelerate deterioration. They are to be installed in such a way that no damage may be caused to surrounding appliances by the vapours generated.

**6.1.2** Storage batteries are to be suitably housed, and compartments (rooms, lockers or boxes) used primarily for their accommodation are to be properly constructed and efficiently ventilated so as to prevent accumulation of flammable gas.

**6.1.3** Starter batteries are to be located as close as practicable to the engine or engines served.

**6.1.4** *Accumulator batteries shall not be located in sleeping quarters except where hermetically sealed to the satisfaction of the Society.*

**6.1.5** Lead-acid batteries and alkaline batteries are not to be installed in the same compartment (room, locker, box), unless of valve-regulated sealed type.

## 6.2 Large vented batteries

**6.2.1** Batteries connected to a charging device of power exceeding 2 kW, calculated from the maximum obtainable charging current and the nominal voltage of the battery (hereafter referred to as "large batteries") are to be installed in a room assigned to batteries only.

Where this is not possible, they may be arranged in a suitable locker on deck.

**6.2.2** Rooms assigned to large batteries are to be provided with mechanical exhaust ventilation. Natural ventilation may be employed for boxes located on open deck.

**6.2.3** The provisions of [6.2.1] and [6.2.2] also apply to several batteries connected to charging devices of total power exceeding 2 kW calculated for each one as stated in [6.2.1].

## 6.3 Moderate vented batteries

**6.3.1** Batteries connected to a charging device of power between 0,2 kW and 2 kW calculated as stated in [6.2.1] (hereafter referred to as "moderate batteries") are to be arranged in the same manner as large batteries or placed in a box or locker in suitable locations such as machinery spaces, storerooms or similar spaces. In machinery spaces and similar well-ventilated compartments, these batteries may be installed without a box or locker provided they are protected from falling objects, dripping water and condensation where necessary.

**6.3.2** Rooms, lockers or boxes assigned to moderate batteries are to be provided with natural ventilation or mechanical exhaust ventilation, except for batteries installed without a box or locker (located open) in well-ventilated spaces.

**6.3.3** The provisions of [6.3.1] and [6.3.2] also apply to several batteries connected to charging devices of total power between 0,2 kW and 2 kW calculated for each one as stated in [6.2.1].

## 6.4 Small vented batteries

**6.4.1** Batteries connected to a charging device of power less than 0,2 kW calculated as stated in [6.2.1] (hereafter referred to as "small batteries") are to be arranged in the same manner as moderate or large batteries, or without a box or locker, provided they are protected from falling objects, or in a box in a ventilated area.

**6.4.2** Boxes for small batteries may be ventilated only by means of openings near the top to permit escape of gas.

## 6.5 Ventilation

**6.5.1** The ventilation of battery compartments is to be independent of ventilation systems for other spaces.

**6.5.2** The quantity of air expelled (by natural or forced ventilation) for compartments containing vented type batteries is to be at least equal to:

$$Q = 110 I n$$

where:

Q : Quantity of air expelled, in litres per hour

I : Maximum current delivered by the charging equipment during gas formation, but not less than one quarter of the maximum obtainable charging current in amperes

n : Number of cells in series.

For natural ventilation, the available inlet and outlet duct free cross-sectional area S, in mm<sup>2</sup> is deemed sufficient provided it complies with following criteria:

$$S \geq 2,8 Q$$

Otherwise, the dimensioning of the natural ventilation is to be considered on a case-by-case basis depending on the actual ducting arrangement. Detailed calculations may be required for this purpose.

**6.5.3** Fans starters cabinet is to be located outside of the energy electric storage system (ESS) room.

**6.5.4** Ventilation fans are not to produce a source of vapor ignition in either the ventilated space or the ventilation system associated with the space. A non-sparking exhaust fan is to be provided.

**6.5.5** The quantity of air expelled (by natural or forced ventilation) for compartments containing valve-regulated sealed batteries is to be at least 25% of that given in [6.5.2].

**6.5.6** Ducts are to be made of a corrosion-resisting material or their interior surfaces are to be painted with corrosion-resistant paint.

**6.5.7** The ventilation ducting system is to be gastight and able to withstand the off-gas temperature and over-pressure. The pipes to and from the battery room are to be made of steel.

**6.5.8** Adequate air inlets (whether connected to ducts or not) are to be provided near the floor of battery rooms or the bottom of lockers or boxes (except for that of small batteries).

Air inlet may be from the open air or, when in lockers and boxes, from another space.

Ventilation air inlets are to be taken from areas which, in the absence of the considered inlet, would be non-hazardous.

**6.5.9** The ventilation exhaust suction is to be located as close as practicable to the ceiling such that light gases are evacuated.

**6.5.10** Exhaust ducts of natural ventilation systems:

- a) are to be run directly from the top of the compartment to the open air above (they may terminate in the open or in well-ventilated spaces)
- b) are to terminate not less than 90 cm above the top of the battery compartment
- c) are to have no part more than 45° from the vertical
- d) are not to contain appliances (for example for barring flames) which may impede the free passage of air or gas mixtures.

Where natural ventilation is impracticable or insufficient, mechanical exhaust ventilation is to be provided.

**6.5.11** In mechanical exhaust ventilation systems:

- a) electric motors for ventilation fans are not to be located in ventilation ducts for hazardous spaces unless the motor is certified for the same hazard zone as the space served
- b) fans are to be so constructed and of a material such as to render sparking impossible in the event of the impeller touching the fan casing
- c) steel or aluminium impellers are not to be used
- d) the system is to be interlocked with the charging device so that the battery cannot be charged without ventilation (trickle charge may be maintained)
- e) a temperature sensor is to be located in the battery compartment to monitor the correct behaviour of the battery in cases where the battery element is sensitive to temperature.

**6.5.12** For natural ventilation systems for deck boxes:

- a) holes for air inlet are to be provided on at least two opposite sides of the box
- b) the exhaust duct is to be of ample dimensions
- c) the duct is to terminate at least 1,25 m above the box in a goose-neck or mushroom-head or the equivalent
- d) the degree of protection is to be in accordance with Ch 2, Sec 3, Tab 2.

## Section 12 Installation

### 1 General

#### 1.1 Protection against injury or damage caused by electrical equipment

1.1.1 All electrical equipment is to be so installed as not to cause injury when handled or touched in the normal manner.

1.1.2 All electrical equipment is to be installed in such a way that live parts cannot be inadvertently touched, unless supplied at a safety voltage.

1.1.3 For protective earthing as a precaution against indirect contact, see Article [2].

1.1.4 Equipment is to be installed so as not to cause, or at least so as to reduce to a minimum, electromagnetic interference.

#### 1.2 Protection against damage to electrical equipment

1.2.1 Electrical equipment is to be so placed that as far as practicable it is not exposed to risk of damage from water, steam, oil or oil vapours.

1.2.2 The air supply for internal ventilation of electrical equipment is to be as clean and dry as practicable; cooling air for internal ventilation is not to be drawn from below the floor plates in engine and/or boiler rooms.

1.2.3 Equipment is to be so mounted that its enclosing arrangements and the functioning of the built-in equipment will not be affected by distortions, vibrations and movements of the ship's structure or by other damage liable to occur.

1.2.4 If electrical fittings, not of aluminium, are attached to aluminium, suitable provision is to be made to prevent galvanic corrosion.

#### 1.3 Accessibility

1.3.1 Equipment is to be so installed that sufficient space is available for inspection and maintenance as required for all its parts (see [6.1.3]).

#### 1.4 Electrical equipment in environmentally controlled spaces

1.4.1 Where electrical equipment is installed within environmentally controlled space the ambient temperature for which the equipment is to be suitable may be reduced from 45°C and maintained at a value not less than 35°C provided:

- a) the equipment is not for use for emergency services
- b) temperature control is achieved by at least two cooling units so arranged that in the event of loss of one cooling unit, for any reason, the remaining unit(s) is capable of satisfactorily maintaining the design temperature
- c) the equipment is able to be initially set to work safely within a 45°C ambient temperature until such a time that the lesser ambient temperature may be achieved; the cooling equipment is to be rated for a 45°C ambient temperature
- d) audible and visual alarms are provided, at a continually manned control station, to indicate any malfunction of the cooling units.

1.4.2 In accepting a lesser ambient temperature than 45°C, it is to be ensured that electrical cables for their entire length are adequately rated for the maximum ambient temperature to which they are exposed along their length.

### 2 Earthing of non-current carrying parts

#### 2.1 Parts which are to be earthed

2.1.1 Exposed metal parts of both fixed and portable electrical machines or equipment which are not intended to be live but which are liable under fault conditions to become live and similar metal parts inside non-metallic enclosures are to be earthed unless the machines or equipment are:

- a) supplied at a voltage not exceeding 50 V direct current or 50 V, root mean square between conductors, achieved without the use of auto-transformers (safety voltage); or
- b) supplied at a voltage not exceeding 250 V by safety isolating transformers supplying one consuming device only; or
- c) constructed in accordance with the principle of double insulation.

**2.1.2** To minimise shock from high frequency voltage induced by the radio transmitter, handles, handrails and other metal elements on the bridge or upper decks are to be in electrical connection with the hull or superstructures.

**2.2 Methods of earthing**

**2.2.1** Metal frames or enclosures of apparatus and electrical machinery may be fixed to, and in metallic contact with, the ship's structure, provided that the surfaces in contact are clean and free from rust, scale or paint when installed and are firmly bolted together.

**2.2.2** For metal frames or enclosures which are not earthed as specified in [2.2.1], earthing connections complying with [2.3] and [2.4] are to be used.

**2.2.3** For requirements regarding the earthing of coverings of cables and the mechanical protection of cables, see [7.11] and [7.12].

**2.3 Earthing connections**

**2.3.1** Every earthing connection is to be of copper or other corrosion-resistant material and is to be securely installed and protected, where necessary, against damage and electrolytic corrosion.

**2.3.2** The nominal cross-sectional area of each copper earthing connection is to be not less than that required in Tab 1. Earthing connections of other metals are to have conductance at least equal to that specified for a copper earthing connection.

**2.3.3** Metal parts of portable appliances are to be earthed, where required (see [2.1.1]), by means of an earth-continuity conductor in the flexible supply cable or cord, which has the cross-sectional area specified in Tab 1 and which is earthed, for example, through the associated plug and socket.

**2.3.4** In no circumstances is the lead sheathing or armour of cables to be relied upon as the sole means of earthing.

**Table 1 : Cross-sectional area of earth-continuity conductors and earthing connections**

Type of earthing connection		Cross-sectional area of associated current carrying conductor	Minimum cross-sectional area of copper earthing connection	
1	Earth-continuity conductor in flexible cable or flexible cord	any	Same as current carrying conductor up to and including 16 mm <sup>2</sup> and one half above 16 mm <sup>2</sup> but at least 16 mm <sup>2</sup>	
2	Earth-continuity conductor incorporated in fixed cable	any	a) for cables having an insulated earth-continuity conductor	
			<ul style="list-style-type: none"> <li>• a cross-section equal to the main conductors up to and including 16 mm<sup>2</sup>, but minimum 1,5 mm<sup>2</sup></li> <li>• a cross-section not less than 50% of the cross-section of the main conductor when the latter is more than 16 mm<sup>2</sup>, but at least 16 mm<sup>2</sup></li> </ul>	
			b) for cables with a bare earth wire in direct contact with the lead sheath	
			Cross-section of main conductor, in mm <sup>2</sup>	Earthing connection, in mm <sup>2</sup>
			1 ÷ 2,5 4 ÷ 6	1 1,5
3	Separate fixed earthing conductor	≤ 2,5 mm <sup>2</sup>	Same as current carrying conductor subject to minimum of 1,5 mm <sup>2</sup> for stranded earthing connection or 2,5 mm <sup>2</sup> for unstranded earthing connection	
		> 2,5 mm <sup>2</sup> but ≤ 120 mm <sup>2</sup>	One half the cross-sectional area of the current carrying conductor, subjected to a minimum of 4 mm <sup>2</sup>	
		> 120 mm <sup>2</sup>	70 mm <sup>2</sup>	

**2.4 Connection to the ship's structure**

**2.4.1** Every connection of an earth-continuity conductor or earthing lead to the ship's structure is to be secured by means of a screw of brass or other corrosion-resistant material of diameter not less than 6 mm.

**2.4.2** Such earthing connection is not to be used for other purposes.

**2.4.3** The connection described in [2.4.1] is to be located in an accessible position where it may readily be checked.

## **2.5 Earthed distribution systems**

**2.5.1** The system earthing of earthed distribution systems is to be effected by means independent of any earthing arrangements of non-current carrying parts and is to be connected to the hull at one point only.

**2.5.2** In an earthed distribution system in which the earthing connection does not normally carry current, this connection is to conform with the requirements of [2.3], except that the lower limit of 70 mm<sup>2</sup> does not apply (see Tab 1).

**2.5.3** In a distribution system with hull return, the system earthing connection is to have at least the same cross-sectional area as the feeder lines.

**2.5.4** The earthing connection is to be in an accessible position where it may readily be inspected and disconnected for insulation testing.

## **2.6 Aluminium superstructures**

**2.6.1** When aluminium superstructures are insulated from the steel hull to prevent electrolytic corrosion, they are to be secured to the hull by means of a separate bonding connection.

**2.6.2** The connections are to be adequately close together and are to have a resistance less than 0,1 Ω.

**2.6.3** The connections are to be located where they may readily be inspected.

## **3 Rotating machines**

### **3.1**

**3.1.1** Every rotating machine is preferably to be installed with the shaft in the fore-and-aft direction. Where a rotating machine of 100 kW (kVA) and over is installed athwartship, or vertically, it is to be ensured that the design of the bearings and the arrangements for lubrication are satisfactory to withstand the rolling specified in Ch 2, Sec 2, Tab 4.

## **4 Semiconductor converters**

### **4.1 Semiconductor power converters**

**4.1.1** Naturally air-cooled semiconductor converters are to be installed such that the circulation of air to and from the stacks or enclosures is not impeded and that the temperature of the cooling inlet air to converter stacks does not exceed the ambient temperature for which the stacks are specified.

## **5 Vented batteries**

### **5.1 General**

**5.1.1** Batteries are to be arranged so that each cell or crate of cells is accessible from the top and at least one side to permit replacement and periodical maintenance.

**5.1.2** Cells or crates are to be carried on insulating supports of material non-absorbent to the electrolyte (e.g. treated wood).

**5.1.3** Cells are to be securely chocked by means of insulating material non-absorbent to the electrolyte, e.g. strips of treated wood. Special mechanical precautions are to be taken to prevent the emergency battery from being damaged by the shock due to a collision.

**5.1.4** Provision is to be made for the free circulation of air.

### **5.2 Protection against corrosion**

**5.2.1** The interior of battery compartments (rooms, lockers, boxes) including all metal parts subject to the electrolyte is to be protected against the deteriorating effect of the latter by electrolyte-resistant coating or other equivalent means, unless corrosion-resistant materials are used.

**5.2.2** Interior surfaces of metal shelves for battery cells, whether or not grouped in crates or trays, are to be protected by a lining of electrolyte-resistant material, watertight and carried up to at least 75 mm on all sides. In particular, linings are to have a minimum thickness of 1,5 mm, if of lead sheet for lead-acid batteries, and of 0,8 mm, if of steel for alkaline batteries. Alternatively, the floor of the room or locker is to be lined as specified above to a height of at least 150 mm.

**5.2.3** Battery boxes are to be lined in accordance with [5.2.2] to a height of at least 75 mm.

## 6 Switchgear and controlgear assemblies

### 6.1 Main switchboard

**6.1.1** The main switchboard is to be so arranged as to give easy access as may be needed to apparatus and equipment, without danger to personnel.

**6.1.2** An unobstructed space is to be left in front of the switchboard wide enough to allow access for operation; such width is generally about 1 metre.

When withdrawable equipment is contained in the switchboard, the width of the space is to be not less than 0,5 m when the equipment is fully withdrawn.

Reduced widths may be considered for small ships.

**6.1.3** Where necessary, an unobstructed space is to be provided at the rear of the switchboard ample to permit maintenance; in general, the width of this passage is to be not less than 0,6 m, except that this may be reduced to 0,5 m in way of stiffeners and frames, and the height sufficient for the operation foreseen.

**6.1.4** Where the switchboard is open at the rear, the rear space in [6.1.3] is to form a locked space provided at each end with an access door. The required IP protection for the corresponding location is to be fulfilled.

**6.1.5** If necessary, the clear height above the switchboard specified by the manufacturer is to be maintained for pressure relief in the event of a short-circuit.

**6.1.6** When the voltage exceeds the safety voltage, non-conducting mats or gratings are to be provided at the front and rear of the switchboard as necessary.

**6.1.7** Piping and conduits are not to be installed directly above or in the vicinity of switchboards.

Where this is unavoidable, pipes and conduits are to have welded joints only or to be provided with protection against spray from steam or pressurised liquids or dripping.

### 6.2 Emergency switchboard

**6.2.1** For the installation of the emergency switchboard, the same requirements apply as given in [6.1] for the installation of the main switchboard.

### 6.3 Section boards and distribution boards

**6.3.1** For the installation of section and distribution boards, the same requirements apply, as far as applicable, as given in [6.1] for the installation of the main switchboard.

## 7 Cables

### 7.1 General

**7.1.1** Cables having insulating materials with different maximum permissible conductor temperatures are not to be bunched together.

Where this is not practicable, the cables are to be so installed that no cable reaches a temperature higher than its rating.

**7.1.2** Cables having a protective covering which may damage the covering of more vulnerable cables are not to be bunched with the latter.

**7.1.3** Cables having a bare metallic sheath (e.g. of copper) or braid or armour are to be installed in such a way that galvanic corrosion by contact with other metals is prevented.

**7.1.4** All cables and wiring external to equipment are to be so installed as not to impair their original flame-retarding properties. To this end, the following methods may be used:

- a) the use of cables in accordance with Ch 2, Sec 9, [2.1.7] or an equivalent standard for cables installed in bunches, or
- b) the use of fire stops having at least B0 penetrations fitted as follows (see Fig 1, Fig 2, Fig 3 and Fig 4):
  - cable entries at the main and emergency switchboard
  - where cables enter engine control rooms
  - cable entries at centralised control panels for propulsion machinery and essential auxiliaries
  - at each end of totally enclosed cable trunks
  - at every second deck or approximately 6 metres for vertical runs and every 14 metres for horizontal runs in enclosed and semi-enclosed spaces
  - at the boundaries of the spaces in cargo areas.

c) the use of fire protection coating applied to at least 1 metre in every 14 metres on horizontal cable runs and over the entire length of vertical cable runs for cables installed in enclosed and semi-enclosed spaces.

The cable penetrations are to be installed in steel plates of at least 3 mm thickness extending all around to twice the largest dimension of the cable run for vertical runs and once for horizontal runs, but need not extend through ceilings, decks, bulkheads or solid sides of trunks. These precautions apply in particular to bunches of 5 or more cables in areas with a high fire risk (such as Category A machinery spaces, galleys etc.) and to bunches of more than 10 cables in other areas.

**Figure 1 : Totally enclosed trunks**

**Figure 2 : Non-totally enclosed trunks, vertical**

Figure 3 : Non-totally enclosed trunks, horizontal

Figure 4 : Open cables runs

**7.2 Radius of bend**

**7.2.1** The internal radius of bend for the installation of cables is to be chosen according to the type of cable as recommended by the manufacturer.

Its value is generally to be not less than the figure given in Tab 2.

**7.2.2** Where the installation of cables across expansion joints is unavoidable, the minimum internal radius of the loop at the end of the travel of the expansion joint is to be not less than 12 times the external diameter of the cable.

**Table 2 : Bending radii**

Cable construction		Overall diameter of cable (D)	Minimum internal radius of bend
Insulation	Outer covering		
Thermoplastic or thermosetting with circular copper conductors	Unarmoured or unbraided	≤ 25 mm	4 D
		> 25 mm	6 D
	Metal braid screened or armoured	Any	6 D
	Metal wire armoured Metal tape armoured or metal-sheathed	Any	6 D
	Composite polyester/metal laminate tape screened units or collective tape screening	Any	8 D
Thermoplastic or thermosetting with shaped copper conductors	Any	Any	8 D

**7.3 Fixing of cables**

**7.3.1** Cables shall be installed and supported in such a manner as to avoid chafing or other damage.

**7.3.2** The supports (tray plates, separate support brackets or hanger ladders) and the corresponding accessories are to be of robust construction and of corrosion-resistant material or suitably treated before erection to resist corrosion.

When cables are installed directly on aluminium structures, fixing devices of aluminium or suitably treated steel are to be used.

For mineral-insulated cables with copper sheath, fixing devices in contact with the sheath are to be of copper alloy.

**7.3.3** With the exception of cables installed in pipes, conduits, trunkings or special casings, cables are to be fixed by means of clips, saddles or straps of suitable material, in order to tighten the cables without their coverings being damaged.

**7.3.4** Cable clips or straps made from a material other than metal are to be manufactured of a flame-retardant material.

**7.3.5** The distances between fastenings and between supports are to be suitably chosen according to the type and number of cables and the probability of vibration.

**7.3.6** When cables are fixed by means of clips or straps made from a material other than metal and these cables are not laid on top of horizontal cable supports (e.g. in the case of vertical installation or suspended cables), suitable metal clips or saddles spaced not more than 1 metre apart are to be used in addition in order to prevent the release of cables during a fire.

**7.4 Mechanical protection**

**7.4.1** Cables exposed to risk of mechanical damage are to be protected by metal casing, profiles or grids or enclosed in metal pipes or conduits, unless the cable covering (e.g. armour or sheath) provides adequate mechanical protection.

**7.4.2** In situations where there would be an exceptional risk of mechanical damage, e.g. in holds, storage spaces, cargo spaces, etc., cables are to be protected by metal casing, trunkings or conduits, even when armoured, if the ship's structure or attached parts do not afford sufficient protection for the cables.

**7.4.3** For the protection of cables passing through decks, see [7.5.3].

**7.4.4** Metal casing used for mechanical protection of cables is to be effectively protected against corrosion.

**7.5 Penetrations of bulkheads and decks**

**7.5.1** If cables have to pass without adequate support through non-watertight bulkheads and generally through holes drilled in sheets of structural steel, these holes are to be fitted with glands or bushings of suitable material.

**7.5.2** If cables have to pass through a watertight bulkhead or deck, the penetration is to be effected in a watertight manner. Either suitable individual watertight glands for single cables or boxes containing several cables and filled with a flame-retardant packing may be used for this purpose.

Whichever type of penetration is used, the watertight integrity of the bulkheads or deck is to be maintained.

**7.5.3** Cables passing through decks and continuing vertically are to be protected against mechanical damage to a suitable height above the deck, considering a minimum height of 100 mm.

**7.5.4** Where cables pass through bulkheads or decks separating areas with a risk of explosion, arrangements are to be such that hazardous gas or dust cannot penetrate through openings for the passage of cables into other areas.

**7.5.5** Where cables pass through a bulkhead or deck which is required to have some degree of fire integrity, penetration is to be so effected as to ensure that the required degree of fire integrity is not impaired.

## **7.6 Expansion joints**

**7.6.1** If there is reason to fear that a tray plate, pipe or conduit may break because of the motion of the ship, different load conditions and temperature variations, appropriate expansion joints are to be provided.

This may apply in particular in the case of cable runs on the weather deck.

## **7.7 Cables in closed pipes or conduits**

**7.7.1** Closed pipes or conduits are to have such internal dimensions and radius of bend as will permit the easy drawing in and out of the cables which they are to contain; the internal radius of bend is to be not less than that permitted for cables and, for pipes exceeding 63 mm external diameter, not less than twice the external diameter of the pipe where this value is greater.

**7.7.2** Closed pipes and conduits are to be suitably smooth on the interior and are to have their ends shaped or bushed in such a way as not to damage the cable covering.

**7.7.3** The space factor (ratio of the sum of the cross-sectional areas corresponding to the external diameters of the cables to the internal cross-sectional areas of the pipe or conduit) is to be not greater than 0,4.

**7.7.4** If necessary, openings are to be provided at the highest and lowest points so as to permit air circulation and ensure that the heat from the cables can be dissipated, and to obviate the possibility of water accumulating at any part of the pipe or conduit.

**7.7.5** Vertical trunking for electrical cables is to be so constructed as not to jeopardise the required passive fire protection between the spaces.

**7.7.6** Metal pipes or conduits are to be protected against corrosion.

**7.7.7** Non-metallic pipes or conduits are to be flame-retardant.

## **7.8 Cables in casings or trunking and conduits with removable covers**

**7.8.1** Covers are to be removable and when they are open, cables are to be accessible.

**7.8.2** Materials used are to comply with [7.7.6] and [7.7.7].

**7.8.3** If the fixing of covers is by means of screws, the latter are to be of non-rusting material and arranged so as not to damage the cables.

**7.8.4** Means are to be provided to ensure that the heat from the cables can be dissipated and water accumulation is avoided (see [7.7.4]).

## **7.9 Cable ends**

**7.9.1** Terminations in all conductors are to be so made as to retain the original electrical, mechanical, flame-retarding properties of the cable.

**7.9.2** Where mechanical clamps are not used, the ends of all conductors having a cross-sectional area greater than 4 mm<sup>2</sup> are to be fitted with soldering sockets or compression-type sockets of sufficient size to contain all the strands of the conductor.

**7.9.3** Cables not having a moisture-resistant insulation (e.g. mineral-insulated) are to have their ends effectively sealed against ingress of moisture.

## **7.10 Joints and tappings (branch circuit)**

**7.10.1** Cable runs are normally not to include joints. Where absolutely necessary, cable joints are to be carried out by a junction method with rebuilding of the insulation and protective coverings.

**7.10.2** Joints in all conductors are to be so made as to retain the original electrical (continuity and isolation), mechanical (strength and protection), flame-retarding and, where necessary, fire-resisting properties of the cable.

**7.10.3** Tappings (branch circuits) are to be made via suitable connections or in suitable boxes of such design that the conductors remain adequately insulated and protected from atmospheric action and are fitted with terminals or busbars of dimensions appropriate to the current rating.

**7.10.4** Cables for safety voltages are not to terminate in the same connection boxes as cable for higher voltages unless separated by suitable means.

### **7.11 Earthing and continuity of metal coverings of cables**

**7.11.1** All metal coverings of cables are to be electrically connected to the metal hull of the ship.

**7.11.2** Metal coverings are generally to be earthed at both ends of the cable, except for [7.11.3] and [7.11.4].

**7.11.3** Single-point earthing is admitted for final sub-circuits (at the supply end), except for those circuits located in areas with a risk of explosion.

**7.11.4** Earthing is to be at one end only in those installations (mineral-insulated cables, intrinsically safe circuits, control circuits (see Ch 3, Sec 5), etc.) where it is required for technical or safety reasons.

**7.11.5** Metal coverings of single-core a.c. cables and special d.c. cables with high "ripple" content (e.g. for thyristor equipment) are to be earthed at one point only (e.g. at the mid-point).

**7.11.6** The electrical continuity of all metal coverings of cables throughout the length of the latter, particularly at joints and tappings, is to be ensured.

**7.11.7** The metal covering of cables may be earthed by means of glands intended for the purpose and so designed as to ensure an effective earth connection.

The glands are to be firmly attached to, and in effective electrical contact with, a metal structure earthed in accordance with these requirements.

**7.11.8** The metal covering of cables may also be earthed by means of clamps or clips of corrosion-resistant material making effective contact with the covering and earthed metal.

### **7.12 Earthing and continuity of metal pipes, conduits and trunking or casings**

**7.12.1** Metal casings, pipes, conduits and trunking are to be effectively earthed.

**7.12.2** Pipes or conduits may be earthed by being screwed into a metal enclosure, or by nuts on both sides of the wall of a metallic enclosure, provided the surfaces in contact are clean and free from rust, scale or paint and that the enclosure is in accordance with these requirements on earthing.

The connection is to be painted immediately after assembly in order to inhibit corrosion.

**7.12.3** Pipes and conduits may be earthed by means of clamps or clips of corrosion-resistant metal making effective contact with the earthed metal.

**7.12.4** Pipes, conduits or trunking together with connection boxes of metallic material are to be electrically continuous.

**7.12.5** All joints in metal pipes and conduits used for earth continuity are to be soundly made and protected, where necessary, against corrosion.

**7.12.6** Individual short lengths of pipes or conduits need not be earthed.

**7.12.7** The connections to earth are to have a resistance less than 0,1  $\Omega$ .

### **7.13 Precautions for single-core cables for a.c.**

**7.13.1** For the earthing of metal coverings see [7.11.5].

**7.13.2** Where it is necessary to use single-core cables for alternating current circuits rated in excess of 20 A, the requirements of [7.13.3] to [7.13.7] are to be complied with.

**7.13.3** Conductors belonging to the same circuit are to be contained within the same pipe, conduit or trunking, unless this is of non-magnetic material.

**7.13.4** Cable clips are to include cables of all phases of a circuit unless the clips are of non-magnetic material.

**7.13.5** In the installation of two, three or four single-core cables forming respectively single-phase circuits, three-phase circuits, or three-phase and neutral circuits, the cables are to be in contact with one another, as far as possible. In any event, the distance between the external covering of two adjacent cables is to be not greater than one diameter.

**7.13.6** When single-core cables having a current rating greater than 250 A are installed near a steel bulkhead, the clearance between the cables and the bulkhead is to be at least 50 mm, unless the cables belonging to the same circuit are installed in trefoil twisted formation.

**7.13.7** Magnetic material is not to be used between single-core cables of a group. Where cables pass through steel plates, all the conductors of the same circuit are to pass through a plate or gland, so made that there is no magnetic material between the cables, and the clearance between the cables and the magnetic material is to be no less than 75 mm, unless the cables belonging to the same circuit are installed in trefoil twisted formation.

## **7.14 Cables in refrigerated spaces**

**7.14.1** For the types of cables permitted in refrigerated spaces, see Ch 2, Sec 3, [9.4].

**7.14.2** Power cables installed in refrigerated spaces are not to be covered by thermal insulation. Moreover, such cables are not to be placed directly on the face of the refrigerated space unless they have a thermoplastic or elastomeric extruded sheath.

**7.14.3** Power cables entering a refrigerated space are to pass through the walls and thermal insulation at right angles, in tubes sealed at each end and protected against oxidation.

## **7.15 Cables in areas with a risk of explosion**

**7.15.1** For the types of cables permitted in areas with a risk of explosion, see Ch 2, Sec 3, [10.3].

**7.15.2** For penetration of bulkheads or decks separating areas with a risk of explosion, see [7.5.4].

**7.15.3** Terminals of intrinsically safe circuits are to be separated from terminals of non-intrinsically safe circuits by a physical distance of at least 50 mm, or by an earthed metallic partition.

**7.15.4** In enclosures, unscreened wirings of intrinsically safe circuits are to be separated from non-intrinsically safe circuits by a physical distance of at least 50mm, or by an earthed metallic partition.

## **7.16 Cables and apparatus for services required to be operable under fire conditions**

**7.16.1** Cables and apparatus for services required to be operable under fire conditions including their power supplies are to be so arranged that the loss of these services is minimized due to a localized fire at any one area or zone listed in Ch 2, Sec 1, [3.26].

## **7.17 Cables in the vicinity of radio equipment**

**7.17.1** All cables between antennas and transmitters are to be routed separately of any other cable.

**7.17.2** Where it is necessary to use single-core cables, the arrangement of conductors is to be such as to avoid complete or partial loops.

## **7.18 Cables for submerged bilge pumps**

**7.18.1** See Ch 2, Sec 3, [9.7].

## **7.19 Cable trays/protective casings made of plastics materials**

**7.19.1** Cable trays or protective casings made of plastics materials (thermoplastic or thermosetting plastic materials) are to be case-by-case approved or type-approved in accordance with IACS recommendation No. 73.

**7.19.2** Cable trays/protective casings are to be supplemented by metallic fixing and straps such that in the event of a fire they, and the cables affixed, are prevented from falling and causing injury to personnel and/or an obstruction to any escape route.

When used on open deck, they are to be protected against U.V. light.

**7.19.3** The load on the cable trays/ protective casings is to be within the Safe Working Load (SWL). The support spacing is not to be greater than the manufacturer recommendations nor in excess of spacing at SWL test. In general, the spacing is not to exceed 2 meters.

**7.19.4** The selection and spacing of cable tray/protective casing supports are to take into account:

- cable trays/protective casings' dimensions
- mechanical and physical properties of their material
- mass of cable trays/protective casings
- loads due weight of cables, external forces, thrust forces and vibrations
- maximum accelerations to which the system may be subjected
- combination of loads.

**7.19.5** The sum of the cables total cross-sectional area, based on the cables external diameter is not to exceed 40% of the protective casing internal cross-sectional area. This does not apply to a single cable in a protective casing.

## **8 Various appliances**

### **8.1 Lighting fittings**

**8.1.1** Lighting fittings are to be so arranged as to prevent temperature rises which could damage the cables and wiring.

Note 1: Where the temperature of terminals of lighting fittings exceeds the maximum conductor temperature permitted for the supplied cable (see Ch 2, Sec 3, [9.9]), special installation arrangements, such as terminal boxes thermally insulated from the light source, are to be provided.

**8.1.2** Lighting fittings are to be so arranged as to prevent surrounding material from becoming excessively hot.

**8.1.3** Lighting fittings are to be secured in place such that they cannot be displaced by the motion of the vessel.

**8.1.4** Emergency lights are to be marked for easy identification.

### **8.2 Heating appliances**

**8.2.1** Space heaters are to be so installed that clothing, bedding and other flammable material cannot come in contact with them in such a manner as to cause risk of fire.

Note 1: To this end, for example, hooks or other devices for hanging garments are not to be fitted above space heaters or, where appropriate, a perforated plate of incombustible material is to be mounted above each heater, slanted to prevent hanging anything on the heater itself.

**8.2.2** Space heaters are to be so installed that there is no risk of excessive heating of the bulkheads or decks on which or next to which they are mounted.

**8.2.3** Combustible materials in the vicinity of space heaters are to be protected by suitable incombustible and thermal-insulating materials.

### **8.3 Heating cables and tapes or other heating elements**

**8.3.1** Heating cables and tapes or other heating elements are not to be installed in contact with combustible materials.

Where they are installed close to such materials, they are to be separated by means of a non-flammable material.

# Section 13 High Voltage Installations

## 1 General

### 1.1 Field of application

**1.1.1** The following requirements apply to a.c. three-phase systems with nominal voltage exceeding 1kV, the nominal voltage being the voltage between phases.

If not otherwise stated herein, construction and installation applicable to low voltage equipment stated in Part C, Chapter 2 generally apply to high voltage equipment.

### 1.2 Nominal system voltage

**1.2.1** The nominal system voltage is not to exceed 15 kV.

Note 1: Where necessary for special application, higher voltages may be accepted by the Society.

### 1.3 High-voltage, low-voltage segregation

**1.3.1** Equipment with voltage above about 1 kV is not to be installed in the same enclosure as low voltage equipment, unless segregation or other suitable measures are taken to ensure that access to low voltage equipment is obtained without danger.

## 2 System design

### 2.1 Distribution

**2.1.1** It is to be possible to split the main switchboard into at least two independent sections, by means of at least one circuit breaker or other suitable disconnecting devices, each supplied by at least one generator. If two separate switchboards are provided and interconnected with cables, a circuit breaker is to be provided at each end of the cable.

Services which are duplicated are to be divided between the sections.

**2.1.2** In the event of an earth fault, the current is not to be greater than full load current of the largest generator on the switchboard or relevant switchboard section and not less than three times the minimum current required to operate any device against earth fault.

It is to be assured that at least one source neutral to ground connection is available whenever the system is in the energised mode. Electrical equipment in directly earthed neutral or other neutral earthed systems is to withstand the current due to a single phase fault against earth for the time necessary to trip the protection device.

**2.1.3** Means of disconnection are to be fitted in the neutral earthing connection of each generator so that the generator may be disconnected for maintenance and for insulation resistance measurement.

**2.1.4** All earthing impedances are to be connected to the hull. The connection to the hull is to be so arranged that any circulating currents in the earth connections do not interfere with radio, radar, communication and control equipment circuits.

**2.1.5** In systems with neutral earthed, connection of the neutral to the hull is to be provided for each section.

**2.1.6** Alternators running in parallel may have a common neutral connection to earth provided they are suitably designed to avoid excessive circulating currents.

This is particularly important if the alternators are of different size and make. Alternators in which the third harmonic content does not exceed 5% may be considered adequate.

Note 1: This would mostly occur with a neutral bus with a single grounding resistor with the associated neutral switching. Where individual resistors are used, circulation of the third harmonic currents between paralleled alternators is minimised.

**2.1.7** In systems with earthed neutral, resistors or other current-limiting devices for the connection of the neutrals to the hull are to be provided for each section in which the systems are split [2.1.2].

### 2.2 Degrees of protection

**2.2.1** Each part of the electrical installation is to be provided with a degree of protection appropriate to the location, as a minimum the requirements of IEC 60092-201.

**2.2.2** The degree of protection of enclosures of rotating electrical machines is to be at least IP 23.

The degree of protection of terminals is to be at least IP 44.

For motors installed in spaces accessible to unqualified personnel, a degree of protection against approaching or contact with live or moving parts of at least IP 4X is required.

**2.2.3** The degree of protection of enclosures of transformers is to be at least IP 23.

For transformers installed in spaces accessible to unqualified personnel, a degree of protection of at least IP 4X is required.

For transformers not contained in enclosures, see [7.1].

**2.2.4** The degree of protection of metal enclosed switchgear, controlgear assemblies and static converters is to be at least IP 32.

For switchgear, control gear assemblies and static converters installed in spaces accessible to unqualified personnel, a degree of protection of at least IP 4X is required.

## 2.3 Insulation

**2.3.1** In general, for non type tested equipment phase-to-phase air clearances and phase-to-earth air clearances between non-insulated parts are to be not less than those specified in Tab 1.

Intermediate values may be accepted for nominal voltages, provided that the next higher air clearance is observed.

In the case of smaller distances, an appropriate voltage impulse test is to be applied.

**Table 1 : Minimum clearances**

Nominal voltage (kV)	Highest voltage for equipment (kV)	Minimum air clearance (mm)
3 - 3,3	3.6	55
6 - 6,6	7.2	90
10 - 11	12	120
15	17.5	160

**2.3.2** Creepage distances between live parts and between live parts and earthed metal parts are to be in accordance with IEC 60092-503 for the nominal voltage of the system, the nature of the insulation material and the transient overvoltage developed by switch and fault conditions.

## 2.4 Protection

**2.4.1** Protective devices are to be provided against phase-to-phase faults in the cables connecting the generators to the main switchboard and against interwinding faults within the generators. The protective devices are to trip the generator circuit breaker and to automatically de-excite the generator.

In distribution systems with a neutral earthed, phase-to-earth faults are also to be treated as above.

**2.4.2** Any earth fault in the system is to be indicated by means of a visual and audible alarm.

In low impedance or direct earthed systems provision is to be made to automatically disconnect the faulty circuits. In high impedance earthed systems, where outgoing feeders will not be isolated in case of an earth fault, the insulation of the equipment is to be designed for the phase-to-phase voltage.

A system is defined effectively earthed (low impedance) when this factor is lower than 0,8. A system is defined non-effectively earthed (high impedance) when this factor is higher than 0,8.

Note 1: Earthing factor is defined as the ratio between the phase-to-earth voltage of the health phase and the phase-to-phase voltage. This factor may vary between  $1/3^{1/2}$  and 1.

**2.4.3** Power transformers are to be provided with overload and short circuit protection.

When transformers are connected in parallel, tripping of the protective devices on the primary side is to automatically trip the switch connected on the secondary side.

**2.4.4** Voltage transformers are to be provided with overload and short circuit protection on the secondary side.

**2.4.5** Fuses are not to be used for overload protection.

**2.4.6** Lower voltage systems supplied through transformers from high voltage systems are to be protected against overvoltages. This may be achieved by:

- a) direct earthing of the lower voltage system
- b) appropriate neutral voltage limiters
- c) earthed screen between the primary and secondary windings of transformers.

### 3 Rotating machinery

#### 3.1 Stator windings of generators

3.1.1 Generator stator windings are to have all phase ends brought out for the installation of the differential protection.

#### 3.2 Temperature detectors

3.2.1 Rotating machinery is to be provided with temperature detectors in its stator windings to actuate a visual and audible alarm in a normally attended position whenever the temperature exceeds the permissible limit.

If embedded temperature detectors are used, means are to be provided to protect the circuit against overvoltage.

#### 3.3 Tests

3.3.1 In addition to the tests normally required for rotating machinery, a high voltage test in accordance with IEC 60034-15 is to be carried out on the individual coils in order to demonstrate a satisfactory withstand level of the inter-turn insulation to steep fronted switching surges.

### 4 Power transformers

#### 4.1 General

4.1.1 Dry type transformers are to comply with IEC 60076-11.

Liquid cooled transformers are to comply with the applicable parts of the IEC 60076 series.

Oil immersed transformers are to be provided with the following alarms and protection:

- liquid level (Low) - alarm
- liquid temperature (High) - alarm
- liquid level (Low) - trip or load reduction
- liquid temperature (High) - trip or load reduction
- gas pressure relay (High) - trip.

### 5 Cables

#### 5.1 General

5.1.1 Cables are to be constructed in accordance with IEC 60092-353 and 60092-354 or other equivalent Standard.

### 6 Switchgear and controlgear assemblies

#### 6.1 General

6.1.1 Switchgear and controlgear assemblies are to be constructed in accordance with IEC 62271-200 and the following additional requirements.

#### 6.2 Construction

6.2.1 Switchgear is to be of metal-enclosed type in accordance with IEC 62271-200 or of the insulation-enclosed type in accordance with IEC 62271-201.

6.2.2 Withdrawable circuit breakers and switches are to be provided with mechanical locking facilities in both service and disconnected positions. For maintenance purposes, key locking of withdrawable circuit breakers and switches and fixed disconnectors is to be possible.

Withdrawable circuit breakers are to be located in the service position so that there is no relative motion between fixed and moving portions.

6.2.3 The fixed contacts of withdrawable circuit breakers and switches are to be so arranged that in the withdrawable position the live contacts are automatically covered.

Shutters are to be clearly marked for incoming and outgoing circuits. This may be achieved with the used of colours or labels.

6.2.4 For maintenance purposes an adequate number of earthing and short-circuiting devices is to be provided to enable circuits to be worked on in safety.

**6.2.5** Switchgear and controlgear assemblies are to be internal arc classified (IAC).

Where switchgear and controlgear are accessible by authorized personnel only, Accessibility Type A is sufficient (IEC 62271-200 Annex AA 2.2). Accessibility Type B is required if accessible by non-authorized personnel.

Installation and location of the switchgear and controlgear is to correspond with its internal arc classification and classified sides (F, L and R)

**6.3 Auxiliary systems**

**6.3.1** If electrical energy and/or physical energy is required for the operation of circuit-breakers and switches, a store supply of such energy is to be provided for at least two operations of all the components.

However, the tripping due to overload or short-circuit, and under-voltage is to be independent of any stored electrical energy sources. This does not preclude shunt tripping provided that alarms are activated upon lack of continuity in the release circuits and power supply failures.

**6.3.2** When external source of supply is necessary for auxiliary circuits, at least two external sources of supply are to be provided and so arranged that a failure or loss of one source will not cause the loss of more than one generator set and/or a main switchboard section as described in [2.1.1] and/or set of essential services.

Where necessary one source of supply is to be from the emergency source of electrical power for the start up from dead ship condition.

**6.4 High voltage test**

**6.4.1** A power-frequency voltage test is to be carried out on any switchgear and controlgear assemblies. The test voltage is to be applied for at least 1 minute and is to be as given in Tab 2.

**Table 2 : Test voltages for high voltage assemblies**

Nominal voltage (kV)	Highest voltage for equipment (kV)	Test voltage a.c. (r.m.s.) (V)
3 - 3,3	3,6	10
6 - 6,6	7,2	20
10 - 11	12,0	28
15	17,5	38

**7 Installation**

**7.1 Electrical equipment**

**7.1.1** Where equipment is not contained in an enclosure but a room forms the enclosure of the equipment, the access doors are to be so interlocked that they cannot be opened until the supply is isolated and the equipment earthed down.

At the entrance to spaces where high-voltage electrical equipment is installed, a suitable marking is to be placed indicating danger of high voltage. As regards high-voltage electrical equipment installed outside the aforementioned spaces, similar marking is to be provided.

An adequate, unobstructed working space is to be left in the vicinity of high voltage equipment for preventing potential severe injuries to personnel performing maintenance activities. In addition, the clearance between the switchboard and the ceiling / deckhead above is to meet the requirements of the Internal Arc Classification according to IEC 62271-200. See [6.2.5].

**7.2 Cables**

**7.2.1** In accommodation spaces, high voltage cables are to be run in enclosed cable transit systems.

**7.2.2** High voltage cables are to be segregated from cables operating at different voltage ratings; in particular, they are not to be run in the same cable bunch, in the same ducts or pipes, or in the same box.

Where high voltage cables of different voltage ratings are installed on the same cable tray, the air clearance between cables is not to be less than the minimum air clearance for the higher voltage side in [2.3.1]. However, high voltage cables are not to be installed on the same cable tray for cables operating at the nominal system voltage of 1 kV and less.

**7.2.3** High voltage cables are generally to be installed on cable trays when they are provided with a continuous metallic sheath or armour which is effectively bonded to earth; otherwise, they are to be installed for their entire length in metallic castings effectively bonded to earth.

**7.2.4** Terminations in all conductors of high voltage cables are, as far as practicable, to be effectively covered with suitable insulating material. In terminal boxes, if conductors are not insulated, phases are to be separated from earth and from each other by substantial barriers of suitable insulating materials.

High voltage cables of the radial field type, i.e. having a conductive layer to control the electric field within the insulation, are to have terminations which provide electric stress control.

Terminations are to be of a type compatible with the insulation and jacket material of the cable and are to be provided with means to ground all metallic shielding components (i.e. tapes, wires etc.).

**7.2.5** High voltage cables are to be readily identifiable by suitable marking.

**7.2.6** Before a new high voltage cable installation, or an addition to an existing installation, is put into service, a voltage withstand test is to be satisfactorily carried out on each completed cable and its accessories.

The test is to be carried out after an insulation resistance test.

For cables with rated voltage ( $U_0/U$ ) above 1,8/3 kV ( $U_m = 3,6$  kV) an a.c. voltage withstand test may be carried out upon advice from high voltage cable manufacturer. One of the following test is to be used:

- test for 5 minutes with the phase to phase voltage of the system applied between the conductor and the metallic screen/sheath
- test for 24 hours with the normal operating voltage of the system. Alternatively, a d.c. test voltage equal to  $4 U_0$  may be applied for 15 minutes.

For cables with rated voltage ( $U_0/U$ ) up to 1,8/3 kV ( $U_m = 3,6$  kV) an d.c. voltage equal to  $4 U_0$  is to be applied for 15 minutes.

**7.2.7** After completion of the test, the conductors are to be connected to earth for a sufficient period in order to remove any trapped electric charge.

An insulation resistance test is then repeated.

# Section 14 Electric Propulsion Plant

## 1 General

### 1.1 Applicable requirements

**1.1.1** The following requirements apply to ships for which the main propulsion plants are provided by at least one electric propulsion motor and its electrical supply. All electrical components of the propulsion plants are to comply with these requirements.

**1.1.2** Prime movers are to comply with the requirements of Ch 1, Sec 2.

**1.1.3** For the torsional vibration characteristics of the electric propulsion plant, the provisions of Ch 1, Sec 9 apply.

**1.1.4** Cooling and lubricating oil systems are to comply with the requirements of Ch 1, Sec 10.

**1.1.5** Monitoring and control systems are to comply with the requirements of Part C, Chapter 3.

**1.1.6** Installations assigned an additional notation for automation are to comply with the requirements of Part F, Chapter 3 and Part F, Chapter 4.

### 1.2 Operating conditions

**1.2.1** The normal torque available on the electric propulsion motors for manoeuvring is to be such as to enable the vessel to be stopped or reversed when sailing at its maximum service speed.

**1.2.2** Adequate torque margin is to be provided for three-phase synchronous motors to avoid the motor pulling out of synchronism during rough weather and when turning.

**1.2.3** Means are to be provided to limit the continuous input to the electric propulsion motor. This value is not to exceed the continuous full load torque for which motor and shafts are designed.

**1.2.4** The plant as a whole is to have sufficient overload capacity to provide the torque, power and reactive power needed during starting and manoeuvring conditions.

Locked rotor torque which may be required in relation to the operation of the vessel (e.g. for navigation in ice) is to be considered.

**1.2.5** The electric motors and shaftline are to be constructed and installed so that, at any speed reached in service, all the moving components are suitably balanced.

## 2 Design of the propulsion plant

### 2.1 General

**2.1.1** The electrical power for the propulsion system may be supplied from generating sets, dedicated to the propulsion system, or from a central power generation plant, which supplies the ship's services and electric propulsion.

The minimum configuration of an electric propulsion plant consists of one prime mover, one generator and one electric motor. When the electrical production used for propulsion is independent of the shipboard production, the diesel engines driving the electric generators are to be considered as main engines.

Note 1: When the electric power plant is constituted with 2 generators, the corresponding prime movers are to be considered as main propulsion medium. For electrical propulsion plant fitted with more than 2 generators, they will be considered as auxiliary generators. The corresponding control and monitoring will be considered accordingly.

**2.1.2** For plants having only one propulsion motor controlled via a static converter, a standby converter which it is easy to switch over to is to be provided. Double stator windings with one converter for each winding are considered as an alternative solution.

**2.1.3** In electric propulsion plants having two or more constant voltage propulsion generating sets, the electrical power for the ship's auxiliary services may be derived from this source. Additional ship's generators for auxiliary services need not be fitted provided that effective propulsion and the services mentioned in Ch 2, Sec 3, [2.2.3] are maintained with any one generating set out of service.

Where transformers are used to supply the ship's auxiliary services, see Ch 2, Sec 5.

**2.1.4** Plants having two or more propulsion generators, two or more static converters or two or more motors on one propeller shaft are to be so arranged that any unit may be taken out of service and disconnected electrically, without affecting the operation of the others.

## **2.2 Power supply**

**2.2.1** Where the plant is intended exclusively for electric propulsion, voltage variations and maximum voltage are to be maintained within the limits required in Ch 2, Sec 2.

**2.2.2** When an energy storage system (ESS) is used to supply the electric propulsion and when this ESS is necessary to maintain the voltage and frequency variations of power supply between the limits of the rules defined in Ch 2, Sec 2 (for instance the peak power load during ice breaking of the pods), the requirements of Pt F, Ch 14, Sec 2 are to be complied with.

**2.2.3** In special conditions (e.g. during crash-stop manoeuvres), frequency variations may exceed the limits stipulated in Ch 2, Sec 3 provided that other equipment operating on the same network is not unduly affected.

**2.2.4** The electric plant is to be so designed as to prevent the harmful effects of electromagnetic interference generated by semiconductor converters, in accordance with Ch 2, Sec 3.

## **2.3 Auxiliary machinery**

**2.3.1** Propeller/thruster auxiliary plants are to be supplied directly from the main switchboard or from the main distribution board or from a distribution board reserved for such circuits, at the auxiliary rated voltage.

**2.3.2** When the installation has one or more lubrication systems, devices are to be provided to ensure the monitoring of the lubricating oil return temperature.

**2.3.3** Propelling machinery installations with a forced lubrication system are to be provided with alarm devices which will operate in the event of oil pressure loss.

## **2.4 Electrical Protection**

**2.4.1** Automatic disconnections of electric propulsion plants which adversely affect the manoeuvrability of the ship are to be restricted to faults liable to cause severe damage to the equipment.

**2.4.2** The following protection of converters is to be provided:

- protection against overvoltage in the supply systems to which converters are connected
- protection against overcurrents in semiconductor elements during normal operation
- short-circuit protection.

**2.4.3** Overcurrent protective devices in the main circuits are to be set sufficiently high so that there is no possibility of activation due to the overcurrents caused in the course of normal operation, e.g. during manoeuvring or in heavy seas.

**2.4.4** Overcurrent protection may be replaced by automatic control systems ensuring that overcurrents do not reach values which may endanger the plant, e.g. by selective tripping or rapid reduction of the magnetic fluxes of the generators and motors.

**2.4.5** In the case of propulsion plants supplied by generators in parallel, suitable controls are to ensure that, if one or more generators are disconnected, those remaining are not overloaded by the propulsion motors.

**2.4.6** In three-phase systems, phase-balance protective devices are to be provided for the motor circuit which de-excite the generators and motors or disconnect the circuit concerned.

## **2.5 Excitation of synchronous electric propulsion motor**

**2.5.1** Each propulsion motor is to have its own exciter.

**2.5.2** For plants where only one generator or only one motor is foreseen, each machine is to be provided with a standby exciter, which it is easy to switch over to.

**2.5.3** In case of multi-propeller propulsion ships, standby exciter may be omitted, provided failure of one exciter on one electric motor doesn't impair the functionality of the remaining motor.

**2.5.4** In excitation circuits, there is to be no overload protection causing the opening of the circuit, except for excitation circuits with semiconductor converters.

**2.5.5** Each exciter is to be supplied by a separate feeder.

## **3 Construction of rotating machines, semiconductor converters and braking resistors**

### **3.1 Ventilation**

**3.1.1** Where electrical machines are fitted with an integrated fan and are to be operated at speeds below the rated speed with full load torque, full load current, full load excitation or the like, the design temperature rise is not to be exceeded.

**3.1.2** Where electrical machines or converters are force-ventilated, at least two fans, or other suitable arrangements, are to be provided so that limited operation is possible in the event of one fan failing.

### **3.2 Protection against moisture and condensate**

**3.2.1** Machines and equipment which may be subject to the accumulation of moisture and condensate are to be provided with effective means of heating. The latter is to be provided for motors above 500 kW, in order to maintain the temperature inside the machine at about 3°C above the ambient temperature.

**3.2.2** Provision is to be made to prevent the accumulation of bilge water, which is likely to enter inside the machine.

### **3.3 Rotating machines**

**3.3.1** Electrical machines are to be able to withstand the excess speed which may occur during operation of the ship.

**3.3.2** The design of rotating machines supplied by static converters is to consider the effects of harmonics.

**3.3.3** The winding insulation of electrical machines is to be capable of withstanding the overvoltage which may occur in manoeuvring conditions.

**3.3.4** The design of a.c. machines is to be such that they can withstand without damage a sudden short-circuit at their terminals under rated operating conditions.

**3.3.5** The obtainable current and voltage of exciters and their supply are to be suitable for the output required during manoeuvring and overcurrent conditions, including short-circuit in the transient period.

### **3.4 Semiconductor converters**

**3.4.1** The following limiting repetitive peak voltages  $U_{RM}$  are to be used as a base for each semiconductor valve:

- when connected to a supply specifically for propeller drives:  
 $U_{RM} = 1,5 U_P$
- when connected to a common main supply:  
 $U_{RM} = 1,8 U_P$

where

$U_P$  : Peak value of the rated voltage at the input of the semiconductor converter.

**3.4.2** For semiconductor converter elements connected in series, the values in [3.4.1] are to be increased by 10%. Equal voltage distribution is to be ensured.

**3.4.3** For parallel-connected converter elements, an equal current distribution is to be ensured.

**3.4.4** Means are to be provided, where necessary, to limit the effects of the rate of harmonics to the system and to other semiconductor converters. Suitable filters are to be installed to keep the current and voltage within the limits given in Ch 2, Sec 2.

**3.4.5** The piping system of the cooling system is to be in accordance with Ch 1, Sec 10.

### **3.5 Braking resistors**

**3.5.1** Braking resistors may be provided to absorb excess amounts of regenerated energy and to reduce the speed of the propulsion motor. When provided, each braking resistor is to be tested according to [6.2].

## **4 Control and monitoring**

### **4.1 General**

**4.1.1** The control and monitoring systems, including computer based systems, are to be type approved, according to Ch 3, Sec 6.

### **4.2 Power plant control systems**

**4.2.1** The power plant control systems are to ensure that adequate propulsion power is available, by means of automatic control systems and/or manual remote control systems.

**4.2.2** The automatic control systems are to be such that, in the event of a fault, the propeller speed and direction of thrust do not undergo substantial variations.

**4.2.3** Failure of the power plant control system is not to cause complete loss of generated power (i.e. blackout) or loss of propulsion.

**4.2.4** The loss of power plant control systems is not to cause variations in the available power; i.e. starting or stopping of generating sets is not to occur as a result.

**4.2.5** Where power-aided control (for example with electrical, pneumatic or hydraulic aid) is used for manual operation, failure of such aid is not to result in interruption of power to the propeller. Any such device is to be capable of purely manual local operation.

**4.2.6** The control system is to include the following main functions:

- monitoring of the alarms: any event critical for the proper operation of an essential auxiliary or a main element of the installation requiring immediate action to avoid a breakdown is to activate an alarm
- speed or pitch control of the propeller
- shutdown or slow down when necessary.

**4.2.7** Where the electric propulsion system is supplied by the main switchboard together with the ship's services, load shedding of the non-essential services and /or power limitation of the electric propulsion is to be provided. An alarm is to be triggered in the event of power limitation or load shedding.

**4.2.8** The risk of blackout due to electric propulsion operation is to be eliminated. At the request of the Society, a failure mode and effects analysis is to be carried out to demonstrate the reliability of the system.

### **4.3 Indicating instruments**

**4.3.1** In addition to the provisions of Part C, Chapter 3 of the Rules, instruments indicating consumed power and power available for propulsion are to be provided at each propulsion remote control position.

**4.3.2** The instruments specified in [4.3.3] and [4.3.4] in relation to the type of plant are to be provided in the main machinery control room.

**4.3.3** The following instruments are required for each alternator:

- an ammeter on each phase, or with a selector switch to all phases
- a voltmeter with a selector switch to all phases
- a wattmeter
- a tachometer or frequency meter
- a power factor meter or a var-meter or a field ammeter for each alternator operating in parallel
- a temperature indicator for the stator windings, for each alternator rated above 500 kVA.

**4.3.4** The following instruments are required for each a.c. propulsion motor:

- an ammeter on the main circuit
- an embedded temperature sensor for the stator windings of motors rated above 500 kW
- an ammeter on the excitation circuit for each synchronous motor
- a voltmeter for the measurement of the voltage between phases of each motor supplied through a semiconductor frequency converter.

**4.3.5** Where a speed measuring system is used for control and indication, the system is to be duplicated with separate sensor circuits and separate power supply.

**4.3.6** An ammeter is to be provided on the supply circuit for each propulsion semiconductor bridge.

### **4.4 Alarm system**

**4.4.1** An alarm system is to be provided, in accordance with the requirements of Part C, Chapter 3. The system is to give an indication at the control positions when the parameters specified in [4.4] assume abnormal values or any event occurs which can affect the electric propulsion.

**4.4.2** Where an alarm system is provided for other essential equipment or installations, the alarms in [4.4.1] may be connected to such system.

**4.4.3** Critical alarms for propulsion are to be indicated to the bridge separately.

**4.4.4** The following alarms are to be provided, where applicable:

- high temperature of the cooling air of machines and semiconductor converters provided with forced ventilation (see Note 1)
- reduced flow of primary and secondary coolants of machines and semiconductor converters having a closed cooling system with a heat exchanger
- leakage of coolant inside the enclosure of machines and semiconductor converters with liquid-air heat exchangers
- high winding temperature of generators and propulsion motors, where required (see [4.3])
- low lubricating oil pressure of bearings for machines with forced oil lubrication
- tripping of protective devices against overvoltages in semiconductor converters (critical alarm)
- tripping of protection on filter circuits to limit the disturbances due to semiconductor converters
- tripping of protective devices against overcurrents up to and including short-circuit in semiconductor converters (critical alarm)
- voltage unbalance of three-phase a.c. systems supplied by semiconductor frequency converters
- earth fault for the main propulsion circuit (see Note 2)
- earth fault for excitation circuits of propulsion machines (see Note 3).

Note 1: As an alternative to the air temperature of converters or to the airflow, the supply of electrical energy to the ventilator or the temperature of the semiconductors may be monitored.

Note 2: In the case of star connected a.c. generators and motors with neutral points earthed, this device may not detect an earth fault in the entire winding of the machine.

Note 3: This may be omitted in brushless excitation systems and in the excitation circuits of machines rated up to 500 kW. In such cases, lamps, voltmeters or other means are to be provided to detect the insulation status under operating conditions.

## **4.5 Reduction of power**

**4.5.1** Power is to be automatically reduced in the following cases:

- low lubricating oil pressure of bearings of propulsion generators and motors
- high winding temperature of propulsion generators and motors
- fan failure in machines and converters provided with forced ventilation, or failure of cooling system
- lack of coolant in machines and semiconductor converters
- load limitation of generators or inadequate available power.

**4.5.2** When power is reduced automatically, this is to be indicated at the propulsion control position (critical alarm).

**4.5.3** Switching-off of the semiconductors in the event of abnormal service operation is to be provided in accordance with the manufacturer's specification.

## **5 Installation**

### **5.1 Ventilation of spaces**

**5.1.1** Loss of ventilation to spaces with forced air cooling is not to cause loss of propulsion. To this end, two sets of ventilation fans are to be provided, one acting as a standby unit for the other. Equivalent arrangements using several independently supplied fans may be considered.

### **5.2 Cable runs**

**5.2.1** Instrumentation and control cables are to comply with the requirements of Ch 3, Sec 5 of the Rules.

**5.2.2** Where there is more than one propulsion motor, all cables for any one machine are to be run as far as is practicable away from the cables of other machines.

**5.2.3** Cables which are connected to the sliprings of synchronous motors are to be suitably insulated for the voltage to which they are subjected during manoeuvring.

## **6 Tests**

### **6.1 Test of rotating machines**

**6.1.1** The test requirements are to comply with Ch 2, Sec 4.

**6.1.2** For rotating machines, such as synchronous generators and synchronous electric motors, of a power of more than 1 MW, a quality plan detailing the different controls during the machine assembly is to be submitted to the Society for approval.

**6.1.3** In relation to the evaluation of the temperature rise, it is necessary to consider the supplementary thermal losses induced by harmonic currents in the stator winding. To this end, two methods may be used:

- direct test method, when the electric propulsion motor is being supplied by its own frequency converter, and/or back to back arrangement according to the supplier's facility
- indirect test method as defined in Ch 2, App 1; in this case, a validation of the estimation of the temperature excess due to harmonics is to be documented. A justification based on a computer program calculation may be taken into consideration, provided that validation of such program is demonstrated by previous experience.

**6.1.4** Rotating machines used for propulsion or manoeuvring are to be subjected to the tests stated in Ch 2, Sec 4, [5.1.1].

## **6.2 Test of braking resistors**

**6.2.1** Each braking resistor is to undergo the following tests after manufacturing:

- visual and mechanical inspection and dimensions check
- ohmic value measurement
- insulation resistance measurement
- dielectric test
- earth continuity check
- cabling verification
- function tests of leakage detector, space heater and thermostat.

## **7 Specific requirements for PODs**

### **7.1 General**

**7.1.1** The requirements for the structural part of a POD are specified in Pt B, Ch 12, Sec 1, [11].

**7.1.2** When used as steering manoeuvring system, the POD is to comply with the requirements of Ch 1, Sec 14.

### **7.2 Electrical slip ring assemblies**

**7.2.1** Electrical slip ring assemblies are to comply with Ch 2, Sec 10, [2.3] and Ch 2, Sec 10, [2.4].

### **7.3 Electric motor**

**7.3.1** The thermal losses are dissipated by the liquid cooling of the bulb and by the internal ventilation of the POD. The justification for the evaluation of the heating balance between the sea water and air cooling is to be submitted to the Society.

Note 1: The calculation method used for the evaluation of the cooling system (mainly based on computer programs) is to be documented. The calculation method is to be justified based on the experience of the designer of the system. The results of scale model tests or other methods may be taken into consideration.

**7.3.2** Means to adjust the air cooler characteristics are to be provided on board, in order to obtain an acceptable temperature rise of the windings. Such means are to be set following the dock and sea trials.

**7.3.3** Vibrations of the electric motor are to be monitored. The alarm set point is to be defined in accordance with the manufacturer recommendation.

### **7.4 Instrumentation and associated devices**

**7.4.1** Means are to be provided to transmit the low level signals connected to the sensors located in the POD.

### **7.5 Additional tests and tests on board**

**7.5.1** Tests of electric propulsion motors are to be carried out in accordance with Ch 2, Sec 4, and other tests in accordance with Ch 1, Sec 18.

**7.5.2** Tests are to be performed to check the validation of the temperature rise calculation.

**7.5.3** Tests on board are described in Ch 1, Sec 18, [3.9].

# Section 15 Testing

## 1 General

### 1.1 Rule application

**1.1.1** Before a new installation, or any alteration or addition to an existing installation, is put into service, the electrical equipment is to be tested in accordance with Articles [3], [4] and [5] to the satisfaction of the Surveyor in charge.

### 1.2 Insulation-testing instruments

**1.2.1** Insulation resistance may be measured with an instrument applying a voltage of at least 500 V. The measurement will be taken when the deviation of the measuring device is stabilised.

Note 1: Any electronic devices present in the installation are to be disconnected prior to the test in order to prevent damage.

**1.2.2** For high voltage installation, the measurement is to be taken with an instrument applying a voltage adapted to the rated value and agreed with the Society.

## 2 Type approved components

### 2.1

**2.1.1** The following components are to be type approved or in accordance with [2.1.2]:

- electrical cables
- transformers
- rotating machines
- electrical converters for primary essential services
- switching devices (circuit-breakers, contactors, disconnectors, etc.) and overcurrent protective devices
- sensors, alarm panels, electronic protective devices, automatic and remote control equipment, actuators, safety devices for installations intended for essential services (steering, controllable pitch propellers, propulsion machinery, etc.), electronic speed regulators for main or auxiliary engines
- computers used for tasks essential to safety
- cable trays or protective casings made of plastics materials (thermoplastic or thermosetting plastic materials).

**2.1.2** Case by case approval based on submission of adequate documentation and execution of tests may also be granted at the discretion of the Society.

## 3 Insulation resistance

### 3.1 Lighting and power circuits

**3.1.1** The insulation resistance between all insulated poles (or phases) and earth and, where practicable, between poles (or phases), is to be at least 1 M $\Omega$  in ordinary conditions.

The installation may be subdivided to any desired extent and appliances may be disconnected if initial tests give results less than that indicated above.

### 3.2 Internal communication circuits

**3.2.1** Circuits operating at a voltage of 50 V and above are to have an insulation resistance between conductors and between each conductor and earth of at least 1 M $\Omega$ .

**3.2.2** Circuits operating at voltages below 50 V are to have an insulation resistance between conductors and between each conductor and earth of at least 0,33 M $\Omega$ .

**3.2.3** If necessary, any or all appliances connected to the circuit may be disconnected while the test is being conducted.

### 3.3 Switchboards

**3.3.1** The insulation resistance between each busbar and earth and between each insulated busbar and the busbar connected to the other poles (or phases) of each main switchboard, emergency switchboard, section board, etc. is to be not less than 1 M $\Omega$ .

**3.3.2** The test is to be performed before the switchboard is put into service with all circuit-breakers and switches open, all fuse-links for pilot lamps, earth fault-indicating lamps, voltmeters, etc. removed and voltage coils temporarily disconnected where otherwise damage may result.

### **3.4 Generators and motors**

**3.4.1** The insulation resistance of generators and motors, in normal working condition and with all parts in place, is to be measured and recorded.

**3.4.2** The test is to be carried out with the machine hot immediately after running with normal load.

**3.4.3** The insulation resistance of generator and motor connection cables, field windings and starters is to be at least 1 M $\Omega$ .

## **4 Earth**

### **4.1 Electrical constructions**

**4.1.1** Tests are to be carried out, by visual inspection or by means of a tester, to verify that all earth-continuity conductors and earthing leads are connected to the frames of apparatus and to the hull, and that in socket-outlets having earthing contacts, these are connected to earth.

### **4.2 Metal-sheathed cables, metal pipes or conduits**

**4.2.1** Tests are to be performed, by visual inspection or by means of a tester, to verify that the metal coverings of cables and associated metal pipes, conduits, trunking and casings are electrically continuous and effectively earthed.

## **5 Operational tests**

### **5.1 Generating sets and their protective devices**

**5.1.1** Generating sets are to be run at full rated load to verify that the following are satisfactory:

- electrical characteristics
- commutation (if any)
- lubrication
- ventilation
- noise and vibration level.

**5.1.2** Suitable load variations are to be applied to verify the satisfactory operation under steady state and transient conditions (see Ch 2, Sec 4, [2]) of:

- voltage regulators
- speed governors.

**5.1.3** Generating sets intended to operate in parallel are to be tested over a range of loading up to full load to verify that the following are satisfactory:

- parallel operation
- sharing of the active load
- sharing of the reactive load (for a.c. generators).

Synchronising devices are also to be tested.

**5.1.4** The satisfactory operation of the following protective devices is to be verified:

- overspeed protection
- overcurrent protection (see Note 1)
- load-shedding devices
- any other safety devices.

For sets intended to operate in parallel, the correct operation of the following is also to be verified:

- reverse-power protection for a.c. installations (or reverse-current protection for d.c. installations)
- minimum voltage protection.

Note 1: Simulated tests may be used to carry out this check where appropriate.

**5.1.5** The satisfactory operation of the emergency source of power and of the transitional source of power, when required, is to be tested. In particular, the automatic starting and the automatic connection to the emergency switchboard, in case of failure of the main source of electrical power, are to be tested.

## **5.2 Switchgear**

**5.2.1** All switchgear is to be loaded and, when found necessary by the attending Surveyor, the operation of overcurrent protective devices is to be verified (see Note 1).

Note 1: The workshop test is generally considered sufficient to ensure that such apparatus will perform as required while in operation.

**5.2.2** Short-circuit tests may also be required at the discretion of the Society in order to verify the selectivity characteristics of the installation.

## **5.3 Harmonic filters**

**5.3.1** The calculation results and the validity of the guidance required in Ch 2, Sec 3, [3.22.2] and Ch 2, Sec 3, [3.22.3] are to be verified by the Surveyor during sea trials.

## **5.4 Consuming devices**

**5.4.1** Electrical equipment is to be operated under normal service conditions (though not necessarily at full load or simultaneously) to verify that it is suitable and satisfactory for its purpose.

**5.4.2** Motors and their starters are to be tested under normal operating conditions to verify that the following are satisfactory:

- power
- operating characteristics
- commutation (if any)
- speed
- direction of rotation
- alignment.

**5.4.3** The remote stops foreseen are to be tested.

**5.4.4** Lighting fittings, heating appliances etc. are to be tested under operating conditions to verify that they are suitable and satisfactory for their purposes (with particular regard to the operation of emergency lighting).

## **5.5 Communication systems**

**5.5.1** Communication systems, order transmitters and mechanical engine-order telegraphs are to be tested to verify their suitability.

## **5.6 Installations in areas with a risk of explosion**

**5.6.1** Installations and the relevant safety certification are to be examined to ensure that they are of a type permitted in the various areas and that the integrity of the protection concept has not been impaired.

## **5.7 Voltage drop**

**5.7.1** Where it is deemed necessary by the attending Surveyor, the voltage drop is to be measured to verify that the permissible limits are not exceeded (see Ch 2, Sec 3, [9.11.4]).

# Appendix 1 Indirect Test Method for Synchronous Machines

## 1 General

### 1.1 Test method

**1.1.1** The machine is to be subject to the three separate running tests specified below (see Fig 1) when it is complete (with covers, heat exchangers, all control devices and sensors), the exciter circuit is connected to its normal supply or to a separate supply having the same characteristics, and the supply is fitted with the necessary measuring instruments:

- Test N° 1: No load test at rated voltage and current on rotor, stator winding in open circuit. The temperature rise of the stator winding depends, in such case, on the magnetic circuit losses and mechanical losses due to ventilation, where:
  - $\Delta t_{s1}$  is the stator temperature rise
  - $\Delta t_{r1}$  is the rotor temperature rise.
- Test N° 2: Rated stator winding current with the terminals short-circuited. The temperature of the stator winding depends on the thermal Joule losses and mechanical losses, as above, where:
  - $\Delta t_{s2}$  is the stator temperature rise
  - $\Delta t_{r2}$  is the rotor temperature rise, which for test N° 2 is negligible.
- Test N° 3: Zero excitation. The temperature of all windings depends on the mechanical losses due to friction and ventilation, where:
  - $\Delta t_{s3}$  is the stator temperature rise
  - $\Delta t_{r3}$  is the rotor temperature rise.

Note 1: The synchronous electric motor is supplied at its rated speed by a driving motor. The temperature balance will be considered as being obtained, when the temperature rise does not vary by more than 2°C per hour.

**Figure 1 : Schematic diagram used for the test**

**1.1.2** Temperature measurements of the stator winding can be based on the use of embedded temperature sensors or measurement of winding resistance. When using the resistance method for calculation of the temperature rise, the resistance measurement is to be carried out as soon as the machine is shut down.

The rotor temperature rise is obtained by calculation of rotor resistance,  $R_{rotor} = U/I_r$ , where  $U$  and  $I$  are the voltage and current in the magnetic field winding.

The following parameters are recorded, every 1/2 hour:

- temperature sensors as well as the stator current and voltage
- the main field voltage and current
- the bearing temperatures (embedded sensor or thermometer), and the condition of cooling of the bearings, which are to be compared to those expected on board.

**1.1.3** The tests described above allow the determination of the final temperature rise of stator and rotor windings with an acceptable degree of accuracy.

- The temperature rise of the stator winding is estimated as follows:

$$\Delta t_{\text{stator}} = \Delta t_{s1} + \Delta t_{s2} - \Delta t_{s3}$$

$\Delta t_{\text{stator}}$  winding is to be corrected by the supplementary temperature rise due to current harmonics evaluated by the manufacturer

- Considering that in test N° 1 the magnetic field winding current  $I_{rt}$  is different from the manufacturer's estimated value  $I_r$  (due to the fact that the  $\cos \phi$  in operation is not equal to 1), the temperature rise of the rotor is to be corrected as follows:

$$\Delta t_{\text{rotor}} = (\Delta t_{r1} - \Delta t_{r3}) \times (\text{rated loading conditions } I_r / \text{test loading conditions } I_{rt})^2 + \Delta t_{r3}$$

**1.1.4** In the indirect method, a possible mutual influence of the temperature rise between the stator and the rotor is not taken into consideration. The test results may be representative of the temperature rise on board ship, but a margin of 10 to 15°C is advisable compared with the permitted temperature of the Rules and the measure obtained during tests.

# Appendix 2 Indirect Test Method for Induction Machines (Static Torque Method)

## 1 General

### 1.1 Test method

**1.1.1** The induction machine is to be subject to the three separate tests specified in Tab 1 when it is completely assembled (with covers, heat exchangers, all control devices and sensors).

**1.1.2** Temperature measurements of the stator winding is based on the use of embedded temperature sensors. The stator temperature taken into account for the temperature rise is the average of all sensors values.

The following parameters are recorded, every 1/2 hour:

- temperature sensors as well as the stator current and voltage
- bearing temperatures (embedded sensor or thermometer), and the condition of cooling of the bearings, which are to be compared to those expected on board.

**1.1.3** The tests described in Tab 1 allow the determination of the final temperature rise of stator windings with an acceptable degree of accuracy.

The stator temperature rise  $\Delta t_{stator}$  is the average of embedded temperature sensors values minus cooling element temperature:

$$\Delta t_{stator} = \Delta\theta_1 - \Delta\theta_2 + \Delta\theta_3$$

where:

- $\Delta\theta_1$  : Stator temperature rise of Test 1 defined in Tab 1
- $\Delta\theta_2$  : Stator temperature rise of Test 2 defined in Tab 1
- $\Delta\theta_3$  : Stator temperature rise of Test 3 defined in Tab 1.

**Table 1 : Tests for induction machines**

Test 1	Test 2	Test 3
Rotor locked (see Fig 1), machine ventilated in normal condition with stator supplied by rated current at reduced voltage and frequency	Rotor running at no-load with stator supplied at the same voltage and frequency as Test 1	Rotor running at no-load at rated speed with stator supplied at rated voltage and rated frequency

### CHAPTER 3

## AUTOMATION

---

Section 1	General Requirements
Section 2	Design Requirements
Section 3	Computer Based Systems
Section 4	Constructional Requirements
Section 5	Installation Requirements
Section 6	Testing
Appendix 1	Type Testing Procedure for Crankcase Oil Mist Detection and Alarm Equipment

# Section 1 General Requirements

## 1 General

### 1.1 Field of application

**1.1.1** The following requirements apply to automation systems, installed on all ships, intended for essential services as defined in Ch 2, Sec 1. They also apply to systems required in Part C, Chapter 1 and Part C, Chapter 2, installed on all ships.

**1.1.2** This chapter is intended to avoid that failures or malfunctions of automation systems associated with essential and non-essential services cause danger to other essential services.

**1.1.3** Requirements for unattended machinery spaces and for additional notations are specified in Part F.

### 1.2 Regulations and standards

**1.2.1** The regulations and standards applicable are those defined in Ch 2, Sec 1.

### 1.3 Definitions

**1.3.1** Unless otherwise stated, the terms used in this chapter have the definitions laid down in Ch 2, Sec 1 or in the IEC standards. The following definitions also apply:

- Alarm indicator is an indicator which gives a visible and/or audible warning upon the appearance of one or more faults to advise the operator that his attention is required.
- Alarm system is a system intended to give a signal in the event of abnormal running condition.
- Application software is a software performing tasks specific to the actual configuration of the computer based system and supported by the basic software.
- Automatic control is the control of an operation without direct or indirect human intervention, in response to the occurrence of predetermined conditions.
- Automation systems are systems including control systems and monitoring systems.
- Basic software is the minimum software, which includes firmware and middleware, required to support the application software.
- Cold standby system is a duplicated system with a manual commutation or manual replacement of cards which are live and non-operational. The duplicated system is to be able to achieve the operation of the main system with identical performance, and be operational within 10 minutes.
- Control station is a group of control and monitoring devices by means of which an operator can control and verify the performance of equipment.
- Control system is a system by which an intentional action is exerted on an apparatus to attain given purposes.
- Fail safe is a design property of an item in which the specified failure mode is predominantly in a safe direction with regard to the safety of the ship, as a primary concern.
- Full redundant is used to describe an automation system comprising two (identical or non-identical) independent systems which perform the same function and operate simultaneously.
- Hot standby system is used to describe an automation system comprising two (identical or non-identical) independent systems which perform the same function, one of which is in operation while the other is on standby with an automatic change-over switch.
- Instrumentation is a sensor or monitoring element.
- Local control is control of an operation at a point on or adjacent to the controlled switching device.
- Monitoring system is a system designed to observe the correct operation of the equipment by detecting incorrect functioning (measure of variables compared with specified value).
- Safety system is a system intended to limit the consequence of failure and is activated automatically when an abnormal condition appears.
- Redundancy is the existence of more than one means for performing a required function.
- Remote control is the control from a distance of apparatus by means of an electrical or other link.
- Inspection of components (only hardware) from sub-suppliers: proof that components and/or sub-assemblies conform to specification.
- Quality control in production: evidence of quality assurance measures on production.
- Final test reports: reports from testing of the finished product and documentation of the test results.

- Hardware description:
  - system block diagram, showing the arrangement, input and output devices and interconnections
  - connection diagrams
  - details of input and output devices
  - details of power supplies.
- Failure analysis for safety related functions only (e.g. FMEA): the analysis is to be carried out using appropriate means, e.g.:
  - fault tree analysis
  - risk analysis
  - FMEA or FMECA.

The purpose is to demonstrate that for single failures, systems will fail to safety and that systems in operation will not be lost or degraded beyond acceptable performance criteria when specified by the Society.

**1.4 General**

**1.4.1** The automation systems and components, as indicated in Ch 2, Sec 15, [2], are to be type approved according to the applicable requirements of these Rules and in particular those stated in this Chapter.

Case by case approval may also be granted at the discretion of the Society, based on submission of adequate documentation and subject to the satisfactory outcome of any required tests.

**1.4.2** *Main and auxiliary machinery essential for the propulsion, control and safety of the ship shall be provided with effective means for its operation and control.*

**1.4.3** Control, alarm and safety systems are to be based on the fail-to-safety principle.

**1.4.4** Failure of automation systems is to generate an alarm.

**1.4.5** Detailed indication, alarm and safety requirements regarding automation systems for individual machinery and installations are to be found in tables located in Part C, Chapter 1 and in Part F, Chapter 3.

Each row of these tables is to correspond to one independent sensor.

**2 Documentation**

**2.1 General**

**2.1.1** Before the actual construction is commenced, the Manufacturer, Designer or Shipbuilder is to submit to the Society the documents (plans, diagrams, specifications and calculations) requested in this Section.

**2.2 Documents to be submitted**

**2.2.1** The documents listed in Tab 1 are to be submitted.

**Table 1 : Documentation to be submitted**

No	I/A (1)	Documentation
1	I	The general specification for the automation of the ship
2	A	The detailed specification of the essential service systems
3	A	The list of components used in the automation circuits, and references (Manufacturer, type, etc.)
4	I	Instruction manuals
5	I	Test procedures for control, alarm and safety systems
6	A	A general diagram showing the monitoring and/or control positions for the various installations, with an indication of the means of access and the means of communication between the positions as well as with the engineers
7	A	The diagrams of the supply circuits of automation systems, identifying the power source
8	A	The list of monitored parameters for alarm/monitoring and safety systems
9	A	Diagram of the engineers’ alarm system
10	I	List of computerized systems as mentioned in Ch 3, Sec 3, [1.2.1]
11	A / I	Documentation as mentioned in Ch 3, Sec 3, Tab 2
12	I	Software Registry as mentioned in Ch 3, Sec 3, [4.3.1]
<b>(1)</b> A = to be submitted for approval; I = to be submitted for information.		

## **2.3 Documents for type approval of equipment**

**2.3.1** Documents to be submitted for type approval of equipment are listed hereafter:

- a request for type approval from the manufacturer or his authorized representative
- the technical specification and drawings depicting the system, its components, characteristics, working principle, installation and conditions of use and, when there is a computer based system, the documents listed in Ch 3, Sec 3, Tab 2.
- any test reports previously prepared by specialized laboratories.

### **2.3.2 Modifications**

Modifications are to be documented by the manufacturer. Subsequent significant modifications to the software and hardware for systems of categories II and III are to be submitted for approval.

Note 1: A significant modification is a modification which influences the functionality and/or the safety of the system.

## **3 Environmental and supply conditions**

### **3.1 General**

#### **3.1.1 General**

The automation system is to operate correctly when the power supply is within the range specified in Ch 3, Sec 2.

#### **3.1.2 Environmental conditions**

The automation system is to be designed to operate satisfactorily in the environment in which it is located. The environmental conditions are described in Ch 2, Sec 2.

#### **3.1.3 Failure behaviour**

The automation system is to have non-critical behaviour in the event of power supply failure, faults or restoration of operating condition following a fault. If a redundant power supply is used, it must be taken from an independent source.

### **3.2 Power supply conditions**

#### **3.2.1 Electrical power supply**

The conditions of power supply to be considered are defined in Ch 2, Sec 2.

#### **3.2.2 Pneumatic power supply**

For pneumatic equipment, the operational characteristics are to be maintained under permanent supply pressure variations of  $\pm 20\%$  of the rated pressure.

Detailed requirements are given in Ch 1, Sec 10.

#### **3.2.3 Hydraulic power supply**

For hydraulic equipment, the operational characteristics are to be maintained under permanent supply pressure variations of  $\pm 20\%$  of the rated pressure.

Detailed requirements are given in Ch 1, Sec 10.

## **4 Materials and construction**

### **4.1 General**

**4.1.1** The choice of materials and components is to be made according to the environmental and operating conditions in order to maintain the proper function of the equipment.

**4.1.2** The design and construction of the automation equipment is to take into account the environmental and operating conditions in order to maintain the proper function of the equipment.

### **4.2 Type approved components**

**4.2.1** See Ch 2, Sec 15.

## Section 2 Design Requirements

### 1 General

#### 1.1

**1.1.1** *All control systems essential for the propulsion, control and safety of the ship shall be independent or designed such that failure of one system does not degrade the performance of another system.*

**1.1.2** Controlled systems are to have manual operation.

*Failure of any part of such systems shall not prevent the use of the manual override.*

**1.1.3** Automation systems are to have constant performance.

**1.1.4** Safety functions are to be independent of control and monitoring functions.

**1.1.5** Control, monitoring and safety systems are to have self-check facilities. In the event of failure, an alarm is to be activated. In particular, failure of the power supply of the automation system is to generate an alarm.

**1.1.6** When a computer based system is used for control, alarm or safety systems, it is to comply with the requirements of Ch 3, Sec 3.

**1.1.7** The automatic change-over switch is to operate independently of both systems. When change-over occurs, no stop of the installation is necessary and the latter is not to enter undefined or critical states.

**1.1.8** Emergency stops are to be hardwired and independent of any computer based system.

Note 1: Computerized systems may be admitted if evidence is given demonstrating they provide a safety level equivalent to a hardwired system.

### 2 Power supply of automation systems

#### 2.1

**2.1.1** Automation systems are to be arranged with an automatic change-over to a continuously available stand-by power supply in case of loss of normal power source.

**2.1.2** The capacity of the stand-by power supply is to be sufficient to allow the normal operation of the automation systems for at least half an hour.

**2.1.3** Failure of any power supply to an automation system is to generate an audible and visual alarm.

**2.1.4** Power supplies are to be protected against short circuit and overload for each independent automation system. Power supplies are to be isolated.

### 3 Control systems

#### 3.1 General

**3.1.1** In the case of failure, the control systems used for essential services are to remain in the last position they had before the failure, unless otherwise specified by these Rules.

#### 3.2 Local control

**3.2.1** Each system is to be able to be operated manually from a position located so as to enable visual control of operation. For detailed instrumentation for each system, refer to Part C, Chapter 1 and Part C, Chapter 2.

*It shall also be possible to control the auxiliary machinery, essential for the propulsion and safety of the ship, at or near the machinery concerned.*

Note 1: For electrically driven units in auxiliary services, the local control is normally to be arranged at the motor starter in motor control centers and, if applicable, also near the equipment under control.

**3.2.2** Local control systems is to be self-contained and not depend on other systems or external communication links for its intended operation.

**3.2.3** When local control is selected, any control signal(s) from the remote control system is to be ignored.

### **3.3 Remote control systems**

**3.3.1** When several remote control stations are provided, control of machinery is to be possible at one station at a time. At each location, an indicator showing which location is in control is to be provided.

**3.3.2** Remote control is to be provided with the necessary instrumentation, in each remote control station, to allow effective control (correct function of the system, indication of control station in operation, alarm display).

**3.3.3** When transferring the control location, no significant alteration of the controlled equipment is to occur. Transfer of control is to be protected by an audible warning and acknowledged by the receiving remote control location. The main remote control location is to be able to take control without acknowledgment.

**3.3.4** Failure in remote control systems is not to prevent local operation.

### **3.4 Automatic control systems**

**3.4.1** *Automatic starting, operational and control systems shall include provisions for manually overriding the automatic controls.*

**3.4.2** Automatic control is to be stable in the range of the controller in normal working conditions.

**3.4.3** Automatic control is to have instrumentation to verify the correct function of the system.

**3.4.4** For machinery systems which due to their complexity requires continuous automatic control, manual control of the individual Equipment Under Control may not be feasible. In such cases, local means are to be provided to both monitor the concerned process- and to enable/disable any automatic functions / modes (a typical example is the gas supply system to a gas fuelled engine).

## **4 Control of propulsion machinery**

### **4.1 Application**

#### **4.1.1 Ships with restricted navigation notations**

The requirements of this article are applicable to all ships except non-propelled units. However, arrangements which are not in compliance with the provisions of this article may be considered for ships with restricted navigation notations.

### **4.2 Remote control**

**4.2.1** The requirements mentioned in [3] are to be applied for propulsion machinery.

**4.2.2** *The design of the remote control system shall be such that in case of its failure an alarm will be given.*

**4.2.3** Supply failure (voltage, fluid pressure, etc.) in propulsion plant remote control is to activate an alarm at the control position. In the event of remote control system failure and unless the Society considers it impracticable, the preset speed and direction of thrust are to be maintained until local control is in operation. This applies in particular in the case of loss of electric, pneumatic or hydraulic supply to the system.

**4.2.4** *Propulsion machinery orders from the navigation bridge shall be indicated in the main machinery control room, and at the manoeuvring platform.*

**4.2.5** *The control shall be performed by a single control device for each independent propeller, with automatic performance of all associated services, including, where necessary, means of preventing overload of the propulsion machinery. Where multiple propellers are designed to operate simultaneously, they must be controlled by one control device.*

**4.2.6** *Indicators shall be fitted on the navigation bridge, in the main machinery control room and at the manoeuvring platform, for:*

- *propeller speed and direction of rotation in the case of fixed pitch propellers; and*
- *propeller speed and pitch position in the case of controllable pitch propellers.*

**4.2.7** *The main propulsion machinery shall be provided with an emergency stopping device on the navigation bridge which shall be independent of the navigation bridge control system.*

In the event that there is no reaction to an order to stop, provision is to be made for an alternative emergency stop. This emergency stopping device may consist of a simple and clearly marked control device, for example a push-button. This fitting is to be capable of suppressing the propeller thrust, whatever the cause of the failure may be.

### 4.3 Remote control from navigating bridge

**4.3.1** Where propulsion machinery is controlled from the navigating bridge, the remote control is to include an automatic device such that the number of operations to be carried out is reduced and their nature is simplified and such that control is possible in both the ahead and astern directions. Where necessary, means for preventing overload and running in critical speed ranges of the propulsion machinery is to be provided.

**4.3.2** On board ships fitted with remote control, direct control of the propulsion machinery is to be provided locally. The local direct control is to be independent from the remote control circuits, and takes over any remote control when in use.

**4.3.3** The local control of the propulsion machinery is to continue to operate in the case of failure of any parts of the remote control system or blackout.

**4.3.4** *Remote control of the propulsion machinery shall be possible only from one location at a time; at such locations interconnected control positions are permitted. At each location there shall be an indicator showing which location is in control of the propulsion machinery.*

**4.3.5** *The transfer of control between the navigating bridge and machinery spaces shall be possible only in the main machinery space or the main machinery control room. The system shall include means to prevent the propelling thrust from altering significantly, when transferring control from one location to another.*

**4.3.6** At the navigating bridge, the control of the routine manoeuvres for one line of shafting is to be performed by a single control device: a lever, a handwheel or a push-button board. However each mechanism contributing directly to the propulsion, such as the engine, clutch, automatic brake or controllable pitch propeller, is to be able to be individually controlled, either locally or at a central monitoring and control position in the engine room.

**4.3.7** Remote starting of the propulsion machinery is to be automatically inhibited if a condition exists which may damage the machinery, e.g. shaft turning gear engaged, drop of lubrication oil pressure or brake engaged.

**4.3.8** As a general rule, the navigating bridge panels are not to be overloaded by alarms and indications which are not required.

**4.3.9** *Automation systems shall be designed in a manner which ensures that threshold warning of impending or imminent slowdown or shutdown of the propulsion system is given to the officer in charge of the navigational watch in time to assess navigational circumstances in an emergency. In particular, the systems shall control, monitor, report, alert and take safety action to slowdown or stop propulsion while providing the officer in charge of the navigational watch an opportunity to manually intervene, except for those cases where manual intervention will result in total failure of the engine and/or propulsion equipment within a short time, for example in the case of overspeed.*

### 4.4 Remote control from navigating bridge for gas fueled ship

**4.4.1** For ships assigned with additional service feature **LNGfuel**, **CNGfuel**, **LPGfuel** or, as relevant, other additional service features defined in Pt A, Ch 1, Sec 2, [4.16.4], the provisions of NR529, 9.4.3; NR529, 15.5(b); NR529, 15.11.4 and NR529, 15.7 are applicable.

### 4.5 Automatic control

**4.5.1** The requirements in Article [3] are applicable. In addition, the following requirements are to be considered, if relevant.

**4.5.2** *Main turbine propulsion machinery and, where applicable, main internal combustion propulsion machinery and auxiliary machinery shall be provided with automatic shutoff arrangements in the case of failures such as lubricating oil supply failure which could lead rapidly to complete breakdown, serious damage or explosion.*

**4.5.3** The automatic control system is to be designed on a fail safe basis, and, in the event of failure, the system is to be adjusted automatically to a predetermined safe state.

**4.5.4** Operations following any setting of the bridge control device (including reversing from the maximum ahead service speed in case of emergency) are to take place in an automatic sequence and with acceptable time intervals, as prescribed by the manufacturer.

**4.5.5** For steam turbines, a slow turning device is to be provided which operates automatically if the turbine is stopped longer than admissible. Discontinuation of this automatic turning from the bridge is to be possible.

### 4.6 Automatic control of propulsion and manoeuvring units

**4.6.1** When the power source actuating the automatic control of propelling units fails, an alarm is to be triggered. In such case, the preset direction of thrust is to be maintained long enough to allow the intervention of engineers. Failing this, minimum arrangements, such as stopping of the shaft line, are to be provided to prevent any unexpected reverse of the thrust. Such stopping may be automatic or ordered by the operator, following an appropriate indication.

## **4.7 Clutches**

**4.7.1** Where the clutch of a propulsion engine is operated electrically, pneumatically or hydraulically, an alarm is to be given at the control station in the event of loss of energy; as far as practicable, this alarm is to be triggered while it is still possible to operate the equipment.

**4.7.2** When only one clutch is installed, its control is to be fail-set. Other arrangements may be considered in relation to the configuration of the propulsion machinery.

## **4.8 Brakes**

**4.8.1** Automatic or remote controlled braking is to be possible only if:

- propulsion power has been shut off
- the turning gear is disconnected
- the shaftline speed (r.p.m.) is below the threshold stated by the builder.

## **5 Communications**

### **5.1 Communications between navigating bridge and machinery space**

**5.1.1** *At least two independent means are to be provided for communicating orders from the navigating bridge to the position in the machinery space or in the control room from which the speed and the direction of the thrust of the propellers are normally controlled; one of these is to be an engine room telegraph, which provides visual indication of the orders and responses both in the machinery space and on the navigating bridge, with audible alarm mismatch between order and response.*

**5.1.2** The engine room telegraph is required in any case, even if the remote control of the engine is foreseen, irrespective of whether the engine room is attended. An alarm is to be given at the navigation bridge in the event of failure of power supply to the engine room telegraph.

**5.1.3** Where the main propulsion system of the ship is controlled from the navigating bridge by a remote control system, the second means of communication may be the same bridge control system.

**5.1.4** The second means for communicating orders is to be fed by an independent power supply and is to be independent of other means of communication.

**5.1.5** *Appropriate means of communication, providing for verification of both engine orders and responses, shall be provided from the navigating bridge and the engine room to any other position from which the speed and direction of thrust of the propellers may be controlled.*

Note 1: This requirement also applies to each local partial control position of the propulsion (e.g. clutches).

**5.1.6** For ships assigned with a restricted navigation notation, the requirements of this sub-article may be relaxed at the Society's discretion.

### **5.2 Engineers' alarm**

**5.2.1** *An engineers' alarm shall be provided to be operated from the engine control room or at the manoeuvring platform as appropriate, and shall be clearly audible in the engineers' accommodation*

## **6 Remote control of valves**

### **6.1**

**6.1.1** The following requirements are applicable to valves whose failure could impair essential services.

**6.1.2** Failure of the power supply is not to permit a valve to move to an unsafe condition.

**6.1.3** An indication is to be provided at the remote control station showing the actual position of the valve or whether the valve is fully open or fully closed. This indication may be omitted for quick-closing valves.

**6.1.4** When valves are remote controlled, a secondary manual means of operating them is to be provided (see Ch 1, Sec 10, [2.7.3]).

## 7 Alarm system

### 7.1 General requirements

**7.1.1** Alarms are to be visual and audible and are to be clearly distinguishable, in the ambient noise and lighting in the normal position of the personnel, from any other signals.

**7.1.2** Sufficient information is to be provided for proper handling of alarms.

**7.1.3** The alarm system is to be of the self-check type; failure within the alarm system, including the outside connection, is to activate an alarm. The alarm circuits are to be independent from each other. All alarm circuits are to be protected so as not to endanger each other.

### 7.2 Alarm functions

#### 7.2.1 Alarm activation

Alarms are to be activated when abnormal conditions appear in the machinery, which need the intervention of personnel on duty, and on the automatic change-over, when standby machines are installed.

An existing alarm is not to prevent the indication of any further fault.

#### 7.2.2 Acknowledgement of alarm

The acknowledgment of an alarm consists in manually silencing the audible signal and additional visual signals (e.g. rotating light signals) while leaving the visual signal on the active control station. Acknowledged alarms are to be clearly distinguishable from unacknowledged alarms. Acknowledgment should not prevent the audible signal to operate for new alarm.

*Alarms shall be maintained until they are accepted and visual indications of individual alarms shall remain until the fault has been corrected, when the alarm system shall automatically reset to the normal operating condition.*

Acknowledgment of alarms is only to be possible at the active control station.

Alarms, including the detection of transient faults, are to be maintained until acknowledgment of the visual indication.

Acknowledgment of visual signals is to be separate for each signal or common to a limited group of signals. Acknowledgment is only to be possible when the user has visual information on the alarm condition for the signal or all signals in a group.

#### 7.2.3 Inhibition of alarms

Manual inhibition of separate alarms may be accepted when this is clearly indicated.

Inhibition of alarm and safety functions in certain operating modes (e.g. during start-up or trimming) is to be automatically disabled in other modes.

#### 7.2.4 Time delay of alarms

It is to be possible to delay alarm activation in order to avoid false alarms due to normal transient conditions (e.g. during start-up or trimming).

#### 7.2.5 Transfer of responsibility

Where several alarm control stations located in different spaces are provided, responsibility for alarms is not to be transferred before being acknowledged by the receiving location. Transfer of responsibility is to give an audible warning. At each control station it is to be indicated which location is in charge.

## 8 Safety system

### 8.1 Design

#### 8.1.1 System failures

A safety system is to be designed so as to limit the consequence of failures. It is to be constructed on the fail-to-safety principle. The safety system is to be of the self-check type; as a rule, failure within the safety system, including the outside connection, is to activate an alarm.

### 8.2 Function

#### 8.2.1 Safety activation

The safety system is to be activated automatically in the event of identified conditions which could lead to damage of associated machinery or systems, such that:

- normal operating conditions are restored (e.g. by the starting of the standby unit), or
- the operation of the machinery is temporarily adjusted to the prevailing abnormal conditions (e.g. by reducing the output of the associated machinery), or
- the machinery is protected, as far as possible, from critical conditions by shutting off the fuel or power supply, thereby stopping the machinery (shutdown), or appropriate shutdown.

### **8.2.2 Safety indication**

When the safety system has been activated, it is to be possible to trace the cause of the safety action. This is to be accomplished by means of a central or local indication.

When a safety system is made inoperative by a manual override, this is to be clearly indicated at corresponding control stations. Override of safety functions in certain operating modes (e.g; during start-up or trimming) is to be automatically disabled in other modes

Automatic safety actions are to activate an alarm at predefined control stations.

### **8.3 Shutdown**

**8.3.1** For shutdown systems of machinery, the following requirements are to be applied:

- when the system has stopped a machine, the latter is not to be restarted automatically before a manual reset of the safety system has been carried out
- the shutdown of the propulsion system is to be limited to those cases which could lead to serious damage, complete breakdown or explosion.

### **8.4 Standby systems**

**8.4.1** For the automatic starting system of the standby units, the following requirements are to be applied:

- faults in the electrical or mechanical system of the running machinery are not to prevent the standby machinery from being automatically started
- when a machine is on standby, ready to be automatically started, this is to be clearly indicated at its control position
- the change-over to the standby unit is to be indicated by a visual and audible alarm
- means are to be provided close to the machine, to prevent undesired automatic or remote starting (e.g. when the machine is being repaired)
- automatic starting is to be prevented when conditions are present which could endanger the standby machine.

### **8.5 Testing**

**8.5.1** The safety systems are to be tested in accordance with the requirements in Ch 3, Sec 6.

# Section 3 Computer Based Systems

## 1 General requirements

### 1.1 Application

#### 1.1.1 Systems covered

This Section applies to design, construction, commissioning and maintenance of computer based systems where they depend on software for the proper achievement of their functions. These requirements focus on the functionality of the software and on the hardware supporting the software. These requirements apply to the use of computer based systems which provide control, alarm, monitoring, safety or internal communication functions which are subject to classification requirements.

Navigation systems required by SOLAS Chapter V, Radio-communication systems required by SOLAS Chapter IV, and vessel loading instrument/stability computer are not in the scope of these requirements.

Note 1: For loading instrument/stability computer, see Pt B, Ch 1, Sec 5, [3].

### 1.2 Requirement for ship

#### 1.2.1 List of computerized systems

List of computerized systems covered by this Section as described [1.1.1] are to be submitted to the Society as soon as possible during design stage of the ship. This list is to include:

- designation of system involved
- category of system according to [2.3]
- manufacturer of system (if available)
- supplier of control system (if available).

#### 1.2.2 Software registry

Initial release of software registry as defined in [4.3.1] is to be submitted for information to the Society after ship sea trials.

The software registry is composed of the four following parts:

- inventory of Integrated Systems components as explained in [8.2]
- logical map of networks as explained in [6.3]
- software inventory as explained in [4.5]
- security events as explained in [4.4].

The additional service feature **SW-Registry** is assigned in accordance to Pt A, Ch 1, Sec 2, [4.16.13] to ships provided with a software registry meeting the above requirements.

### 1.3 Requirements for computerized systems

**1.3.1** Computerized systems are to follow requirements mentioned in Articles [4], [5], [6], [8] and [9].

**1.3.2** The response time between the detection of an event and the related action or signalization is to be compatible with the application. As a general requirement without other specification, this time is to be less than 5 seconds.

### 1.4 References

**1.4.1** For the purpose of application of the requirements contained in this Section, the following identified standards can be used for the development of hardware/software of computer based systems. Other industry standards may be considered:

- IEC 61508: Functional safety of electrical/electronic/programmable electronic safety-related systems
- ISO/IEC 12207: Systems and software engineering - Software life cycle processes
- ISO 9001:2008 Quality Management Systems - Requirements
- ISO/IEC 90003: Software engineering - Guidelines for the application of ISO 9001:2008 to computer software
- IEC 60092-504: Electrical installations in ships - Part 504: Special features - Control and instrumentation
- ISO/IEC 25000: Systems and software engineering - Systems and software Quality Requirements and Evaluation (SQuaRE) - Guide to SQuaRE
- ISO/IEC 25041: Systems and software engineering - Systems and software Quality Requirements and Evaluation (SQuaRE) - Evaluation guide for developers, acquirers and independent evaluators
- IEC 61511: Functional safety - Safety instrumented systems for the process industry sector
- ISO/IEC 15288: Systems and software engineering - System life cycle process.

## 2 Definitions

### 2.1 Stakeholders

#### 2.1.1 Owner

The Owner is responsible for contracting the system integrator and/or suppliers to provide a hardware system including software according to the owner's specification. The Owner could be the Ship Builder Integrator (Builder or Shipyard) during initial construction. After vessel delivery, the owner may delegate some responsibilities to the vessel operating company.

#### 2.1.2 System integrator

The role of system integrator is to be taken by the Yard unless an alternative organization is specifically contracted/assigned this responsibility. The system integrator is responsible for the integration of systems and products provided by suppliers into the system invoked by the requirements specified herein and for providing the integrated system. The system integrator may also be responsible of integration of systems in the vessel.

If there are multiple parties performing system integration at any one time a single party is to be responsible for overall system integration and coordinating the integration activities. If there are multiple stages of integration different System Integrators may be responsible for specific stages of integration but a single party is to be responsible for defining and coordinating all of the stages of integration.

#### 2.1.3 Supplier

The Supplier is any contracted or subcontracted provider of system components or software under the coordination of the System Integrator or Shipyard. The supplier is responsible for providing programmable devices, sub-systems or systems to the system integrator. The supplier provides a description of the software functionality that meets the Owner's specification, applicable international and national standards, and the requirements specified herein.

#### 2.1.4 Local Area Network (LAN)

A LAN is a network of connected devices that exist within a specific location.

#### 2.1.5 Virtual Local Area Network (VLAN)

A VLAN is a custom network created from one or more existing LANs. It enables groups of devices from multiple networks (both wired and wireless) to be combined into a single logical network. The result is a virtual LAN that can be administered like a physical local area network.

#### 2.1.6 Media Access Control (MAC)

A media access control address of a device is a unique identifier assigned to network interfaces for communications at the data link layer of a network segment.

#### 2.1.7 Communication device

A computer based equipment, ensuring service or function for the ship, connected to the network, either receiving information and/or sending information. This includes operating system based computers from operational and information systems as programmable logic controllers from industrial control systems.

#### 2.1.8 Network communication device

A computer based equipment, ensuring service or function for the communication devices of the ship, who handles, manages and routes packets over the networks.

### 2.2 Objects

2.2.1 Fig 1 shows the hierarchy and relationships of a typical computer based system.

Figure 1 : Illustrative system hierarchy

**2.2.2 Object definitions**

- a) Vessel: Ship where the system is to be installed
- b) System: Combination of interacting programmable devices and/or sub-systems organized to achieve one or more specified purposes.
- c) Sub-system: Identifiable part of a system, which may perform a specific function or set of functions.
- d) Programmable device: Physical component where software is installed.
- e) Software module: A module is a standalone piece of code that provides specific and closely coupled functionality.

**2.3 System categories**

**2.3.1** Tab 1 shows how to assign system categories based on their effects on system functionality.

The following systems typically belong to Category III, the exact category being dependent on the risk assessment for all operational scenarios:

- Propulsion system of a ship, meaning the means to generate and control mechanical thrust in order to move the ship (devices used only during manoeuvring are not in the scope of this requirement such as bow tunnel thrusters)
- Steering system control system
- Electric power system (including power management system)
- Ship safety systems covering fire detection and fighting, flooding detection and fighting, internal communication systems involved in evacuation phases, ship systems involved in operation of life saving appliances equipment
- Dynamic positioning system of equipment classes 2 and 3 according to Pt F, Ch 11, Sec 5
- Drilling systems

The following systems typically belong to Category II, the exact category being dependent on the risk assessment for all operational scenarios:

- liquid cargo transfer control system
- bilge level detection and associated control of pumps
- fuel oil treatment system:
  - ballast transfer valve remote control system
  - stabilization and ride control systems
- alarm and monitoring systems for propulsion systems.

The example systems are not exhaustive.

**Table 1 : System categories**

Category	Effects	Typical system functionality
I	Those systems, failure of which will not lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment	<ul style="list-style-type: none"> <li>• Monitoring function for informational/administrative tasks</li> </ul>
II	Those systems, failure of which could eventually lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment	<ul style="list-style-type: none"> <li>• Alarm and monitoring functions</li> <li>• Control functions which are necessary to maintain the ship in its normal operational and habitable conditions</li> </ul>
III	Those systems, failure of which could immediately lead to dangerous situations for human safety, safety of the vessel and/or threat to the environment	<ul style="list-style-type: none"> <li>• Control functions for maintaining the vessel's propulsion and steering</li> <li>• Vessel Safety functions</li> </ul>

**2.4 Other terminology**

**2.4.1 Simulation tests**

Control system testing where the equipment under control is partly or fully replaced with simulation tools, or where parts of the communication network and lines are replaced with simulation tools.

**2.4.2 Expert system**

Expert system is an intelligent knowledge-based system that is designed to solve a problem with information that has been compiled using some form of human expertise.

**2.4.3 Integrated system**

Integrated system is a system consisting of two or more subsystems having independent functions connected by a data transmission network and operated from one or more workstations.

#### **2.4.4 Data communication link**

Data communication link includes point to point links, instrument net and local area networks, normally used for inter-computer communication on board units. The software and hardware which support the data communication are also included.

### **3 Documentation and test attendance**

#### **3.1**

**3.1.1** Documentation to be submitted and test to be attended are listed in Tab 2.

#### **3.1.2 User interface description**

The documentation is to contain:

- a description of the functions allocated to each operator interface (keyboard/screen or equivalent)
- a description of individual screen views (schematics, colour photos, etc.)
- a description of how menus are operated (tree presentation)
- an operator manual providing necessary information for installation and use.

### **4 Requirements for software and supporting hardware**

#### **4.1 Life cycle approach**

**4.1.1** A global top to bottom approach is to be undertaken regarding software and the integration in a system, spanning the software lifecycle. This approach is to be accomplished according to software development standards as listed herein or other standards recognized by the Society.

#### **4.1.2 Quality system**

System integrators and suppliers shall operate a quality system regarding software development and testing and associated hardware such as ISO 9001 taking into account ISO 90003.

Satisfaction of this requirement is to be demonstrated by either:

- The quality system being certified as compliant to the recognized standard by an organization with accreditation under a national accreditation scheme, or
- The Society confirming compliance to the standard through a specific assessment.

This quality system is to include:

- a) Relevant procedures regarding responsibilities, system documentation, configuration management and competent staff.
- b) Relevant procedures regarding software lifecycle and associated hardware:
  - organization set in place for acquisition of related hardware and software from suppliers
  - organization set in place for software code writing and verification
  - organization set in place for system validation before integration in the vessel.
- c) Minimum requirements for approval of Quality system:
  - having a specific procedure for verification of software code of Category II and III at the level of systems, sub-systems and programmable devices and modules
  - having check points for the Class Society for Category II and III systems (see Tab 2 for the minimum check points, see Note 1)
  - having a specific procedure for software modification and installation on board the vessel defining interactions with owners.

#### **d) Quality Plan**

A document, referred to herein as a Quality Plan, is to be produced that records how the quality management system will be applied for the specific computer based system and that includes, as a minimum, all of material required by [4.1.2], items a) to c) inclusively.

Note 1: Examples of check points can be a required submittal of documentation, a test event, a technical design review meeting, or peer review meeting.

#### **4.1.3 Design phase**

##### **a) Risk assessment of system**

This step is to be undertaken to determine the risk to the system throughout the lifecycle by identifying and evaluating the hazards associated with each function of the system. A risk assessment report is upon request to be submitted to the Society. This document is normally to be submitted by the System Integrator or the Supplier, including data coming from other suppliers.

IEC/ISO31010 "Risk management - Risk assessment techniques" may be applied in order to determine method of risk assessment. The method of risk assessment is to be agreed by the society.

Based on the risk assessment, a revised system category might need to be agreed between Class and the system supplier.

Where the risks associated with a computer based system are well understood, it is permissible for the risk assessment to be omitted, however in such cases the supplier or the system integrator is to provide a justification for the omission. The justification should give consideration to:

- how the risks are known
- the equivalence of the context of use of the current computer based system and the computer based system initially used to determine the risks
- the adequacy of existing control measures in the current context of use.

b) Code production and testing

The following documentation is to be provided to the Society for Category II and III systems:

- Software modules functional description and associated hardware description for programmable devices. This is to be provided by Supplier and System Integrator.
- Evidence of verification (detection and correction of software errors) for software modules, in accordance with the selected software development standard. Evidence requirements of the selected software standard might differ depending on how critical the correct operation of the software is to the function it performs (i.e. IEC 61508 has different requirements depending on SILs, similar approaches are taken by other recognized standard). This is to be supplied by the Supplier and System Integrator.
- Evidence of functional tests for programmable devices at the software module, sub-system, and system level. This is to be supplied by the Supplier via the System Integrator. The functional testing is to be designed to test the provisions of features used by the software but provided by the operating system, function libraries, customized layer of software and any set of parameters.

#### 4.1.4 Integration testing before installation on board

Intra-system integration testing is to be done between system and sub-system software modules before being integrated on board. The objective is to check that software functions are properly executed, that the software and the hardware it controls interact and function properly together and that software systems react properly in case of failures. Faults are to be simulated as realistically as possible to demonstrate appropriate system fault detection and system response. The results of any required failure analysis are to be observed. Functional and failure testing can be demonstrated by simulation tests.

For Category II and III systems:

- a) Test programs and procedures for functional tests and failure tests are to be submitted to the Society. A FMEA may be requested by the Society in order to support containment of failure tests programs.
- b) Factory acceptance test including functional and failure tests are to be witnessed by the Society.

Following documentation is to be provided:

- 1) Functional description of software
- 2) List and versions of software installed in system
- 3) User manual including instructions for use during software maintenance
- 4) List of interfaces between system and other ship systems
- 5) List of standards used for data communication links
- 6) Additional documentation as requested by the Society which might include an FMEA or equivalent to demonstrate the adequacy of failure test case applied.

For Category III systems:

Simulation tests required in [4.1.4] are to fulfill in following conditions:

- software of control system identical to those that shall be installed on board are to be used for testing
- the environment of the control system is to be simulated with sufficient details and accuracy to run functional and failure tests
- the devices used for simulating the environment of the control system need to be evaluated by the Society before test is undertaken.

#### 4.1.5 Approval of programmable devices for Category II and III systems

Approval of programmable devices integrated inside a system is to be delivered to the system integrator or supplier. Approval can be granted on case by case basis, or as part of a product type approval, so long as above mentioned documents have been reviewed/approved (as per Tab 2) and the required tests have been witnessed by the Society (also see Ch 3, Sec 6, [2.2] regarding hardware environmental type tests). Documentation should address the compatibility of the programmable device in the ship's application, the necessity to have on board tests during ship integration and should identify the components of system using the approved programmable devices.

#### 4.1.6 Final integration and on board testing

Simulation tests are to be undertaken before installation, when it is found necessary to check safe interaction with other computerized systems and functions that could not be tested previously.

On board tests are to check that a computer based system in its final environment, integrated with all other systems with which it interacts is:

- performing functions it was designed for
- reacting safely in case of failures originated internally or by devices external to the system
- interacting safely with other systems implemented on board vessel.

For final integration and on board testing of Category II and III systems:

- test specifications are to be submitted to the Society for approval
- the tests are to be witnessed by the Society.

**4.2 Limited approval**

**4.2.1** Sub-systems and programmable devices may be approved for limited applications with service restrictions by the Class Society when the ship system where they will be integrated is not known. In this case, requirements about Quality systems under [4.1.2] might need to be fulfilled as required by the Society. Additional drawings, details, tests reports and surveys related to the Standard declared by the Supplier may be required by the Society upon request.

Sub-systems and programmable devices may in this case be granted with a limited approval mentioning the required checks and tests performed.

**Table 2 : Documentation and test attendance**

Requirement	Supplier involved	System integrator involved	Owner involved	Category I	Category II	Category III
Quality Plan	X	X		A (2)	A	A
Risk assessment report		X		I (2)	I (2)	I (2)
Software modules functional description and associated hardware description	X (if necessary)	X			I	I
Software registry	X	X	X	I	I	I
Evidence of verification of software code	X (if necessary)	X			I	I
Evidence of functional tests for elements included in systems of Category II and III at the level of software module, sub-system and system	X	X			I	I
Test programs and procedures for functional tests and failure tests including a supporting FMEA or equivalent, at the request of the Class Society		X			A	A
Factory acceptance test event including functional and failure tests	X	X			W	W
Test program for simulation tests for final integration		X			A	A
Simulation tests for final integration		X			W	W
Test program for on board tests (includes wireless network testing)		X			A	A
On board integration tests (includes wireless network testing)		X			W	W
<ul style="list-style-type: none"> <li>• List and versions of software installed in system</li> <li>• Functional description of software</li> <li>• User manual including instructions during software maintenance</li> <li>• List of interfaces between system and other ship systems</li> </ul>		X			I	I
Updated software registry		X	X		I	I
Procedures and documentation related to security policy					I	I
Test reports according to Ch 3, Sec 6, [2.2] requirements	X	X		A (3)	A	A
User interface description see [3.1.2]	X	X		I	I	I
<p>(1) Additional documentation may be required upon request                      (2) Upon request                      (3) If in the scope of Class requirement  <b>Note 1:</b> A = to be submitted for approval, I = to be submitted for information, W = Test to be witnessed by the Surveyor</p>						

### **4.3 Modifications during operation**

#### **4.3.1 Responsibilities**

Organizations in charge of software modifications are to be clearly declared by Owner to the Society. A system Integrator is to be designated by the Owner and is to fulfill the requirements mentioned in [4.1]. Limited life cycle steps may be considered for modifications already considered and accepted in the scope of initial approval. The level of documentation needed to be provided for the modification are to be determined by the Society.

At the vessel level, it is the responsibility of Owner to manage traceability of these modifications; the achievement of this responsibility is to be supported by system integrators updating the software registry. This software registry is to contain elements as described in [1.2.2].

#### **4.3.2 Change management**

The Owner is to ensure that necessary procedures for software and hardware change management exist on board, and that any software modification/upgrade are performed according to the procedure. All changes to computer based systems in the operational phase are to be recorded and be traceable by number, date or other appropriate means.

### **4.4 System security**

**4.4.1** Owner, system integrator and suppliers shall adopt security policies and include these in their quality systems and procedures.

For Category I, II, and III systems, physical and logical security measures are to be in place to prevent unauthorized or unintentional modification of software, whether undertaken at the physical system or remotely.

Prior to installation, all artefacts, software code, executables and the physical medium used for installation on the vessel are to be scanned for viruses and malicious software. Results of the scan are to be documented and kept with the software registry.

**4.4.2** Unused communication ports are to be disabled.

**4.4.3** Results of the scan are to be documented and recorded to security events (could be electronic file).

**4.4.4** Security events are kept with the software registry.

### **4.5 Software inventory**

**4.5.1** The software inventory is part of the software registry.

**4.5.2** The responsibilities of each parties are detailed hereafter:

- a) Suppliers shall deliver a software inventory for their equipment as described in [4.5.5].
- b) Shipyards shall verify equipment compliance with delivered software inventory from Supplier. Verification may be done in a passive way or in an active way by using discovery tools to identify software on a single equipment or to identify network connected devices within systems. If software inventory is missing, The Shipyard is to write it. Shipyard ensures software inventory revision by adding any supplied equipment during integration.
- c) Owner is to maintain software inventory delivered by the Shipyard. If missing, this document is to be established by the Owner. Maintenance of the software inventory is to be done in accordance with the Life Cycle of the equipment as described in [4.1]. Modification history is to be kept.

**4.5.3** The software inventory may be a numeric document (e.g. spreadsheet file) containing elements described in [4.5.4] to [4.5.7].

#### **4.5.4 Global information**

The software inventory is to be structured per equipment and is to contain:

- equipment name, brand, model or reference, supplier name, function and global version
- history of changes with dates, actors and motivations.

#### **4.5.5 Operating system related information**

If an equipment has multi, dual-boot system, each operating system is to be considered.

About operating system, the following information is to be delivered:

- operating system distribution name, editor's name, global version
- operating system detailed version (applied CVE should be listed)
- operating system installed desktop applications, relevant versions and motivations [4.5.6] is to be applied)
- operating system installed system services, relevant versions and motivations [4.5.7] is to be applied)
- license number.

#### **4.5.6 Desktop applications related information**

Desktop applications are software editors' applications used on the equipment. Desktop applications may be reserved to a local usage (e.g. notepad) but Desktop applications may also connect to remote computers (e.g. ftp client). But desktop applications cannot accept connections. Application using entering connections are called "Network Services" and are addressed in [4.5.7].

The following information are to be delivered regarding desktop applications:

- software name and publisher
- installation date, version number and motivations
- local and remote roles
- generic accounts
- dedicated accounts
- access control list with read, write and execution rights
- when existing, outgoing connections shall be considered (IP/Ports destination). If unknown, information shall be identified as "missing"
- license number.

#### **4.5.7 Network services related information**

Network services are application using entering connections through listening interface (e.g. called ports for TCP/IP) over the network or any serial connection.

In addition to the information listed in [4.5.6] the following information is to be delivered.

For IP based Services:

- protocol name and version
- listening ports
- motivation for ports listening

For Non/IP based Services:

- listening interface
- motivation for interface listening.

## **5 Requirements for hardware**

### **5.1 Requirements for hardware regarding environment**

**5.1.1** Evidence of environmental type testing according to Ch 3, Sec 6, [2.2] regarding hardware elements included in the system and sub-systems is to be submitted to the Society for Category I, II and III computer based systems. This requirement is not mandatory for Category I computer based systems not considered by Class.

### **5.2 Requirements for hardware regarding construction**

#### **5.2.1 General**

The construction of systems is to comply with the requirements of Ch 3, Sec 4.

#### **5.2.2 Housing**

- a) The housing of the system is to be designed to face the environmental conditions, as defined in Ch 2, Sec 2, [1], in which it will be installed. The design will be such as to protect the printed circuit board and associated components from external aggression. When required, the cooling system is to be monitored, and an alarm activated when the normal temperature is exceeded.
- b) The mechanical construction is to be designed to withstand the vibration levels defined in Ch 2, Sec 2, depending on the applicable environmental condition.

### **5.3 Hardware inventory**

**5.3.1** Hardware inventory is part of the software registry. The hardware inventory is to comply with requirement listed in [8.2].

## **6 Requirements for data communication links for Category II and III systems**

### **6.1 General requirements**

**6.1.1** Loss of a data link is to be specifically addressed in risk assessment analysis.

**6.1.2** A single failure in data link hardware is to be automatically treated in order to restore proper working of system. For Category III systems a single failure in data link hardware is not to influence the proper working of the system.

**6.1.3** Characteristics of data link are to prevent overloading in any operational condition of system.

**6.1.4** Data link is to be self-checking, detecting failures on the link itself and data communication failures on nodes connected to the link. Detected failures are to initiate an alarm.

**6.1.5** Loss of a data communication link is not to affect the ability to operate essential services by alternative means.

**6.1.6** The data communication link is to be automatically started when power is turned on, or restarted after loss of power.

**6.1.7** The choice of transmission cable is to be made according to the environmental conditions. Particular attention is to be given to the level characteristics required for electromagnetic interferences.

**6.1.8** The installation of transmission cables is to comply with the requirements stated in Ch 2, Sec 11. In addition, the routing of transmission cables is to be chosen so as to be in less exposed zones regarding mechanical, chemical or EMI damage. As far as possible, the routing of each cable is to be independent of any other cable. These cables are not normally allowed to be routed in bunches with other cables on the cable tray.

**6.1.9** The coupling devices are to be designed, as far as practicable, so that in the event of a single fault, they do not alter the network function. When a failure occurs, an alarm is to be activated.

Addition of coupling devices is not to alter the network function.

Hardware connecting devices are to be chosen, when possible, in accordance with international standards.

When a computer based system is used with a non-essential system and connected to a network used for essential systems, the coupling device is to be of an approved type.

## **6.2 Specific requirements for wireless data links**

**6.2.1** Category III systems are not to use wireless data links unless specifically considered by the Class Society on the basis of an engineering analysis carried out in accordance with an International or National Standard acceptable to the Society.

**6.2.2** Other categories of systems may use wireless data communication links with following requirements:

- a) Recognized international wireless communication system protocols are to be employed, incorporating:
  - Message integrity. Fault prevention, detection, diagnosis, and correction so that the received message is not corrupted or altered when compared to the transmitted message.
  - Configuration and device authentication. Is only to permit connection of devices that are included in the system design.
  - Message encryption. Protection of the confidentiality and or criticality of the data content.
  - Security management. Protection of network assets, prevention of unauthorized access to network assets.
- b) The internal wireless system within the vessel is to comply with the radio frequency and power level requirements of International Telecommunication Union and flag state requirements.

Consideration should be given to system operation in the event of port state and local regulations that pertain to the use of radio-frequency transmission prohibiting the operation of a wireless data communication link due to frequency and power level restrictions.
- c) For wireless data communication equipment, tests during harbour and sea trials are to be conducted to demonstrate that radio-frequency transmission does not cause failure of any equipment and does not its self-fail as a result of electromagnetic interference during expected operating conditions.

## **6.3 Logical map of networks**

**6.3.1** The logical map of networks is part of the software registry.

**6.3.2** Responsibilities are detailed in [4.5.2].

**6.3.3** The Logical Map focuses on the logical topology of networks (e.g. IP and non-IP addressing scheme, subnet names, logical links, principal devices in operation). This map can be organized in the form of inventories and a diagram.

### **6.3.4 Logical inventories**

- a) List of IP address ranges with, for each one:
  - the list of switches concerned
  - the functional description of the IP range
  - the list of Dynamic Host Configuration Protocol (DHCP) servers, relevant IP address management plan and IP history recording policy
  - the list of equipment MAC address
  - interconnections with other ranges
  - flow matrix with source, destination, ip, ports, service, motivation, roles, volume estimation and time windows if any

- b) List of non-IP networks with, for each network:
  - the list of MAC addresses or addresses specific to the industrial protocols on the network
  - the list of switches concerned
  - functional description of the network
  - devices connected to other networks (connectors)
- c) List of non-Ethernet access points with, for each one:
  - the list of access ports
  - addressing, if there is a special protocol
  - the list of connected devices
- d) List of logical servers and desktops with, for each one, if applicable:
  - IP addressing (network, mask, gateway)
  - operating system version
  - underlying physical server
  - applications and their versions
  - services and versions
- e) List of connectors and communicating field devices (remote I/O, smart sensors, smart actuators, etc.) with, for each one:
  - IP addressing (network, mask, gateway), the associated MAC addressing and network or the specific addressing, if appropriate
  - applications.

### 6.3.5 Diagram

This diagram is a representation of the IP ranges (networks and sub-networks) and their interconnections, showing:

- the functional description of the IP range
- interconnections with other ranges
- routers, switches and firewalls
- IT security devices (e.g. filtering gateways, sensors, intrusion detection sensors).

In particular, this map should show interconnection points with "external" entities (e.g. partners, service providers) and all interconnections with the Internet.

## 7 Man-machine interface

### 7.1 General

**7.1.1** The design of the operator interface is to follow ergonomic principles. The standard IEC 60447 Man-machine interface or equivalent recognized standard may be used.

### 7.2 System functional indication

**7.2.1** A means is to be provided to verify the activity of the system, or subsystem, and its proper function.

**7.2.2** A visual and audible alarm is to be activated in the event of malfunction of the system, or subsystem. This alarm is to be such that identification of the failure is simplified.

### 7.3 Input devices

**7.3.1** Input devices are to be positioned such that the operator has a clear view of the related display.

The operation of input devices, when installed, is to be logical and correspond to the direction of action of the controlled equipment.

The user is to be provided with positive confirmation of action.

Control of essential functions is only to be available at one control station at any time. Failing this, conflicting control commands are to be prevented by means of interlocks and/or warnings.

**7.3.2** When keys are used for common/important controls, and several functions are assigned to such keys, the active function is to be recognizable.

If use of a key may have unwanted consequences, provision is to be made to prevent an instruction from being executed by a single action (e.g. simultaneous use of 2 keys, repeated use of a key, etc.).

Means are to be provided to check validity of the manual input data into the system (e.g. checking the number of characters, range value, etc.).

**7.3.3** If use of a push button may have unwanted consequences, provision is to be made to prevent an instruction from being executed by a single action (e.g. simultaneous use of 2 push buttons, repeated use of push buttons, etc.). Alternatively, this push button is to be protected against accidental activation by a suitable cover, or use of a pull button, if applicable.

## **7.4 Output devices**

**7.4.1** VDU's (video display units) and other output devices are to be suitably lighted and dimmable when installed in the wheelhouse. The adjustment of brightness and colour of VDU's is to be limited to a minimum discernible level.

When VDU's are used for alarm purposes, the alarm signal, required by the Rules, is to be displayed whatever the other information on the screen. The alarms are to be displayed according to the sequence of occurrence.

When alarms are displayed on a colour VDU, it is to be possible to distinguish alarm in the event of failure of a primary colour.

The position of the VDU is to be such as to be easily readable from the normal position of the personnel on watch. The size of the screen and characters is to be chosen accordingly.

When several control stations are provided in different spaces, an indication of the station in control is to be displayed at each control station. Transfer of control is to be effected smoothly and without interruption to the service.

## **7.5 Workstations**

**7.5.1** The number of workstations at control stations is to be sufficient to ensure that all functions may be provided with any one unit out of operation, taking into account any functions which are required to be continuously available.

**7.5.2** Multifunction workstations for control and display are to be redundant and interchangeable.

**7.5.3** The choice of colour, graphic symbols, etc. is to be consistent in all systems on board.

## **7.6 Computer dialogue**

**7.6.1** The computer dialogue is to be as simple and self-explanatory as possible.

The screen content is to be logically structured and show only what is relevant to the user.

Menus are to be organized so as to have rapid access to the most frequently used functions.

**7.6.2** A means to go back to a safe state is always to be accessible.

**7.6.3** A clear warning is to be displayed when using functions such as alteration of control condition, or change of data or programs in the memory of the system.

**7.6.4** A "wait" indication is to warn the operator when the system is executing an operation.

## **8 Integrated systems**

### **8.1 General**

**8.1.1** Operation with an integrated system is to be at least as effective as it would be with individual, stand alone equipment.

**8.1.2** Failure of one part (individual module, equipment or subsystem) of the integrated system is not to affect the functionality of other parts, except for those functions directly dependent on information from the defective part.

**8.1.3** A failure in connection between parts, cards connections or cable connections is not to affect the independent functionality of each connected part.

**8.1.4** Alarm messages for essential functions are to have priority over any other information presented on the display.

### **8.2 Inventory of integrated systems components**

**8.2.1** The inventory of integrated systems components is part of the software registry.

**8.2.2** Responsibilities are detailed in [4.5.2].

**8.2.3** The computer based systems mapping is to be recorded. This may be graphically or tables etc. The mapping is to be managed under a formal control management system, and kept secure.

### **8.2.4 Physical inventories**

The list of communicating devices should be included, for example: PLCs, remote I/O, sensors, actuators, variable speed drives, meters, circuit breakers, switches, physical servers, desktops and storage units. For each element, specify:

- name, brand, model or reference (some devices (e.g. modular PLCs) contain several references)
- the version of the embedded firmware (software version) and the product version if appropriate
- physical characteristics, if appropriate
- physical location (building, room, cabinet, bay)
- list of switches connected.

The list of network communication devices should be included, for example, switches, routers and protocol gateways. For each device, specify:

- brand, model and reference
- embedded firmware version
- physical location (building, room, cabinet, bay).

For Ethernet switches, also specify the Virtual Local Area Network (VLAN) numbers for each port.

### **8.2.5 Diagram**

This is a representation of the various geographical locations, showing:

- switches, associated VLAN numbers
- links between devices
- firewall and relevant rules
- passive and active network based cyber security equipment
- for remote connections, interconnection identifiers if any (MultiProtocol Label Switching (MPLS) or Virtual Private LAN Service (VPLS) ...)
- any other relevant devices.

## **9 Expert system**

### **9.1**

**9.1.1** The expert system software is not to be implemented on a computer linked with essential functions.

**9.1.2** Expert system software is not to be used for direct control or operation, and needs human validation by personnel on watch.

## Section 4 Constructional Requirements

### 1 General

#### 1.1 General

1.1.1 Automation systems are to be so constructed as:

- to withstand the environmental conditions, as defined in Ch 2, Sec 2, [1], in which they operate
- to have necessary facilities for maintenance work.

#### 1.2 Materials

1.2.1 Materials are generally to be of the flame-retardant type.

1.2.2 Connectors are to be able to withstand standard vibrations, mechanical constraints and corrosion conditions as given in Ch 3, Sec 6.

#### 1.3 Component design

1.3.1 Automation components are to be designed to simplify maintenance operations. They are to be so constructed as to have:

- easy identification of failures
- easy access to replaceable parts
- easy installation and safe handling in the event of replacement of parts (plug and play principle) without impairing the operational capability of the system, as far as practicable
- facility for adjustment of set points or calibration
- test point facilities, to verify the proper operation of components.

#### 1.4 Environmental and supply conditions

1.4.1 The environmental and supply conditions are specified in Ch 3, Sec 1. Specific environmental conditions are to be considered for air temperature and humidity, vibrations, corrosion from chemicals and mechanical or biological attacks.

## 2 Electrical and/or electronic systems

### 2.1 General

2.1.1 Electrical and electronic equipment is to comply with the requirements of Part C, Chapter 2 and Part C, Chapter 3.

2.1.2 A separation is to be done between any electrical components and liquids, if they are in a same enclosure. Necessary drainage will be provided where liquids are likely to leak.

2.1.3 When plug-in connectors or plug-in elements are used, their contacts are not to be exposed to excessive mechanical loads. They are to be provided with a locking device.

2.1.4 All replaceable parts are to be so arranged that it is not possible to connect them incorrectly or to use incorrect replacements. Where this not practicable, the replacement parts as well as the associated connecting devices are to be clearly identified. In particular, all connection terminals are to be properly tagged. When replacement cannot be carried out with the system on, a warning sign is to be provided.

2.1.5 Forced cooling systems are to be avoided. Where forced cooling is installed, an alarm is to be provided in the event of failure of the cooling system.

2.1.6 The interface connection is to be so designed to receive the cables required. The cables are to be chosen according to Ch 2, Sec 3.

### 2.2 Electronic system

2.2.1 Printed circuit boards are to be so designed that they are properly protected against the normal aggression expected in their environment.

**2.2.2** Electronic systems are to be constructed taking account of electromagnetic interferences.

Special precautions are to be taken for:

- measuring elements such as the analogue amplifier or analog/digital converter; and
- connecting different systems having different ground references.

**2.2.3** The components of electronic systems (printed circuit board, electronic components) are to be clearly identifiable with reference to the relevant documentation.

**2.2.4** Where adjustable set points are available, they are to be readily identifiable and suitable means are to be provided to protect them against changes due to vibrations and uncontrolled access.

**2.2.5** The choice of electronic components is to be made according to the normal environmental conditions, in particular the temperature rating.

**2.2.6** All stages of fabrication of printed circuit boards are to be subjected to quality control. Evidence of this control is to be documented.

**2.2.7** Burn-in tests or equivalent tests are to be performed.

**2.2.8** The programmable components are to be clearly tagged with the program date and reference.

Components are to be protected against outside alteration when loaded.

## **2.3 Electrical system**

**2.3.1** Cables and insulated conductors used for internal wiring are to be at least of the flame-retardant type, and are to comply with the requirements in Part C, Chapter 2.

**2.3.2** If specific products (e.g. oil) are likely to come into contact with wire insulation, the latter is to be resistant to such products or properly shielded from them, and to comply with the requirements in Part C, Chapter 2.

## **3 Pneumatic systems**

### **3.1**

**3.1.1** Pneumatic automation systems are to comply with Ch 1, Sec 10, [17].

**3.1.2** Pneumatic circuits of automation systems are to be independent of any other pneumatic circuit on board.

## **4 Hydraulic systems**

### **4.1**

**4.1.1** Hydraulic automation systems are to comply with Ch 1, Sec 10, [14].

**4.1.2** Suitable filtering devices are to be incorporated into the hydraulic circuits.

**4.1.3** Hydraulic circuits of automation systems are to be independent of any other hydraulic circuit on board.

## **5 Automation consoles**

### **5.1 General**

**5.1.1** Automation consoles are to be designed on ergonomic principles. Handrails are to be fitted for safe operation of the console.

### **5.2 Indicating instruments**

**5.2.1** The operator is to receive feed back information on the effects of his orders.

**5.2.2** Indicating instruments and controls are to be arranged according to the logic of the system in control. In addition, the operating movement and the resulting movement of the indicating instrument are to be consistent with each other.

**5.2.3** The instruments are to be clearly labelled. When installed in the wheelhouse, all lighted instruments of consoles are to be dimmable, where necessary.

### **5.3 VDU's and keyboards**

**5.3.1** VDU's in consoles are to be located so as to be easily readable from the normal position of the operator. The environmental lighting is not to create any reflection which makes reading difficult.

**5.3.2** The keyboard is to be located to give easy access from the normal position of the operator. Special precautions are to be taken to avoid inadvertent operation of the keyboard.

## Section 5 Installation Requirements

### 1 General

#### 1.1

1.1.1 Automation systems are to be installed taking into account:

- the maintenance requirements (test and replacement of systems or components)
- the influence of EMI. The IEC 60533 standard is to be taken as guidance
- the environmental conditions corresponding to the location in accordance with Ch 2, Sec 1 and Ch 2, Sec 3, [6].

1.1.2 Control stations are to be arranged for the convenience of the operator.

1.1.3 Automation components are to be properly fitted. Screws and nuts are to be locked, where necessary.

### 2 Sensors and components

#### 2.1 General

2.1.1 Sensors are to be selected and located such that their output is a realistic measure of the parameter. Sensors are to be installed in places where there is a minimum risk for damage during normal overhaul and maintenance.

2.1.2 The enclosure of the sensor and the cable entry are to be appropriate to the space in which they are located.

2.1.3 Means are to be provided for testing, calibration and replacement of automation components. Such means are to be designed, as far as practicable, so as to avoid perturbation of the normal operation of the system.

2.1.4 A tag number is to identify automation components and is to be clearly marked and attached to the component. These tag numbers are to be collected on the instrument list mentioned in Ch 3, Sec 1, Tab 1.

2.1.5 Electrical connections are to be arranged for easy replacement and testing of sensors and components. They are to be clearly marked.

2.1.6 Low level signal sensors are to be avoided. When installed they are to be located as close as possible to amplifiers, so as to avoid external influences. Failing this, the wiring is to be provided with suitable EMI protection and temperature correction.

#### 2.2 Temperature elements

2.2.1 Temperature sensors, thermostats or thermometers are to be installed in a thermowell of suitable material, to permit easy replacement and functional testing. The thermowell is not to significantly modify the response time of the whole element.

#### 2.3 Pressure elements

2.3.1 Three-way valves or other suitable arrangements are to be installed to permit functional testing of pressure elements, such as pressure sensors, pressure switches, without stopping the installation.

2.3.2 In specific applications, where high pulsations of pressure are likely to occur, a damping element, such as a capillary tube or equivalent, is to be installed.

#### 2.4 Level switches

2.4.1 Level switches fitted to flammable oil tanks, or similar installations, are to be installed so as to reduce the risk of fire.

### 3 Cables

#### 3.1 Installation

3.1.1 Cables are to be installed according to the requirements in Ch 2, Sec 12, [7].

3.1.2 Suitable installation features such as screening and/or twisted pairs and/or separation between signal and other cables are to be provided in order to avoid possible interference on control and instrumentation cables.

**3.1.3** Specific transmission cables (coaxial cables, twisted pairs, etc.) are to be routed in specific cable-ways and mechanically protected to avoid loss of any important transmitted data. Where there is a high risk of mechanical damage, the cables are to be protected with pipes or equivalent.

**3.1.4** The cable bend radius is to be in accordance with the requirements of Ch 2, Sec 12, [7.2].

For mineral insulated cables, coaxial cables or fibre optic cables, whose characteristics may be modified, special precautions are to be taken according to the manufacturer's instructions.

## **3.2 Cable terminations**

**3.2.1** Cable terminations are to be arranged according to the requirements in Part C, Chapter 2. Particular attention is to be paid to the connections of cable shields. Shields are to be connected only at the sensor end when the sensor is earthed, and only at the processor end when the sensor is floating.

**3.2.2** Cable terminations are to be able to withstand the identified environmental conditions (shocks, vibrations, salt mist, humidity, etc.).

**3.2.3** Terminations of all special cables such as mineral insulated cables, coaxial cables or fibre optic cables are to be arranged according to the manufacturer's instructions.

## **4 Pipes**

### **4.1**

**4.1.1** For installation of piping circuits used for automation purposes, see the requirements in Ch 1, Sec 10.

**4.1.2** As far as practicable, piping containing liquids is not to be installed in or adjacent to electrical enclosures (see Ch 3, Sec 4, [2.1.2]).

**4.1.3** Hydraulic and pneumatic piping for automation systems is to be marked to indicate its function.

## **5 Automation consoles**

### **5.1 General**

**5.1.1** Consoles or control panels are to be located so as to enable a good view of the process under control, as far as practicable. Instruments are to be clearly readable in the ambient lighting.

**5.1.2** The location is to be such as to allow easy access for maintenance operations.

# Section 6 Testing

## 1 General

### 1.1 General

**1.1.1** Automation systems are to be tested for type approval, at works and on board, when required. Tests are to be carried out under the supervision of a Surveyor of the Society.

**1.1.2** The type testing conditions for electrical, control and instrumentation equipment, computers and peripherals are described in Article [2].

**1.1.3** Automation systems are to be inspected at works, according to the requirements of Article [3], in order to check that the construction complies with the Rules.

**1.1.4** Automation systems are to be tested when installed on board and prior to sea trials, to verify their performance and adaptation on site, according to Article [4].

## 2 Type approval

### 2.1 General

**2.1.1** The following requirements are applicable, but not confined, to electrical and electronic equipment which are intended to be type approved for control, monitoring, alarm and protection systems for use in ships.

**2.1.2** The necessary documents to be submitted, prior to type testing, are listed in Ch 3, Sec 1, [2.3.1] and Ch 3, Sec 3, [3.1.1]. The type approval of automation systems refers to hardware type approval or software type approval, as applicable.

### 2.2 Hardware type approval

**2.2.1** Hardware type approval of automation systems is obtained subject to the successful outcome of the tests described in Tab 1. These tests are to demonstrate the ability of the equipment to function as intended under the specified test conditions.

**2.2.2** The extent of testing (i.e. selection and sequence of carrying out tests and number of pieces to be tested) is to be determined upon examination and evaluation of the equipment or component subject to testing, giving due regards to its intended usage. Equipment is to be tested in its normal position if otherwise not specified in the test specification.

Vibration and salt mist testing may be performed on different specimens, where applicable.

Reset of the automation system is accepted between each test, where necessary.

Note 1: As used in this Section, and in contrast to a complete performance test, a functional test is a simplified test sufficient to verify that the equipment under test (EUT) has not suffered any deterioration caused by the individual environmental tests.

**2.2.3** The following additional tests may be required, depending on particular manufacturing or operational conditions:

- mechanical endurance test
- temperature shock test (e.g. 12 shocks on exhaust gas temperature sensors from  $20^{\circ}\text{C} \pm 5^{\circ}\text{C}$  to maximum temperature of the range)
- immersion test
- oil resistance test
- shock test.

The test procedure is to be defined with the Society in each case.

### 2.3 Software type approval

**2.3.1** Software of computer based systems are to be approved in accordance with Ch 3, Sec 3.

### 2.4 Loading instruments

**2.4.1** Loading instrument approval consists of:

- approval of hardware according to [2.2], unless two computers are available on board for loading calculations only
- approval of basic software according to [2.3]

- approval of application software, consisting in data verification which results in the Endorsed Test Condition according to Part B
- installation testing according to [4].

**2.5 Oil mist detection system**

**2.5.1** Type test of oil mist detection system are to be carried out according to Ch 3, App 1.

**Table 1 : Type tests**

21	Flame retardant	IEC 60092-101 or IEC 60695-11-5	Flame application: 5 times 15 s each Interval between each application: 15 s or 1 time 30 s	<ul style="list-style-type: none"> <li>the burnt out or damaged part of the specimen by not more than 60mm long</li> <li>no flame, no incandescence or in the event of a flame or incandescence being present, it shall extinguish itself within 30 s of the removal of the needle flame without full combustion of the test specimen</li> <li>any dripping material shall extinguish itself in such a way as not to ignite a wrapping tissue. The drip height is 200 mm ± 5 mm</li> </ul>
<p>(1) Dry heat at 70 °C is to be carried out to automation, control and instrumentation equipment subject to high degree of heat, for example mounted in consoles, housings, etc. together with other heat dissipating power equipment.</p> <p>(2) For equipment installed in non-weather protected locations or cold locations, test is to be carried out at -25°C.</p> <p>(3) Salt mist test is to be carried out for equipment installed in weather exposed areas.</p> <p>(4) Performance criterion B: (for transient phenomena): The Equipment Under Test shall continue to operate as intended after the tests. No degradation of performance or loss of function is allowed as defined in the technical specification published by the Manufacturer. During the test, degradation or loss of function or performance which is self recoverable is however allowed but no change of actual operating state or stored data is allowed.</p> <p>(5) Performance criterion A (for continuous phenomena): The EUT shall continue to operate as intended during and after the test. No degradation of performance or loss of function is allowed as defined in relevant equipment standard and the technical specification published by the Manufacturer.</p> <p>(6) Column 3 indicates the testing procedure which is normally to be applied. However, equivalent testing procedure may be accepted by the Society provided that what is required in the other columns is fulfilled.</p> <p>(7) For equipment installed on the bridge and deck zone, the test levels shall be increased to 10V rms for spot frequencies in accordance with IEC 60945 at 2,3,4,6,2, 8.2, 12.6, 16.5, 18.8, 22, 25 MHz.</p> <p>(8) Figure - Test set-up for Conducted Low Frequency - Refer to IEC Publication 60945 (1996).</p> <div style="text-align: center;"> <p style="text-align: center;">*) Decoupling (optional)</p> </div>				
<p>(9) See [2.2.2], Note 1.</p>				

### 3 Acceptance testing

#### 3.1 General

3.1.1 Acceptance tests are generally to be carried out at the manufacturer’s facilities before the shipment of the equipment, when requested.

Acceptance tests refer to hardware and software tests as applicable.

#### 3.2 Hardware testing

3.2.1 Final acceptance will be granted subject to:

- the results of the tests listed in [3.2.2]
- the type test report or type approval certificate.

**3.2.2** Hardware acceptance tests include, where applicable:

- visual inspection
- operational tests and, in particular:
  - tests of all alarm and safety functions
  - verification of the required performance (range, calibration, repeatability, etc.) for analogue sensors
  - verification of the required performance (range, set points, etc.) for on/off sensors
  - verification of the required performance (range, response time, etc.) for actuators
  - verification of the required performance (full scale, etc.) for indicating instruments
- endurance test (burn-in test or equivalent)
- high voltage test
- hydrostatic tests.

Additional tests may be required by the Society.

**3.3 Software testing**

**3.3.1** Software acceptance tests of computer based systems are to be carried out according to Ch 3, Sec 3.

**4 On board tests**

**4.1 General**

**4.1.1** Testing is to be performed on the completed system comprising actual hardware components with the final application software, in accordance with an approved test program. After test completion, installed versions of computer based systems software are to be recorded inside the Software Registry.

**4.1.2** On board tests are to be carried out on automation systems associated with essential services to verify their compliance with the Rules, by means of visual inspection and the performance and functionality according to Tab 2.

On board testing is to verify that correct functionality has been achieved with all systems integrated.

When completed, automation systems are to be such that a single failure, for example loss of power supply, is not to result in a major degradation of the propulsion or steering of the ship. In addition, a blackout test is to be carried out to show that automation systems are continuously supplied.

Upon completion of on board tests, test reports are to be made available to the Surveyor.

**4.1.3** For wireless data communication equipment, tests during harbour and sea trials are to be conducted to demonstrate that radio-frequency transmission does not cause failure of any equipment and does not itself fail as a result of electromagnetic interference during expected operating conditions.

Note 1: Where electromagnetic interference caused by wireless data communication equipment is found to be causing failure of equipment required for Category II or III systems, the layout and/or equipment are/is to be changed to prevent further failures occurring.

**Table 2 : On board tests**

Equipment	Nature of tests
Electronic equipment	Main hardware and software functionalities with all systems integrated
Analogue sensors	Signal calibration, trip set point adjustment
On/off sensors	Simulation of parameter to verify and record the set points
Actuators	Checking of operation in whole range and performance (response time, pumping)
Reading instruments	Checking of calibration, full scale and standard reference value

# Appendix 1      Type Testing Procedure for Crankcase Oil Mist Detection and Alarm Equipment

## 1 General

### 1.1 Scope

**1.1.1** This Appendix is to specify the tests required to demonstrate that crankcase oil mist detection and alarm equipment intended to be fitted to diesel engines.

Note 1: This test procedure is also applicable to oil mist detection and alarm equipment intended for gear cases.

### 1.2 Reference

**1.2.1** See Ch 3, Sec 6, [2] for test specification for type approval.

### 1.3 Purpose

**1.3.1** The purpose of type testing crankcase oil mist detection and alarm equipment is to verify:

- the functionality of the system
- the effectiveness of the oil mist detectors
- the accuracy of oil mist detectors
- the alarm set points
- time delays between oil mist leaving the source and alarm activation
- functional failure detection
- the influence of optical obscuration on detection.

### 1.4 Test facilities

**1.4.1** Test houses carrying out type testing of crankcase oil mist detection and alarm equipment are to satisfy the following criteria:

- A full range of facilities for carrying out the environmental and functionality tests required by this procedure shall be available and be acceptable to the Society
- The test house that verifies the functionality of the equipment is to be equipped so that it can control, measure and record oil mist concentration levels in terms of mg/l to an accuracy of  $\pm 10\%$  in accordance with this procedure.
- When verifying the functionality, test houses are to consider the possible hazards associated with the generation of the oil mist required and take adequate precautions. The Society will accept the use of low toxicity, low hazard oils as used in other applications, provided it is demonstrated to have similar properties to SAE 40 monograde mineral oil specified.

## 2 Testing

### 2.1 Equipment testing

**2.1.1** The range of tests for the alarm/monitoring panel is to include the following:

- a) functional tests described in [2.2]
- b) electrical power supply failure test
- c) power supply variation test
- d) dry heat test
- e) damp heat test
- f) vibration test
- g) EMC test
- h) insulation resistance test
- i) high voltage test
- j) static and dynamic inclinations, if moving parts are contained.

**2.1.2** The range of tests for the detectors is to include the following:

- a) functional tests described in [2.2]
- b) electrical power supply failure test
- c) power supply variation test
- d) dry heat test
- e) damp heat test
- f) vibration test
- g) EMC test where susceptible
- h) insulation resistance test
- i) high voltage test
- j) static and dynamic inclinations.

## **2.2 Functional tests**

**2.2.1** All tests to verify the functionality of crankcase oil mist detection and alarm equipment are to be carried out in accordance with [2.2.2] to [2.2.7] with an oil mist concentration in air, known in terms of mg/l to an accuracy of  $\pm 10\%$ .

**2.2.2** The concentration of oil mist in the test chamber is to be measured in the top and bottom of the chamber and these concentrations are not to differ by more than 10%. See also [2.4.1], item a).

**2.2.3** The oil mist detector monitoring arrangements are to be capable of detecting oil mist in air concentrations of between 0 and 10% of the lower explosive limit (LEL) or between 0 and a percentage of weight of oil in air determined by the Manufacturer based on the sensor measurement method (e.g. obscuration or light scattering) that is acceptable to the Society taking into account the alarm level specified in [2.2.4].

Note 1: The LEL corresponds to an oil mist concentration of approximately 50 mg/l (~4,1% weight of oil in air mixture).

**2.2.4** The alarm set point for oil mist concentration in air is to provide an alarm at a maximum level corresponding to not more than 5% of the LEL or approximately 2,5 mg/l.

**2.2.5** Where alarm set points can be altered, the means of adjustment and indication of set points are to be verified against the equipment manufacturer's instructions.

**2.2.6** The performance of the oil mist detector in mg/l is to be demonstrated. This is to include the following:

- range (oil mist detector)
- resolution (oil mist detector)
- sensitivity (oil mist detector)

Note 1: Sensitivity of a measuring system: quotient of the change in an indication of a measuring system and the corresponding change in a value of a quantity being measured.

Note 2: Resolution: smallest change in a quantity being measured that causes a perceptible change in the corresponding indication.

**2.2.7** Where oil mist is drawn into a detector via piping arrangements, the time delay between the sample leaving the crankcase and operation of the alarm is to be determined for the longest and shortest lengths of pipes recommended by the manufacturer. The pipe arrangements are to be in accordance with the manufacturer's instructions/recommendations. Piping is to be arranged to prevent pooling of oil condensate which may cause a blockage of the sampling pipe over time.

**2.2.8** It is to be demonstrated that the openings of detector equipment does not become occluded or blocked under continuous splash and spray of engine lubricating oil, as may occur in the crankcase atmosphere. Testing is to be in accordance with arrangements proposed by the manufacturer and agreed by the classification society. The temperature, quantity and angle of impact of the oil to be used is to be declared and their selection justified by the manufacturer.

**2.2.9** Detector equipment may be exposed to water vapour from the crankcase atmosphere which may affect the sensitivity of the equipment and it is to be demonstrated that exposure to such conditions will not affect the functional operation of the detector equipment. Where exposure to water vapour and/or water condensation has been identified as a possible source of equipment malfunctioning, testing is to demonstrate that any mitigating arrangements such as heating are effective. Testing is to be in accordance with arrangements proposed by the manufacturer and agreed by the Society.

Note 1: This testing is in addition to that required by [2.1.2], item e) and is concerned with the effects of condensation caused by the detection equipment being at a lower temperature than the crankcase atmosphere.

**2.2.10** It is to be demonstrated that an indication is given where lenses fitted in the equipment and used in determination of the oil mist level have been partially obscured to a degree that will affect the reliability of the information and alarm indication as required by Ch 1, Sec 2, [2.3.5].

## **2.3 Detectors and alarm equipment to be tested**

**2.3.1** The detectors and alarm equipment selected for the type testing are to be selected from the manufacturer's normal production line by the Surveyor witnessing the tests.

**2.3.2** Two detectors are to be tested. One is to be tested in clean condition and the other in a condition representing the maximum level of lens obscuration specified by the manufacturer.

## **2.4 Method**

**2.4.1** The following requirements for oil mist generation are to be satisfied at type testing:

- a) The ambient temperature in and around the test chamber is to be at the standard atmospheric conditions defined in Ch 3, Sec 6, [2] before any test run is started.
- b) Oil mist is to be generated with suitable equipment using an SAE 40 monograde mineral oil or equivalent and supplied to a test chamber. The selection of the oil to be used is to take into consideration risks to health and safety, and the appropriate controls implemented. A low toxicity, low flammability oil of similar viscosity may be used as an alternative. The oil mist produced is to have an average (or arithmetic mean) droplet size not exceeding 5 µm. The oil droplet size is to be checked using the sedimentation method or an equivalent method to a relevant international or national standard. If the sedimentation method is chosen, the test chamber is to have a minimum height of 1m and a volume of not less than 1m<sup>3</sup>.

Note 1: The calculated oil droplet size using the sedimentation method represents the average droplet size.

- c) The oil mist concentrations used are to be ascertained by the gravimetric deterministic method or equivalent. Where an alternative technique is used its equivalence is to be demonstrated.

Note 2: For this test, the gravimetric deterministic method is a process where the difference in weight of a 0,8 µm pore size membrane filter is ascertained from weighing the filter before and after drawing 1 litre of oil mist through the filter from the oil mist test chamber. The oil mist chamber is to be fitted with a recirculating fan.

- d) Samples of oil mist are to be taken at regular intervals and the results plotted against the oil mist detector output. The oil mist detector is to be located adjacent to where the oil mist samples are drawn off.
- e) The results of a gravimetric analysis are considered invalid and are to be rejected if the resultant calibration curve has an increasing gradient with respect to the oil mist detection reading. This situation occurs when insufficient time has been allowed for the oil mist to become homogeneous. Single results that are more than 10% below the calibration curve are to be rejected. This situation occurs when the integrity of the filter unit has been compromised and not all of the oil is collected on the filter paper.
- f) The filters require to be weighed to a precision of 0,1mg and the volume of air/oil mist sampled to 10 ml.

**2.4.2** For type testing approval by the Society the testing is to be witnessed by authorised personnel from the Society.

**2.4.3** Oil mist detection equipment is to be tested in the orientation (vertical, horizontal or inclined) in which it is intended to be installed on an engine or gear case as specified by the equipment manufacturer.

**2.4.4** Type testing is to be carried out for each type of oil mist detection and alarm equipment for which a manufacturer seeks approval. Where sensitivity levels can be adjusted, testing is to be carried out at the extreme and mid-point level settings.

## **2.5 Assessment**

**2.5.1** Assessment of oil mist detection equipment after testing is to address the following:

- The equipment to be tested is to have evidence of design appraisal/approval.
- Details of the detection equipment to be tested are to be recorded such as name of manufacturer, type designation, oil mist concentration assessment capability and alarm settings, the maximum percentage level of lens obscuration used in [2.3.2].
- After completing the tests, the detection equipment is to be examined and the condition of all components ascertained and documented. Photographic records of the monitoring equipment condition are to be taken and included in the report.

## **2.6 Design series qualification**

**2.6.1** The approval of one type of detection equipment may be used to qualify other devices having identical construction details. Proposals are to be submitted for consideration.

## **2.7 Test report**

**2.7.1** The test house is to provide a full report which includes the following information and documents:

- test specification
- details of equipment tested

- results of tests are to include a declaration by the manufacturer of the oil mist detector of its:
  - performance, in mg/L
  - accuracy, of oil mist concentration in air
  - precision, of oil mist concentration in air
  - range, of oil mist detector
  - resolution, of oil mist detector
  - response time, of oil mist detector
  - sensitivity, of oil mist detector
  - obscuration of sensor detection, declared as percentage of obscuration. 0% totally clean, 100% totally obscure
  - detector failure alarm.

### 2.8 Acceptance

**2.8.1** Acceptance of crankcase oil mist detection equipment is at the discretion of the Society based on the appraisal plans and particulars and the test house report of the results of type testing.

**2.8.2** The following information is to be submitted to the Society for acceptance of oil mist detection equipment and alarm arrangements:

- Description of oil mist detection equipment and system including alarms
- Copy of the test house report identified in [2.7]
- Schematic layout of engine oil mist detection arrangements showing location of detectors/sensors and piping arrangements and dimensions
- Maintenance and test manual which is to include the following information:
  - intended use of equipment and its operation
  - functionality tests to demonstrate that the equipment is operational and that any faults can be identified and corrective actions notified
  - maintenance routines and spare parts recommendations
  - limit setting and instructions for safe limit levels
  - where necessary, details of configurations in which the equipment is and is not to be used.

## Part C

### Machinery, Electricity, Automation and Fire Protection

---

## CHAPTER 4

# FIRE PROTECTION, DETECTION AND EXTINCTION

Section 1	General
Section 2	Prevention of Fire
Section 3	Suppression of Fire: Detection and Alarm
Section 4	Suppression of Fire: Control of Smoke Spread
Section 5	Suppression of Fire: Containment of Fire
Section 6	Suppression of Fire: Fire Fighting
Section 7	Suppression of Fire: Structural Integrity
Section 8	Escape
Section 9	Fire Control Plans
Section 10	Helicopter Facilities
Section 11	Fuel for Auxiliary Vehicles
Section 12	Carriage of Dangerous Goods
Section 13	Protection of Vehicle, Special Category and Ro-ro Spaces
Section 14	Safety Centre on Passenger Ships
Section 15	Fire Safety Systems

# Section 1 General

## 1 Application

### 1.1 General

**1.1.1** This Chapter applies to passenger ships and cargo ships (including tankers) of 500 gross tonnage and upwards, engaged in international voyages. Ships other than those specified above are to comply with the specific Rules of the Society.

Note 1: This Chapter includes requirements of:

- Chapter II-2 of SOLAS 1974 as amended
- International Code of Fire Safety System (FSS Code), as adopted by IMO Maritime Safety Committee by Resolution MSC.98(73), as amended by the following IMO Resolutions: MSC.206(81), MSC.217(82), MSC.292(87), MSC.311(88), MSC.327(90), MSC.339(91), MSC.367(93), MSC.403(96), MSC.410(97), MSC.457(101), MSC.484(103)

### 1.1.2 Alternative design and arrangements

The Society may consider the acceptance of alternatives to the requirements set out in the present Chapter. If deemed necessary, the Society may require engineering analysis, evaluation and approval of the alternative design and arrangement to be carried out in accordance with IMO Circular MSC/Circ.1002, as amended.

### 1.2 National regulations

**1.2.1** When the Administration of the State whose flag the ship is entitled to fly has issued specific rules covering fire protection, the Society may accept such rules for classification purposes in lieu of those given in this Chapter.

In such cases a special notation regarding the above is entered on the Certificate of Class of the ship concerned.

This may apply to cargo ships of less than 500 gross tonnage or to ships not engaged in international voyages.

### 1.3 Applicable requirements depending on ship type

**1.3.1** Unless expressly provided otherwise:

- requirements not referring to a specific ship type are applied to ships of all types
- requirements referring to “passenger ships” are applied to passenger ships as defined in [2.36]
- requirements referring to “cargo ships” are applied to cargo ships as defined in [2.8] and tankers as defined in [2.49].

**1.3.2** Ships having the additional service feature **SPxxx** or **SPxxx-capable** are to comply with the requirements of this chapter, considering the ship:

- as a cargo ship, when xxx is not more than 60
- as a passenger ship carrying not more than 36 passengers, when xxx is not more than 240 but greater than 60
- as a passenger ship carrying more than 36 passengers, when xxx is greater than 240.

### 1.4 Documentation to be submitted

**1.4.1** The interested party is to submit to the Society the documents listed in Tab 1.

**Table 1 : Documentation to be submitted**

No	I/A (1)	Document (2)
1	A	Structural fire protection, showing the method of construction, purpose and category of the various spaces of the ships, the fire rating of bulkheads and decks, means of closings of openings in A and B class divisions, draught stops
2	A	Natural and mechanical ventilation systems showing the penetrations on A class divisions, location of dampers, means of closing, arrangements of air conditioning rooms
3	A	Means of escape and, where required, the relevant dimensioning. Escape route signage
4	A	Automatic fire detection systems and manually operated call points
5	A	Fire pumps and fire main including pumps head and capacity, hydrant and hose locations
6	A	Arrangement of fixed fire-extinguishing systems (2)
7	A	Arrangement of sprinkler or sprinkler equivalent systems including the capacity and head of the pumps (2)
8	A	Fire control plan
9	A	Fixed fire-extinguishing system in scavenge spaces of two-stroke crosshead type engines (see Ch 1, Sec 2, [2.4.1])

No	I/A (1)	Document (2)
10	A	Electrical diagram of the fixed gas fire-extinguishing systems
11	A	Electrical diagram of the sprinkler systems
12	A	Electrical diagram of power control and position indication circuits for fire doors
13	I	General arrangement plan
14	A	When fuel for auxiliary vehicles is intended to be carried onboard (3): <ul style="list-style-type: none"> <li>• Arrangement of the fuel storage and distribution system</li> <li>• Plan of hazardous areas</li> <li>• Diagram of the fuel storage and distribution system</li> <li>• Drawings showing the scantlings, material and arrangement of the fuel storage tank</li> </ul>

(1) A : to be submitted for approval ; I : to be submitted for information

(2) Plans are to be schematic and functional and to contain all information necessary for their correct understanding and verification such as:

- service pressures
- capacity and head of pumps and compressors, if any
- materials and dimensions of piping and associated fittings
- volumes of protected spaces, for gas and foam fire-extinguishing systems
- surface areas of protected zones for automatic sprinkler and pressure water-spraying, low expansion foam and powder fire-extinguishing systems
- capacity, in volume and/or in mass, of vessels or bottles containing the extinguishing media or propelling gases, for gas, automatic sprinkler, foam and powder fire-extinguishing systems
- type, number and location of nozzles of extinguishing media for gas, automatic sprinkler, pressure water-spraying, foam and powder fire-extinguishing systems.

All or part of the information may be provided, instead of on the above plans, in suitable operation manuals or in specifications of the systems.

(3) In the case of a retrofit, the drawings of the systems serving spaces related to fuel for auxiliary vehicles will also have to be submitted. Especially, attention is drawn on the following drawings:

- Diagrams of the bilge, scupper, discharge and drainage systems serving spaces related to the fuel for auxiliary vehicles
- Diagram of drip trays and gutterway draining system serving spaces related to the fuel for auxiliary vehicles
- Natural and mechanical ventilation systems
- Automatic fire detection systems and manually operated call points
- Arrangement of fixed fire-extinguishing systems
- Fire control plan
- Structural fire protection

## 1.5 Type approved products

**1.5.1** The following materials, equipment, systems or products in general used for fire protection are to be type approved by the Society, except for special cases for which the acceptance may be given for individual ships on the basis of suitable documentation or ad hoc tests:

- A, B class fire divisions (bulkheads or decks) and associated openings
- C-class divisions
- Materials for pipes penetrating A or B class divisions (where they are not of steel or other equivalent material)
- Bulkhead or deck penetrations for electrical cables passing through A or B class divisions
- Fire dampers
- Prefabricated sanitary units
- Prefabricated window casings
- Fire door control systems
- Flexible pipes and expansion bellows of non-conventional material for any type of fluid
- Materials with low flame spread characteristic including paints, varnishes and similar, when they are required to have such characteristic
- Non-combustible materials
- Non-readily igniting materials for primary deck coverings
- Fixed foam fire-extinguishing systems and associated foam-forming liquids
- Fixed powder fire-extinguishing systems, including the powder
- Equivalent water-mist fire-extinguishing systems
- Equivalent fixed gas fire-extinguishing systems

- q) Fixed water-based local application fire-extinguishing systems
- r) Equivalent water-mist automatic sprinkler systems
- s) Fixed fire-extinguishing systems for protection of galley cooking equipment
- t) Portable fire-fighting device for stacked containers (according to Pt F, Ch 13, Sec 2, [5.1])
- u) Portable fire-extinguishers
- v) Non-portable and transportable extinguishers
- w) Fire hoses
- x) Portable foam applicators
- y) Water and foam monitor
- z) Foam proportioner/inductor
- aa) Sprinkler heads for automatic sprinkler systems
- ab) Nozzles for fixed pressure water-spraying fire-extinguishing systems for machinery spaces, boiler rooms, deep fat cooking equipment fire-extinguishing systems, and spaces intended for the carriage of vehicles and for hangars
- ac) Sensing heads for automatic fire alarm and fire detection systems
- ad) Fixed fire detection and fire alarm systems
- ae) Flammable gas detection system
- af) Explosive mixture detecting systems
- ag) Portable explosive mixture detecting apparatus
- ah) Fixed instruments for measuring the oxygen content for inert gas systems serving cargo tanks
- ai) Portable instruments for measuring the oxygen content for inert gas systems serving cargo tanks
- aj) Upholstered furniture, excluding the frame (for spaces defined in [2.38])
- ak) Textile and non-textile materials suspended vertically, for example curtains (for spaces defined in [2.38])
- al) Bedding components (for spaces defined in [2.38])
- am) Low location lighting systems
- an) Inert gas systems serving cargo tank.

As regards the granting of type approval, the requirements of Part A apply.

The Society may request type approval for other materials, equipment, systems or products required by the applicable provisions for ships or installations of special types.

## 2 Definitions

### 2.1 A class divisions

**2.1.1** "A" class divisions are those divisions formed by bulkheads and decks which comply with the following criteria:

- a) they are constructed of steel or other equivalent material
- b) they are suitably stiffened
- c) they are insulated with approved non-combustible materials such that the average temperature of the unexposed side will not rise more than 140°C above the original temperature, nor will the temperature, at any one point, including any joint, rise more than 180°C above the original temperature, within the time listed below:
  - class "A-60" : 60 minutes
  - class "A-30" : 30 minutes
  - class "A-15" : 15 minutes
  - class "A-0" : 0 minutes
- d) they are so constructed as to be capable of preventing the passage of smoke and flame to the end of the one-hour standard fire test; and
- e) the Society required a test of a prototype bulkhead or deck in accordance with the Fire Test Procedures Code (see [2.21]) to ensure that it meets the above requirements for integrity and temperature rise.

**2.1.2** The products indicated in Tab 2 may be installed without testing or approval.

Table 2 : Products installed without testing or approval

Classification	Product description
Class A-0 bulkhead	A steel bulkhead with dimensions not less than the minimum dimensions given below: <ul style="list-style-type: none"> <li>• thickness of plating: 4 mm</li> <li>• stiffeners 60 x 60 x 5 mm spaced at 600 mm or structural equivalent</li> </ul>
Class A-0 deck	A steel deck with dimensions not less than the minimum dimensions given below: <ul style="list-style-type: none"> <li>• thickness of plating: 4 mm</li> <li>• stiffeners 95 x 65 x 7 mm spaced at 600 mm or structural equivalent</li> </ul>

## 2.2 Accommodation spaces

**2.2.1** Accommodation spaces are those spaces used for public spaces, corridors, stairs, lavatories, cabins, offices, hospitals, cinemas, games and hobbies rooms, barber shops, pantries containing no cooking appliances and similar spaces.

**2.2.2** Pantries or isolated pantries containing no cooking appliances may contain:

- toasters, microwave ovens, induction heaters and similar appliances each of them with a maximum power of 5 kW; and
- electrically heated cooking plates and hot plates for keeping food warm each of them with a maximum power of 2 kW and a surface temperature not above 150°C.

These pantries may also contain coffee machines, dish washers and water boilers with no exposed hot surfaces regardless of their power. A dining room containing such appliances should not be regarded as a pantry.

## 2.3 Atriums

**2.3.1** Atriums are public spaces within a single main vertical zone spanning three or more open decks.

## 2.4 B class divisions

**2.4.1** "B" class divisions are those divisions formed by bulkheads, decks, ceilings or linings which comply with the following criteria:

- they are constructed of approved non-combustible materials and all materials used in the construction and erection of "B" class divisions are non-combustible, with the exception that combustible veneers may be permitted provided they meet other appropriate requirements of this Chapter
- they have an insulation value such that the average temperature of the unexposed side will not rise more than 140°C above the original temperature, nor will the temperature at any one point, including any joint, rise more than 225°C above the original temperature, within the time listed below:
  - class "B-15" : 15 minutes
  - class "B-0" : 0 minutes
- they are so constructed as to be capable of preventing the passage of flame to the end of the first half hour of the standard fire test; and
- the Society required a test of a prototype division in accordance with the Fire Test Procedures Code (see [2.21]) to ensure that it meets the above requirements for integrity and temperature rise.

**2.4.2** In order to be defined as B class, a metal division is to have plating thickness not less than 2 mm when constructed of steel.

## 2.5 Bulkhead decks

**2.5.1** The bulkhead deck is the uppermost deck up to which the transverse watertight bulkheads are carried.

## 2.6 C class divisions

**2.6.1** "C" class divisions are divisions constructed of approved non-combustible materials. They need meet neither requirements relative to the passage of smoke and flame nor limitations relative to the temperature rise. Combustible veneers are permitted provided they meet the requirements of this Chapter.

## 2.7 Cabin balconies

**2.7.1** Cabin balcony is an open deck which is provided for the exclusive use of the occupants of a single cabin and has direct access from such a cabin.

## 2.8 Cargo ship

**2.8.1** Cargo ship is any ship which is not a passenger ship.

## **2.9 Cargo spaces**

**2.9.1** *Cargo spaces are spaces used for cargo, cargo oil tanks, tanks for other liquid cargo and trunks to such spaces.*

## **2.10 Central control station**

**2.10.1** *The central control station is a control station in which the following control and indicator functions are centralized:*

- a) fixed fire detection and fire alarm systems*
- b) automatic sprinkler, fire detection and fire alarm systems*
- c) fire door indicator panels*
- d) fire door closures*
- e) watertight door indicator panels*
- f) watertight door closures*
- g) ventilation fans*
- h) general/fire alarms*
- i) communication systems including telephones; and*

*Note 1: The communication systems referred to are only those required by this Chapter.*

- j) microphones to public address systems.*

## **2.11 Chemical tankers**

**2.11.1** *A chemical tanker is a cargo ship constructed or adapted and used for the carriage in bulk of any liquid product of a flammable nature listed in Pt D, Ch 8, Sec 17.*

## **2.12 Closed ro-ro spaces**

**2.12.1** *Closed ro-ro spaces are ro-ro spaces which are neither open ro-ro spaces nor weather decks.*

## **2.13 Closed vehicle spaces**

**2.13.1** *Closed vehicle spaces are vehicle spaces which are neither open vehicle spaces nor weather decks.*

## **2.14 Combination carriers**

**2.14.1** *A combination carrier is a cargo ship designed to carry both oil and solid cargoes in bulk.*

## **2.15 Continuous B class ceilings or linings**

**2.15.1** *Continuous "B" class ceilings or linings are those "B" class ceilings or linings which terminate at an "A" or "B" class division.*

## **2.16 Continuously manned central control stations**

**2.16.1** *A continuously manned central control station is a central control station which is continuously manned by a responsible member of the crew.*

## **2.17 Control stations**

**2.17.1** *Control stations are those spaces in which the ship's radio or main navigating equipment or the emergency source of power is located or where the fire recording or fire control equipment is centralized.*

Any other spaces containing a centralized server used for the navigation and safety systems of the vessel (e.g. a data centre) are to be considered as control stations.

## **2.18 Dangerous goods**

**2.18.1** Dangerous goods are those goods belonging to the following classes:

- class 1 - Explosives
- class 2 - Gases: compressed, liquefied or dissolved under pressure
- class 3 - Flammable liquids
- class 4.1 - Flammable solids
- class 4.2 - Substances liable to spontaneous combustion
- class 4.3 - Substances which, in contact with water, emit flammable gases
- class 5.1 - Oxidising substances
- class 5.2 - Organic peroxides
- class 6.1 - Poisonous (toxic) substances
- class 6.2 - Infectious substances
- class 7 - Radioactive materials
- class 8 - Corrosives
- class 9 - Miscellaneous dangerous substances (that is any other substance which experience has shown, or may show, to be of such a dangerous character that the provisions of Part A, Chapter VII of SOLAS Convention are to be applied).

## **2.19 Deadweight**

**2.19.1** *The deadweight is the difference in tonnes between the displacement of a ship in water of a specific gravity of 1,025 at the load waterline corresponding to the assigned summer freeboard and the lightweight of the ship.*

## **2.20 Fire damper**

**2.20.1** *Fire damper is a device installed in a ventilation duct, which under normal conditions remains open allowing flow in the duct, and is closed during a fire, preventing the flow in the duct to restrict the passage of fire. In using the above definition the following terms may be associated:*

- a) *automatic fire damper is a fire damper that closes independently in response to exposure to fire products*
- b) *manual fire damper is a fire damper that is intended to be opened or closed by the crew by hand at the damper itself; and*
- c) *remotely operated fire damper is a fire damper that is closed by the crew through a control located at a distance away from the controlled damper.*

## **2.21 Fire Test Procedures Code**

**2.21.1** *Fire Test Procedures Code means the "International Code for Application of Fire Test Procedures, 2010" (2010 FTP Code), as adopted by the Maritime Safety Committee of the IMO by Resolution MSC.307 (88), as may be amended by the IMO.*

## **2.22 Gas carriers**

**2.22.1** *A gas carrier is a cargo ship constructed or adapted and used for the carriage in bulk of any liquefied gas or other products of a flammable nature listed in Pt D, Ch 9, Sec 19.*

## **2.23 Helicopter facility**

**2.23.1** *Helicopter facility is a helideck including any refuelling and hangar facilities.*

## **2.24 Helicopter landing area**

**2.24.1** *Helicopter landing area is an area on a ship designated for occasional or emergency landing of helicopters but not designed for routine helicopter operations.*

## **2.25 Helideck**

**2.25.1** *Helideck is a purpose-built helicopter landing area located on a ship including all structure, fire-fighting appliances and other equipment necessary for the safe operation of helicopters.*

## **2.26 Lightweight**

**2.26.1** *The lightweight is the displacement of a ship, in tonnes, without cargo, fuel, lubricating oil, ballast water, fresh water and feed water in tanks, consumable stores and passengers and crew and their effects, but including liquids in piping and mediums required for the fixed fire-fighting systems (e.g. fresh water, CO<sub>2</sub>, dry chemical powder, foam concentrate, etc.).*

## **2.27 Low flame-spread**

**2.27.1** A low flame-spread means that the surface thus described will adequately restrict the spread of flame, this being determined in accordance with the Fire Test Procedures Code.

**2.27.2** Non-combustible materials are considered as low flame spread. However, due consideration will be given by the Society to the method of application and fixing.

## **2.28 Machinery spaces**

**2.28.1** Machinery spaces are machinery spaces of category A and other spaces containing propulsion machinery, boilers, oil fuel units, steam and internal combustion engines, generators and major electrical machinery, oil filling stations, refrigerating, stabilizing, ventilation and air conditioning machinery, and similar spaces, and trunks to such spaces.

## **2.29 Machinery spaces of category A**

**2.29.1** Machinery spaces of category A are those spaces and trunks to such spaces which contain either:

- a) internal combustion machinery used for main propulsion
- b) internal combustion machinery used for purposes other than main propulsion where such machinery has in the aggregate a total power output of not less than 375 kW; or
- c) any oil-fired boiler or oil fuel unit, or any oil-fired equipment other than boilers, such as inert gas generators, incinerators, etc.

## **2.30 Main vertical zones**

**2.30.1** Main vertical zones are those sections into which the hull, superstructure and deckhouses are divided by "A" class divisions, the mean length and width of which on any deck does not in general exceed 40 m.

## **2.31 Non-combustible material**

**2.31.1** Non-combustible material is a material which neither burns nor gives off flammable vapours in sufficient quantity for self-ignition when heated to approximately 750°C, this being determined in accordance with the Fire Test Procedures Code. Any other material is a combustible material.

**2.31.2** In general, products made only of glass, concrete, ceramic products, natural stone, masonry units, common metals and metal alloys are considered as being non-combustible and may be installed without testing and approval.

## **2.32 Non-sparking fan**

**2.32.1** A fan is considered as non-sparking if in either normal or abnormal conditions it is unlikely to produce sparks. For this purpose, the following criteria are to be met:

- a) Design criteria
  - 1) The air gap between the impeller and the casing is to be not less than 1/10 of the shaft diameter in way of the impeller bearing and in any case not less than 2 mm, but need not exceed 13 mm.
  - 2) Protective screens with square mesh of not more than 13 mm are to be fitted to the inlet and outlet of ventilation ducts to prevent objects entering the fan housing.
- b) Materials
  - 1) The impeller and the housing in way of the impeller are to be made of spark-proof materials which are recognised as such by means of an appropriate test to the satisfaction of the Society.
  - 2) Electrostatic charges, both in the rotating body and the casing, are to be prevented by the use of antistatic materials. Furthermore, the installation on board of ventilation units is to be such as to ensure their safe bonding to the hull.
  - 3) Tests may not be required for fans having the following material combinations:
    - impellers and/or housings of non-metallic material, due regard being paid to the elimination of static electricity
    - impellers and housings of non-ferrous materials
    - impellers of aluminium alloys or magnesium alloys and a ferrous (including austenitic stainless steel) housing on which a ring of suitable thickness of non-ferrous material is fitted in way of the impeller
    - any combination of ferrous (including austenitic stainless steel) impellers and housings with not less than 13 mm design tip clearance.

- 4) The following impeller and housing combinations are considered as sparking and therefore are not permitted:
- impellers of an aluminium alloy or a magnesium alloy and a ferrous housing, regardless of tip clearance
  - housings made of an aluminium alloy or a magnesium alloy and a ferrous impeller, regardless of tip clearance
  - any combination of ferrous impeller and housing with less than 13 mm design tip clearance.
- 5) Complete fans are to be type-tested in accordance with either the Society's requirements or national or international standards accepted by the Society.

### **2.33 Oil fuel unit**

**2.33.1** *The oil fuel unit is the equipment used for the preparation of oil fuel for delivery to an oil-fired boiler, or equipment used for the preparation for delivery of heated oil to an internal combustion engine, and includes any oil pressure pumps, filters and heaters dealing with oil at a pressure of more than 0,18 MPa.*

**2.33.2** Oil fuel unit includes any equipment used for the preparation and delivery of oil fuel, heated or not, to boilers (including inert gas generators) and engines (including gas turbines) at a pressure of more than 0,18 N/mm<sup>2</sup>. Oil fuel transfer pumps are not considered as oil fuel units.

### **2.34 Open ro-ro spaces**

**2.34.1** *Open ro-ro spaces are those ro-ro spaces which are either open at both ends or have an opening at one end, and are provided with adequate natural ventilation effective over their entire length through permanent openings distributed in the side plating or deckhead or from above, having a total area of at least 10% of the total area of the space sides.*

### **2.35 Open vehicle spaces**

**2.35.1** *Open vehicle spaces are those vehicle spaces which are either open at both ends or have an opening at one end and are provided with adequate natural ventilation effective over their entire length through permanent openings distributed in the side plating or deckhead or from above, having a total area of at least 10% of the total area of the space sides.*

### **2.36 Passenger ship**

**2.36.1** *Passenger ship is a ship which carries more than twelve passengers*

### **2.37 Public spaces**

**2.37.1** *Public spaces are those portions of the accommodation which are used for halls, dining rooms, lounges and similar permanently enclosed spaces.*

### **2.38 Rooms containing furniture and furnishings of restricted fire risk**

**2.38.1** *Rooms containing furniture and furnishings of restricted fire risk, for the purpose of Ch 4, Sec 5, [1.3.3], are those rooms containing furniture and furnishings of restricted fire risk (whether cabins, public spaces, offices or other types of accommodation) in which:*

- case furniture such as desks, wardrobes, dressing tables, bureaux, or dressers are constructed entirely of approved non-combustible materials, except that a combustible veneer not exceeding 2 mm may be used on the working surface of such articles*
- free-standing furniture such as chairs, sofas, or tables are constructed with frames of non-combustible materials*
- draperies, curtains and other suspended textile materials have qualities of resistance to the propagation of flame not inferior to those of wool having a mass of 0,8 kg/m<sup>2</sup>, this being determined in accordance with the Fire Test Procedures Code (see [2.21])*
- floor coverings have low flame-spread characteristics;*
- exposed surfaces of bulkheads, linings and ceilings have low flame-spread characteristics*
- upholstered furniture has qualities of resistance to the ignition and propagation of flame, this being determined in accordance with the Fire Test Procedures Code (see [2.21]), and*
- bedding components have qualities of resistance to the ignition and propagation of flame, this being determined in accordance with the Fire Test Procedures Code (see [2.21]).*

### **2.39 Ro-ro passenger ship**

**2.39.1** *Ro-ro passenger ship means a passenger ship with ro-ro spaces or special category spaces as defined in [2.46].*

## 2.40 Ro-ro spaces

**2.40.1** *Ro-ro spaces are spaces not normally subdivided in any way and normally extending to either a substantial length or the entire length of the ship in which motor vehicles with fuel in their tanks for their own propulsion and/or goods (packaged or in bulk, in or on rail or road cars, vehicles (including road or rail tankers), trailers, containers, pallets, demountable tanks or in or on similar stowage units or other receptacles) can be loaded and unloaded normally in a horizontal direction.*

## 2.41 Safety centre

**2.41.1** *Safety centre is a control station dedicated to the management of emergency situations. Safety systems' operation, control and/or monitoring are an integral part of the safety centre.*

## 2.42 Sauna

**2.42.1** *Sauna is a hot room with temperatures normally varying between 80°C and 120°C where the heat is provided by a hot surface (e.g. by an electrically heated oven). The hot room may also include the space where the oven is located and adjacent bathrooms.*

## 2.43 Semi-enclosed space

**2.43.1** *A semi-enclosed space is a space limited by decks and/or bulkheads in such a manner that the natural conditions of ventilation in the space are notably different from those obtained on open deck.*

## 2.44 Service spaces

**2.44.1** *Service spaces are those spaces used for galleys, pantries containing cooking appliances, lockers, mail and specie rooms, store-rooms, workshops other than those forming part of the machinery spaces, and similar spaces and trunks to such spaces.*

### 2.44.2

- a) Main pantries and pantries containing cooking appliances may contain:
- 1) toasters, microwave ovens, induction heaters and similar appliances, each of them with a power of more than 5 kW; and
  - 2) electrically heated cooking plates and hot plates for keeping food warm, each of them with a maximum power of 5 kW.
- These pantries may also contain coffee machines, dish washers and water boilers, regardless of their power.
- b) Spaces containing any electrically heated cooking plate or hot plate for keeping food warm with a power of more than 5 kW are to be regarded, for the purpose of Ch 4, Sec 5, as galleys.

## 2.45 Smoke damper

**2.45.1** *Smoke damper is a device installed in a ventilation duct, which under normal conditions remains open allowing flow in the duct, and is closed during a fire, preventing the flow in the duct to restrict the passage of smoke and hot gases. A smoke damper is not expected to contribute to the integrity of a fire rated division penetrated by a ventilation duct. In using the above definition the following terms may be associated:*

- a) *automatic smoke damper is a smoke damper that closes independently in response to exposure to smoke or hot gases;*
- b) *manual smoke damper is a smoke damper intended to be opened or closed by the crew by hand at the damper itself; and*
- c) *remotely operated smoke damper is a smoke damper that is closed by the crew through a control located at a distance away from the controlled damper.*

## 2.46 Special category spaces

**2.46.1** *Special category spaces are those enclosed vehicle spaces above and below the bulkhead deck, into and from which vehicles can be driven and to which passengers have access. Special category spaces may be accommodated on more than one deck provided that the total overall clear height for vehicles does not exceed 10 m.*

## 2.47 Standard fire test

**2.47.1** *A standard fire test is a test in which specimens of the relevant bulkheads or decks are exposed in a test furnace to temperatures corresponding approximately to the standard time-temperature curve in accordance with the test method specified in the Fire Test Procedures Code (see [2.21]).*

## 2.48 Steel or other equivalent material

**2.48.1** *Steel or other equivalent material means any non-combustible material which, by itself or due to insulation provided, has structural and integrity properties equivalent to steel at the end of the applicable exposure to the standard fire test (e.g., aluminium alloy with appropriate insulation).*

## **2.49 Tanker**

**2.49.1** *Tanker is a cargo ship constructed or adapted for the carriage in bulk of liquid cargoes of an inflammable nature.*

Note 1: For the purpose of this Chapter, the term tanker includes the following service notations (see Pt A, Ch 1, Sec 2, Tab 1): **chemical tanker, combination carrier/OBO, combination carrier/OOC, oil tanker, FLS tanker, oil recovery or liquefied gas carrier.**

## **2.50 Vehicle carrier**

**2.50.1** *Vehicle carrier means a cargo ship which only carries cargo in ro-ro spaces or vehicle spaces, and which is designed for the carriage of unoccupied motor vehicles without cargo, as cargo.*

## **2.51 Vehicle spaces**

**2.51.1** *Vehicle spaces are cargo spaces intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion, including special category spaces.*

## **2.52 Weather decks**

**2.52.1** *Weather deck is a deck which is completely exposed to the weather from above and from at least two sides.*

## **2.53 Winching area**

**2.53.1** *Winching area is a pick-up area provided for the transfer by helicopter of personnel or stores to or from the ship, while the helicopter hovers above the deck.*

## Section 2 Prevention of Fire

### 1 Probability of ignition

#### 1.1 Arrangements for fuel oil, lubrication oil and other flammable oils

##### 1.1.1 Limitation in the use of oils as fuel

See Ch 1, Sec 1, [2.9].

##### 1.1.2 Arrangements for fuel oil

See Ch 1, Sec 10.

##### 1.1.3 Arrangements for lubricating oil

See Ch 1, Sec 10.

##### 1.1.4 Arrangements for other flammable oils

See Ch 1, Sec 10.

#### 1.2 Arrangements for gaseous fuel for domestic purposes

**1.2.1** *Where gaseous fuel is used for domestic purposes the arrangements for the storage, distribution and utilisation of the fuel shall be such that, having regard to the hazards of fire and explosion which the use of such fuel may entail, the safety of the ship and the persons on board is preserved.*

See also Ch 1, Sec 10.

**1.2.2** Gaseous fuel systems may only be considered for cargo ships.

**1.2.3** *Storage of the gas bottles is to be located on the open deck or in a well ventilated space which opens only to the open deck.*

#### 1.3 Miscellaneous items of ignition sources and ignitability

##### 1.3.1 Electric radiators

*Electric radiators, if used, shall be fixed in position and so constructed as to reduce fire risks to a minimum. No such radiators shall be fitted with an element so exposed that clothing, curtains, or other similar materials can be scorched or set on fire by heat from the element.*

##### 1.3.2 Cellulose-nitrate based films

*Cellulose-nitrate based films shall not be used for cinematograph installations.*

##### 1.3.3 Waste receptacles

*In principle, all waste receptacles shall be constructed of non-combustible materials with no openings in the sides or bottom.*

##### 1.3.4 Insulation surfaces against oil penetration

*In spaces where penetration of oil products is possible, the surface of insulation shall be impervious to oil or oil vapours.*

##### 1.3.5 Primary deck coverings

*Primary deck coverings, if applied within accommodation and service spaces and control stations or if applied on cabin balconies of passenger ships, shall be of approved material which will not readily ignite, this being determined in accordance with the Fire Test Procedures Code (see Ch 4, Sec 1, [2.21]).*

### 2 Fire growth potential

#### 2.1 Control of air supply and flammable liquid to the space

##### 2.1.1 Closing appliances and stopping devices of ventilation

*a) The main inlets and outlets of all ventilation systems shall be capable of being closed from outside the spaces being ventilated. The means of closing shall be easily accessible as well as prominently and permanently marked and shall indicate whether the shut-off is open or closed.*

Ventilation inlets and outlets located at outside boundaries are to be fitted with closing appliances as required above and need not comply with Ch 4, Sec 5, [6.4.1].

- b) *Power ventilation of accommodation spaces, service spaces, cargo spaces, control stations and machinery spaces shall be capable of being stopped from an easily accessible position outside the space being served. This position shall not be readily cut off in the event of a fire in the spaces served.*

These requirements do not apply to closed recirculating systems within a single space.

- c) *In passenger ships carrying more than 36 passengers, all power ventilation, except machinery space and cargo space ventilation and any alternative system which may be required under Ch 4, Sec 4, [2.1.1], shall be fitted with controls so grouped that all fans may be stopped from either of two separate positions which shall be situated as far apart as practicable. Fans serving power ventilation systems to cargo spaces shall be capable of being stopped from a safe position outside such spaces.*

### **2.1.2 Means of control in machinery spaces**

- a) *Means of control shall be provided for opening and closure of skylights, closure of openings in funnels which normally allow exhaust ventilation and closure of ventilator dampers.*

The controls of ventilation fans and fire dampers serving engine rooms should also comply with Ch 4, Sec 15, [8.2.1], Note 1.

- b) *Means of control shall be provided for stopping ventilating fans. Controls provided for the power ventilation serving machinery spaces shall be grouped so as to be operable from two positions, one of which shall be outside such spaces. The means provided for stopping the power ventilation of the machinery spaces shall be entirely separate from the means provided for stopping ventilation of other spaces.*

- c) *Means of control shall be provided for stopping forced and induced draught fans, oil fuel transfer pumps, oil fuel unit pumps, lubricating oil service pumps, thermal oil circulating pumps and oil separators (purifiers). However, items d) and e) hereafter need not apply to oily water separators.*

- d) *The controls required in a) to c) above shall be located outside the space concerned so they will not be cut off in the event of fire in the space they serve.*

In machinery spaces of category A, controls to close off ventilation ducts and pipes are to be installed with due regard to the hot gases produced by a fire in the space concerned.

- e) *In passenger ships, the controls required in items a) to d) above and in Ch 4, Sec 4, [3.2.1] and Ch 4, Sec 5, [4.2.2] and the controls for any required fire-extinguishing system shall be situated at one control position or grouped in as few positions as possible to the satisfaction of the Society. Such positions shall have a safe access from the open deck.*

### **2.1.3 Closing appliances in emergency generator rooms**

The following requirements apply to closable ventilation louvers and ventilator closing appliances serving emergency generator rooms, where fitted:

- a) *Ventilation louvers and closing appliances may either be hand-operated or power-operated (hydraulic/pneumatic/electric) and are to be operable under a fire condition.*
- b) *Hand-operated ventilation louvers and closing appliances are to be kept open during normal operation of the vessel. Corresponding instruction plates are to be provided at the location where hand-operation is provided.*
- c) *Power-operated ventilation louvers and closing appliances shall be of a fail-to-open type. Closed power-operated ventilation louvers and closing appliances are acceptable during normal operation of the vessel. Power-operated ventilation louvers and closing appliances shall open automatically whenever the emergency generator is starting/in operation.*
- d) *It shall be possible to close ventilation openings by a manual operation from a clearly marked safe position outside the space where the closing operation can be easily confirmed. The louver status (open/closed) shall be indicated at this position. Such closing shall not be possible from any other remote position.*

Note 1: See also the requirements of Pt B, Ch 11, Sec 12, [9.1] regarding closing appliances for ventilation systems.

## **2.2 Fire protection materials**

### **2.2.1 Use of non-combustible materials**

- a) *Insulating materials*

*Insulating materials shall be non-combustible, except in cargo spaces, mail rooms, baggage rooms and refrigerated compartments of service spaces. Vapour barriers and adhesives used in conjunction with insulation, as well as insulation of pipe fittings for cold service systems, need not be of non-combustible materials, but they shall be kept to the minimum quantity practicable and their exposed surfaces shall have low flame-spread characteristics.*

Cold service means refrigeration systems and chilled water piping for air conditioning systems.

- b) *Ceilings and linings*

1) *Item 2 below applies to passenger ships and item 3 applies to cargo ships.*

2) *Except in cargo spaces, all linings, grounds, draught stops and ceilings shall be of non-combustible materials except in mail rooms, baggage rooms, saunas or refrigerated compartments of service spaces.*

- 3) *All linings, ceilings, draught stops and their associated grounds shall be of non-combustible materials:*
  - *in accommodation and service spaces and control stations for ships where method IC is specified as referred to in Ch 4, Sec 5, [1.4.1]; and*
  - *in corridors and stairway enclosures serving accommodation and service spaces and control stations for ships where methods IIC or IIIC are specified as referred to in Ch 4, Sec 5, [1.4.1].*
- c) *Partial bulkheads and decks on passenger ships*
  - 1) *Partial bulkheads or decks used to subdivide a space for utility or artistic treatment shall be of non-combustible materials.*
  - 2) *Linings, ceilings and partial bulkheads or decks used to screen or to separate adjacent cabin balconies shall be of non-combustible materials.*

### **2.2.2 Use of combustible materials**

#### a) *General*

- 1) *Item 2) below applies to passenger ships and item 3) applies to cargo ships.*
- 2) *“A”, “B” or “C” class divisions in accommodation and service spaces and cabin balconies which are faced with combustible materials, facings, mouldings, decorations and veneers shall comply with the provisions of b) to d) below and Article [3]. However, the provisions of c) need not apply to cabin balconies.*
- 3) *Non-combustible bulkheads, ceilings and linings fitted in accommodation and service spaces may be faced with combustible materials, facings, mouldings, decorations and veneers provided such spaces are bounded by non-combustible bulkheads, ceilings and linings in accordance with the provisions of b) to d) below and article [3].*

#### b) *Maximum calorific value of combustible materials*

*Combustible materials used on the surfaces and linings specified in item a) shall have a calorific value (see Note 1) not exceeding 45 MJ/m<sup>2</sup> of the area for the thickness used. The requirements of this paragraph are not applicable to the surfaces of furniture fixed to linings or bulkheads.*

#### c) *Total volume of combustible materials*

*Where combustible materials are used in accordance with the previous item a), the total volume of combustible facings, mouldings, decorations and veneers in accommodation and service spaces shall not exceed a volume equivalent to 2,5 mm veneer on the combined area of the walls and ceiling linings. Furniture fixed to linings, bulkheads or decks need not be included in the calculation of the total volume of combustible materials.*

#### d) *Low flame-spread characteristics of exposed surface in passenger ships*

*The following surfaces shall have low flame-spread characteristics in accordance with the Fire Test Procedures Code:*

- 1) *exposed surfaces in corridors and stairway enclosures and of bulkhead and ceiling linings in accommodation and service spaces (except saunas) and control station*
- 2) *surfaces and grounds in concealed or inaccessible spaces in accommodation and services spaces and control stations*
- 3) *exposed surfaces of cabin balconies, except for natural wood decking systems.*

#### e) *Low flame spread characteristics of exposed surface in cargo ships*

*The following surfaces shall have low flame spread characteristics in accordance with the Fire Test Procedures Code:*

- 1) *exposed surfaces in corridors and stairway enclosures and of ceilings in accommodation and service spaces (except saunas) and control stations; and*
- 2) *surfaces and grounds in concealed or inaccessible spaces in accommodation and service spaces and control stations.*

*Note 1: The gross calorific value measured in accordance with ISO Standard 1716 “Building Materials - Determination of Calorific Potential” should be quoted.*

### **2.2.3 Furniture in stairway enclosures**

#### a) *[2.2.3] applies to passenger ships.*

- b) *Furniture in stairway enclosures shall be limited to seating. It shall be fixed, limited to six seats on each deck in each stairway enclosure, be of restricted fire risk determined in accordance with the Fire Test Procedures Code, and shall not restrict the passenger escape route. The Society may permit additional seating in the main reception area within a stairway enclosure if it is fixed, non-combustible and does not restrict the passenger escape route. Furniture shall not be permitted in passenger and crew corridors forming escape routes in cabin areas. In addition to the above, lockers of non-combustible material, providing storage for non-hazardous safety equipment required by these regulations, may be permitted.*

*Drinking water dispensers and ice cube machines may be permitted in corridors provided they are fixed and do not restrict the width of the escape routes. This applies as well to decorative flower or plant arrangements, statues or other objects of art such as paintings and tapestries in corridors and stairways*

### **2.2.4 Furniture and furnishings on cabin balconies of passenger ships**

*On passenger ships, furniture and furnishings shall comply with Ch 4, Sec 1, [2.38.1], items a), b), c), f) and g) unless such balconies are protected by a fixed pressure water-spraying and fixed fire detection and alarm systems complying with Ch 4, Sec 3, [4.6] and Ch 4, Sec 6, [5.1.3].*

### **3 Smoke generation potential and toxicity**

#### **3.1 Paints, varnishes and other finishes**

**3.1.1** *Paints, varnishes and other finishes used on exposed interior surfaces shall not be capable of producing excessive quantities of smoke and toxic products, this being determined in accordance with the Fire Test Procedures Code.*

**3.1.2** This requirement only applies to accommodation spaces, service spaces and control stations as well as stairway enclosures.

**3.1.3** *On passenger ships, paints, varnishes and other finishes used on exposed surfaces of cabin balconies shall not be capable of producing excessive quantities of smoke and toxic products, this being determined in accordance with the Fire Test Procedures Code.*

#### **3.2 Primary deck coverings**

**3.2.1** *Primary deck coverings, if applied within accommodation and service spaces and control stations, shall be of approved material which will not give rise to smoke or toxic or explosive hazards at elevated temperatures, this being determined in accordance to the Fire Test Procedures Code.*

**3.2.2** *On passenger ships, primary deck coverings on cabin balconies shall be of approved material which will not give rise to smoke or toxic or explosive hazards at elevated temperatures, this being determined in accordance to the Fire Test Procedures Code.*

## Section 3                      Suppression of Fire: Detection and Alarm

### 1 General

#### 1.1 Passenger ships

**1.1.1** A fixed fire detection and fire alarm system for passenger ships shall be capable of remotely and individually identifying each detector and manually operated call point.

#### 1.2 Minimum number of detectors

**1.2.1** Where a fixed fire detection and fire alarm system is required for the protection of spaces other than those specified in [4.2.1], at least one detector complying with the requirements given in Ch 4, Sec 15 shall be installed in each such space.

### 2 Initial and periodical tests

#### 2.1 General

**2.1.1** The function of fixed fire detection and fire alarm systems required by the relevant Sections of this Chapter shall be tested under varying conditions of ventilation after installation.

**2.1.2** The function of fixed fire detection and fire alarm systems shall be periodically tested to the satisfaction of the Society by means of equipment producing hot air at the appropriate temperature, or smoke or aerosol particles having the appropriate range of density or particle size, or other phenomena associated with incipient fires to which the detector is designed to respond.

### 3 Protection of machinery spaces

#### 3.1 Installation

**3.1.1** A fixed fire detection and fire alarm system complying with the relevant provisions given in Ch 4, Sec 15 shall be installed in:

- a) periodically unattended machinery spaces of category A,
- b) machinery spaces of category A where:
  - 1) the installation of automatic and remote control systems and equipment has been approved in lieu of continuous manning of the space, and
  - 2) the main propulsion and associated machinery, including the main sources of electrical power, are provided with various degrees of automatic or remote control and are under continuous manned supervision from a control room,
- c) enclosed spaces containing incinerators,
- d) spaces containing an inert gas generator or an ozone generator,
- e) spaces intended for the storage or handling of solvent (as defined in Ch 1, Sec 12, [1.3.6]) on board ships fitted with an onboard carbon capture and storage system (OCC).

For fixed fire detection and fire alarm system in unattended machinery spaces, see also Part F, Chapter 3.

#### 3.2 Design

**3.2.1** The fixed fire detection and fire alarm system required in [3.1.1] a) shall be so designed and the detectors so positioned as to detect rapidly the onset of fire in any part of those spaces and under any normal conditions of operation of the machinery and variations of ventilation as required by the possible range of ambient temperatures. Except in spaces of restricted height and where their use is specially appropriate, detection systems using only thermal detectors shall not be permitted.

The detection system shall initiate audible and visual alarms distinct in both respects from the alarms of any other system not indicating fire, in sufficient places to ensure that the alarms are heard and observed on the navigation bridge and by a responsible engineer officer. When the navigation bridge is unmanned, the alarm shall sound in a place where a responsible member of the crew is on duty.

#### 3.3 Protection of spaces containing a ballast water management system

##### 3.3.1 Arrangement of the fire detectors

A section of fire detectors which covers a control station, a service space or an accommodation space is not to include a ballast water management room containing equipment related to ozone based ballast water management system.

## 4 Protection of accommodation and service spaces and control stations

### 4.1 Application

4.1.1 The provisions of [4.2] apply to ships of all types, those of [4.3] to [4.5] apply to passenger ships and those of [4.7] apply to cargo ships.

### 4.2 Smoke detectors in accommodation spaces

4.2.1 *Smoke detectors shall be installed in all stairways, corridors and escape routes within accommodation spaces. Consideration shall be given to the installation of special purpose smoke detectors within ventilation ducting.*

### 4.3 Requirements for passenger ships carrying more than 36 passengers

4.3.1 *A fixed fire detection and fire alarm system shall be so installed and arranged as to provide smoke detection in service spaces, control stations and accommodation spaces, including corridors, stairways and escape routes within accommodation spaces. Smoke detectors need not be fitted in private bathrooms and galleys. Spaces having little or no fire risk such as voids, public toilets, carbon dioxide rooms and similar spaces need not be fitted with a fixed fire detection and alarm system.*

Heat detectors in lieu of smoke detectors may be installed in galleys. CO<sub>2</sub> rooms need not be protected by a fire detection system or a sprinkler system.

*Detectors fitted in cabins, when activated, shall also be capable of emitting, or cause to be emitted, an audible alarm within the space where they are located.*

### 4.4 Requirements for passenger ships carrying not more than 36 passengers

4.4.1 *There shall be installed throughout each separate zone, whether vertical or horizontal, in all accommodation and service spaces and, where it is considered necessary by the Society, in control stations, except spaces which afford no substantial fire risk such as void spaces, sanitary spaces, etc., either:*

- a) *a fixed fire detection and fire alarm system so installed and arranged as to detect the presence of fire in such spaces and providing smoke detection in corridors, stairways and escape routes within accommodation spaces. Detectors fitted in cabins, when activated, shall also be capable of emitting, or cause to be emitted, an audible alarm within the space where they are located; or*
- b) *an automatic sprinkler, fire detection and fire alarm system of an approved type complying with the relevant requirements of Ch 4, Sec 15 and so installed and arranged as to protect such spaces and, in addition, a fixed fire detection and fire alarm system so installed and arranged as to provide smoke detection in corridors, stairways and escape routes within accommodation spaces.*

CO<sub>2</sub> rooms need not be protected by a fire detection system or a sprinkler system.

### 4.5 Protection of atriums

4.5.1 *The entire main vertical zone containing the atrium shall be protected throughout with a smoke detection system.*

### 4.6 Protection of cabin balconies on passenger ships

4.6.1 A fixed fire detection and fire alarm system complying with the requirements of Ch 4, Sec 15 is to be installed on cabin balconies to which Ch 4, Sec 2, [2.2.4] applies, when furniture and furnishings on such balconies are not defined in Ch 4, Sec 1, [2.38.1], items a), b), c), f) and g).

### 4.7 Cargo ships

4.7.1 *Accommodation and service spaces and control stations of cargo ships shall be protected by a fixed fire detection and fire alarm system and/or an automatic sprinkler, fire detection and fire alarm system as follows, depending on a protection method adopted in accordance with Ch 4, Sec 5, [1.4.1].*

a) *Method IC*

*A fixed fire detection and fire alarm system shall be so installed and arranged as to provide smoke detection in all corridors, stairways and escape routes within accommodation spaces.*

b) *Method IIC*

*An automatic sprinkler, fire detection and fire alarm system of an approved type complying with the relevant requirements of Ch 4, Sec 15 shall be so installed and arranged as to protect accommodation spaces, galleys and other service spaces, except spaces which afford no substantial fire risk such as void spaces, sanitary spaces, etc. In addition, a fixed fire detection and fire alarm system shall be so installed and arranged as to provide smoke detection in all corridors, stairways and escape routes within accommodation spaces.*

c) *Method IIIC*

*A fixed fire detection and fire alarm system shall be so installed and arranged as to detect the presence of fire in all accommodation spaces and service spaces, providing smoke detection in corridors, stairways and escape routes within accommodation spaces, except spaces which afford no substantial fire risk such as void spaces, sanitary spaces, etc. In addition, a fixed fire detection and fire alarm system shall be so installed and arranged as to provide smoke detection in all corridors, stairways and escape routes within accommodation spaces.*

CO<sub>2</sub> rooms need not be protected by a fire detection system or a sprinkler system.

## **5 Protection of cargo spaces**

### **5.1 Application and general requirements**

**5.1.1** The present Article applies to passenger ships.

**5.1.2** *A fixed fire detection and fire alarm system complying with the requirements of Ch 4, Sec 15 or a sample extraction smoke detection system complying with the requirements of Ch 4, Sec 15 shall be provided in any cargo space which, in the opinion of the Society, is not accessible, except where it is shown to the satisfaction of the Society that the ship is engaged on voyages of such short duration that it would be unreasonable to apply this requirement.*

## **6 Manually operated call points**

### **6.1 General requirements**

**6.1.1** *Manually operated call points complying with the requirements of Ch 4, Sec 15 shall be installed throughout the accommodation spaces, service spaces and control stations. One manually operated call point shall be located at each exit. Manually operated call points shall be readily accessible in the corridors of each deck such that no part of the corridor is more than 20 m from a manually operated call point.*

## **7 Inspection hatches**

### **7.1 Application**

**7.1.1** The present Article applies to passenger ships.

### **7.2 Inspection hatches**

**7.2.1** *The construction of ceilings and bulkheads shall be such that it will be possible, without impairing the efficiency of the fire protection, for the fire patrols to detect any smoke originating in concealed and inaccessible places, except where in the opinion of the Society there is no risk of fire originating in such places.*

## **8 Fire alarm signalling systems**

### **8.1 Application**

**8.1.1** The present Article applies to passenger ships.

### **8.2 Control panel**

**8.2.1** *The control panel of fixed fire detection and fire alarm systems shall be designed on the fail-safe principle, e.g. an open detector circuit shall cause an alarm condition.*

### **8.3 Passenger ships carrying more than 36 passengers**

**8.3.1** *Passenger ships carrying more than 36 passengers shall have the fire detection alarms for the systems required by [4.3] centralized in a continuously manned central control station. In addition, controls for remote closing of the fire doors and shutting down the ventilation fans shall be centralized in the same location. The ventilation fans shall be capable of reactivation by the crew at the continuously manned control station. The control panels in the central control station shall be capable of indicating open or closed positions of fire doors and closed or off status of the detectors, alarms and fans. The control panel shall be continuously powered and shall have an automatic change-over to standby power supply in case of loss of normal power supply. The control panel shall be powered from the main source of electrical power and the emergency source of electrical power defined in Pt D, Ch 11, Sec 5, [2] unless other arrangements are permitted by the Rules, as applicable.*

## **8.4 Special alarm**

**8.4.1** *A special alarm, operated from the navigation bridge or fire control station, shall be fitted to summon the crew. This alarm may be part of the ship's general alarm system and shall be capable of being sounded independently of the alarm to the passenger spaces.*

## Section 4                      Suppression of Fire: Control of Smoke Spread

### 1 General

#### 1.1 Application

1.1.1 The provisions of [2.1] to [4.1] except [3.2.2] apply to ships of all types. Those of [3.2.2] and [5.1] apply to passenger ships.

### 2 Protection of control stations outside machinery spaces

#### 2.1 General

2.1.1 *Practicable measures shall be taken for control stations outside machinery spaces in order to ensure that ventilation, visibility and freedom from smoke are maintained so that, in the event of fire, the machinery and equipment contained therein may be supervised and continue to function effectively. Alternative and separate means of air supply shall be provided and air inlets of the two sources of supply shall be so disposed that the risk of both inlets drawing in smoke simultaneously is minimized. At the discretion of the Society, such requirements need not apply to control stations situated on, and opening onto, an open deck or where local closing arrangements would be equally effective.*

*The ventilation system serving safety centres may be derived from the ventilation system serving the navigation bridge, unless located in an adjacent main vertical zone.*

2.1.2 For ships other than passenger ships carrying more than 36 passengers, equally effective local closing arrangements means that in the case of ventilators these are to be fitted with fire dampers or smoke dampers which are to be easily closed within the control station in order to maintain the absence of smoke in the event of fire.

### 3 Release of smoke from machinery spaces

#### 3.1 Release of smoke

3.1.1 *Suitable arrangements shall be made to permit the release of smoke, in the event of fire, from the space to be protected. The normal ventilation systems may be acceptable for this purpose.*

#### 3.2 Controls

3.2.1 *Means of control shall be provided for permitting the release of smoke and such controls shall be located outside the space concerned so that they will not be cut off in the event of fire in the space they serve.*

3.2.2 *The controls required by [3.2.1] shall be situated at one control position or grouped in as few positions as possible to the satisfaction of the Society. Such positions shall have a safe access from the open deck.*

### 4 Draught stops

#### 4.1

4.1.1 *Air spaces enclosed behind ceilings, panelling or linings, including raised floors, shall be divided by close-fitting draught stops spaced not more than 14 m apart. In the vertical direction, such enclosed air spaces, including those behind linings of stairways, trunks, etc., shall be closed at each deck.*

### 5 Smoke extraction systems

#### 5.1 Atriums

5.1.1 *Atriums shall be equipped with a smoke extraction system. The smoke extraction system shall be activated by the required smoke detection system and be capable of manual control. The fans shall be sized such that the entire volume within the space can be exhausted in 10 min or less.*

# Section 5                      Suppression of Fire: Containment of Fire

## 1 Thermal and structural boundaries

### 1.1 Application

1.1.1 The provisions of [1.2] apply to ships of all types, those of [1.3] apply to passenger ships, those of [1.4] apply to cargo ships and those of [1.5] apply to tankers.

### 1.2 Thermal and structural subdivision

1.2.1 *Ships of all types shall be subdivided into spaces by thermal and structural divisions having regard to the fire risk of the space.*

### 1.3 Passenger ships

#### 1.3.1 Main vertical zones and horizontal zones

a) *In ships carrying more than 36 passengers, the hull, superstructure and deckhouses shall be subdivided into main vertical zones by A-60 class divisions. Steps and recesses shall be kept to a minimum, but where they are necessary they shall also be A-60 class divisions. Where a category (5), (9) or (10) space defined in item b) of [1.3.3] is on one side or where fuel oil tanks are on both sides of the division the standard may be reduced to A-0.*

b) *In ships carrying not more than 36 passengers, the hull, superstructure and deckhouses in way of accommodation and service spaces shall be subdivided into main vertical zones by A class divisions. These divisions shall have insulation values in accordance with Tab 3 and Tab 4.*

c) *As far as practicable, the bulkheads forming the boundaries of the main vertical zones above the bulkhead deck shall be in line with watertight subdivision bulkheads situated immediately below the bulkhead deck. The length and width of main vertical zones may be extended to a maximum of 48 m in order to bring the ends of main vertical zones to coincide with watertight subdivision bulkheads or in order to accommodate a large public space extending for the whole length of the main vertical zone provided that the total area of the main vertical zone is not greater than 1600 m<sup>2</sup> on any deck. The length or width of a main vertical zone is the maximum distance between the furthestmost points of the bulkheads bounding it.*

*If a stairway serves two main vertical zones, the maximum length of any one main vertical zone need not be measured from the far side of the stairway enclosure. In this case all boundaries of the stairway enclosure are to be insulated as main vertical zone bulkheads and access doors leading into the stairway are to be provided from the two outside zones. The number of main vertical zones of 48 m length is not limited as long as they comply with all the requirements.*

d) *Such bulkheads shall extend from deck to deck and to the shell or other boundaries.*

e) *On ships designed for special purposes, such as automobile or railroad car ferries, where the provision of main vertical zone bulkheads would defeat the purpose for which the ship is intended, equivalent means for controlling and limiting a fire shall be substituted and specifically approved by the Society.*

*However, in a ship with special category spaces, such spaces shall comply with the applicable provisions of Ch 4, Sec 13 and, where such compliance would be inconsistent with other requirements for passenger ships specified in this Chapter, the requirements of Ch 4, Sec 13 shall prevail.*

#### 1.3.2 Bulkheads within a main vertical zone

a) *For ships carrying more than 36 passengers, bulkheads which are not required to be A class divisions shall be at least B class or C class divisions as prescribed in Tab 1 and Tab 2.*

b) *For ships carrying not more than 36 passengers, bulkheads within accommodation and service spaces which are not required to be A class divisions shall be at least B class or C class divisions as prescribed in Tab 3 and Tab 4. In addition, corridor bulkheads, where not required to be A class, shall be B class divisions which shall extend from deck to deck except:*

1) *when continuous B class ceilings or linings are fitted on both sides of the bulkhead, the portion of the bulkhead behind the continuous ceiling or lining shall be of material which, in thickness and composition, is acceptable in the construction of B class divisions, but which shall be required to meet B class integrity standards only in so far as is reasonable and practicable in the opinion of the Society; and*

2) *in the case of a ship protected by an automatic sprinkler system complying with the provisions of Ch 4, Sec 15, the corridor bulkheads may terminate at a ceiling in the corridor provided such bulkheads and ceilings are of B class standard in compliance with [1.3.4]. All doors and frames in such bulkheads shall be of non-combustible materials and shall have the same fire integrity as the bulkhead in which they are fitted.*

c) Bulkheads required to be B class divisions, except corridor bulkheads as prescribed in item b) above, shall extend from deck to deck and to the shell or other boundaries. However, where a continuous B class ceiling or lining is fitted on both sides of a bulkhead which is at least of the same fire resistance as the adjoining bulkhead, the bulkhead may terminate at the continuous ceiling or lining.

**Table 1 : Bulkheads not bounding either main vertical zones or horizontal zones in passenger ships carrying more than 36 passengers**

SPACES	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	(13)	(14)
Control stations (1)	B-0 [a]	A-0	A-0	A-0	A-0	A-60	A-60	A-60	A-0	A-0	A-60	A-60	A-60	A-60
Stairways (2)		A-0 [a]	A-0	A-0	A-0	A-0	A-15	A-15	A-0 [c]	A-0	A-15	A-30	A-15	A-30
Corridors (3)			B-15	A-60	A-0	B-15	B-15	B-15	B-15	A-0	A-15	A-30	A-0	A-30
Evacuation stations and external escape routes (4)				–	A-0	A-60 [b][d]	A-60 [b][d]	A-60 [b][d]	A-0 [d]	A-0	A-60 [b]	A-60 [b]	A-60 [b]	A-60 [b]
Open deck spaces (5)					–	A-0	A-0	A-0	A-0	A-0	A-0	A-0	A-0	A-0
Accommodation spaces of minor fire risk (6)						B-0	B-0	B-0	C	A-0	A-0	A-30	A-0	A-30
Accommodation spaces of moderate fire risk (7)							B-0	B-0	C	A-0	A-15	A-60	A-15	A-60
Accommodation spaces of greater fire risk (8)								B-0	C	A-0	A-30	A-60	A-15	A-60
Sanitary and similar spaces (9)									C	A-0	A-0	A-0	A-0	A-0
Tanks, voids and auxiliary machinery spaces having little or no fire risk (10)										A-0 [a]	A-0	A-0	A-0	A-0
Auxiliary machinery spaces, cargo spaces, cargo and other oil tanks and other similar spaces of moderate fire risk (11)											A-0 [a]	A-0	A-0	A-15
Machinery spaces and main galleys (12)												A-0 [a]	A-0	A-60
store-rooms, workshops, pantries etc. (13)													A-0 [a]	A-0
Other spaces in which flammable liquids are stowed (14)														A-30

**Note 1:** (to be applied to Tab 1 and Tab 2, as appropriate)

- [a] : Where adjacent spaces are in the same numerical category and letter “a” appears, a bulkhead or deck between such spaces need not be fitted if deemed unnecessary by the Society. For example, in category (12) a bulkhead need not be required between a galley and its annexed pantries provided the pantry bulkheads and decks maintain the integrity of the galley boundaries. A bulkhead is, however, required between a galley and machinery space even though both spaces are in category (12).
- [b] : The ship's side, to the waterline in the lightest seagoing condition, superstructure and deckhouse sides situated below and adjacent to liferafts and evacuation slides may be reduced to A-30.
- [c] : Where public toilets are installed completely within the stairway enclosure, the public toilet bulkhead within the stairway enclosure can be of B class integrity.
- [d] : Where spaces of category (6), (7), (8) and (9) are located completely within the outer perimeter of the assembly station, the bulkheads of these spaces are allowed to be of B-0 class integrity. Control positions for audio, video and light installations may be considered as part of the assembly station.

store-rooms, workshops, pantries, etc. (13)	A-60	A-30	A-15	A-60	A-0	A-15	A-30	A-30	A-0	A-0	A-0	A-0	A-0	A-0
Other spaces in which flammable liquids are stowed (14)	A-60	A-60	A-60	A-60	A-0	A-30	A-60	A-60	A-0	A-0	A-0	A-0	A-0	A-0

**Note 1:** The notes of Tab 1 apply to Tab 2, as appropriate.

**1.3.3 Fire integrity of bulkheads and decks in ships carrying more than 36 passengers**

- a) In addition to complying with the specific provisions for fire integrity of bulkheads and decks mentioned in [1.3.1] and [1.3.2], the minimum fire integrity of all bulkheads and decks shall be as prescribed in Tab 1 and Tab 2. Where, due to any particular structural arrangements in the ship, difficulty is experienced in determining from the tables the minimum fire integrity value of any divisions, such values shall be determined to the satisfaction of the Society.
- b) The following requirements shall govern application of Tab 1 and Tab 2:
  - 1) Tab 1 shall apply to bulkheads not bounding either main vertical zones or horizontal zones. Tab 2 shall apply to decks not forming steps in main vertical zones nor bounding horizontal zones.
  - 2) For determining the appropriate fire integrity standards to be applied to boundaries between adjacent spaces, such spaces are classified according to their fire risk as shown in categories (1) to (14) below. Where the contents and use of a space are such that there is a doubt as to its classification for the purpose of the present Section, or where it is possible to assign two or more classifications to a space, it shall be treated as a space within the relevant category having the most stringent boundary requirements. Smaller, enclosed rooms within a space that have less than 30 % communicating openings to that space are considered separate spaces. The fire integrity of the boundary bulkheads and decks of such smaller rooms shall be as prescribed in Tab 1 and Tab 2. The title of each category is intended to be typical rather than restrictive. The number in parentheses preceding each category refers to the applicable column or row in the tables.

- (1) *Control stations*  
*Spaces containing emergency sources of power and lighting*  
*Wheelhouse and chartroom*  
*Spaces containing the ship's radio equipment*  
*Fire control stations*  
*Control room for propulsion machinery when located outside the propulsion machinery space*  
*Spaces containing centralized fire alarm equipment*  
*Spaces containing centralized emergency public address system stations and equipment.*
- (2) *Stairways*  
*Interior stairways, lifts, totally enclosed emergency escape trunks, and escalators (other than those wholly contained within the machinery spaces) for passengers and crew and enclosures thereto*  
*In this connection a stairway which is enclosed at only one level shall be regarded as part of the space from which it is not separated by a fire door.*
- (3) *Corridors*  
*Passenger and crew corridors and lobbies.*
- (4) *Evacuation stations and external escape routes*  
*Survival craft stowage area*  
*Open deck spaces and enclosed promenades forming lifeboat and liferaft embarkation and lowering stations*  
*Assembly stations, internal and external*  
*External stairs and open decks used for escape routes*  
*The ship's side to the waterline in the lightest seagoing condition, superstructure and deckhouse sides situated below and adjacent to the liferaft and evacuation slide embarkation areas.*
- (5) *Open deck spaces*  
*Open deck spaces and enclosed promenades clear of lifeboat and liferaft embarkation and lowering stations. To be considered in this category, enclosed promenades shall have no significant fire risk, meaning that furnishings shall be restricted to deck furniture. In addition, such spaces are to be naturally ventilated through permanent openings, having a combined area of at least 30% of the total area of the space boundaries adjacent to the outside.*  
*Air spaces (the space outside superstructures and deckhouses).*
- (6) *Accommodation spaces of minor fire risk*  
*Cabins containing furniture and furnishings of restricted fire risk*  
*Offices and dispensaries containing furniture and furnishings of restricted fire risk*  
*Public spaces containing furniture and furnishings of restricted fire risk and having a deck area of less than 50 m<sup>2</sup>.*
- (7) *Accommodation spaces of moderate fire risk*  
*Spaces as in category (6) above but containing furniture and furnishings of other than restricted fire risk*  
*Public spaces containing furniture and furnishings of restricted fire risk and having a deck area of 50 m<sup>2</sup> or more*  
*Isolated lockers and small store-rooms in accommodation spaces having areas less than 4 m<sup>2</sup> (in which flammable liquids are not stowed)*  
*Motion picture projection and film stowage rooms*  
*Diet kitchens (containing no open flame)*  
*Cleaning gear lockers (in which flammable liquids are not stowed)*  
*Laboratories (in which flammable liquids are not stowed)*  
*Pharmacies*  
*Small drying rooms (having a deck area of 4 m<sup>2</sup> or less)*  
*Specie rooms*  
*Operating rooms.*
- (8) *Accommodation spaces of greater fire risk*  
*Public spaces containing furniture and furnishings of other than restricted fire risk and having a deck area of 50 m<sup>2</sup> or more*  
*Barber shops and beauty parlours*  
*Sale shops*  
*Saunas.*

- (9) *Sanitary and similar spaces*  
*Communal sanitary facilities, showers, baths, water closets, etc.*  
*Small laundry rooms*  
*Indoor swimming pool area*  
*Isolated pantries containing no cooking appliances in accommodation spaces*  
*Private sanitary facilities shall be considered a portion of the space in which they are located.*
- (10) *Tanks, voids and auxiliary machinery spaces having little or no fire risk*  
*Water tanks forming part of the ship's structure*  
*Voids and cofferdams*  
*Auxiliary machinery spaces which do not contain machinery having a pressure lubrication system and where storage of combustibles is prohibited, such as:*
  - *ventilation and air-conditioning rooms*
  - *windlass room*
  - *steering gear room*
  - *stabiliser equipment room*
  - *electric propulsion motor room*
  - *rooms containing section switchboards and purely electrical equipment other than oil-filled electrical transformers (above 10 kVA)*
  - *shaft alleys and pipe tunnels, and*
  - *spaces for pumps and refrigeration machinery (not handling or using flammable liquids)**Closed trunks serving the spaces listed above*  
*Other closed trunks such as pipe and cable trunks*  
*Spaces dedicated to urea or sodium hydroxide solution tanks for selective catalytic reduction (SCR) systems, exhaust gas recirculation (EGR) systems or exhaust gas cleaning systems (EGCS), when separated from the engine room.*  
*Ballast Water Management Rooms (BWMR) not containing oil-fired inert gas generators (i.e. for ballast water management systems other than category 3b and 3c according to Ch 1, Sec 13, Tab 1).*
- (11) *Auxiliary machinery spaces, cargo spaces, cargo and other oil tanks and other similar spaces of moderate fire risk*  
*Cargo oil tanks*  
*Cargo holds, trunkways and hatchways*  
*Refrigerated chambers*  
*Oil fuel tanks (where installed in a separate space with no machinery)*  
*Shaft alleys and pipe tunnels allowing storage of combustibles*  
*Auxiliary machinery spaces as in category (10) which contain machinery having a pressure lubrication system or where storage of combustibles is permitted*  
*Oil fuel filling stations*  
*Spaces containing oil-filled electrical transformers (above 10 kVA)*  
*Spaces containing turbine and reciprocating steam engine driven auxiliary generators and small internal combustion engines of power output up to 110 kW driving generators, sprinkler, drencher or fire pumps, bilge pumps, etc.*  
*Closed trunks serving the spaces listed above*  
*Spaces intended for the storage or handling of solvent (as defined in Ch 1, Sec 12, [1.3.6]) on board ships fitted with an onboard carbon capture and storage system (OCC).*
- (12) *Machinery spaces and main galleys*  
*Main propulsion machinery rooms (other than electric propulsion motor rooms) and boiler rooms*  
*Auxiliary machinery spaces other than those in categories (10) and (11) which contain internal combustion machinery or other oil-burning, heating or pumping units*  
*Main galleys and annexes*  
*Trunks and casings to the spaces listed above*  
*Ballast Water Management Rooms (BWMR) containing oil-fired inert gas generators (i.e. for ballast water management systems category 3b and 3c according to Ch 1, Sec 13, Tab 1).*

- (13) Store-rooms, workshops, pantries, etc.

Main pantries not annexed to galleys

Main laundry

Large drying rooms (having a deck area of more than 4 m<sup>2</sup>)

Miscellaneous stores

Mail and baggage rooms

Garbage rooms

Workshops (not part of machinery spaces, galleys, etc.)

Lockers and store-rooms having areas greater than 4 m<sup>2</sup>, other than those spaces that have provisions for the storage of flammable liquids

Spaces where the storage of liquid or solid chemicals for ballast water management systems is intended if no flammable products are stored

Note 1: Only chemical injection (cat.6 as per Ch 1, Sec 13, Tab 1), in-line flocculation (cat.2 as per Ch 1, Sec 13, Tab 1) and technologies using neutralizer injection (cat.4, 5, 6 and 7 as per Ch 1, Sec 13, Tab 1) require chemical or additive storage.

- (14) Other spaces in which flammable liquids are stowed

Paint lockers

Store-rooms containing flammable liquids (including dyes, medicines, etc.)

Laboratories (in which flammable liquids are stowed)

Spaces where the storage of liquid or solid chemicals for ballast water management systems is intended if flammable products are stored

Note 2: Only chemical injection (cat.6 as per Ch 1, Sec 13, Tab 1), in-line flocculation (cat.2 as per Ch 1, Sec 13, Tab 1) and technologies using neutralizer injection (cat.4, 5, 6 and 7 as per Ch 1, Sec 13, Tab 1) require chemical or additive storage.

Spaces where oxygen is stored or produced.

- 3) Notwithstanding the provisions of [1.3.2], there are no special requirements for material or integrity of boundaries where only a dash appears in the tables.
  - 4) The Society shall determine in respect of category (5) spaces whether the insulation values in Tab 1 shall apply to ends of deckhouses and superstructures, and whether the insulation values in Tab 2 shall apply to weather decks. In no case shall the requirements of category (5) of Tab 1 or Tab 2 necessitate enclosure of spaces which in the opinion of the Society need not be enclosed.
- c) Continuous B class ceilings or linings, in association with the relevant decks or bulkheads, may be accepted as contributing, wholly or in part, to the required insulation and integrity of a division.
- d) In approving structural fire protection details, the Society shall have regard to the risk of heat transmission at intersections and terminal points of required thermal barriers.
- e) Construction and arrangement of saunas
- The perimeter of the sauna shall be of "A" class boundaries and may include changing rooms, showers and toilets. The sauna shall be insulated to "A-60" standard against other spaces except those inside the perimeter and spaces of categories (5), (9) and (10).
  - Bathrooms with direct access to saunas may be considered as part of them. In such cases, the door between sauna and the bathroom need not comply with fire safety requirements.
  - The traditional wooden lining on the bulkheads and ceiling are permitted in the sauna. The ceiling above the oven shall be lined with a non-combustible plate with an air gap of at least 30 mm. The distance from the hot surfaces to combustible materials shall be at least 500 mm or the combustible materials shall be protected (e.g. non-combustible plate with an air gap of at least 30 mm).
  - The traditional wooden benches are permitted to be used in the sauna.
  - The sauna door shall open outwards by pushing.
  - Electrically heated ovens shall be provided with a timer.

Note 3: For the purpose of this Chapter, hammams are treated as saunas.

### 1.3.4 Fire integrity of bulkheads and decks in ships carrying not more than 36 passengers

- a) In addition to complying with the specific provisions for fire integrity of bulkheads and decks mentioned in [1.3.1] and [1.3.2], the minimum fire integrity of bulkheads and decks shall be as prescribed in Tab 3 and Tab 4.
- b) The following requirements govern application of the tables:
  - 1) Tab 3 and Tab 4 shall apply, respectively, to the bulkheads and decks separating adjacent spaces.
  - 2) For determining the appropriate fire integrity standards to be applied to divisions between adjacent spaces, such spaces are classified according to their fire risk as shown in categories (1) to (11) below. Where the contents and use of a space are such that there is a doubt as to its classification for the purpose of the present Section, or where it is possible to assign two or more classifications to a space, it shall be treated as a space within the relevant category having the most stringent boundary requirements. Smaller, enclosed rooms within a space that have less than 30% communicating openings to that

space are considered separate spaces. The fire integrity of the boundary bulkheads and decks of such smaller rooms shall be as prescribed in Tab 3 and Tab 4. The title of each category is intended to be typical rather than restrictive. The number in parentheses preceding each category refers to the applicable column or row in the tables.

- (1) Control stations  
Spaces containing emergency sources of power and lighting  
Wheelhouse and chartroom  
Spaces containing the ship's radio equipment  
Fire control stations  
Control room for propulsion machinery when located outside the machinery space  
Spaces containing centralized fire alarm equipment.
  - (2) Corridors  
Passenger and crew corridors and lobbies.
  - (3) Accommodation spaces  
Spaces as defined in Ch 4, Sec 1, [2.2] excluding corridors.
  - (4) Stairways  
Interior stairways, lifts, totally enclosed emergency escape trunks, and escalators (other than those wholly contained within the machinery spaces) and enclosures thereto  
In this connection, a stairway which is enclosed only at one level shall be regarded as part of the space from which it is not separated by a fire door.
  - (5) Service spaces (low risk)  
Lockers and store-rooms not having provisions for the storage of flammable liquids and having areas less than 4 m<sup>2</sup> and drying rooms and laundries.  
Spaces where the storage of liquid or solid chemicals for ballast water management systems is intended if no flammable products are stored and if the area of the space is less than 4m<sup>2</sup>
- Note 1: Only chemical injection (cat.6 as per Ch 1, Sec 13, Tab 1), in-line flocculation (cat.2 as per Ch 1, Sec 13, Tab 1) and technologies using neutralizer injection (cat.4, 5, 6 and 7 as per Ch 1, Sec 13, Tab 1) require chemical or additive storage.
- (6) Machinery spaces of category A  
Spaces as defined in Ch 4, Sec 1, [2.29]  
Ballast Water Management Rooms (BWMR) containing oil-fired inert gas generators (i.e. for ballast water management systems category 3b and 3c according to Ch 1, Sec 13, Tab 1).
  - (7) Other machinery spaces  
Electrical equipment rooms (auto-telephone exchange, air-conditioning duct spaces)  
Spaces as defined in Ch 4, Sec 1, [2.28], excluding machinery spaces of category A.  
Spaces dedicated to urea or sodium hydroxide solution tanks for selective catalytic reduction (SCR) systems, exhaust gas recirculation (EGR) systems or exhaust gas cleaning systems (EGCS), when separated from the engine room  
Ballast Water Management Rooms (BWMR) not containing oil-fired inert gas generators (i.e. for ballast water management systems other than category 3b and 3c according to Ch 1, Sec 13, Tab 1)  
Spaces intended for the storage or handling of solvent (as defined in Ch 1, Sec 12, [1.3.6]) on board ships fitted with an onboard carbon capture and storage system (OCC).
  - (8) Cargo spaces  
All spaces used for cargo (including cargo oil tanks) and trunkways and hatchways to such spaces, other than special category spaces.
  - (9) Service spaces (high risk)  
Galley, pantries containing cooking appliances, paint lockers, lockers and store-rooms having areas of 4 m<sup>2</sup> or more, spaces for the storage of flammable liquids, saunas and workshops other than those forming part of the machinery spaces.  
Spaces where the storage of liquid or solid chemicals for ballast water management systems is intended if flammable products are stored or if the area of the space is above 4m<sup>2</sup>.
- Note 2: Only chemical injection (cat.6 as per Ch 1, Sec 13, Tab 1), in-line flocculation (cat.2 as per Ch 1, Sec 13, Tab 1) and technologies using neutralizer injection (cat.4, 5, 6 and 7 as per Ch 1, Sec 13, Tab 1) require chemical or additive storage.  
Spaces where oxygen is stored or produced.
- (10) Open decks  
Open deck spaces and enclosed promenades having little or no fire risk. Enclosed promenades shall have no significant fire risk, meaning that furnishing shall be restricted to deck furniture. In addition, such spaces are to be naturally ventilated through permanent openings, having a combined area of at least 30% of the total area of the space boundaries adjacent to the outside.  
Air spaces (the space outside superstructures and deckhouses).

- (11) *Special category and ro-ro spaces*  
Spaces as defined in Ch 4, Sec 1, [2.40] and Ch 4, Sec 1, [2.46].
- 3) *In determining the applicable fire integrity standard of a boundary between two spaces within a main vertical zone or horizontal zone which is not protected by an automatic sprinkler system complying with the provisions of Ch 4, Sec 15 or between such zones neither of which is so protected, the higher of the two values given in the tables shall apply.*
- 4) *In determining the applicable fire integrity standard of a boundary between two spaces within a main vertical zone or horizontal zone which is protected by an automatic sprinkler system complying with the provisions of Ch 4, Sec 15 or between such zones both of which are so protected, the lesser of the two values given in the tables shall apply. Where a zone with sprinklers and a zone without sprinklers meet within accommodation and service spaces, the higher of the two values given in the tables shall apply to the division between the zones.*
- c) *Continuous B class ceilings or linings, in association with the relevant decks or bulkheads, may be accepted as contributing, wholly or in part, to the required insulation and integrity of a division.*
- d) *External boundaries which are required in Ch 4, Sec 7, [2.1.1] to be of steel or other equivalent material may be pierced for the fitting of windows and sidescuttles provided that there is no requirement for such boundaries of passenger ships to have A class integrity. Similarly, in such boundaries which are not required to have A class integrity, doors may be constructed of materials which are to the satisfaction of the Society.*
- e) *In approving structural fire protection details, the Society shall have regard to the risk of heat transmission at intersections and terminal points of required thermal barriers.*
- f) *Saunas shall comply with [1.3.3], item e).*
- g) *A navigation locker that can only be accessed from the wheelhouse should be considered as a control station with respect to the provisions of Tab 3 and the bulkhead separating the wheelhouse and such a locker should have fire integrity of at least “B-0” class.*

**Table 3 : Fire integrity of bulkheads separating adjacent spaces in passenger ships carrying not more than 36 passengers**

SPACES	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)
Control stations (1)	A-0 [c]	A-0	A-60	A-0	A-15	A-60	A-15	A-60	A-60	*	A-60
Corridors (2)		C [e]	B-0 [e]	A-0 [a] B-0 [e]	B-0 [e]	A-60	A-0	A-0	A-15 A-0 [d]	*	A-30
Accommodation spaces (3)			C [e]	A-0 [a] B-0 [e]	B-0 [e]	A-60	A-0	A-0	A-15 A-0 [d]	*	A-30 A-0 [d]
Stairways (4)				A-0 [a] B-0 [e]	A-0 [a] B-0 [e]	A-60	A-0	A-0	A-15 A-0 [d]	*	A-30
Service spaces (low risk) (5)					C [e]	A-60	A-0	A-0	A-0	*	A-0
Machinery spaces of category A (6)						*	A-0	A-0	A-60	*	A-60
Other machinery spaces (7)							A-0 [b]	A-0	A-0	*	A-0
Cargo spaces (8)								*	A-0	*	A-0
Service spaces (high risk) (9)									A-0 [b]	*	A-30
Open decks (10)										–	A-0
Special category and ro-ro spaces (11)											A-30

**Note 1:** (to be applied to Tab 3 and Tab 4, as appropriate)

- [a] : For clarification as to which applies, see [1.3.2] and [1.3.5].
- [b] : Where spaces are of the same numerical category and letter “b” appears, a bulkhead or deck of the rating shown in the tables is only required when the adjacent spaces are for a different purpose, e.g. in category (9). A galley next to a galley does not require a bulkhead, but a galley next to a paint room requires an A-0 bulkhead.
- [c] : Bulkheads separating the wheelhouse and chartroom from each other may have a B-0 rating. No fire rating is required for those partitions separating the navigation bridge and the safety centre when the latter is within the navigation bridge.
- [d] : See items b) 3) and b) 4) of [1.3.4].
- [e] : For the application of item b) of [1.3.1], B-0 and C, where appearing in Tab 3, are to be read as A-0.
- [f] : Fire insulation need not be fitted if the machinery space in category (7), in the opinion of the Society, has little or no fire risk.
- \* : Where an asterisk appears in the tables, the division is required to be of steel or other equivalent material, but is not required to be of A class standard. However, where a deck, except in a category (10) space, is penetrated for the passage of electric cables, pipes and vent ducts, such penetrations are to be made tight to prevent the passage of flame and smoke. Divisions between control stations (emergency generators) and open decks may have air intake openings without means for closure, unless a fixed gas fire-extinguishing system is fitted.  
For the application of item b) of [1.3.1], an asterisk, where appearing in Tab 4, except for categories (8) and (10), is to be read as A-0.

**Table 4 : Fire integrity of decks separating adjacent spaces in passenger ships carrying not more than 36 passengers**

SPACE below	SPACE above										
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)

**Note 1:** The notes to Tab 3 apply to this table as appropriate.

**1.3.5 Protection of stairways and lifts in accommodation area**

- a) Stairways shall be within enclosures formed of A class divisions, with positive means of closure at all openings, except that:
- 1) a stairway connecting only two decks need not be enclosed, provided the integrity of the deck is maintained by proper bulkheads or self-closing doors in one 'tweendeck space. When a stairway is closed in one 'tweendeck space, the stairway enclosure shall be protected in accordance with the tables for decks in [1.3.3] or [1.3.4].  
The door provided at this stairway enclosure is to be of the self-closing type.
  - 2) stairways may be fitted in the open in a public space, provided they lie wholly within the public space.
- b) Lift trunks shall be so fitted as to prevent the passage of smoke and flame from one 'tweendeck to another and shall be provided with means of closing so as to permit the control of draught and smoke. Machinery for lifts located within stairway enclosures shall be arranged in a separate room, surrounded by steel boundaries, except that small passages for lift cables are permitted. Lifts which open into spaces other than corridors, public spaces, special category spaces, stairways and external areas shall not open into stairways included in the means of escape.

**1.3.6 Arrangement of cabin balconies**

Non-load bearing partial bulkheads which separate adjacent cabin balconies shall be capable of being opened by the crew from each side for the purpose of fighting fires.

**1.3.7 Protection of atriums**

- a) Atriums shall be within enclosures formed of "A" class divisions having a fire rating determined in accordance with Tab 2 and Tab 4, as applicable.
- b) Decks separating spaces within atriums shall have a fire rating determined in accordance with Tab 2 and Tab 4, as applicable.

**1.4 Cargo ships except tankers**

**1.4.1 Methods of protection in accommodation area**

- a) One of the following methods of protection shall be adopted in accommodation and service spaces and control stations:
- 1) Method IC  
The construction of internal divisional bulkheads of non-combustible B or C class divisions generally without the installation of an automatic sprinkler, fire detection and fire alarm system in the accommodation and service spaces, except as required by item a) of Ch 4, Sec 3, [4.7.1], or
  - 2) Method IIC  
The fitting of an automatic sprinkler, fire detection and fire alarm system as required by item b) of Ch 4, Sec 3, [4.7.1] for the detection and extinction of fire in all spaces in which fire might be expected to originate, generally with no restriction on the type of internal divisional bulkheads, or

3) *Method IIIC*

*The fitting of a fixed fire detection and fire alarm system, as required by item c) of Ch 4, Sec 3, [4.7.1], in spaces in which a fire might be expected to originate, generally with no restriction on the type of internal divisional bulkheads, except that in no case shall the area of any accommodation space or spaces bounded by an A or B class division exceed 50 m<sup>2</sup>. However, consideration may be given by the Society to increasing this area for public spaces.*

- b) *The requirements for the use of non-combustible materials in the construction and insulation of boundary bulkheads of machinery spaces, control stations, service spaces, etc., and the protection of the above stairway enclosures and corridors will be common to all three methods outlined in a).*
- c) *In approving structural fire protection details, the Society shall have regard to the risk of heat transmission at intersections and terminal points of required thermal barriers.*

**1.4.2 Bulkheads within accommodation area**

- a) *Bulkheads required to be B class divisions shall extend from deck to deck and to the shell or other boundaries. However, where a continuous B class ceiling or lining is fitted on both sides of the bulkhead, the bulkhead may terminate at the continuous ceiling or lining.*

b) *Method IC*

*Bulkheads not required by this or other Sections for cargo ships to be A or B class divisions shall be of at least C class construction.*

c) *Method IIC*

*There shall be no restriction on the construction of bulkheads not required by this or other Sections for cargo ships to be A or B class divisions except in individual cases where C class bulkheads are required in accordance with Tab 5.*

d) *Method IIIC*

*There shall be no restriction on the construction of bulkheads not required for cargo ships to be A or B class divisions except that the area of any accommodation space or spaces bounded by a continuous A or B class division shall in no case exceed 50 m<sup>2</sup>, except in individual cases where C class bulkheads are required in accordance with Tab 5. However, consideration may be given by the Society to increasing this area for public space.*

**1.4.3 Fire integrity of bulkheads and decks**

- a) *In addition to complying with the specific provisions for fire integrity of bulkheads and decks of cargo ships, the minimum fire integrity of bulkheads and decks shall be as prescribed in Tab 5 and Tab 6.*
- b) *The following requirements shall govern application of Tab 5 and Tab 6:*

- 1) *Tab 5 and Tab 6 shall apply respectively to the bulkheads and decks separating adjacent spaces.*
- 2) *For determining the appropriate fire integrity standards to be applied to divisions between adjacent spaces, such spaces are classified according to their fire risk as shown in categories (1) to (11) below. Where the contents and use of a space are such that there is a doubt as to its classification for the purpose of the present Section, or where it is possible to assign two or more classifications to a space, it shall be treated as a space within the relevant category having the most stringent boundary requirements. Smaller, enclosed rooms within a space that have less than 30 % communicating openings to that space are considered separate spaces. The fire integrity of the boundary bulkheads and decks of such smaller rooms shall be as prescribed in Tab 5 and Tab 6. The title of each category is intended to be typical rather than restrictive. The number in parentheses preceding each category refers to the applicable column or row in the tables.*

• (1) *Control stations*

*Spaces containing emergency sources of power and lighting*

*Wheelhouse and chartroom*

*Spaces containing the ship's radio equipment*

*Fire control stations*

*Control room for propulsion machinery when located outside the machinery space*

*Spaces containing centralised fire alarm equipment.*

• (2) *Corridors*

*Corridors and lobbies.*

• (3) *Accommodation spaces*

*Spaces as defined in Ch 4, Sec 1, [2.2], excluding corridors.*

• (4) *Stairways*

*Interior stairways, lifts, totally enclosed emergency space trunks, and escalators (other than those wholly contained within the machinery spaces) and enclosures thereto*

*In this connection, a stairway which is enclosed only at one level shall be regarded as part of the space from which it is not separated by a fire door.*

- (5) *Service spaces (low risk)*

*Lockers and store-rooms not having provisions for the storage of flammable liquids and having areas less than 4 m<sup>2</sup> and drying rooms and laundries.*

Spaces where the storage of liquid or solid chemicals for ballast water management systems is intended if no flammable products are stored and if the area of the space is less than 4m<sup>2</sup>

Note 1: Only chemical injection (cat.6 as per Ch 1, Sec 13, Tab 1), in-line flocculation (cat.2 as per Ch 1, Sec 13, Tab 1) and technologies using neutralizer injection (cat.4, 5, 6 and 7 as per Ch 1, Sec 13, Tab 1) require chemical or additive storage.

- (6) *Machinery spaces of category A*

*Spaces as defined in Ch 4, Sec 1, [2.29]*

Ballast Water Management Rooms (BWMR) containing oil-fired inert gas generators (i.e. for ballast water management systems category 3b and 3c according to Ch 1, Sec 13, Tab 1).

- (7) *Other machinery spaces*

*Electrical equipment rooms (auto-telephone exchange, air-conditioning duct spaces)*

*Spaces as defined in Ch 4, Sec 1, [2.28], excluding machinery spaces of category A.*

Spaces dedicated to urea or sodium hydroxide solution tanks for selective catalytic reduction (SCR) systems, exhaust gas recirculation (EGR) systems or exhaust gas cleaning systems (EGCS), when separated from the engine room.

Ballast Water Management Rooms (BWMR) not containing oil-fired inert gas generators (i.e. for ballast water management systems other than category 3b and 3c according to Ch 1, Sec 13, Tab 1)

Spaces intended for the storage or handling of solvent (as defined in Ch 1, Sec 12, [1.3.6]) on board ships fitted with an onboard carbon capture system (OCC).

- (8) *Cargo spaces*

*All spaces used for cargo (including cargo oil tanks) and trunkways and hatchways to such spaces.*

- (9) *Service spaces (high risk)*

*Galleys, pantries containing cooking appliances, saunas, paint lockers and store-rooms having areas of 4 m<sup>2</sup> or more, spaces for the storage of flammable liquids, and workshops other than those forming part of the machinery spaces.*

Spaces where the storage of liquid or solid chemicals for ballast water management systems is intended if flammable products are stored or if the area of the space is above 4 m<sup>2</sup>.

Note 2: Only chemical injection (cat.6 as per Ch 1, Sec 13, Tab 1), in-line flocculation (cat.2 as per Ch 1, Sec 13, Tab 1) and technologies using neutralizer injection (cat.4, 5, 6 and 7 as per Ch 1, Sec 13, Tab 1) require chemical or additive storage.

Spaces where oxygen is stored or produced.

- (10) *Open decks*

*Open deck spaces and enclosed promenades having little or no fire risk. To be considered in this category, enclosed promenades shall have no significant fire risk, meaning that furnishings shall be restricted to deck furniture.* In addition, such spaces are to be naturally ventilated through permanent openings, having a combined area of at least 30% of the total area of the space boundaries adjacent to the outside.

*Air spaces (the space outside superstructures and deckhouses).*

- (11) *Ro-ro and vehicle spaces*

*Ro-ro spaces as defined in Ch 4, Sec 1, [2.40]*

*Vehicle spaces as defined in Ch 4, Sec 1, [2.51].*

3) *Continuous B class ceilings or linings, in association with the relevant decks or bulkheads, may be accepted as contributing, wholly or in part, to the required insulation and integrity of a division.*

4) *External boundaries which are required in Ch 4, Sec 7, [2.1.1] to be of steel or other equivalent material may be pierced for the fitting of windows and sidescuttles provided that there is no requirement for such boundaries of cargo ships to have A class integrity. Similarly, in such boundaries which are not required to have A class integrity, doors may be constructed of materials which are to the satisfaction of the Society.*

c) *Saunas shall comply with [1.3.3], item e).*

d) A navigation locker that can only be accessed from the wheelhouse should be considered as a control station with respect to the provisions of Tab 5 and the bulkhead separating the wheelhouse and such a locker should have fire integrity of at least "B-0" class.

**Table 5 : Fire integrity of bulkheads separating adjacent spaces in cargo ships**

SPACES	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	
Control stations	(1)	A-0 [e]	A-0	A-60	A-0	A-15	A-60	A-15	A-60	A-60	*	A-60
Corridors	(2)		C	B-0	A-0 [c] B-0	B-0	A-60	A-0	A-0	A-0	*	A-30
Accommodation spaces	(3)			C [a,b]	A-0 [c] B-0	B-0	A-60	A-0	A-0	A-0	*	A-30
Stairways	(4)				A-0 [c] B-0	A-0 [c] B-0	A-60	A-0	A-0	A-0	* *	A-30
Service spaces (low risk)	(5)					C	A-60	A-0	A-0	A-0	*	A-0
Machinery spaces of category A	(6)						*	A-0	A-0 [g]	A-60	*	A-60 [f]
Other machinery spaces	(7)							A-0 [d]	A-0	A-0	*	A-0
Cargo spaces	(8)								*	A-0	*	A-0
Service spaces (high risk)	(9)									A-0 [d]	*	A-30
Open decks	(10)										–	A-0
Ro-ro and vehicle spaces	(11)											A-30

**Note 1:** (to be applied to Tab 5 and Tab 6, as appropriate)

- [a] : No special requirements are imposed upon bulkheads in methods IIC and IIIC fire protection.
- [b] : In case of method IIIC, B class bulkheads of B-0 rating are to be provided between spaces or groups of spaces of 50m<sup>2</sup> and over in area.
- [c] : For clarification as to which applies, see [1.4.2] and [1.4.4].
- [d] : Where spaces are of the same numerical category and letter “d” appears, a bulkhead or deck of the rating shown in the tables is only required when the adjacent spaces are for a different purpose, e.g. in category (9). A galley next to a galley does not require a bulkhead, but a galley next to a paint room requires an A-0 bulkhead.
- [e] : Bulkheads separating the wheelhouse, chartroom and radio room from each other may have a B-0 rating.
- [f] : An A-0 rating may be used if no dangerous goods are intended to be carried or if such goods are stowed not less than 3 m horizontally from such a bulkhead.
- [g] : For cargo spaces in which dangerous goods are intended to be carried, Ch 4, Sec 12, [2.9] applies.
- [h] : Fire insulation need not be fitted in the machinery space in category (7) if, in the opinion of the Society, it has little or no fire risk.
- \* : Where an asterisk appears in the tables, the division is required to be of steel or other equivalent material but is not required to be of A class standard. However where a deck, except an open deck, is penetrated for the passage of electric cables, pipes and vent ducts, such penetrations are to be made tight to prevent the passage of flame and smoke. Divisions between control stations (emergency generators) and open decks may have air intake openings without means for closure, unless a fixed gas fire-extinguishing system is fitted.

**Table 6 : Fire integrity of decks separating adjacent spaces in cargo ships**

Ro-ro and vehicle spaces	(11)	A-60	A-30	A-30	A-30	A-0	A-60	A-0	A-0	A-30	A-0	A-30

**Note 1:** The notes to Tab 5 apply to this Table as appropriate.

**1.4.4 Protection of stairways and lift trunks in accommodation spaces, service spaces and control stations**

a) Stairways which penetrate only a single deck shall be protected, at a minimum, at one level by at least B-0 class divisions and self-closing doors. Lifts which penetrate only a single deck shall be surrounded by A-0 class divisions with steel doors at both levels. Stairways and lift trunks which penetrate more than a single deck shall be surrounded by at least A-0 class divisions and be protected by self-closing doors at all levels.

Dumb-waiters are to be regarded as lifts.

b) On ships having accommodation for 12 persons or less, where stairways penetrate more than a single deck and where there are at least two escape routes direct to the open deck at every accommodation level, the A-0 requirements of item a) above may be reduced to B-0.

**1.5 Tankers**

**1.5.1 Application**

For tankers, only method IC as defined in item a) of [1.4.1] shall be used.

**1.5.2 Fire integrity of bulkheads and decks**

a) In lieu of the requirements of [1.4] and in addition to complying with the specific provisions for fire integrity of bulkheads and decks of tankers, the minimum fire integrity of bulkheads and decks shall be as prescribed in Tab 7 and Tab 8.

b) The following requirements shall govern application of Tab 7 and Tab 8:

1) Tab 7 and Tab 8 shall apply respectively to the bulkheads and decks separating adjacent spaces.

2) For determining the appropriate fire integrity standards to be applied to divisions between adjacent spaces, such spaces are classified according to their fire risk as shown in categories (1) to (10) below. Where the contents and use of a space are such that there is a doubt as to its classification for the purpose of the present Section, or where it is possible to assign two or more classifications to a space, it shall be treated as a space within the relevant category having the most stringent boundary requirements. Smaller, enclosed areas within a space that have less than 30 % communicating openings to that space are considered separate areas. The fire integrity of the boundary bulkheads and decks of such smaller spaces shall be as prescribed in Tab 7 and Tab 8. The title of each category is intended to be typical rather than restrictive. The number in parentheses preceding each category refers to the applicable column or row in the tables.

- (1) Control stations

Spaces containing emergency sources of power and lighting

Wheelhouse and chartroom

Spaces containing the ship's radio equipment

Fire control stations

Control room for propulsion machinery when located outside the machinery space

Spaces containing centralized fire alarm equipment.

- (2) Corridors

Corridors and lobbies.

- (3) Accommodation spaces

Spaces as defined in Ch 4, Sec 1, [2.2], excluding corridors.

- (4) Stairways

Interior stairways, lifts, totally enclosed emergency escape trunks, and escalators (other than those wholly contained within the machinery spaces) and enclosures thereto

In this connection a stairway which is enclosed only at one level shall be regarded as part of the space from which it is not separated by a fire door.

- (5) Service spaces (low risk)

Lockers and store-rooms not having provisions for the storage of flammable liquids and having areas less than 4 m<sup>2</sup> and drying rooms and laundries

Spaces where the storage of liquid or solid chemicals for ballast water management systems is intended if no flammable products are stored and if the area of the space is less than 4m<sup>2</sup>

Note 1: Only chemical injection (cat.6 as per Ch 1, Sec 13, Tab 1), in-line flocculation (cat.2 as per Ch 1, Sec 13, Tab 1) and technologies using neutralizer injection (cat.4, 5, 6 and 7 as per Ch 1, Sec 13, Tab 1) require chemical or additive storage.

- (6) Machinery spaces of category A

Spaces as defined in Ch 4, Sec 1, [2.29]

Ballast Water Management Rooms (BWMR) containing oil-fired inert gas generators (i.e. for ballast water management systems category 3b and 3c according to Ch 1, Sec 13, Tab 1).

- (7) Other machinery spaces

Electrical equipment rooms (auto-telephone exchange and air-conditioning duct spaces)

Spaces as defined in Ch 4, Sec 1, [2.28], excluding machinery spaces of category A.

Spaces dedicated to urea or sodium hydroxide solution tanks for selective catalytic reduction (SCR) systems, exhaust gas recirculation (EGR) systems or exhaust gas cleaning systems (EGCS), when separated from the engine room.

Ballast Water Management Rooms (BWMR) not containing oil-fired inert gas generators (i.e. for ballast water management systems other than category 3b and 3c according to Ch 1, Sec 13, Tab 1)

Spaces intended for the storage or handling of solvent (as defined in Ch 1, Sec 12, [1.3.6]) on board ships fitted with an onboard carbon capture and storage system (OCC).

- (8) *Cargo pump-rooms*

*Spaces containing cargo pumps and entrances and trunks to such spaces*

Spaces where the storage of liquid or solid chemicals for ballast water management systems is intended, if located in the cargo area in accordance with Ch 1, Sec 13

Note 2: Only chemical injection (cat.6 as per Ch 1, Sec 13, Tab 1), in-line flocculation (cat.2 as per Ch 1, Sec 13, Tab 1) and technologies using neutralizer injection (cat.4, 5, 6 and 7 as per Ch 1, Sec 13, Tab 1) require chemical or additive storage.

Ballast Water Management Rooms (BWMR), if located in the cargo area in accordance with Ch 1, Sec 13

- (9) *Service spaces (high risk)*

*Galleys, pantries containing cooking appliances, saunas, paint lockers and store-rooms having areas of 4 m<sup>2</sup> or more, spaces for the storage of flammable liquids, and workshops other than those forming part of the machinery spaces.*

Spaces where the storage of liquid or solid chemicals for ballast water management systems is intended if flammable products are stored or if the area of the space is above 4 m<sup>2</sup>.

Note 3: Note 3: Only chemical injection (cat.6 as per Ch 1, Sec 13, Tab 1), in-line flocculation (cat.2 as per Ch 1, Sec 13, Tab 1) and technologies using neutralizer injection (cat.4, 5, 6 and 7 as per Ch 1, Sec 13, Tab 1) require chemical or additive storage.

Spaces where oxygen is stored or produced.

- (10) *Open decks*

*Open deck spaces and enclosed promenades having little or no fire risk. To be considered in this category, enclosed promenades shall have no significant fire risk, meaning that furnishings shall be restricted to deck furniture. In addition, such spaces are to be naturally ventilated through permanent openings, having a combined area of at least 30% of the total area of the space boundaries adjacent to the outside.*

*Air spaces (the space outside superstructures and deckhouses).*

c) *Continuous B class ceilings or linings, in association with the relevant decks or bulkheads, may be accepted as contributing, wholly or in part, to the required insulation and integrity of a division.*

d) *External boundaries which are required in Ch 4, Sec 7, [2.1.1] to be of steel or other equivalent material may be pierced for the fitting of windows and sidescuttles provided that there is no requirement for such boundaries of tankers to have A class integrity. Similarly, in such boundaries which are not required to have A class integrity, doors may be constructed of materials which are to the satisfaction of the Society.*

e) *Exterior boundaries of superstructures and deckhouses enclosing accommodation and including any overhanging decks which support such accommodation shall be constructed of steel and insulated to A-60 standard for the whole of the portions which face the cargo area and on the outward sides for a distance of 3 m from the end boundary facing the cargo area. The distance of 3 m shall be measured horizontally and parallel to the middle line of the ship from the boundary which faces the cargo area at each deck level. In the case of the sides of those superstructures and deckhouses, such insulation shall be carried up to the underside of the deck of the navigation bridge.*

Windows and side scuttles within these limits are to be of the fixed type and constructed to the A-60 standard.

f) *Skylights to cargo pump-rooms shall be of steel, shall not contain any glass and shall be capable of being closed from outside the pump-room.*

g) *In approving structural fire protection details, the Society shall have regard to the risk of heat transmission at intersections and terminal points of required thermal barriers.*

h) *Saunas shall comply with [1.3.3], item e).*

i) A navigation locker that can only be accessed from the wheelhouse should be considered as a control station with respect to the requirements in Tab 7 and the bulkhead separating the wheelhouse and such a locker should have fire integrity of at least "B-0" class.

**Table 7 : Fire integrity of bulkheads separating adjacent spaces in tankers**

SPACES	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)
Control stations (1)	A-0 [c]	A-0	A-60	A-0	A-15	A-60	A-15	A-60	A-60	*
Corridors (2)		C	B-0	A-0 [a] B-0	B-0	A-60	A-0	A-60	A-0	*

Service spaces (high risk) (9)									A-0 [b]	*
Open decks (10)										–

**Note 1:** (to be applied to Tab 7 and Tab 8, as appropriate)

- [a] : For clarification as to which applies, see [1.4.2] and [1.4.4].
- [b] : Where spaces are of the same numerical category and letter “b” appears, a bulkhead or deck of the rating shown in the tables is only required when the adjacent spaces are for a different purpose, e.g. in category (9). A galley next to a galley does not require a bulkhead, but a galley next to a paint room requires an A-0 bulkhead.
- [c] : Bulkheads separating the wheelhouse, chartroom and radio room from each other may have a B-0 rating.
- [d] : Bulkheads and decks between cargo pump-rooms and machinery spaces of category A may be penetrated by cargo pump shaft glands and similar gland penetrations, provided that gastight seals with efficient lubrication or other means of ensuring the permanence of the gas seal are fitted in way of the bulkheads or decks.
- [e] : Fire insulation need not be fitted in the machinery space in category (7) if, in the opinion of the Society, it has little or no fire risk.
- \* : Where an asterisk appears in the tables, the division is required to be of steel or other equivalent material, but is not required to be of A class standard. However, where a deck, except an open deck, is penetrated for the passage of electric cables, pipes and vent ducts, such penetrations are to be made tight to prevent the passage of flame and smoke. Divisions between control stations (emergency generators) and open decks may have air intake openings without means for closure, unless a fixed gas fire-extinguishing system is fitted.

**Note 1:** The notes to Tab 7 apply to this Table as appropriate.

## 2 Penetrations in fire-resisting divisions and prevention of heat transmission

### 2.1 Penetrations in A class divisions

**2.1.1** Where A class divisions are penetrated, such penetration shall be tested in accordance with the Fire Test Procedures Code. In the case of ventilation ducts, requirements [6.2.2] and [6.4.1] apply. However, where a pipe penetration is made of steel or equivalent material having a thickness of 3 mm or greater and a length of not less than 900 mm (preferably 450 mm on each side of the division), and there are no openings, testing is not required. Such penetrations shall be suitably insulated by extension of the insulation at the same level of the division.

### 2.2 Penetrations in B class divisions

**2.2.1** Where B class divisions are penetrated for the passage of electric cables, pipes, trunks, ducts, etc., or for the fitting of ventilation terminals, lighting fixtures and similar devices, arrangements shall be made to ensure that the fire resistance is not impaired, subject to the provisions of paragraph [6.4.2]. Pipes other than steel or copper that penetrate B class divisions shall be protected by either:

- a fire-tested penetration device suitable for the fire resistance of the division pierced and the type of pipe used, or
- a steel sleeve, having a thickness of not less than 1,8 mm and a length of not less than 900 mm for pipe diameters of 150 mm or more and not less than 600 mm for pipe diameters of less than 150 mm (preferably equally divided to each side of the division). The pipe shall be connected to the ends of the sleeve by flanges or couplings; or the clearance between the sleeve and the pipe shall not exceed 2,5 mm; or any clearance between pipe and sleeve shall be made tight by means of non-combustible or other suitable material.

### 2.3 Pipes penetrating A or B class divisions

**2.3.1** Uninsulated metallic pipes penetrating A or B class divisions shall be of materials having a melting temperature which exceeds 950°C for A-0 and 850°C for B-0 class divisions.

**2.3.2** Where the Society may permit the conveying of oil and combustible liquids through accommodation and service spaces, the pipes conveying oil or combustible liquids shall be of a material approved by the Society having regard to the fire risk.

### 2.4 Prevention of heat transmission

**2.4.1** In approving structural fire protection details, the Administration shall have regard to the risk of heat transmission at intersections and terminal points of required thermal barriers. The insulation of a deck or bulkhead shall be carried past the penetration, intersection or terminal point for a distance of at least 450 mm in the case of steel and aluminium structures. If a space is divided with a deck or a bulkhead of A class standard having insulation of different values, the insulation with the higher value shall continue on the deck or bulkhead with the insulation of the lesser value for a distance of at least 450 mm.

## 3 Protection of openings in fire-resisting divisions

### 3.1 Application

**3.1.1** The provisions of [3.2] apply to passenger ships and those of [3.3] apply to cargo ships.

### 3.2 Openings in bulkheads and decks

#### 3.2.1 Openings in A class divisions

- Except for hatches between cargo, special category, store and baggage spaces, and between such spaces and the weather decks, openings shall be provided with permanently attached means of closing which shall be at least as effective for resisting fires as the divisions in which they are fitted.*
- The construction of doors and door frames in A class divisions, with the means of securing them when closed, shall provide resistance to fire as well as to the passage of smoke and flame equivalent to that of the bulkheads in which the doors are situated, this being determined in accordance with the Fire Test Procedures Code. Such doors and door frames shall be constructed of steel or other equivalent material.*

*Doors approved without the sill being part of the frame shall be installed such that the gap under the door does not exceed 12 mm.*

*A non-combustible sill shall be installed under the door such that floor coverings do not extend beneath the closed door.*
- Watertight doors need not be insulated.*
- It shall be possible for each door to be opened and closed from each side of the bulkhead by one person only.*
- Fire doors in main vertical zone bulkheads, galley boundaries and stairway enclosures other than power-operated watertight doors and those which are normally locked shall satisfy the following requirements:*
  - the doors shall be self-closing and be capable of closing with an angle of inclination of up to 3,5° opposing closure*

- 2) *the approximate time of closure for hinged fire doors shall be no more than 40 s and no less than 10 s from the beginning of their movement with the ship in upright position. The approximate uniform rate of closure for sliding doors shall be of no more than 0,2 m/s and no less than 0,1 m/s with the ship in upright position*
- 3) *the doors, except those for emergency escape trunks, shall be capable of remote release from the continuously manned central control station, either simultaneously or in groups, and shall be capable of release also individually from a position at both sides of the door. Release switches shall have an on-off function to prevent automatic resetting of the system*
- 4) *hold-back hooks not subject to central control station release are prohibited*
- 5) *a door closed remotely from the central control station shall be capable of being re-opened from both sides of the door by local control. After such local opening, the door shall automatically close again*
- 6) *indication shall be provided at the fire door indicator panel in the continuously manned central control station whether each door is closed*
- 7) *the release mechanism shall be so designed that the door will automatically close in the event of disruption of the control system or central power supply*
- 8) *local power accumulators for power-operated doors shall be provided in the immediate vicinity of the doors to enable the doors to be operated at least ten times (fully opened and closed) after disruption of the control system or central power supply using the local controls*
- 9) *disruption of the control system or central power supply at one door shall not impair the safe functioning of the other doors*
- 10) *remote-released sliding or power-operated doors shall be equipped with an alarm that sounds at least 5 s but no more than 10 s, after the door is released from the central control station and before the door begins to move and continues sounding until the door is completely closed*
- 11) *a door designed to re-open upon contacting an object in its path shall re-open not more than 1 m from the point of contact*
- 12) *double-leaf doors equipped with a latch necessary for their fire integrity shall have a latch that is automatically activated by the operation of the doors when released by the system*
- 13) *doors giving direct access to special category spaces which are power-operated and automatically closed need not be equipped with the alarms and remote-release mechanisms required in items 3) and 10)*
- 14) *the components of the local control system shall be accessible for maintenance and adjusting*
- 15) *power-operated doors shall be provided with a control system of an approved type which shall be able to operate in case of fire and be in accordance with the Fire Test Procedures Code. This system shall satisfy the following requirements:*
  - *the control system shall be able to operate the door at the temperature of at least 200°C for at least 60 min, served by the power supply*
  - *the power supply for all other doors not subject to fire shall not be impaired, and*
  - *at temperatures exceeding 200°C, the control system shall be automatically isolated from the power supply and shall be capable of keeping the door closed up to at least 945°C.*
- f) *The requirements for A class integrity of the outer boundaries of a ship shall not apply to glass partitions, windows and sidescuttles, provided that there is no requirement for such boundaries to have A class integrity in item c) of [3.2.3]. The requirements for A class integrity of the outer boundaries of the ship shall not apply to exterior doors, except for those in superstructures and deckhouses facing life-saving appliances, embarkation and external assembly station areas, external stairs and open decks used for escape routes. Stairway enclosure doors need not meet this requirement.*
- g) *Except for watertight doors, weathertight doors (semi-watertight doors), doors leading to the open deck and doors which need to be reasonably gas-tight, all A class doors located in stairways, public spaces and main vertical zone bulkheads in escape routes shall be equipped with a self-closing hose port. The material, construction and fire resistance of the hose port shall be equivalent to the door into which it is fitted, and shall be a 150 mm square clear opening with the door closed and shall be inset into the lower edge of the door, opposite the door hinges or, in the case of sliding doors, nearest the opening.*

### **3.2.2 Openings in B class divisions**

- a) *Doors and door frames in B class divisions and means of securing them shall provide a method of closure which shall have resistance to fire equivalent to that of the divisions, this being determined in accordance with the Fire Test Procedures Code, except that ventilation openings may be permitted in the lower portion of such doors. Where such opening is in or under a door, the total net area of any such opening or openings shall not exceed 0,05 m<sup>2</sup>. Alternatively, a non-combustible air balance duct routed between the cabin and the corridor, and located below the sanitary unit, is permitted where the cross-sectional area of the duct does not exceed 0,05 m<sup>2</sup>. All ventilation openings shall be fitted with a grill made of non-combustible material. Doors shall be non-combustible.*

*Doors approved without the sill being part of the frame shall be installed such that the gap under the door does not exceed 25 mm.*
- b) *Cabin doors in B class divisions shall be of a self-closing type. Hold-back hooks are not permitted.*
- c) *The requirements for B class integrity of the outer boundaries of a ship shall not apply to glass partitions, windows and sidescuttles. Similarly, the requirements for B class integrity shall not apply to exterior doors in superstructures and*

deckhouses. For ships carrying not more than 36 passengers, the Society may permit the use of combustible materials in doors separating cabins from the individual interior sanitary spaces such as showers.

- d) B15 doors for shops leading to corridors shall be self-closing and equipped with hold-back capable of remote release from the continuous manned central control station. Such remote release may be grouped with the release of the nearest remote controlled A class fire door. Individual release shall also be possible locally from a position in the corridor close to the door.

### **3.2.3 Windows and sidescuttles**

- a) Windows and sidescuttles in bulkheads within accommodation and service spaces and control stations other than those to which the provisions of item f) of [3.2.1] and item c) of [3.2.2] apply shall be so constructed as to preserve the integrity requirements of the type of bulkheads in which they are fitted, this being determined in accordance with the Fire Test Procedures Code.
- b) Notwithstanding the requirements of Tab 1 to Tab 4, windows and sidescuttles in bulkheads separating accommodation and service spaces and control stations from weather shall be constructed with frames of steel or other suitable material. The glass shall be retained by a metal glazing bead or angle.
- c) For ships carrying more than 36 passengers, windows facing survival craft, embarkation and assembly stations, external stairs and open decks used for escape routes, and windows situated below liferaft and escape slide embarkation areas shall have fire integrity as required in Tab 1. Where automatic dedicated sprinkler heads are provided for windows, A-0 windows may be accepted as equivalent. To be considered under this paragraph, the sprinkler heads must either be:
- 1) dedicated heads located above the windows, and installed in addition to the conventional ceiling sprinklers; or
  - 2) conventional ceiling sprinkler heads arranged such that the window is protected by an average application rate of at least 5 l/min per square metre and the additional window area is included in the calculation of the area of coverage; or
  - 3) approved water-mist nozzles; and
- Windows located in the ship's side below the lifeboat embarkation area shall have fire integrity at least equal to A-0 class.
- d) For ships carrying not more than 36 passengers, windows facing survival craft and escape slide, embarkation areas and windows situated below such areas shall have fire integrity at least equal to A-0 class.

## **3.3 Doors in fire-resisting divisions**

**3.3.1** The fire resistance of doors shall be equivalent to that of the division in which they are fitted, this being determined in accordance with the Fire Test Procedures Code.

Doors approved as A class without the sill being part of the frame shall be installed such that the gap under the door does not exceed 12 mm and a non-combustible sill shall be installed under the door such that floor coverings do not extend beneath the closed door. Doors approved as B class without the sill being part of the frame shall be installed such that the gap under the door does not exceed 25 mm.

Doors and door frames in A class divisions shall be constructed of steel. Doors in B class divisions shall be non-combustible. Doors fitted in boundary bulkheads of machinery spaces of category A shall be reasonably gas-tight and self-closing. In ships constructed according to method IC, the Society may permit the use of combustible materials in doors separating cabins from individual interior sanitary accommodation such as showers.

**3.3.2** Doors required to be self-closing shall not be fitted with hold-back hooks. However, hold-back arrangements fitted with remote release devices of the fail-safe type may be utilized.

**3.3.3** In corridor bulkheads, ventilation openings may be permitted in and under the doors of cabins and public spaces. Ventilation openings are also permitted in B class doors leading to lavatories, offices, pantries, lockers and store-rooms. Except as permitted below, the openings shall be provided only in the lower half of a door. Where such an opening is in or under a door, the total net area of any such opening or openings shall not exceed 0,05 m<sup>2</sup>. Alternatively, a non-combustible air balance duct routed between the cabin and the corridor, and located below the sanitary unit, is permitted where the cross-sectional area of the duct does not exceed 0,05 m<sup>2</sup>. Ventilation openings, except those under the door, shall be fitted with a grill made of non-combustible material.

**3.3.4** Watertight doors need not be insulated.

## **4 Protection of openings in machinery space boundaries**

### **4.1 Application**

**4.1.1** The provisions of Article [4] shall apply to machinery spaces of category A and, where the Society considers it desirable, to other machinery spaces.

The provisions of [4.2] apply to ships of all types, except those of [4.2.3] and [4.2.5] which apply to passenger ships.

## **4.2 Protection of openings in machinery space boundaries**

### **4.2.1**

- a) *The number of skylights, doors, ventilators, openings in funnels to permit exhaust ventilation and other openings to machinery spaces shall be reduced to a minimum consistent with the needs of ventilation and the proper and safe working of the ship.*
- b) *Skylights shall be of steel and shall not contain glass panels.*

**4.2.2** *Means of control shall be provided for closing power-operated doors or actuating release mechanisms on doors other than power-operated watertight doors. The controls shall be located outside the space concerned, where they will not be cut off in the event of fire in the space they serve.*

**4.2.3** *The means of control required in [4.2.2] shall be situated at one control position or grouped in as few positions as possible, to the satisfaction of the Society. Such positions shall have safe access from the open deck.*

**4.2.4** *When access to any machinery space of category A is provided at a low level from an adjacent shaft tunnel, there shall be provided in the shaft tunnel, near the watertight door, a light steel fire-screen door operable from each side.*

**4.2.5** *Doors, other than power-operated watertight doors, shall be so arranged that positive closure is assured in case of fire in the space by power-operated closing arrangements or by the provision of self-closing doors capable of closing against an inclination of 3,5° opposing closure, and having a fail-safe hold-back arrangement, provided with a remotely operated release device. Doors for emergency escape trunks need not be fitted with a fail-safe hold-back facility and a remotely operated release device.*

**4.2.6** *Windows shall not be fitted in machinery space boundaries. However, this does not preclude the use of glass in control rooms within the machinery spaces.*

## **5 Protection of cargo space boundaries**

### **5.1 Application**

**5.1.1** The provisions of [5.2] to [5.3] apply to passenger ships.

### **5.2 Passenger ships carrying more than 36 passengers**

**5.2.1** *The boundary bulkheads and decks of special category and ro-ro spaces shall be insulated to A-60 class standard. However, where a category (5), (9) or (10) space, as defined in [1.3.3], is on one side of the division, the standard may be reduced to A-0. Where fuel oil tanks are below a special category space, the integrity of the deck between such spaces may be reduced to A-0 standard.*

### **5.3 Indicators**

**5.3.1** *Indicators shall be provided on the navigation bridge which shall indicate when any fire door leading to or from the special category spaces is closed.*

## **6 Ventilation systems**

### **6.1 Application**

**6.1.1** The provisions of [6.2]] to [6.4], [6.6], and [6.7] apply to ships of all types.

The provisions of [6.5] and [6.8] apply to passenger ships carrying more than 36 passengers.

### **6.2 General**

**6.2.1** *Ventilation ducts, including single and double wall ducts, shall be of steel or equivalent material except flexible bellows of short length not exceeding 600 mm used for connecting fans to the ducting in air-conditioning rooms. Unless expressly provided otherwise in [6.2.6], any other material used in the construction of ducts, including insulation, shall also be non-combustible.*

However, short ducts, not generally exceeding 2 m in length and with a free cross-sectional area not exceeding 0.02 m<sup>2</sup>, need not be of steel or equivalent material, subject to the following conditions:

- a) the ducts shall be made of non-combustible material, which may be faced internally and externally with membranes having low flame-spread characteristics and, in each case, a calorific value not exceeding 45 MJ/m<sup>2</sup> of their surface area for the thickness used;
- b) the ducts are only used at the end of the ventilation device; and
- c) the ducts are not situated less than 600 mm, measured along the duct, from an opening in an "A" or "B" class division, including continuous "B" class ceiling.

Note 1: The term free cross-sectional area means, even in the case of a pre-insulated duct, the area calculated on the basis of the inner dimensions of the duct itself and not the insulation.

**6.2.2** The following arrangements shall be tested in accordance with the Fire Test Procedures Code:

- a) fire dampers, including their relevant means of operation. However, the testing is not required for dampers located at the lower end of the duct in exhaust ducts for galley ranges, which must be of steel and capable of stopping the draught in the duct; and
- b) duct penetrations through "A" class divisions. However, the test is not required where steel sleeves are directly joined to ventilation ducts by means of riveted or screwed connections or by welding.

**6.2.3** Fire dampers shall be easily accessible. Where they are placed behind ceilings or linings, these ceilings or linings shall be provided with an inspection hatch on which the identification number of the fire damper is marked. The fire damper identification number shall also be marked on any remote controls provided.

**6.2.4** Ventilation ducts shall be provided with hatches for inspection and cleaning. The hatches shall be located near the fire dampers.

**6.2.5** The main inlets and outlets of ventilation systems shall be capable of being closed from outside the spaces being ventilated. The means of closing shall be easily accessible as well as prominently and permanently marked and shall indicate the operating position of the closing device.

**6.2.6** Combustible gaskets in flanged ventilation duct connections are not permitted within 600 mm of openings in "A" or "B" class divisions and in ducts required to be of "A" class construction.

**6.2.7** Ventilation openings or air balance ducts between two enclosed spaces shall not be provided except as permitted by [3.2.2] and [3.3.3].

### 6.3 Arrangement of ducts

**6.3.1** The ventilation systems for machinery spaces of category A, vehicle spaces, ro-ro spaces, galleys, special category spaces and cargo spaces shall, in general, be separated from each other and from the ventilation systems serving other spaces. However, the galley ventilation systems on cargo ships of less than 4,000 gross tonnage and in passenger ships carrying not more than 36 passengers need not be completely separated from other ventilation systems, but may be served by separate ducts from a ventilation unit serving other spaces. In such a case, an automatic fire damper shall be fitted in the galley ventilation duct near the ventilation unit.

**6.3.2** Ducts provided for the ventilation of machinery spaces of category A, galleys, vehicle spaces, ro-ro spaces or special category spaces shall not pass through accommodation spaces, service spaces, or control stations unless they comply with [6.3.4].

**6.3.3** Ducts provided for the ventilation of accommodation spaces, service spaces or control stations shall not pass through machinery spaces of category A, galleys, vehicle spaces, ro-ro spaces or special category spaces unless they comply with [6.3.4].

**6.3.4** As permitted by [6.3.2] and [6.3.3] ducts shall be either:

- a)
  - 1) constructed of steel having a thickness of at least 3 mm for ducts with a free cross-sectional area of less than 0.075 m<sup>2</sup>, at least 4 mm for ducts with a free cross-sectional area of between 0.075 m<sup>2</sup> and 0.45 m<sup>2</sup>, and at least 5 mm for ducts with a free cross-sectional area of over 0.45 m<sup>2</sup>;
  - 2) suitably supported and stiffened;
  - 3) fitted with automatic fire dampers close to the boundaries penetrated; and
  - 4) insulated to "A-60" class standard from the boundaries of the spaces they serve to a point at least 5 m beyond each fire damper; or
- b)
  - 1) constructed of steel in accordance with item a) 1) and item a) 2); and
  - 2) insulated to "A-60" class standard throughout the spaces they pass through, except for ducts that pass through spaces of category (9) or (10) as defined in [1.3.3], item b).

**6.3.5** For the purposes of [6.3.4], item a) 4) and [6.3.4], item b) 2), ducts shall be insulated over their entire cross-sectional external surface. Ducts that are outside but adjacent to the specified space, and share one or more surfaces with it, shall be considered to pass through the specified space, and shall be insulated over the surface they share with the space for a distance of 450 mm past the duct.

**6.3.6** Where it is necessary that a ventilation duct passes through a main vertical zone division, an automatic fire damper shall be fitted adjacent to the division. The damper shall also be capable of being manually closed from each side of the division. The control location shall be readily accessible and be clearly and prominently marked. The duct between the division and the damper shall be constructed of steel in accordance with [6.3.4], item a) 1) and [6.3.4], item a) 2) and insulated to at least the same fire integrity as the division penetrated. The damper shall be fitted on at least one side of the division with a visible indicator showing the operating position of the damper.

## **6.4 Details of fire dampers and duct penetrations**

**6.4.1** Ducts passing through "A" class divisions shall meet the following requirements:

- a) Where a thin plated duct with a free cross sectional area equal to, or less than,  $0,02 \text{ m}^2$  passes through "A" class divisions, the opening shall be fitted with a steel sheet sleeve having a thickness of at least 3 mm and a length of at least 200 mm, divided preferably into 100 mm on each side of the bulkhead or, in the case of a deck, wholly laid on the lower side of the decks penetrated.
- b) Where ventilation ducts with a free cross-sectional area exceeding  $0,02 \text{ m}^2$ , but not more than  $0,075 \text{ m}^2$ , pass through "A" class divisions, the openings shall be lined with steel sheet sleeves. The ducts and sleeves shall have a thickness of at least 3 mm and a length of at least 900 mm. When passing through bulkheads, this length shall be divided preferably into 450 mm on each side of the bulkhead. These ducts, or sleeves lining such ducts, shall be provided with fire insulation. The insulation shall have at least the same fire integrity as the division through which the duct passes.

Equivalent penetration protection may be provided to the satisfaction of the Society, and

- c) Automatic fire dampers shall be fitted in all ducts with a free cross-sectional area exceeding  $0,075 \text{ m}^2$  that pass through "A" class divisions. Each damper shall be fitted close to the division penetrated and the duct between the damper and the division penetrated shall be constructed of steel in accordance with [6.3.4] item a) 1) and [6.3.4] item a) 2). The fire damper shall operate automatically, but shall also be capable of being closed manually from both sides of the division. The damper shall be fitted with a visible indicator which shows the operating position of the damper. Fire dampers are not required, however, where ducts pass through spaces surrounded by "A" class divisions, without serving those spaces, provided those ducts have the same fire integrity as the divisions which they penetrate. A duct of cross-sectional area exceeding  $0,075 \text{ m}^2$  shall not be divided into smaller ducts at the penetration of an "A" class division and then recombined into the original duct once through the division to avoid installing the damper required by this provision.

**6.4.2** Ventilation ducts with a free cross-sectional area exceeding  $0,02 \text{ m}^2$  passing through "B" class bulkheads shall be lined with steel sheet sleeves of 900 mm in length, divided preferably into 450 mm on each side of the bulkheads unless the duct is of steel for this length.

**6.4.3** All fire dampers shall be capable of manual operation. The dampers shall have a direct mechanical means of release or, alternatively, be closed by electrical, hydraulic, or pneumatic operation. All dampers shall be manually operable from both sides of the division. Automatic fire dampers, including those capable of remote operation, shall have a failsafe mechanism that will close the damper in a fire even upon loss of electrical power or hydraulic or pneumatic pressure loss. Remotely operated fire dampers shall be capable of being reopened manually at the damper.

## **6.5 Ventilation systems for passenger ships carrying more than 36 passengers**

**6.5.1** In addition to the requirements in [6.2], [6.3] and [6.4], the ventilation system of a passenger ship carrying more than 36 passengers shall also meet the following requirements.

**6.5.2** In general, the ventilation fans shall be so arranged that the ducts reaching the various spaces remain within a main vertical zone.

**6.5.3** Stairway enclosures shall be served by an independent ventilation fan and duct system (exhaust and supply) which shall not serve any other spaces in the ventilation systems.

**6.5.4** A duct, irrespective of its cross-section, serving more than one 'tween-deck accommodation space, service space or control station, shall be fitted, near the penetration of each deck of such spaces, with an automatic smoke damper that shall also be capable of being closed manually from the protected deck above the damper. Where a fan serves more than one 'tween-deck space through separate ducts within a main vertical zone, each dedicated to a single 'tween-deck space, each duct shall be provided with a manually operated smoke damper fitted close to the fan.

**6.5.5** Vertical ducts shall, if necessary, be insulated as required by Tab 1 and Tab 2. Ducts shall be insulated as required for decks between the space they serve and the space being considered, as applicable.

## **6.6 Exhaust ducts from galley ranges**

### **6.6.1 Requirements for passenger ships carrying more than 36 passengers**

a) *In addition to the requirements in [6.2], [6.3] and [6.4], exhaust ducts from galley ranges shall be constructed in accordance with [6.3.4], item b) 1) and [6.3.4], item b) 2). They shall also be fitted with:*

- 1) *a grease trap readily removable for cleaning unless an alternative approved grease removal system is fitted;*
- 2) *a fire damper located in the lower end of the duct at the junction between the duct and the galley range hood which is automatically and remotely operated and, in addition, a remotely operated fire damper located in the upper end of the duct close to the outlet of the duct;*
- 3) *a fixed means for extinguishing a fire within the duct;*
- 4) *remote-control arrangements for shutting off the exhaust fans and supply fans, for operating the fire dampers mentioned in item a) 2) and for operating the fire-extinguishing system, which shall be placed in a position outside the galley close to the entrance to the galley. Where a multi-branch system is installed, a remote means located with the above controls shall be provided to close all branches exhausting through the same main duct before an extinguishing medium is released into the system; and*
- 5) *suitably located hatches for inspection and cleaning, including one provided close to the exhaust fan and one fitted in the lower end where grease accumulates.*

The requirements given in item a) 1) to item a) 5) apply to all exhaust ducts from galley ranges in which grease or fat is likely to accumulate from galley ranges.

b) *Exhaust ducts from ranges for cooking equipment installed on open decks shall conform to item a), as applicable, when passing through accommodation spaces or spaces containing combustible materials.*

### **6.6.2 Requirements for cargo ships and passenger ships carrying not more than 36 passengers**

*When passing through accommodation spaces or spaces containing combustible materials, the exhaust ducts from galley ranges shall be constructed in accordance with [6.3.4], item a) 1) and [6.3.4], item a) 2). Each exhaust duct shall be fitted with:*

- a) *a grease trap readily removable for cleaning;*
- b) *an automatically and remotely operated fire damper located in the lower end of the duct at the junction between the duct and the galley range hood and, in addition, a remotely operated fire damper in the upper end of the duct close to the outlet of the duct;*
- c) *arrangements, operable from within the galley, for shutting off the exhaust and supply fans; and*
- d) *fixed means for extinguishing a fire within the duct.*

## **6.7 Ventilation rooms serving machinery spaces of category A containing internal combustion machinery**

**6.7.1** *Where a ventilation room serves only such an adjacent machinery space and there is no fire division between the ventilation room and the machinery space, the means for closing the ventilation duct or ducts serving the machinery space shall be located outside of the ventilation room and machinery space.*

**6.7.2** *Where a ventilation room serves such a machinery space as well as other spaces and is separated from the machinery space by a "A-0" class division, including penetrations, the means for closing the ventilation duct or ducts for the machinery space can be located in the ventilation room.*

## **6.8 Ventilation systems for laundries in passenger ships carrying more than 36 passengers**

**6.8.1** *Exhaust ducts from laundries and drying rooms of category (13) spaces as defined in [1.3.3], item b) shall be fitted with:*

- a) *filters readily removable for cleaning purposes;*
- b) *a fire damper located in the lower end of the duct which is automatically and remotely operated;*
- c) *remote-control arrangements for shutting off the exhaust fans and supply fans from within the space and for operating the fire damper mentioned in item b); and*
- d) *suitably located hatches for inspection and cleaning.*

# Section 6                      Suppression of Fire: Fire Fighting

## 1 Water supply systems

### 1.1 General

**1.1.1** *Ships shall be provided with fire pumps, fire mains, hydrants and hoses complying with the applicable requirements of this Section.*

### 1.2 Fire mains and hydrants

#### 1.2.1 General

*Materials readily rendered ineffective by heat shall not be used for fire mains and hydrants unless adequately protected. The pipes and hydrants shall be so placed that the fire hoses may be easily coupled to them. The arrangement of pipes and hydrants shall be such as to avoid the possibility of freezing. Suitable drainage provisions shall be provided for fire main piping. Isolation valves shall be installed for all open deck fire main branches used for purposes other than fire fighting. In ships where deck cargo may be carried, the positions of the hydrants shall be such that they are always readily accessible and the pipes shall be arranged as far as practicable to avoid risk of damage by such cargo.*

#### 1.2.2 Ready availability of water supply

*The arrangements for the ready availability of water supply shall be:*

a) *in passenger ships:*

- 1) *of 1000 gross tonnage and upwards such that at least one effective jet of water is immediately available from any hydrant in an interior location and so as to ensure the continuation of the output of water by the automatic starting of one required fire pump,*
- 2) *of less than 1000 gross tonnage by automatic start of at least one fire pump or by remote starting from the navigation bridge of at least one fire pump. If the pump starts automatically or if the bottom valve cannot be opened from where the pump is remotely started, the bottom valve shall always be kept open, and*
- 3) *if fitted with periodically unattended machinery spaces, the Society shall determine provisions for fixed water fire-extinguishing arrangements for such spaces equivalent to those required for normally attended machinery spaces;*

b) *in cargo ships:*

*with a periodically unattended machinery space or when only one person is required on watch, there shall be immediate water delivery from the fire main system at a suitable pressure, either by remote starting of one of the main fire pumps with remote starting from the navigation bridge and fire control station, if any, or permanent pressurization of the fire main system by one of the main fire pumps, except that the Society may waive this requirement for cargo ships of less than 1600 gross tonnage if the fire pump starting arrangement in the machinery space is in an easily accessible position.*

#### 1.2.3 Diameter of fire mains

*The diameter of the fire main and water service pipes shall be sufficient for the effective distribution of the maximum required discharge from two fire pumps operating simultaneously, except that in the case of cargo ships other than those included in [6.3], the diameter need only be sufficient for the discharge of 140 m<sup>3</sup>/hour.*

#### 1.2.4 Isolating valves and relief valves

- a) *Isolating valves to separate the section of the fire main within the machinery space containing the main fire pump or pumps from the rest of the fire main shall be fitted in an easily accessible and tenable position outside the machinery spaces. The fire main shall be so arranged that when the isolating valves are shut all the hydrants on the ship, except those in the machinery space referred to above, can be supplied with water by another fire pump or an emergency fire pump. The emergency fire pump, its seawater inlet, and suction and delivery pipes and isolating valves shall be located outside the machinery space. If this arrangement cannot be made, the sea-chest may be fitted in the machinery space if the sea inlet valve is remotely controlled from a position in the same compartment as the emergency fire pump and the suction pipe is as short as practicable. Short lengths of suction or discharge piping may penetrate the machinery space, provided they are enclosed in a substantial steel casing or are insulated to A-60 class standards. The pipes shall have substantial wall thickness, but in no case less than 11 mm, and shall be welded except for the flanged connection to the sea inlet valve.*
- b) *Any part of the fire main routed through a category A machinery space, except for short lengths of suction or discharge piping complying with item a), is to be fitted with isolating valves outside of the space. The arrangements of the fire mains are to allow for fire water from the fire pumps or emergency fire pump to reach all hydrants outside of the isolated space. Isolation requirements of item a) are not applicable to the piping from fire pumps located in spaces other than category A machinery spaces.*

- c) In cases where suction or discharge piping of emergency fire pumps penetrating machinery spaces are enclosed in a substantial steel casing, or are insulated to "A-60" class standards, it is not necessary to enclose or insulate "distance pieces", "sea inlet valves" and "sea-chests". The method for insulating pipes to "A-60" class standards is that they are to be covered/protected in a practical manner by insulation material which is approved as a part of "A-60" class divisions in accordance with the IMO FTP Code. Where the sea inlet valve is in the machinery space, the valve is not to be a fail-close type. Where the sea inlet valve is in the machinery space and is not a fail-open type, measures are to be taken so that the valve can be opened in the event of fire, e.g. control piping, actuating devices and/or electric cables with fire resistant protection equivalent to "A-60" class standards.
- d) In cases where main fire pumps are provided in compartments outside machinery spaces and where the emergency fire pump suction or discharge piping penetrates such compartments, the above interpretation of item c) is to be applied to the piping.
- e) A valve shall be fitted to serve each fire hydrant so that any fire hose may be removed while the fire pumps are in operation.
- f) Relief valves shall be provided in conjunction with fire pumps if the pumps are capable of developing a pressure exceeding the design pressure of the water service pipes, hydrants and hoses. These valves shall be so placed and adjusted as to prevent excessive pressure in any part of the fire main system.
- g) In tankers, isolation valves shall be fitted in the fire main at the poop front in a protected position and on the tank deck at intervals of not more than 40 m to preserve the integrity of the fire main system in case of fire or explosion.

### 1.2.5 Number and position of hydrants

- a) The number and position of hydrants shall be such that at least two jets of water not emanating from the same hydrant, one of which shall be from a single length of hose, may reach any part of the ship normally accessible to the passengers or crew while the ship is being navigated and any part of any cargo space when empty, any ro-ro space or any vehicle space, in which latter case the two jets shall reach any part of the space, each from a single length of hose. Furthermore, such hydrants shall be positioned near the accesses to the protected spaces.

At least two hydrants are to be provided in machinery spaces of category A.

- b) In addition to the requirements in item a) above, passenger ships shall comply with the following:
  - 1) in the accommodation, service and machinery spaces, the number and position of hydrants shall be such that the requirements of item a) above may be complied with when all watertight doors and all doors in main vertical zone bulkheads are closed, and
  - 2) where access is provided to a machinery space of category A at a low level from an adjacent shaft tunnel, two hydrants shall be provided external to, but near the entrance to, that machinery space. Where such access is provided from other spaces, in one of those spaces two hydrants shall be provided near the entrance to the machinery space of category A. Such provision need not be made where the tunnel or adjacent spaces are not part of the escape route.

### 1.2.6 Pressure at hydrants

With the two pumps simultaneously delivering water through the nozzles specified in [1.4.3], with the quantity of water as specified in [1.2.3], through any adjacent hydrants, the following minimum pressures shall be maintained at all hydrants:

- a) for passenger ships:
  - 4000 gross tonnage and upwards : 0,40 N/mm<sup>2</sup>
  - less than 4000 gross tonnage : 0,30 N/mm<sup>2</sup>
- b) for cargo ships:
  - 6000 gross tonnage and upwards : 0,27 N/mm<sup>2</sup>
  - less than 6000 gross tonnage : 0,25 N/mm<sup>2</sup>and
- c) the maximum pressure at any hydrant shall not exceed that at which the effective control of a fire hose can be demonstrated.

### 1.2.7 International shore connection

Ships of 500 gross tonnage and upwards shall be provided with at least one international shore connection complying with Ch 4, Sec 15. Facilities shall be available enabling such a connection to be used on either side of the ship.

## 1.3 Fire pumps

### 1.3.1 Pumps accepted as fire pumps

Sanitary, ballast, bilge or general service pumps may be accepted as fire pumps, provided that they are not normally used for pumping oil and that, if they are subject to occasional duty for the transfer or pumping of oil fuel, suitable change-over arrangements are fitted.

The emergency fire pump mentioned in [1.3.3] may also be used for other suitable purposes subject to approval by the Society in each case.

### **1.3.2 Number of fire pumps**

*Ships shall be provided with independently driven fire pumps as follows:*

a) *in passenger ships of:*

- *4000 gross tonnage and upwards : at least 3*
- *less than 4000 gross tonnage : at least 2*

b) *in cargo ships of:*

- *1000 gross tonnage and upwards : at least 2*
- *less than 1000 gross tonnage : at least 2 power-driven pumps, one of which shall be independently driven.*

### **1.3.3 Arrangement of fire pumps and fire mains**

a) *Fire pumps*

*The arrangement of sea connections, fire pumps and their sources of power shall be as to ensure that:*

1) *in passenger ships of*

- *1000 gross tonnage and upwards, in the event of a fire in any one compartment, all the fire pumps will not be put out of action*
- *less than 1000 gross tonnage, if a fire in any one compartment could put all the pumps out of action, there shall be an alternative means consisting of an emergency fire pump complying with Ch 4, Sec 15, [11.1.1] with its source of power and sea connection located outside the space where the main fire pumps or their sources of power are located.*

2) *in cargo ships of 500 gross tonnage and upwards,*

- *unless the two main fire pumps and the fuel supply or source of power for each pump are situated within compartments separated at least by an A-0 class division, so that a fire in any one compartment will not render both fire pumps inoperable, a fixed independent power operated emergency fire pump complying with the following requirements and those of Ch 4, Sec 15, [11] is to be fitted (for cargo ships of less than 2000 gross tonnage only, Ch 4, Sec 15, [11.1.1] applies). An arrangement in which one main fire pump is located in a steel compartment having more than one bulkhead and/or deck adjacent to the compartment containing the other main fire pump will also require an emergency fire pump*
- *Where a power operated emergency fire pump is fitted, its fuel or power supply is to be so arranged that it will not readily be affected by a fire in the compartment containing the main fire pumps.*

b) *Requirements for the space containing the emergency fire pump in cargo ships*

1) *Location of the space*

*The space containing the fire pump shall not be contiguous to the boundaries of machinery spaces of category A or those spaces containing main fire pumps. Where this is not practicable, the common bulkhead between the two spaces shall be insulated to a standard of structural fire protection equivalent to that required for a control station in Ch 4, Sec 5, [1.4.3].*

2) *Access to the emergency fire pump*

*No direct access shall be permitted between the machinery space and the space containing the emergency fire pump and its source of power. When this is impracticable, the Society may accept an arrangement where the access is by means of an airlock with the door of the machinery space being of A-60 class standard and the other door being at least steel, both reasonably gastight, self-closing and without any hold-back arrangements. Alternatively, the access may be through a watertight door capable of being operated from a space remote from the machinery space and the space containing the emergency fire pump and unlikely to be cut off in the event of fire in those spaces. In such cases, a second means of access to the space containing the emergency fire pump and its source of power shall be provided.*

*When a single access to the emergency fire pump room is through another space adjoining a machinery space of category A or the spaces containing the main fire pumps, an A-60 class boundary is required between such other space and the machinery space of category A or the spaces containing the main fire pumps.*

3) *Ventilation of the emergency fire pump space*

*Ventilation arrangements to the space containing the independent source of power for the emergency fire pump shall be such as to preclude, as far as practicable, the possibility of smoke from a machinery space fire entering or being drawn into that space.*

*If the space is mechanically ventilated the power is to be supplied by the emergency source.*

4) *Illumination of the space*

*The room where the emergency fire pump prime mover is located is to be illuminated from the emergency source of supply and is to be well ventilated.*

c) *Additional pumps for cargo ships*

*In addition, in cargo ships where other pumps, such as general service, bilge and ballast, etc., are fitted in a machinery space, arrangements shall be made to ensure that at least one of these pumps, having the capacity and pressure required by [1.3.4] item b) and by [1.2.6] item b), is capable of providing water to the fire main.*

### **1.3.4 Capacity of fire pumps**

a) *Total capacity of required fire pumps*

The required fire pumps shall be capable of delivering for fire-fighting purposes a quantity of water, at the pressure specified in [1.2.6], as follows:

- 1) *pumps in passenger ships: the quantity of water is not less than two thirds of the quantity required to be dealt with by the bilge pumps when employed for bilge pumping, and*
- 2) *pumps in cargo ships, other than any emergency pump: the quantity of water is not less than four thirds of the quantity required in Ch 1, Sec 10 to be dealt with by each of the independent bilge pumps in a passenger ship of the same dimension when employed in bilge pumping, provided that in no cargo ship other than those included in [6.3], need the total required capacity of the fire pumps exceed 180 m<sup>3</sup>/hour.*

b) When the main water supply for other fixed fire-extinguishing systems is from the fire pumps, the total capacity of the fire pumps is to be sufficient for the simultaneous use of:

- the minimum required number of jets of water at the required pressure from the fire main, and
- other fixed fire-extinguishing systems primarily fed by the fire main at their required output, or likely combination thereof.

c) *Capacity of each fire pump*

*Each of the required fire pumps (other than any emergency pump required in [1.3.3] a) for cargo ships) shall have a capacity not less than 80% of the total required capacity divided by the minimum number of required fire pumps, but in any case not less than 25 m<sup>3</sup>/hour, and each such pump shall in any event be capable of delivering at least the two required jets of water. These fire pumps shall be capable of supplying the fire main system under the required conditions. Where more pumps than the minimum of required pumps are installed, such additional pumps shall have a capacity of at least 25 m<sup>3</sup>/h and shall be capable of delivering at least the two jets of water required in [1.2.5] a).*

d) Specific requirements for ships designed to carry five or more tiers of containers on or above the weather deck

- in cases where the mobile water monitors are supplied by separate pumps and piping system, the total capacity of the main fire pumps need not exceed 180 m<sup>3</sup>/h and the diameter of the fire main and water service pipes (hereinafter referred to "the pipework diameter") need only be sufficient for the discharge of 140 m<sup>3</sup>/h.
- in cases where the mobile water monitors are supplied by the main fire pumps; the total capacity of required main fire pumps and the pipework diameter shall be sufficient for simultaneously supplying both the required number of fire hoses and mobile water monitors. However, the total capacity shall not be less than the following, whichever is smaller:
  - four thirds of the capacity required under Ch 1, Sec 10, [6.7.4] for each bilge pump or group of bilge pump; or
  - 180m<sup>3</sup>/h
- in cases where the mobile water monitors and the "water spray system" (fixed arrangement of spraying nozzles or flooding the cargo space with water) required by Ch 4, Sec 12, [2.2.3] are supplied by the main fire pumps, the total capacity of the main fire pumps and the pipework diameter need only be sufficient to supply whichever of the following is the greater:
  - the mobile water monitors and the four nozzles required by Ch 4, Sec 12, [2.2.2]; or
  - the four nozzles required by Ch 4, Sec 12, [2.2.2] and the water spray system required by Ch 4, Sec 12, [2.2.3]

The total capacity, however, is not to be less than specified in the above bullet point.

## **1.4 Fire hoses and nozzles**

### **1.4.1 General specifications**

a) *Fire hoses shall be of non-perishable material approved by the Society and shall be sufficient in length to project a jet of water to any of the spaces in which they may be required to be used. Each hose shall be provided with a nozzle and the necessary couplings. Hoses specified in this Chapter as "fire hoses" shall, together with any necessary fittings and tools, be kept ready for use in conspicuous positions near the water service hydrants or connections. Additionally, in interior locations in passenger ships carrying more than 36 passengers, fire hoses shall be connected to the hydrants at all times. Fire hoses shall have a length of at least 10 m, but not more than:*

- 15 m in machinery spaces
- 20 m in other spaces and open decks, and
- 25 m for open decks on ships with a maximum breadth in excess of 30 m.

b) *Unless one hose and nozzle is provided for each hydrant in the ship, there shall be complete interchangeability of hose couplings and nozzles.*

### **1.4.2 Number and diameter of fire hoses**

- a) Ships shall be provided with fire hoses, the number and diameter of which shall be to the satisfaction of the Society.
- b) In passenger ships, there shall be at least one fire hose for each of the hydrants required by [1.2.5] and these hoses shall be used only for the purposes of extinguishing fires or testing the fire-extinguishing apparatus at fire drills and surveys.
- c) In cargo ships:
  - 1) of 1000 gross tonnage and upwards, the number of fire hoses to be provided shall be one for each 30 m length of the ship and one spare, but in no case less than five in all. This number does not include any hoses required in any engine-room or boiler room. The Society may increase the number of hoses required so as to ensure that hoses in sufficient number are available and accessible at all times, having regard to the type of ship and the nature of trade in which the ship is employed. Ships carrying dangerous goods in accordance with Ch 4, Sec 12 shall be provided with three hoses and nozzles, in addition to those required above.  
Hydrants in machinery spaces of category A shall be provided with fire hoses, and
  - 2) of less than 1000 gross tonnage, the number of fire hoses to be provided shall be calculated in accordance with the provisions of item 1) above. However the number of hoses shall in no case be less than three.

### **1.4.3 Size and type of nozzles**

- a) For the purposes of this Chapter, standard nozzle sizes shall be 12 mm, 16 mm and 19 mm or as near thereto as possible. Larger diameter nozzles may be permitted at the discretion of the Society.
- b) For accommodation and service spaces, a nozzle size greater than 12 mm need not be used.
- c) For machinery spaces and exterior locations, the nozzle size shall be such as to obtain the maximum discharge possible from two jets at the pressure mentioned in [1.2.6] from the smallest pump, provided that a nozzle size greater than 19 mm need not be used.
- d) Nozzles shall be of an approved dual-purpose type (i.e. spray/jet type) incorporating a shut-off.

## **2 Portable fire extinguishers**

### **2.1 Type and design**

**2.1.1** Portable fire extinguishers shall comply with the requirements of Ch 4, Sec 15.

### **2.2 Arrangement of fire extinguishers**

**2.2.1** Accommodation spaces, service spaces and control stations shall be provided with portable fire extinguishers of appropriate types and in sufficient number to the satisfaction of the Society. Ships of 1000 gross tonnage and upwards shall carry at least five portable fire extinguishers.

The number and the type of portable fire extinguishers required for the above-mentioned spaces are to be as follows:

- in accommodation and service spaces of passenger ships: one foam extinguisher or equivalent, for each group of adjacent spaces with easy access between them having total deck area not exceeding 200 m<sup>2</sup>
- in accommodation spaces of cargo ships of 1000 gross tonnage and upwards: at least five foam extinguishers or equivalent, but not less than one for each 'tweendeck
- in accommodation spaces of cargo ships of less than 1000 gross tonnage: at least two foam extinguishers or equivalent, but not less than one for each 'tweendeck
- in the proximity of any electric switchboard or section board having a power of 20 kW and upwards: at least one CO<sub>2</sub> or powder extinguisher
- in any service space where deep fat cooking equipment is installed: at least one foam extinguisher or equivalent
- in the proximity of any paint or flammable product locker: at least one foam extinguisher or equivalent
- on the navigating bridge: one CO<sub>2</sub> extinguisher or equivalent.

**2.2.2** One of the portable fire extinguishers intended for use in any space shall be stowed near the entrance to that space.

## **3 Fixed fire-extinguishing systems**

### **3.1 Types of fixed fire-extinguishing systems**

**3.1.1** A fixed fire extinguishing system required by article [4] may be any of the following systems:

- a) a fixed gas fire-extinguishing system complying with the provisions of Ch 4, Sec 15
- b) a fixed high-expansion foam fire-extinguishing system complying with the provisions of Ch 4, Sec 15, and
- c) a fixed pressure water-spraying fire-extinguishing system complying with the provisions of Ch 4, Sec 15.

**3.1.2** Where a fixed fire-extinguishing system not required by this Chapter is installed, it shall meet the relevant requirements of this Chapter.

**3.1.3** Fire-extinguishing systems using Halon 1211, 1301, and 2402 and perfluorocarbons shall be prohibited.

**3.1.4** In general, the Society shall not permit the use of steam as a fire-extinguishing medium in fixed fire-extinguishing systems.

### **3.2 Closing appliances for fixed gas fire-extinguishing systems**

**3.2.1** Where a fixed gas fire-extinguishing system is used, openings which may admit air to, or allow gas to escape from, a protected space shall be capable of being closed from outside the protected space.

### **3.3 Storage rooms of fire-extinguishing medium**

**3.3.1** When the fire-extinguishing medium is stored outside a protected space, it shall be stored in a room which is located behind the forward collision bulkhead, and is used for no other purposes. Any entrance to such a storage room shall preferably be from the open deck and shall be independent of the protected space. If the storage space is located below deck, it shall be located no more than one deck below the open deck and shall be directly accessible by a stairway or ladder from the open deck. Spaces which are located below deck or spaces where access from the open deck is not provided shall be fitted with a mechanical ventilation system designed to take exhaust air from the bottom of the space and shall be sized to provide at least 6 air changes per hour. Access doors shall open outwards, and bulkheads and decks, including doors and other means of closing any opening therein, which form the boundaries between such rooms and adjacent enclosed spaces, shall be gastight. For the purpose of the application of Ch 4, Sec 5, Tab 1 to Ch 4, Sec 5, Tab 8, such storage rooms shall be treated as fire control stations.

### **3.4 Water pumps for other fire-extinguishing systems**

**3.4.1** Pumps, other than those serving the fire main, required for the provision of water for fire-extinguishing systems required by the present Chapter, their sources of power and their controls shall be installed outside the space or spaces protected by such systems and shall be so arranged that a fire in the space or spaces protected will not put any such system out of action.

## **4 Fire-extinguishing arrangements in machinery spaces**

### **4.1 Machinery spaces arrangement**

#### **4.1.1 General**

- a) The arrangement of machinery spaces is to be such that safe storage and handling of flammable liquids is ensured.
- b) All spaces where oil-consuming installations, settling tanks or daily service fuel tanks are located are to be easily accessible and well ventilated.
- c) Where leakage of flammable liquids may occur during normal service or routine maintenance work, special arrangement is to be made to prevent these fluids from reaching other parts of the machinery where danger of ignition may arise.
- d) Materials used in machinery spaces are not normally to have properties increasing the fire potential of these rooms. Neither combustible nor oil-absorbing materials are to be used as flooring, bulkhead lining, ceiling or deck in the control room, machinery spaces, shaft tunnel or rooms where oil tanks are located. Where penetration of oil products is possible, the surface of the insulation is to be impervious to oil or oil vapours.

#### **4.1.2 Segregation of fuel oil purifiers and other systems for preparing flammable liquids**

The following systems:

- systems (such as purifiers) for preparing flammable liquids for use in boilers and machinery,
- separate oil systems with working pressure above 1.5 MPa and which are not part of the main engines, auxiliary engines or boilers, etc,

are subjected to the following additional requirements:

- a) The main components in the systems are to be placed in a separate room, enclosed by steel bulkheads extending from deck to deck and provided with self-closing steel doors.

Transfer pumps may be placed outside this room.

Note 1: Lubricating oil systems part of the main machinery may be located in the main engine room in location ventilated by extraction.

- b) Rooms in which flammable liquids are handled, are to be provided with:
  - independent mechanical ventilation or ventilation arrangements which can be isolated from the machinery space ventilation
  - a fire detecting system
  - a fixed fire-extinguishing installation. The extinguishing installation is to be capable of being activated from outside the room. The extinguishing system is to be separated for the room, but may be a part of the main fire-extinguishing system for the machinery space. Closing of ventilation openings is to be effected from a position close to where the extinguishing system is activated.

- c) Where the size and/or the design of the engine room makes it impracticable to locate the main components of such systems in a separate space, specific measures with regard to the location, containment of possible leakages and shielding of the components, and to ventilation, are to be provided to the satisfaction of the Society, such as:
- fitting of drip trays and shielding for leakage containment
  - location close to ventilation exhaust so as to avoid flammable gas accumulation in vicinity
  - fitting of dedicated hood above for ventilation exhaust.

A local fixed fire-extinguishing system as required by [4.7] is to be provided, capable of being activated automatically or activated manually from the machinery control position or from another suitable location. If automatic release is provided, additional manual release is to be arranged.

## **4.2 Machinery spaces containing oil-fired boilers or oil fuel units**

### **4.2.1 Fixed fire-extinguishing systems**

*Machinery spaces of category A containing oil fired boilers or oil fuel units shall be provided with any one of the fixed fire-extinguishing systems in [3.1].*

*In each case, if the engine-room and boiler room are not entirely separate, or if fuel oil can drain from the boiler room into the engine-room, the combined engine and boiler rooms shall be considered as one compartment.*

### **4.2.2 Additional fire-extinguishing arrangements**

- a) *There shall be in each boiler room or at an entrance outside of the boiler room at least one portable foam applicator unit complying with the provisions of Ch 4, Sec 15.*
- b) *There shall be at least two portable foam extinguishers or equivalent in each firing space in each boiler room and in each space in which a part of the oil fuel installation is situated. There shall be not less than one approved foam-type extinguisher of at least 135 l capacity or equivalent in each boiler room. These extinguishers shall be provided with hoses on reels suitable for reaching any part of the boiler room. In the case of domestic boilers of less than 175 kW, or boilers protected by fixed water-based local application fire-extinguishing systems as required by [4.7], an approved foam-type extinguisher of at least 135 l capacity is not required.*

*In the proximity of any electric switchboard or section board having a power of 20 kW and upwards at least one CO<sub>2</sub> or powder extinguisher is to be fitted.*

- c) *In each firing space there shall be a receptacle containing at least 0,1 m<sup>3</sup> sand, sawdust impregnated with soda, or other approved dry material, along with a suitable shovel for spreading the material. An approved portable extinguisher may be substituted as an alternative.*

## **4.3 Machinery spaces of category A containing internal combustion machinery**

### **4.3.1 Fixed fire-extinguishing systems**

*Machinery spaces of category A containing internal combustion machinery shall be provided with one of the fixed fire-extinguishing systems required in [3.1].*

### **4.3.2 Additional fire-extinguishing arrangements**

- a) *There shall be at least one portable foam applicator unit complying with the provisions of Ch 4, Sec 15.*
- b) *There shall be in each such space approved foam-type fire extinguishers, each of at least 45 l capacity or equivalent, sufficient in number to enable foam or its equivalent to be directed onto any part of the fuel and lubricating oil pressure systems, gearing and other fire hazards. In addition, there shall be provided a sufficient number of portable foam extinguishers or equivalent which shall be so located that no point in the space is more than 10 m walking distance from an extinguisher and that there are at least two such extinguishers in each such space. For smaller spaces of cargo ships, the Society may consider relaxing this requirement.*
- c) *In the case of machinery spaces containing both boilers and internal combustion engines, [4.2] and [4.3] apply, with the exception that one of the foam fire extinguishers of at least 45 l capacity or equivalent may be omitted provided that the 136 l extinguisher can efficiently and readily protect the area covered by the 45 l extinguishers.*
- d) *There shall be at least one CO<sub>2</sub> or powder extinguisher in the proximity of any electric switchboard or section board having a power of 20 kW and upwards.*

## **4.4 Machinery spaces containing steam turbines or enclosed steam engines**

### **4.4.1 Fixed fire-extinguishing systems**

*In spaces containing steam turbines or enclosed steam engines used for main propulsion or other purposes having in the aggregate a total output of not less than 375 kW, one of the fire-extinguishing systems specified in [3.1] shall be provided if such spaces are periodically unattended.*

#### **4.4.2 Additional fire-extinguishing arrangements**

- a) *There shall be approved foam fire extinguishers, each of at least 45 l capacity or equivalent, sufficient in number to enable foam or its equivalent to be directed on to any part of the pressure lubrication system, on to any part of the casings enclosing pressure-lubricated parts of the turbines, engines or associated gearing, and any other fire hazards. However, such extinguishers shall not be required if protection, at least equivalent to that required by this item, is provided in such spaces by a fixed fire-extinguishing system fitted in compliance with [3.1].*
- b) *There shall be a sufficient number of portable foam extinguishers or equivalent which shall be so located that no point in the space is more than 10 m walking distance from an extinguisher and that there are at least two such extinguishers in each such space, except that such extinguishers shall not be required in addition to any provided in compliance with item b) of [4.2.2].*
- c) *There shall be at least one CO<sub>2</sub> or powder extinguisher in the proximity of any electric switchboard or section board having a power of 20 kW and upwards.*

#### **4.5 Other machinery spaces**

**4.5.1** *Where, in the opinion of the Society, a fire hazard exists in any machinery space for which no specific provisions for fire-extinguishing appliances are prescribed in [4.2], [4.3] and [4.4], there shall be provided in, or adjacent to, that space such a number of approved portable fire extinguishers or other means of fire extinction as the Society may deem sufficient.*

#### **4.5.2 Spaces intended for the storage or handling of solvent onboard ships fitted with an onboard carbon capture and storage system (OCC)**

Spaces intended for the storage or handling of solvent (as defined in Ch 1, Sec 12, [1.3.6]) on board ships fitted with an OCC are to be provided with one of the following fixed fire-extinguishing system:

- a fixed high-expansion foam fire-extinguishing system complying with the provisions of Ch 4, Sec 15 and using a foam concentrate suitable for extinguishing amine-based solvent fires, or
- a fixed pressure water-spraying fire-extinguishing system complying with the provisions of Ch 4, Sec 15.

#### **4.6 Additional requirements for passenger ships**

**4.6.1** *In passenger ships carrying more than 36 passengers, each machinery space of category A shall be provided with at least two suitable water fog applicators, complying with Ch 4, Sec 15.*

#### **4.7 Fixed local application fire-extinguishing systems**

**4.7.1** *The present sub-article shall apply to passenger ships of 500 gross tonnage and above and cargo ships of 2000 gross tonnage and above.*

**4.7.2** *Machinery spaces of category A above 500 m<sup>3</sup> in volume shall, in addition to the fixed fire-extinguishing system required in [4.2.1], be protected by a fixed water-based or equivalent local application fire-extinguishing system complying with the provisions of Ch 4, Sec 15. In the case of periodically unattended machinery spaces, the fire-extinguishing system shall have both automatic and manual release capabilities. In the case of continuously manned machinery spaces, the fire-extinguishing system is only required to have a manual release capability.*

**4.7.3** *Fixed local application fire-extinguishing systems are to protect areas such as the following without the necessity of engine shutdown, personnel evacuation, or sealing of the spaces:*

- a) *the fire hazard portions of internal combustion machinery. In multi-engine installations, at least two sections are to be arranged.*
- b) *boiler fronts*
- c) *the fire hazard portions of incinerators, and*
- d) *purifiers for heated fuel oil.*

**4.7.4** *Activation of any local application system shall give a visual and distinct audible alarm in the protected space and at continuously manned stations. The alarm shall indicate the specific system activated. The system alarm requirements described within this requirement are in addition to, and not a substitute for, the detection and fire alarm system required elsewhere in this Chapter.*

## 5 Fire-extinguishing arrangements in control stations, accommodation and service spaces

### 5.1 Sprinkler and water spray systems in passenger ships

**5.1.1** Passenger ships carrying more than 36 passengers shall be equipped with an automatic sprinkler, fire detection and fire alarm system of an approved type complying with the requirements of Ch 4, Sec 15 in all control stations, accommodation and service spaces, including corridors and stairways. Alternatively, control stations, where water may cause damage to essential equipment, may be fitted with an approved fixed fire-extinguishing system of another type. Spaces having little or no fire risk such as voids, public toilets, carbon dioxide rooms and similar spaces need not be fitted with an automatic sprinkler system.

**5.1.2** In passenger ships carrying not more than 36 passengers, when a fixed smoke detection and fire alarm system complying with the provisions of Ch 4, Sec 15 is provided only in corridors, stairways and escape routes within accommodation spaces, an automatic sprinkler system shall be installed in accordance with Ch 4, Sec 3, [4.4.1], item b).

**5.1.3** A fixed pressure water-spraying fire-extinguishing system complying with the provisions of Ch 4, Sec 15, [6.1.3] shall be installed on cabin balconies to which Ch 4, Sec 2, [2.2.4] applies, when furniture and furnishings on such balconies are not as defined in Ch 4, Sec 1, [2.38.1], items a), b), c), f) and g).

### 5.2 Sprinkler systems for cargo ships

**5.2.1** In cargo ships in which method IIC specified in a)2) of Ch 4, Sec 5, [1.4.1] is adopted, an automatic sprinkler, fire detection and fire alarm system shall be fitted in accordance with the requirements of Ch 4, Sec 3, [4.7.1], item b).

### 5.3 Spaces containing flammable liquid

**5.3.1** Paint lockers shall be protected by:

- a) a carbon dioxide system, designed to give a minimum volume of free gas equal to 40% of the gross volume of the protected space
- b) a dry powder system, designed for at least 0,5 kg powder/m<sup>3</sup>
- c) a water spraying or sprinkler system, designed for 5 l/m<sup>2</sup> min. Water spraying systems may be connected to the fire main of the ship, or
- d) a system providing equivalent protection, as determined by the Society.

In all cases, the system shall be operable from outside the protected space.

**5.3.2** Flammable liquid lockers shall be protected by an appropriate fire-extinguishing arrangement approved by the Society.

**5.3.3** For lockers of a deck area of less than 4 m<sup>2</sup>, which do not give access to accommodation spaces, a portable carbon dioxide fire extinguisher sized to provide a minimum volume of free gas equal to 40% of the gross volume of the space may be accepted in lieu of a fixed system. A discharge port shall be arranged in the locker to allow the discharge of the extinguisher without having to enter into the protected space. The required portable fire extinguisher shall be stowed adjacent to the port. Alternatively, a port or hose connection may be provided to facilitate the use of fire main water.

### 5.4 Deep-fat cooking equipment

**5.4.1** Deep-fat cooking equipment installed in enclosed spaces or on open decks shall be fitted with the following:

- a) an automatic or manual fire-extinguishing system tested to an international standard
- b) a primary and backup thermostat with an alarm to alert the operator in the event of failure of either thermostat
- c) arrangements for automatically shutting off the electrical power upon activation of the fire-extinguishing system
- d) an alarm for indicating operation of the fire-extinguishing system in the galley where the equipment is installed, and
- e) controls for manual operation of the fire-extinguishing system which are clearly labelled for ready use by the crew.

## 6 Fire-extinguishing arrangements in cargo spaces

### 6.1 Fixed gas fire-extinguishing systems for general cargo

**6.1.1** Except as provided for in [6.2], the cargo spaces of passenger ships of 1000 gross tonnage and upwards shall be protected by a fixed carbon dioxide or inert gas fire-extinguishing system complying with the provisions of Ch 4, Sec 15 or by a fixed high-expansion foam fire-extinguishing system which gives equivalent protection.

**6.1.2** Where it is shown to the satisfaction of the Society that a passenger ship is engaged on voyages of such short duration that it would be unreasonable to apply the requirements of [6.1.1] and also in ships of less than 1000 gross tonnage, the arrangements in cargo spaces shall be to the satisfaction of the Society, provided that the ship is fitted with steel hatch covers and effective means of closing all ventilators and other openings leading to the cargo spaces.

**6.1.3** Except for ro-ro and vehicle spaces (see Ch 4, Sec 13), cargo spaces on cargo ships of 2000 gross tonnage and upwards shall be protected by a fixed carbon dioxide or inert gas fire-extinguishing system complying with the provisions of Ch 4, Sec 15, or by a fire-extinguishing system which gives equivalent protection.

**6.1.4** The Society may exempt from the requirements of [6.1.3] and [6.2] cargo spaces of any cargo ship if constructed, and solely intended, for the carriage of ore, coal, grain, unseasoned timber, non-combustible cargoes or cargoes which, in the opinion of the Society, constitute a low fire risk. Such exemptions may be granted only if the ship is fitted with steel hatch covers and effective means of closing all ventilators and other openings leading to the cargo spaces. When such exemptions are granted, this will be reported on the Certificate of Classification.

Note 1: The list of solid bulk cargoes for which a fixed gas fire-extinguishing system may be exempted is given in the IMO Circular MSC.Circ.1395, as amended.

## **6.2 Fixed gas fire-extinguishing systems for dangerous goods**

**6.2.1** A ship engaged in the carriage of dangerous goods on deck or in any cargo spaces shall be provided with a fixed carbon dioxide or inert gas fire-extinguishing system complying with the provisions of Ch 4, Sec 15 or with a fire-extinguishing system which, in the opinion of the Society, gives equivalent protection for the cargoes carried.

## **6.3 Firefighting for ships designed to carry containers on or above the weather deck**

**6.3.1** Ships shall carry, in addition to the equipment and arrangements required by article [1], at least one water mist lance. The water mist lance shall consist of a tube with a piercing nozzle which is capable of penetrating a container wall and producing water mist inside a confined space (container, etc.) when connected to the fire main.

**6.3.2** Ships designed to carry five or more tiers of containers on or above the weather deck shall carry, in addition to the requirements of [6.3.1], mobile water monitors as follows, and comply with item a) to e):

- ships with breadth less than 30 m: at least two mobile water monitors; or
  - ships with breadth of 30 m or more: at least four mobile water monitors.
- a) The mobile water monitors, all necessary hoses, fittings and required fixing hardware shall be kept ready for use in a location outside the cargo space area not likely to be cut-off in the event of a fire in the cargo spaces.
- b) A sufficient number of fire hydrants shall be provided such that:
- 1) all provided mobile water monitors can be operated simultaneously for creating effective water barriers forward and aft of each container bay;
  - 2) the two jets of water required by item a) of [1.2.5] can be supplied at the pressure required by [1.2.6]; and
  - 3) each of the required mobile water monitors can be supplied by separate hydrants at the pressure necessary to reach the top tier of containers on deck.
- c) The mobile water monitors may be supplied by the fire main, provided the capacity of fire pumps and fire main diameter are adequate to simultaneously operate the mobile water monitors and two jets of water from fire hoses at the required pressure values. If carrying dangerous goods, the capacity of fire pumps and fire main diameter shall also comply with Ch 4, Sec 12, [2.2.5], as far as applicable to on-deck cargo areas.
- d) The operational performance of each mobile water monitor shall be tested during initial survey on board the ship to the satisfaction of the Society. The test shall verify that:
- 1) the mobile water monitor can be securely fixed to the ship structure ensuring safe and effective operation; and
  - 2) the mobile water monitor jet reaches the top tier of containers with all required monitors and water jets from fire hoses operated simultaneously.
- e) The mobile water monitors are to be of a type approved by the Society according to IMO Circular MSC.1/Circ.1472.

## **7 Fire-extinguishing arrangements for ballast water management rooms**

### **7.1 Fixed fire-extinguishing system**

**7.1.1** Where fitted, fixed fire-extinguishing systems are to comply with the relevant provisions of Ch 4, Sec 15.

#### **7.1.2 Ozone-based ballast water management systems**

Ballast water management rooms containing equipment related to ozone-based ballast water management systems are to be provided with a fixed fire-extinguishing system suitable for category A machinery spaces and capable of manual release.

**7.1.3** Where a fixed fire-extinguishing system is provided in the ballast water management room, it is to be compatible with the ballast water management system and the chemical products that are used, produced or stored in the ballast water management room. Specific attention is to be paid to potential chemical reactions between the fire-extinguishing medium and chemical products used for water treatment.

Especially, water-based fire-extinguishing systems are to be avoided in case of sulfuric acid storage.

**7.1.4 Foam fixed fire-extinguishing system**

For all kinds of ballast water management systems, in case a foam fire-extinguishing system is installed in the ballast water management room, its efficiency is not to be impaired by chemicals used by the ballast water management system where relevant.

**7.1.5** Where a fixed fire-extinguishing system is installed in the ballast water management room, automatic shutdown of the ballast water management system upon release of the fixed fire-extinguishing system is to be arranged. Any need for cooldown necessary for safe shutdown is to be considered in the shutdown sequence.

**7.1.6** Where a ballast water management system that includes air or O<sub>2</sub> storage is located in a room covered by a fixed gas fire-extinguishing system, air or O<sub>2</sub> storage is to be taken into account for the gas capacity calculation, unless the discharge pipe from safety valves for air or O<sub>2</sub> storage are led directly to outside the room.

**7.2 Portable fire-fighting equipment**

**7.2.1** At least one portable fire extinguisher complying with the provisions of Ch 4, Sec 15, [3] and suitable for electrical fires is to be provided in the ballast water management room containing UV-type ballast water management system.

# Section 7                      Suppression of Fire: Structural Integrity

## 1 Application

### 1.1 General

1.1.1 The provisions of Articles [2] to [5] apply to ships of all types and those of Article [6] apply to tankers.

## 2 Material of hull, superstructures, structural bulkheads, decks and deckhouses

### 2.1 General

2.1.1 *The hull, superstructures, structural bulkheads, decks and deckhouses shall be constructed of steel or other equivalent material. For the purpose of applying the definition of steel or other equivalent material as given in Ch 4, Sec 1, [2.48.1], the "applicable fire exposure" shall be according to the integrity and insulation standards given in Ch 4, Sec 5, Tab 1 to Ch 4, Sec 5, Tab 4. For example, where divisions such as decks or sides and ends of deckhouses are permitted to have B-0 fire integrity, the "applicable fire exposure" shall be half an hour.*

## 3 Structure of aluminium alloy

### 3.1 General

3.1.1 *Unless otherwise specified in [2.1.1], in cases where any part of the structure is of aluminium alloy, the following shall apply:*

- a) *The insulation of aluminium alloy components of A or B class divisions, except structure which, in the opinion of the Society, is non-load-bearing, shall be such that the temperature of the structural core does not rise more than 200°C above the ambient temperature at any time during the applicable fire exposure to the standard fire test, and*
- b) *Special attention shall be given to the insulation of aluminium alloy components of columns, stanchions and other structural members required to support lifeboat and liferaft stowage, launching and embarkation areas, and A and B class divisions to ensure:*
  - 1) *that for such members supporting lifeboat and liferaft areas and A class divisions, the temperature rise limitation specified in the preceding item a) shall apply at the end of one hour, and*
  - 2) *that for such members required to support B class divisions, the temperature rise limitation specified in the preceding item a) shall apply at the end of half an hour.*

## 4 Machinery spaces of category A

### 4.1 Crowns and casings

4.1.1 *Crowns and casings of machinery spaces of category A shall be of steel construction and shall be insulated as required by Ch 4, Sec 5, Tab 5 and Ch 4, Sec 5, Tab 7, as appropriate.*

### 4.2 Floor plating

4.2.1 *The floor plating of normal passageways in machinery spaces of category A shall be made of steel.*

## 5 Materials of overboard fittings

### 5.1 General

5.1.1 *Materials readily rendered ineffective by heat shall not be used for overboard scuppers, sanitary discharges, and other outlets which are close to the waterline and where the failure of the material in the event of fire would give rise to danger of flooding.*

## **6 Protection of cargo tank structure against pressure or vacuum**

### **6.1 Reference to Part D**

**6.1.1** The requirements relevant to the protection of cargo tank structure against pressure or vacuum are given in Pt D, Ch 7, Sec 4, [4.2] and Pt D, Ch 7, Sec 4, [4.5].

# Section 8

## Escape

### 1 Notification of crew and passengers

#### 1.1 Application

1.1.1 The provisions of [1.2] apply to ships of all types and those of [1.3] and [1.4] apply to passenger ships.

#### 1.2 General emergency alarm system

1.2.1 A general emergency alarm system required in Ch 2, Sec 3, [3.14] shall be used for notifying crew and passengers of a fire.

#### 1.3 Special alarm to summon the crew

1.3.1 A special alarm, operated from the navigating bridge or fire control station, shall be fitted to summon the crew. This alarm may be part of the ship's general alarm system but it shall be capable of being sounded independently of the alarm to the passenger spaces.

#### 1.4 Public address systems

1.4.1 A public address system or other effective means of communication complying with the requirements of Ch 2, Sec 3, [3.15] shall be available throughout the accommodation and service spaces and control stations and open decks.

### 2 Means of escape

#### 2.1 General requirements

2.1.1 Unless expressly provided otherwise in this Article, at least two widely separated and ready means of escape shall be provided from all spaces or groups of spaces.

2.1.2 Lifts shall not be considered as forming one of the means of escape as required by this Article.

#### 2.2 Means of escape from control stations, accommodation spaces and service spaces

##### 2.2.1 Application

The provisions of [2.2.2] apply to ships of all types, those of [2.2.3] apply to passenger ships and those of [2.2.4] apply to cargo ships.

##### 2.2.2 General requirements

- a) Stairways and ladders shall be so arranged as to provide ready means of escape to the lifeboat and liferaft embarkation deck from passenger and crew accommodation spaces and from spaces in which the crew is normally employed, other than machinery spaces.
- b) Unless expressly provided otherwise in this Article, a corridor, lobby, or part of a corridor from which there is only one route of escape shall be prohibited. Dead-end corridors used in service areas which are necessary for the practical utility of the ship, such as fuel oil stations and athwartship supply corridors, shall be permitted, provided such dead-end corridors are separated from crew accommodation areas and are inaccessible from passenger accommodation areas. Also, a part of a corridor that has a depth not exceeding its width is considered a recess or local extension and is permitted.
- c) All stairways in accommodation and service spaces and control stations shall be of steel frame construction except where the Society sanctions the use of other equivalent material.
- d) If a radiotelegraph station has no direct access to the open deck, two means of escape from, or access to, the station shall be provided, one of which may be a porthole or window of sufficient size or other means to the satisfaction of the Society.
- e) Doors in escape routes shall, in general, open in way of the direction of escape, except that:
  - 1) individual cabin doors may open into the cabins in order to avoid injury to persons in the corridor when the door is opened, and
  - 2) doors in vertical emergency escape trunks may open out of the trunk in order to permit the trunk to be used both for escape and for access.

**2.2.3 Means of escape in passenger ships**

*a) Escape from spaces below the bulkhead deck*

- 1) *Below the bulkhead deck, two means of escape, at least one of which shall be independent of watertight doors, shall be provided from each watertight compartment or similarly restricted space or group of spaces. Exceptionally, the Society may dispense with one of the means of escape for crew spaces that are entered only occasionally, if the required escape route is independent of watertight doors.*
- 2) *Where the Society has granted dispensation under the provisions of a) 1) above, this sole means of escape shall provide safe escape. However, stairways shall not be less than 800 mm in clear width with handrails on both sides.*

*b) Escape from spaces above the bulkhead deck*

*Above the bulkhead deck there shall be at least two means of escape from each main vertical zone or similarly restricted space or group of spaces, at least one of which shall give access to a stairway forming a vertical escape.*

*c) Direct access to stairway enclosures*

*Stairway enclosures in accommodation and service spaces shall have direct access from the corridors and be of a sufficient area to prevent congestion, having in view the number of persons likely to use them in an emergency. Within the perimeter of such stairway enclosures, only public toilets, lockers of non-combustible material providing storage for non-hazardous safety equipment and open information counters are permitted. Only corridors, lifts, public toilets, special category spaces and open ro-ro spaces to which any passengers carried can have access, other escape stairways required by the following item d) and external areas are permitted to have direct access to these stairway enclosures. Public spaces may also have direct access to stairway enclosures except for the backstage of a theatre. Small corridors or lobbies used to separate an enclosed stairway from galleys or main laundries may have direct access to the stairway provided they have a minimum deck area of 4,5 m<sup>2</sup>, a width of no less than 900 mm and contain a fire hose station.*

*d) Details of means of escape*

- 1) *At least one of the means of escape required by the preceding items a) 1) and b) shall consist of a readily accessible enclosed stairway, which shall provide continuous fire shelter from the level of its origin to the appropriate lifeboat and liferaft embarkation decks, or to the uppermost weather deck if the embarkation deck does not extend to the main vertical zone being considered. In the latter case, direct access to the embarkation deck by way of external open stairways and passageways shall be provided and shall have emergency lighting in accordance with Ch 2, Sec 3 and slip-free surfaces underfoot. Boundaries facing external open stairways and passageways forming part of an escape route and boundaries in such a position that their failure during a fire would impede escape to the embarkation deck shall have fire integrity, including insulation values, in accordance with Ch 4, Sec 5, Tab 1 to Ch 4, Sec 5, Tab 4, as appropriate.*
- 2) *Protection of access from the stairway enclosures to the lifeboat and liferaft embarkation areas shall be provided either directly or through protected internal routes which have fire integrity and insulation values for stairway enclosures as determined by Ch 4, Sec 5, Tab 1 to Ch 4, Sec 5, Tab 4, as appropriate.*
- 3) *Stairways serving only a space and a balcony in that space shall not be considered as forming one of the required means of escape.*
- 4) *Each level within an atrium shall have two means of escape, one of which shall give direct access to an enclosed vertical means of escape meeting the requirements of d) 1) above.*

*The same requirement applies in general to public spaces spanning two decks.*

- 5) *The widths, number and continuity of escapes shall be in accordance with the requirements in Ch 4, Sec 15.*

*e) Marking of escape routes*

- 1) *In addition to the emergency lighting required by Pt D, Ch 11, Sec 5 and Ch 2, Sec 3, the means of escape, including stairways and exits, shall be marked by lighting or photoluminescent strip indicators placed not more than 300 mm above the deck at all points of the escape route, including angles and intersections. The marking must enable passengers to identify the routes of escape and readily identify the escape exits. If electric illumination is used, it shall be supplied by the emergency source of power and it shall be so arranged that the failure of any single light or cut in a lighting strip will not result in the marking being ineffective. Additionally, escape route signs and fire equipment location markings shall be of photoluminescent material or marked by lighting. The Society shall ensure that such lighting or photoluminescent equipment has been evaluated, tested and applied in accordance with Ch 4, Sec 15.*
- 2) *In passenger ships carrying more than 36 passengers, the requirements of item e) 1) above shall also apply to the crew accommodation areas.*
- 3) *In lieu of the escape route lighting system required by item e) 1) above, alternative evacuation guidance systems may be accepted if approved.*

f) *Normally locked doors that form part of an escape route*

Cabin and stateroom doors shall not require keys to unlock them from inside the room. Neither shall there be any doors along any designated escape route which require keys to unlock them when moving in the direction of escape.

Escape doors from public spaces that are normally latched shall be fitted with a means of quick release. Such means shall consist of a door-latching mechanism incorporating a device that releases the latch upon the application of a force in the direction of escape flow. Quick release mechanisms shall be designed and installed to the satisfaction of the Society and, in particular:

- 1) consist of bars or panels, the actuating portion of which extends across at least one half of the width of the door leaf, at least 760 mm and not more than 1120 mm above the deck
- 2) cause the latch to release when a force not exceeding 67 N is applied, and
- 3) not be equipped with any locking device, set screw or other arrangement that prevents the release of the latch when pressure is applied to the releasing device.

g) *Evacuation analysis for passenger ships*

For passenger ships carrying more than 36 passengers and ro-ro passenger ships, escape routes shall be evaluated by an evacuation analysis early in the design process, in line with IMO Circular MSC.1/Circ.1533 "Revised Guidelines on evacuation analyses for new and existing passenger ships".

The analysis shall be used to identify and eliminate, as far as practicable, congestion which may develop during an abandonment, due to normal movement of passengers and crew along escape routes, including the possibility that crew may need to move along these routes in a direction opposite to the movement of passengers. In addition, the analysis shall be used to demonstrate that escape arrangements are sufficiently flexible to provide for the possibility that certain escape routes, assembly stations, embarkation stations or survival craft may not be available as a result of a casualty.

## **2.2.4 Means of escape in cargo ships**

a) *General*

At all levels of accommodation there shall be provided at least two widely separated means of escape from each restricted space or group of spaces.

b) *Escape from spaces below the lowest open deck*

Below the lowest open deck the main means of escape shall be a stairway and the second escape may be a trunk or a stairway.

c) *Escape from spaces above the lowest open deck*

Above the lowest open deck the means of escape shall be stairways or doors to an open deck or a combination thereof.

d) *Dead-end corridors*

No dead-end corridors having a length of more than 7 m shall be accepted.

e) *Width and continuity of escape routes*

The width, number and continuity of escape routes shall be in accordance with the requirements in Ch 4, Sec 15.

f) *Dispensation from two means of escape*

Exceptionally the Society may dispense with one of the means of escape, for crew spaces that are entered only occasionally, if the required escape route is independent of watertight doors.

## **2.3 Means of escape from machinery spaces**

### **2.3.1 Application**

The provisions of [2.3.2] apply to passenger ships, those of [2.3.3] apply to cargo ships.

### **2.3.2 Means of escape on passenger ships**

Means of escape from each machinery space in passenger ships shall comply with the following provisions:

a) *Escape from spaces below the bulkhead deck*

Where the space is below the bulkhead deck, the two means of escape shall consist of either:

- 1) two sets of steel ladders as widely separated as possible, leading to doors in the upper part of the space, similarly separated and from which access is provided to the appropriate lifeboat and liferaft embarkation decks. One of these ladders shall be located within a protected enclosure that satisfies Ch 4, Sec 5, [1.3.3], category (2), or Ch 4, Sec 5, [1.3.4], category (4), as appropriate, from the lower part of the space it serves to a safe position outside the space. Self-closing fire doors of the same fire integrity standards shall be fitted in the enclosure. The ladder shall be fixed in such a way that heat is not transferred into the enclosure through non-insulated fixing points. The protected enclosure shall have minimum internal dimensions of at least 800 mm × 800 mm, and shall have emergency lighting provisions, or
- 2) one steel ladder leading to a door in the upper part of the space from which access is provided to the embarkation deck and additionally, in the lower part of the space and in a position well separated from the ladder referred to, a steel door capable of being operated from each side and which provides access to a safe escape route from the lower part of the space to the embarkation deck.

b) *Escape from spaces above the bulkhead deck*

Where the space is above the bulkhead deck, the two means of escape shall be as widely separated as possible and the doors leading from such means of escape shall be in a position from which access is provided to the appropriate lifeboat and liferaft embarkation decks. Where such means of escape require the use of ladders, these shall be of steel.

c) *Dispensation from two means of escape*

In a ship of less than 1000 gross tonnage, the Society may dispense with one of the means of escape, due regard being paid to the width and disposition of the upper part of the space. In a ship of 1000 gross tonnage and above, the Society may dispense with one means of escape from any such space, including a normally unattended auxiliary machinery space, so long as either a door or a steel ladder provides a safe escape route to the embarkation deck, due regard being paid to the nature and location of the space and whether persons are normally employed in that space. In the steering gear space, a second means of escape shall be provided when the emergency steering position is located in that space unless there is direct access to the open deck.

d) *Escape from machinery control rooms*

Two means of escape shall be provided from a machinery control room located within a machinery space, at least one of which will provide continuous fire shelter to a safe position outside the machinery space.

e) *Inclined ladders and stairways*

All inclined ladders/stairways fitted to comply with a) with open treads in machinery spaces being part of or providing access to escape routes but not located within a protected enclosure shall be made of steel. Such ladders/stairways shall be fitted with steel shields attached to their undersides, such as to provide escaping personnel protection against heat and flame from beneath.

Inclined ladders/stairways in machinery spaces being part of, or providing access to, escape routes but not located within a protected enclosure shall not have an inclination greater than 60° and shall not be less than 600 mm in clear width. Such requirement need not be applied to ladders/stairways not forming part of an escape route, only provided for access to equipment or components, or similar areas, from one of the main platforms or deck levels within such spaces.

f) *Escape from main workshops within machinery spaces*

Two means of escape shall be provided from the main workshop within a machinery space. At least one of these escape routes shall provide a continuous fire shelter to a safe position outside the machinery space.

**2.3.3 Means of escape on cargo ships**

Means of escape from each machinery space in cargo ships shall comply with the following provisions:

a) *Escape from machinery spaces of category A*

Except as provided in the following item b), two means of escape shall be provided from each machinery space of category A. In particular, one of the following provisions shall be complied with:

- 1) two sets of steel ladders, as widely separated as possible, leading to doors in the upper part of the space, similarly separated and from which access is provided to the open deck. One of these ladders shall be located within a protected enclosure that satisfies Ch 4, Sec 5, [1.4.3], category (4), from the lower part of the space it serves to a safe position outside the space. Self-closing fire doors of the same fire integrity standards shall be fitted in the enclosure. The ladder shall be fixed in such a way that heat is not transferred into the enclosure through non-insulated fixing points. The enclosure shall have minimum internal dimensions of at least 800 mm × 800 mm, and shall have emergency lighting provisions, or
- 2) one steel ladder leading to a door in the upper part of the space from which access is provided to the open deck and, additionally, in the lower part of the space and in a position well separated from the ladder referred to, a steel door capable of being operated from each side and which provides access to a safe escape route from the lower part of the space to the open deck.

b) *Dispensation from two means of escape*

In a ship of less than 1000 gross tonnage, the Society may dispense with one of the means of escape required under item a), due regard being paid to the dimension and disposition of the upper part of the space.

In addition, the means of escape from machinery spaces of category A need not comply with the requirement for an enclosed fire shelter listed in item a) 1) above. In the steering gear space, a second means of escape shall be provided when the emergency steering position is located in that space unless there is direct access to the open deck.

c) *Escape from machinery spaces other than those of category A*

From machinery spaces other than those of category A, two escape routes shall be provided except that a single escape route may be accepted for spaces that are entered only occasionally and for spaces where the maximum travel distance to the door is 5 m or less.

Note 1: In machinery spaces other than those of category A, which are not entered only occasionally, the travel distance shall be measured from any point normally accessible to the crew, taking into account machinery and equipment within the space.

d) With regard to application of items b) and c), the following applies:

- Steering gear spaces which do not contain the emergency steering position need only have one means of escape.
- Steering gear spaces containing the emergency steering position can have one means of escape provided it leads directly onto the open deck. Otherwise, two means of escape are to be provided but they do not need to lead directly onto the open deck.
- Escape routes that pass only through stairways and/or corridors are considered as providing a “direct access to the open deck”, provided that the escape routes from the steering gear spaces have fire integrity protection equivalent to steering gear spaces or stairways/corridors, whichever is more stringent.

e) *Inclined ladders and stairways*

*All inclined ladders/stairways fitted to comply with a) with open treads in machinery spaces being part of or providing access to escape routes but not located within a protected enclosure shall be made of steel. Such ladders/stairways shall be fitted with steel shields attached to their undersides, such as to provide escaping personnel protection against heat and flame from beneath.*

Inclined ladders/stairways in machinery spaces being part of, or providing access to, escape routes but not located within a protected enclosure shall not have an inclination greater than 60° and shall not be less than 600 mm in clear width. Such requirement need not be applied to ladders/stairways not forming part of an escape route, only provided for access to equipment or components, or similar areas, from one of the main platforms or deck levels within such spaces.

f) *Escape from machinery control rooms in machinery spaces of category “A”*

*Two means of escape shall be provided from the machinery control room located within a machinery space. At least one of these escape routes shall provide a continuous fire shelter to a safe position outside the machinery space.*

g) *Escape from main workshops in machinery spaces of category “A”*

*Two means of escape shall be provided from the main workshop within a machinery space. At least one of these escape routes shall provide a continuous fire shelter to a safe position outside the machinery space.*

## **2.4 Means of escape on passenger ships from special category and open ro-ro spaces to which any passengers carried can have access**

**2.4.1** *In special category and open ro-ro spaces to which any passengers carried can have access, the number and locations of the means of escape both below and above the bulkhead deck shall be to the satisfaction of the Society and, in general, the safety of access to the embarkation deck shall be at least equivalent to that provided for in items a) 1), b), d) 1) and d) 2) of [2.2.3].*

*Such spaces shall be provided with designated walkways to the means of escape with a breadth of at least 600 mm. The parking arrangements for the vehicles shall maintain the walkways clear at all times.*

### **2.4.2 Direct access to special category spaces**

*One of the escape routes from the machinery spaces where the crew is normally employed shall avoid direct access to any special category space.*

## **2.5 Means of escape from ro-ro spaces**

**2.5.1** *At least two means of escape shall be provided in ro-ro spaces where the crew are normally employed. The escape routes shall provide a safe escape to the lifeboat and liferaft embarkation decks and shall be located at the fore and aft ends of the space.*

*One of the means of escape should be a stairway, the second escape may be a trunk or a stairway.*

*The fore and aft ends of the ro-ro space are considered as the areas being within the distance equal to the breadth of the ro-ro space, measured at its widest point, from its forward most and aftmost point.*

## **2.6 Additional requirements for ro-ro passenger ships**

### **2.6.1 General**

a) *Escape routes shall be provided from every normally occupied space on the ship to an assembly station. These escape routes shall be arranged so as to provide the most direct route possible to the assembly station, and shall be marked with symbols in accordance with the recommendations of IMO Resolution A.1116 (30).*

b) *The escape route from cabins to stairway enclosures shall be as direct as possible, with a minimum number of changes in direction. It shall not be necessary to cross from one side of the ship to the other to reach an escape route. It shall not be necessary to climb more than two decks up or down in order to reach an assembly station or open deck from any passenger space.*

c) *External routes shall be provided from open decks, as referred to in item b), to the survival craft embarkation stations.*

d) *Where enclosed spaces adjoin an open deck, openings from the enclosed space to the open deck shall, where practicable, be capable of being used as an emergency exit.*

- e) *Escape routes shall not be obstructed by furniture and other obstructions. With the exception of tables and chairs which may be cleared to provide open space, cabinets and other heavy furnishings in public spaces and along escape routes shall be secured in place to prevent shifting if the ship rolls or lists. Floor coverings shall also be secured in place. When the ship is under way, escape routes shall be kept clear of obstructions such as cleaning carts, bedding, luggage and boxes of goods.*

**2.6.2 Instruction for safe escape**

- a) *Decks shall be sequentially numbered, starting with "1" at the tank top or lowest deck. The numbers shall be prominently displayed at stair landings and lift lobbies. Decks may also be named, but the deck number shall always be displayed with the name.*
- b) *Simple "mimic" plans showing the "you are here" position and escape routes marked by arrows shall be prominently displayed on the inside of each cabin door and in public spaces. The plan shall show the directions of escape and shall be properly oriented in relation to its position on the ship.*

**2.6.3 Strength of handrails and corridors**

- a) *Handrails or other handholds shall be provided in corridors along the entire escape route so that a firm handhold is available at every step of the way, where possible, to the assembly stations and embarkation stations. Such handrails shall be provided on both sides of longitudinal corridors more than 1,8 m in width and transverse corridors more than 1 m in width. Particular attention shall be paid to the need to be able to cross lobbies, atriums and other large open spaces along escape routes. Handrails and other handholds shall be of such strength as to withstand a distributed horizontal load of 750 N/m applied in the direction of the centre of the corridor or space, and a distributed vertical load of 750 N/m applied in the downward direction. The two loads need not be applied simultaneously.*
- b) *The lowest 0,5 m of bulkheads and other partitions forming vertical divisions along escape routes shall be able to sustain a load of 750 N/m to allow them to be used as walking surfaces from the side of the escape route with the ship at large angles of heel.*

# Section 9 Fire Control Plans

## 1 Application

### 1.1 General

1.1.1 This Section applies to passenger ships and cargo ships.

## 2 Fire control plans

### 2.1 Compilation of the fire control plans

2.1.1 *General arrangement plans shall be permanently exhibited for the guidance of the ship's officers, showing clearly for each deck the control stations, the various fire sections enclosed by A class divisions, the sections enclosed by B class divisions together with particulars of the fire detection and fire alarm systems, the sprinkler installation, the fire-extinguishing appliances, means of access to different compartments, decks, etc. and the ventilating system, including particulars of the fan control positions, the position of dampers and identification numbers of the ventilating fans serving each section, and the position of fuel oil quick-closing valve remote control and fuel oil pump stops, or, for ships assigned with the additional service feature **CNGfuel**, **LNGfuel**, **LPGfuel**, **methanolfuel**, **ammoniafuel**, **hydrogenfuel** or **LFPfuel**, position of the fuel supply closing valve and fuel supply pumps or compressor stops.*

*Alternatively, at the discretion of the Society, the aforementioned details may be set out in a booklet, a copy of which shall be supplied to each officer, and one copy shall at all times be available on board in an accessible position.*

*Plans and booklets shall be kept up to date; any alterations thereto shall be recorded as soon as practicable. Description in such plans and booklets shall be in the language or languages required by the Society. If the language is neither English nor French, a translation into one of those languages shall be included.*

*In addition, instructions concerning the maintenance and operation of all the equipment and installations on board for the fighting and containment of fire shall be kept under one cover, readily available in an accessible position.*

The graphical symbols for the fire control plan are to be in accordance with IMO Resolution A.952(23) and table 3 of IMO Resolution A.1116(30) where the symbols for a specific item are differently expressed in IMO Resolutions A.952(23) and A.1116(30).

2.1.2 The number of portable equipment available at each location is to be specified.

2.1.3 *In ships carrying more than 36 passengers, plans and booklets required by [2.1.1] shall provide information regarding fire protection, fire detection and fire extinction including:*

- ship's keel laying date and application of the SOLAS Convention and amendments
- which additional fire safety measures, if any, were applied
- dates and description of any modifications to the ship which in any way alter its fire safety.

2.1.4 Special equipment provided for the carriage of dangerous goods, if fitted, is to be shown.

2.1.5 Where fitted in compliance with the requirements of Ch 4, Sec 11, [2], the controls for jettisoning fuel for auxiliary vehicles are to be shown.

2.1.6 In compliance with the requirements of NR547, Section 8, for ships assigned the additional service feature **fuelcell**, the emergency shutdown push buttons are to be shown.

2.1.7 In compliance with the requirements of NR529, for ships assigned the additional service feature **LNGfuel** or **CNGfuel** and provided with ESD-protected machinery space, the emergency shutdown push buttons are to be shown.

2.1.8 In compliance with the requirements of NR678, for ships assigned the additional service feature **hydrogenfuel**, storage location of personal protective equipment (PPE) is to be shown.

2.1.9 In compliance with the requirements of Pt F, Ch 10, Sec 3, for ships assigned the additional class notation **CBRN** or **CBRN-WASHDOWN**, the following elements are to be shown:

- citadel and/or shelter
- storage location of personal protective equipment (PPE)
- CBRN detection system
- pre-wetting and wash down system and associated control valves.

**2.1.10** In compliance with the requirements of Pt F, Ch 13, Sec 2, for ships assigned the additional class notation **ECFP-1**, **ECFP-2** or **ECFP-3**, the following elements are to be shown, as applicable:

- Storage location of portable equipment (water mist lances, portable fire-fighting devices for stacked containers, fire fighter's outfits, portable thermal imaging camera)
- Compressed air system for breathing apparatus
- Fixed water monitors covering the on-deck cargo stowage area and associated controls
- Water-spray system below hatch cover and associated control valves
- Flooding system for the cargo hold and associated control valves
- Water-spray system for the protection of the superstructure block or equivalent system and associated control valves.

## **2.2 Location of the fire control plans**

**2.2.1** *A duplicate set of fire control plans or a booklet containing such plans shall be permanently stored in a prominently marked weathertight enclosure outside the deckhouse for the assistance of shore-side fire-fighting personnel.*

# Section 10 Helicopter Facilities

## 1 General

### 1.1 Application

**1.1.1** In addition to complying with the requirements of the other Sections of this Chapter, as appropriate, ships equipped with helicopter or airborne vehicle facilities are to comply with those of this Section. For the purpose of applying the requirements of this Section, airborne vehicles are to be considered as helicopters.

Items d) and e) of [3.1.1] and Articles [5] and [6] do not contain requirements applicable for the purpose of classification; they have been reproduced for reference purposes only.

## 2 Structure

### 2.1 Construction of steel or other equivalent materials

**2.1.1** *In general, the construction of the helidecks shall be of steel or other equivalent materials. If the helideck forms the deckhead of a deckhouse or superstructure, it shall be insulated to A-60 class standard.*

### 2.2 Construction of aluminium or other low melting point metals

**2.2.1** *If the Society permits aluminium or other low melting point metal construction that is not made equivalent to steel and if the platform is located above the ship's deckhouse or similar structure, the following conditions shall be satisfied:*

- a) *the deckhouse top and bulkheads under the platform shall have no opening*
- b) *windows under the platform shall be provided with steel shutters.*

### 2.3 Means of escape

**2.3.1** *A helideck shall be provided with both a main and an emergency means of escape and access for fire-fighting and rescue personnel. These shall be located as far apart from each other as is practicable and preferably on opposite sides of the helideck.*

## 3 Fire-fighting appliances

### 3.1 General

**3.1.1** *In close proximity to the helideck, the following fire-fighting appliances shall be provided and stored near the means of access to that helideck:*

- a) *at least two dry powder extinguishers having a total capacity of not less than 45 kg*
- b) *carbon dioxide extinguishers of a total capacity of not less than 18 kg or equivalent*
- c) *foam firefighting appliances complying with the provisions of Ch 4, Sec 15, [14]*
- d) *two sets of fire-fighter's outfits, and*
- e) *at least the following equipment, stored in a manner that provides for immediate use and protection from the elements:*
  - *adjustable wrench*
  - *blanket, fire-resistant*
  - *cutters, bolt 60 cm*
  - *hook, grab or salving*
  - *hacksaw, heavy duty complete with 6 spare blades*
  - *ladder*
  - *lift line 5 mm diameter and 15 m in length*
  - *pliers, side-cutting*
  - *set of assorted screwdrivers, and*
  - *harness knife complete with sheath.*

### 3.2 Drainage facilities

**3.2.1** *Drainage facilities in way of helidecks shall be constructed of steel and shall lead directly overboard independent of any other system and shall be designed so that drainage does not fall onto any part of the ship.*

## **4 Helicopter refuelling and hangar facilities (if fitted)**

### **4.1 Helicopter fuel system and refuelling facilities**

**4.1.1** Helicopter fuel systems and refuelling facilities for fuels having a flashpoint below or equal to 43°C are to comply with the requirements of Sec 11.

Helicopter fuel systems and refuelling facilities for fuels having a flashpoint above 43°C are to comply with the following requirements:

- Ch 4, Sec 11, [1.4.1]
- Ch 4, Sec 11, [1.4.3]
- Ch 4, Sec 11, [2.2.1]
- Ch 4, Sec 11, [3.6.1]
- Ch 4, Sec 11, [3.6.2]
- Ch 4, Sec 11, [3.6.3]
- Ch 4, Sec 11, [3.6.4]
- Ch 4, Sec 11, [4.1.1]
- Ch 4, Sec 11, [4.2.2]
- Ch 4, Sec 11, [4.2.3]

### **4.2 Arrangement of spaces containing the refuelling installations**

#### **4.2.1 Ventilation**

Helicopter hangars or enclosed spaces containing refuelling installations are to comply with the requirements of Ch 4, Sec 11, [3.8.1] and Ch 4, Sec 11, [4.4.2].

#### **4.2.2 Electric equipment and wiring**

*Electric equipment and wiring in enclosed hangars or enclosed spaces containing refuelling installations shall comply with the requirements of Ch 4, Sec 13, [2.2], Ch 4, Sec 13, [2.3], and Ch 4, Sec 13, [2.4].*

## **5 Occasional and emergency helicopter operations**

### **5.1 General**

**5.1.1** *Where helicopters land or conduct winching operations on an occasional or emergency basis on ships without helidecks, fire-fighting equipment fitted in accordance with the requirements of Ch 4, Sec 1 may be used. This equipment shall be made readily available in close proximity to the landing or winching areas during helicopter operations.*

## **6 Operations manual**

### **6.1 General**

**6.1.1** *Each helicopter facility shall have an operations manual, including a description and a checklist of safety precautions, procedures and equipment requirements. This manual may be part of the ship's emergency response procedures.*

# Section 11 Fuel for Auxiliary Vehicles

## 1 General

### 1.1 Application

**1.1.1** This Section applies to filling, storage and refuelling arrangements for oil fuels dedicated to auxiliary vehicles used during normal ship operation such as zodiac, jet ski or helicopter.

**1.1.2** This Section applies neither to the transportation of petroleum products as cargo nor to the ship fuel oil system.

**1.1.3** Fuels covered by this section are typically jet A-1 aviation fuel, diesel or gasoline and may have a flashpoint below 60°C.

**1.1.4** This Section does not cover installations for toxic fuels. In case an installation for toxic fuel is foreseen, a dedicated risk assessment covering this specific risk is to be performed and the installation is to be considered on a case-by-case basis by the Society.

**1.1.5** The requirements of this Section may be disregarded for fuels having a flashpoint above 43°C provided:

- the fuel tanks are located outside of machinery spaces of category A
- provisions for the measurement of oil temperature are provided on the suction pipe of the fuel pumps
- stop valves and/or cocks are provided on the inlet side and outlet side of the fuel strainers
- pipe joints of welded construction or of circular cone type or spherical type union joint are applied as much as possible
- fuel pipes are routed out of high fire risk spaces such as machinery spaces of category A, galleys, stores, ro-ro spaces, cargo spaces
- the relevant provisions of Ch 1, Sec 10 are complied with.

Whatever their flashpoint, helicopter and airborne vehicle fuel systems are to comply with the requirements of Ch 4, Sec 10, [4].

**1.1.6** Two types of installations are foreseen:

- Jettisonable fuel tanks, with manual refuelling of the auxiliary vehicles. In addition to the requirements of Article [1] and [4], the arrangement of jettisonable fuel tanks is to comply with the requirements of Article [2]
- Fixed installations including fuel tanks, filling station and refuelling station. In addition to the requirements of Article [1] and [4], fixed fuel installation are to comply with the requirements of Article [3].

Both kinds of installations may be installed on a ship, if dedicated to different fuels.

As a general principle, the aggregate quantity of fuel for auxiliary vehicles carried on board is to be kept to a minimum, considering fuel(s) carried in portable and fixed fuel tanks. It is to be demonstrated that the total quantity of fuel for auxiliary vehicles carried on board corresponds to, and does not exceed, the ship's operational needs, taking into account the intended use of the auxiliary vehicles, possible refilling frequency etc.

### 1.2 Definitions

#### 1.2.1 Fuel

In this Section, "fuel" refers to fuel for auxiliary vehicles.

#### 1.2.2 Jettisonable tank

A jettisonable tank is a tank capable of being jettisoned, i.e. thrown overboard, in case of an emergency.

#### 1.2.3 Flame screen

A flame screen is a device utilizing wire mesh to prevent the passage of unconfined flames. Flame screens required in this section are to be approved in accordance with Pt D, Ch 7, App 1.

#### 1.2.4 Fuel handling

Fuel handling includes fuel pumping as well as any operation on the fuel that could be needed between storage onboard and refuelling the auxiliary vehicle.

#### 1.2.5 Filling station

The filling station refers to the area or space containing the connection between the shipboard fuel piping system and the shore piping system, for the purpose of filling the fuel tanks. The filling station is sometimes referred to as the "bunkering station".

#### 1.2.6 Refuelling station

In this Section, the refuelling station refers to the area or space where the auxiliary vehicles or portable tanks are refuelled.

### **1.2.7 Storage hold**

In this Section, the storage hold refers the space where an independent tank containing fuel for auxiliary vehicles is located.

## **1.3 Segregation**

**1.3.1** Facilities for fuel for auxiliary vehicles are to be segregated from any other fuel system.

## **1.4 Storage arrangement**

**1.4.1** A designated area is to be provided for the storage of fuel tanks, which is to be:

- as remote as practicable from accommodation spaces, escape routes and embarkation stations, and
- isolated from areas containing a source of vapour ignition.

**1.4.2** The fuel tank storage area is to be located outside of machinery spaces not dedicated to the storage or handling of this fuel, accommodation spaces, service spaces and control stations, and is to comply with the requirements of [2.1] or [3.2] as applicable.

**1.4.3** The fuel storage area is to be provided with arrangements whereby fuel spillage may be collected and drained to a safe location.

## **1.5 Vapour detection**

**1.5.1** The ship is to be provided with at least two portable gas detectors capable of measuring flammable vapour concentrations in air and at least two portable oxygen analysers.

Note 1: The number of portable detection instruments required above is considered equivalent to one portable instrument for measuring flammable vapour concentration, one portable instrument for measuring oxygen and sufficient spares.

Note 2: Gas detectors are to be of a type approved by the Society.

## **1.6 Marking and instructions**

**1.6.1** All facilities for the storage and handling of fuel for auxiliary vehicles on board are to be grade identified.

**1.6.2** The fuel storage and handling areas are to be permanently marked. Instructions for filling fuel and, if appropriate, emptying fuel, are to be posted in the vicinity of the filling area.

**1.6.3** Installations for fuel for auxiliary vehicles are to be taken into consideration in the emergency procedures related to safety and pollution prevention.

# **2 Jettisonable fuel tanks**

## **2.1 Storage arrangement**

**2.1.1** Jettisonable fuel tanks are in principle to be stored on the open deck at a location complying with the requirements of [2.1.2], [2.1.3] and [2.1.4].

As an alternative, jettisonable tanks may be installed in an enclosed space provided compliance with [2.1.2], [2.1.3] and with the requirements dedicated to independent tanks storage holds in [3.1.3] and [3.2], except [3.2.2], are complied with.

**2.1.2** In case of an emergency, it is to be possible to:

- Either dispose quickly of the tanks through an overboard chute or equivalent arrangement; or
- Quickly drain the full content of the tank to the sea through a quick-draining mechanism.

The control for the disposal or quick-drainage of the tanks is to be available from a location:

- as remote as possible from the storage area but from which the proper activation of the system can be visually ascertained, and
- as remote as possible from any pre-designed evacuation route

This control position is to be reported on the fire control and safety plan and is to be provided with adequate signage.

**2.1.3** The proper functioning of overboard chutes is to be demonstrated through a functioning test. The test is to be carried out under load after installation of the chute on board.

**2.1.4** For jettisonable fuel tanks stored on the open deck:

- a) The tanks are to be suitably secured and protected from physical damage due to e.g. dropped objects or severe weather conditions
- b) The tanks are to be stored in a well-ventilated area
- c) Suitable drip trays are to be provided in way of the fuel tanks, fitted with means to drain any fuel leakage to a dedicated tank complying with the requirements of [3.5.2]. Alternatively, drip trays without draining means may be accepted provided their capacity is sufficient to contain all the fuel stored in any one of the tanks, considering a 10% margin. The arrangement of the drip tray is to prevent splashing due to ship motion. Drip trays are also to comply with the relevant requirements of Ch 1, Sec 10, [5.10.4].

## **2.2 Tank design**

**2.2.1** Where portable fuel tanks are used, special attention shall be given to:

- design of the tank for its intended purpose
- mounting and securing arrangements
- electric bonding; and
- inspection procedures.

**2.2.2** Portable tanks are to be constructed and approved according to IMO IMDG Code for the transported fuel.

**2.2.3** Each portable tank is to be clearly marked to indicate its content.

**2.2.4** Non portable fuel tanks are to comply with the requirements of [3.1].

## **3 Fixed fuel installations**

### **3.1 Tank design**

**3.1.1** Fuel tanks are to comply with the requirements of Ch 1, Sec 10 for fuel oil tanks and flammable liquid tanks. The scantlings of fuel tanks are to be in compliance with the provisions of Pt B, Ch 5, Sec 6 and Part B, Chapter 7.

**3.1.2** High and low level alarm arrangements are to be provided. High level alarm is to indicate when fuel tanks are close to being filled in excess of maximum operating levels.

**3.1.3** Fuel tanks are to be part of the ship's structure.

Independent fuel tanks of limited capacity may however be permitted provided:

- a) the scantlings of independent tanks are in compliance with the provisions of Pt B, Ch 5, Sec 6 and Part B, Chapter 7, except that the net thickness is not to be less than 5 mm.
- b) the requirements of [3.2] are complied with.
- c) suitable drip trays are provided in way of the tanks, in line with [3.4.7].

**3.1.4** Fuel tanks are to be fitted with a cock or valve directly on the tank capable of being closed from a safe position outside the space concerned in the event of a fire occurring in the space in which the tanks are situated.

**3.1.5** The venting outlet of the fuel tank is to be led to the atmosphere in a safe and well ventilated position and is to be provided with a flame screen.

**3.1.6** Overflow pipes are to be fitted to tanks which can be filled by pumping and are designed for a hydrostatic pressure lower than that corresponding to the height of the air pipe. Where fitted, overflow systems are to be dedicated to this specific fuel and are to comply with the applicable requirements of Ch 1, Sec 10.

### **3.2 Tank location and protection**

#### **3.2.1 Application**

Structural tanks are to comply with the requirements of [3.2.2] to [3.2.4].

Independent tanks are to comply with [3.2.2] to [3.2.4] and with:

- the requirements of [3.2.5] and [3.2.6] when located in an enclosed space
- the requirements of [3.2.7] and [3.2.8] when located on the open deck.

### **3.2.2 Protection against collision and grounding**

Fuel tanks are to be located as follows, with respect to the rule length L defined in Pt B, Ch 1, Sec 3, [2.1.1] and ship's moulded breadth B defined in Pt B, Ch 1, Sec 3, [2.1.4]:

- inboard from the ship's side:  
B/5 or 11,5 m, whichever is less, measured inboard from the ship side at right angles to the centreline at the level of the summer load line draught. Alternatively, the calculation methodology given in Rule Note NR529, 5.3.4, as amended, may be used to determine the acceptable location of the fuel tanks

Note 1: NR529 Gas fuelled ships

- inboard from the shell plating or from aft terminal of the ship:  
the greater of B/10 or 0,8 m. However, this distance need not be greater than B/15 or 2 m, whichever is less, where the shell plating is located inboard of B/5 or 11,5 m, whichever is less, as required above.
- above the bottom shell plating:  
B/15 or 2,0 m, whichever is less, measured from the moulded line of the bottom shell plating at the centreline.
- abaft a transverse plane at 0,08L measured from the forward perpendicular.

Note 2: These distances are to be measured considering the most restrictive between the outermost and the lowermost boundary of the fuel tank.

**3.2.3** *Fuel tanks are to be located outside of category A machinery spaces.* Fuel tanks may however be located in the storage hold or fuel handling room dedicated to this fuel.

### **3.2.4 Segregation from other spaces**

Fuel tanks are to be segregated from machinery spaces, propeller shaft tunnels, dry cargo spaces, accommodation, service spaces and control stations and from drinking water and stores for human consumption, by means of a cofferdam, void space, pump-room, empty tank, ship oil fuel tank, or other similar space complying with the requirements of [3.3]. In the case of independent tanks, a cofferdam need not be required provided:

- the hold space complies with the requirements of [3.3]; or
- the fuel tank is located on the open deck and the distance between the tank boundaries and the boundaries of the spaces from which the tank is to be segregated complies with the requirements of [3.3.3].

**3.2.5** Storage holds are to be treated as a category A machinery spaces for structural fire protection, fire extinction and detection purposes.

The boundaries between storage holds and other category A machinery spaces are to have A-60 fire integrity and the boundaries between storage holds for different fuels are to have A-30 fire integrity.

**3.2.6** Storage holds are to be dedicated to the storage of one specific fuel. Fuel pumps and other equipment intended for handling this fuel may however be located in the storage hold.

**3.2.7** Fuel tanks located on the open deck are to be protected by a manually activated water-spray system with a capacity of at least 5L/min/m<sup>2</sup> of protected area. The water-spray system is to provide coverage for exposed parts of the fuel tank and for the boundaries of normally manned superstructures facing the fuel tanks and located within 10 m of their boundaries.

Note 1: Both horizontal and vertical surfaces to be protected are to be considered when determining the capacity of the water-spray system.

**3.2.8** Decks and superstructure boundaries located within 10 m of the boundaries of the fuel tanks are to be provided with fire integrity equivalent to the fire integrity required with respect to a category A machinery space. Navigation bridge windows however are not required to have such fire integrity.

In addition, fuel tanks are to be segregated from cargo in accordance with the requirements of the International Maritime Dangerous Goods (IMDG) Code where the fuel tanks are regarded as a class 2.1 bulk package.

## **3.3 Cofferdams**

**3.3.1** Cofferdams surrounding structural fuel tanks and required by [3.2.4] are to comply with the requirement of this sub-article.

### **3.3.2 Direct access from the open deck**

Access to the cofferdams is to be direct from the open deck. Alternatively, access to the cofferdams may be provided through void spaces or spaces dedicated to fuel handling or storage or machinery spaces, subject to consideration of ventilation aspects.

**3.3.3** Access to the cofferdams is to be provided through gas-tight openings, with the following minimum clear width:

- 600 x 600 mm for horizontal openings
- 600 x 800 mm for vertical openings.

**3.3.4** Drainage from the cofferdams surrounding fuel tanks is to comply with the requirements of [3.5.1].

## **3.4 Piping**

**3.4.1** Fuel piping is to comply with the requirements of Ch 1, Sec 10 for fuel oil piping and flammable liquid piping.

**3.4.2** The connections between the various pipe sections are to be carried out by means of butt welding. Other types of connections including threaded connections and flange connections are not permitted.

**3.4.3** Fuel piping is to be located at a distance from the ship's side of at least 800 mm measured inboard from the ship's side at right angles to the centerline at the level of the summer load line draught.

**3.4.4** Fuel piping is not to be led directly through accommodation spaces, service spaces, electrical equipment rooms, control stations or category A machinery spaces not related to the handling of this specific fuel.

**3.4.5** Fuel piping led through ro-ro spaces, special category spaces and on open decks is to be protected against mechanical damage.

**3.4.6** Fuel piping in non-hazardous enclosed spaces is to be completely enclosed by a steel gastight double pipe or duct which is to be:

- at an inclination such that the fuel naturally returns towards a safe draining location in the case of leakage or failure in delivery pressure
- fitted with inspection openings with gastight doors in way of connections of pipes within it, with an automatic closing drain-trap leading to a safe location, set in such a way as to discharge leakage of fuel into a safe location
- fitted with a vent pipe at the highest part of the duct. This vent pipe is to be led to the atmosphere in a safe position. The outlet is to be fitted with a flame screen
- of a thickness not less than the minimum thickness given in Ch 1, Sec 10, Tab 6 for pipes in general.

#### **3.4.7 Containment and detection of a leakage**

Suitable drip trays are to be provided at locations where fuel leakage could occur, i.e. in way of independent tanks, pumps, tank connections, piping connections, filling manifold etc. The drip trays are to be fitted with means to drain any fuel leakage to a dedicated drainage tank complying with [3.5.2].

An alarm is to be provided in case of fuel leakage in the drip tray.

Note 1: Double walled independent tanks need not be provided with an additional drip tray. It should however be possible to detect, and dispose of, any fuel leakage in the interbarrier space.

**3.4.8** Means are to be provided to drain fuel piping after filling and refuelling operations. Means of drainage may however be omitted for fuel piping located in the storage hold.

### **3.5 Drainage**

**3.5.1** Drainage and/or bilge pumping of cofferdams and of spaces intended for fuel storage or fuel handling is to be separated from the ship bilge system, and is not to be led to machinery spaces or to other spaces where ignition sources may be present. Drainage directly to the sea is to be avoided as far as possible.

#### **3.5.2 Drainage tank**

The tank intended to gather drainage from for spaces intended for fuel storage or fuel handling is to be:

- closed
- dedicated to these spaces
- located outside of the machinery spaces
- provided with a vent pipe to a safe location on the open deck
- fitted with level position indicators with relevant alarms, in order to detect leakages.
- provided with a capacity sufficient to manage the whole content of any one fuel tank.

**3.5.3** The space containing the bilge pumps is to be provided with mechanical ventilation complying with [4.4]. If the space has access from another enclosed space, the door is to be self-closing.

### **3.6 Fuel handling**

**3.6.1** *Storage tank fuel pumps are to be provided with means which permit shutdown from a safe remote location in the event of a fire. Where a gravity fuelling system is installed, equivalent closing arrangements are to be provided to isolate the fuel source.*

**3.6.2** *The fuel pumping unit is to be connected to one tank at a time. The piping between the tank and the pumping unit are to be of steel or equivalent material, as short as possible, and protected against damage.*

**3.6.3** *Electrical fuel pumping units and associated control equipment are to be of a type suitable for the location and potential hazards.*

**3.6.4** *Fuel pumping units are to incorporate a device which will prevent over-pressurization of the delivery or filling hose.*

**3.6.5** Spaces containing fuel handling equipment are to be treated as category A machinery spaces for structural fire protection, fire extinction and detection purposes.

### **3.7 Filling station**

**3.7.1** For structural fire protection purposes, enclosed or semi-enclosed filling stations are to be handled as:

- auxiliary machinery spaces of moderate fire risk i.e. cat(11) on passenger ships carrying more than 36 passengers
- other machinery spaces i.e. cat(7) on other ships

In addition, the safety measures detailed in [3.7.2] to [3.7.4] are to be applied.

**3.7.2** The boundaries between enclosed or semi-enclosed filling stations and other enclosed spaces are to be A-60 class divisions and reasonably gastight.

#### **3.7.3 Fixed fire-extinguishing system**

Enclosed filling stations are to be provided with a fixed fire-extinguishing system suitable for category A machinery spaces. Depending on the quantity of fuel, duration of the filling operation and filling procedure, alternative arrangements based on portable fire extinguishing equipment may be accepted on a case-by-case basis.

Open or semi enclosed filling stations are to be covered by a manually activated water-spray system with a capacity of at least 5L/min/m<sup>2</sup> of protected area (horizontally projected surfaces).

#### **3.7.4 Fixed fire detection and fire alarm system**

Enclosed and semi-enclosed filling stations are to be covered by a fixed fire detection and fire alarm system complying with the requirements of Ch 4, Sec 15, [8]. The fixed fire detection system is to combine smoke detection and another way of detecting fire which may be by means of fusible elements designed to melt at temperatures between 98°C and 104°C, or by area fire detection methods.

In the case of an open filling station, a fixed fire detection and alarm system is to cover the filling manifold.

### **3.8 Refuelling station**

**3.8.1** *Hangar, refuelling and maintenance facilities and spaces where fuel handling is intended are to be treated as a category A machinery space with regards to fire protection, fixed fire extinguishing and detection system requirements.*

**3.8.2** Open or semi-enclosed refuelling stations are to be covered by a manually activated water-spray system with a capacity of at least 5L/min/m<sup>2</sup> of protected area (horizontally projected surfaces).

#### **3.8.3 Refuelling equipment**

Refuelling hoses are to be designed and constructed according to a recognized standard, made of one continuous length, smooth bore, synthetic rubber construction, and semi-conducting.

Recognized standards for refuelling hoses include, but are not limited to, ISO 1825:2017 type C and EI 1529:2015.

**3.8.4** It is to be possible to shut down the refuelling pump from the refuelling station. This control is to be located at an easily accessible position close to the escape from this space or area.

## **4 Prevention of explosion**

### **4.1 Electrical bonding**

**4.1.1** Fuel tanks, piping and *equipment used in refuelling or filling operations are to be electrically bonded.*

### **4.2 Source of ignition**

**4.2.1** Access to areas intended for or affected by filling, storage, and refuelling of fuel for auxiliary vehicles is to be limited to crew members on duty.

**4.2.2** *“NO SMOKING” signs are to be displayed at appropriate locations* in areas intended for the filling, storage, and refuelling of fuel for auxiliary vehicles.

**4.2.3** Any equipment which may constitute a source of ignition of flammable vapours is not to be installed in hazardous spaces or areas.

**4.2.4** As a general rule, electrical equipment and wiring is not to be fitted in hazardous spaces or areas, unless it is essential for operational purposes or enhancing safety. If electrical equipment is fitted in such spaces, it is to be suitable for use in dangerous environment as per Ch 2, Sec 3, [10].

Portable equipment that need to be used in hazardous spaces or areas is to be of a suitable certified safe type.

Note 1: On a case-by-case basis, the Society might however allow electrical equipment not suitable for use in dangerous environment to be installed in hazardous spaces or areas related to refilling or refuelling operations, provided:

- suitable interlocks and operational procedures are provided to ensure that non-certified safe equipment will be disconnected in all scenarios that may lead to the presence of an explosive atmosphere
- such equipment need not be used during refuelling or refilling operations
- suitable justification of the above is provided

**4.2.5** Exhausts of internal combustion machinery are to be led outside of hazardous areas.

**4.3 Hazardous areas**

**4.3.1** In order to facilitate the selection of appropriate electrical apparatus and the design of suitable electrical installations, hazardous areas are divided into zone 0, 1 and 2 according to Ch 2, Sec 1, [3.25.3]. The different spaces and areas are to be classified according to Tab 1.

Note 1: As an alternative to Table 1, more refined hazardous spaces and areas may be defined in line with the requirements of IEC 60079-10 and based on relevant analysis to the satisfaction of the Society.

**Table 1 : Space descriptions and hazardous area zones**

No.	Description of spaces	Hazardous area
1	The interior of fuel tanks, any pipework or pressure-relief or other venting system for fuel, pipes and equipment containing the fuel or developing flammable gases and vapours. <ul style="list-style-type: none"> <li>• Drainage tanks as defined in [3.5.2] are covered by this item.</li> <li>• Scuppers and discharges as defined in [3.5.1] are covered by this item</li> <li>• Overflow tanks are covered by this item</li> </ul>	Zone 0
2	Enclosed or semi-enclosed filling stations, refuelling stations and, storage holds and fuel handling spaces	Zone 1
3	Ventilation ducts serving the spaces identified in item 2 and item 8	Zone 1
4	Areas on open deck, or semi-enclosed spaces on open deck: <ul style="list-style-type: none"> <li>• within 1,5 m of any exhaust ventilation outlet of a hazardous area zone 1</li> <li>• within 1,5 m of entrances to, or openings in, filling station or fuel pump room entrances</li> <li>• Within 0.5 m of ventilation inlets of filling stations or fuel pump rooms</li> <li>• Within 0.5 m of any opening into zone 1 spaces</li> </ul>	Zone 1
5	Areas on open deck, or semi-enclosed spaces on open deck, within 3m of any venting outlet from the spaces defined in item 1	Zone 1
6	Areas on open deck within filling manifold drip trays and 1,5 m around these	Zone 1
7	Enclosed or semi-enclosed spaces having a direct opening into any of the spaces as identified in item 2 or item 3, unless appropriate measures are taken to prevent flammable gas from entering such spaces (protection by overpressure as per [4.3.2], airlock as per [4.3.3] or gastight door as detailed in item 11). This item does not cover areas adjacent to ventilation inlets and outlets which are covered by item 4.	Zone 1
8	Air space between the fuel piping and the wall of the outer pipe or duct of double walled fuel piping as per [3.4.6]	Zone 1
9	Spaces adjacent to fuel tanks including cofferdams required in [3.2.4]	Zone 1
10	Areas on open deck within 1,5 m of fuel tank surfaces exposed to the weather <b>(2)</b>	Zone 1
11	Enclosed or semi-enclosed spaces having a direct opening into any of the spaces as identified in item 2 or item 3, which are separated from such space by a self-closing, substantially gastight, steel door without holding back arrangement. This item does not cover areas adjacent to ventilation inlets and outlets which are covered by item 4.	Zone 2
12	Spaces forming an airlock as defined in [4.3.3]	Zone 2
13	Areas of 1,5 m surrounding open or semi-enclosed spaces of zone 1	Zone 2
<b>(1)</b> Drainage tanks as defined in [3.5.2], scuppers and discharges as defined in [3.5.1] and overflow tanks are covered by this item.		
<b>(2)</b> In the case of double wall tanks, this hazardous area may be omitted provided the secondary barrier of the tank is able to contain any leakage from the tank and remain gastight.		

### **4.3.2 Protection by overpressure**

Where a space has an opening into an adjacent hazardous space or area, it may be made into a non-hazardous space in accordance with the following requirements:

- a) A minimum overpressure of 25 Pa (0,25 mbar) with respect to the adjacent, hazardous space or area is to be maintained at all points inside the space and its associated ducts at which leaks are liable to occur, all doors and windows being closed.
- b) During initial start-up or after shut-down, it is necessary, before energizing any electrical apparatus within the space which is not suitably protected for the classification of the space in the absence of pressurization, to either ensure that the internal atmosphere is non-hazardous, or proceed with prior purging of sufficient duration that the internal atmosphere may be considered as non-hazardous, and pressurize the space.

The atmosphere is considered non-hazardous when, at all points in the space, the equipment enclosures and any associated ducts, the concentration of explosive gases or vapours is below 30% of the lower explosive limit. The place of measurement should be judiciously chosen to determine the highest concentration of gas.

- c) Monitoring is to be provided to ensure the satisfactory functioning of pressurization of spaces having an opening into a more hazardous zone.
- d) Where a flow monitoring device is used to indicate failure of pressurization, it should be verified that either the pressurization level required by item a) is maintained with any door or other opening open, or an alarm is given if any door or opening is not closed.
- e) In the event of the loss of overpressure, the following protective measures are to apply to electrical equipment not protected for use in hazardous areas:
  - suitable alarm (visible and audible)
  - immediate action to restore pressurization
  - programmed disconnection of power supply if the pressurization cannot be restored for an extended period or if the concentration of flammable gas is rising to a dangerous level.

### **4.3.3 Airlock**

Access between a hazardous area Zone 1 and a non-hazardous area may be provided through an airlock, consisting of two self-closing, substantially gastight, steel doors without holding back arrangements and capable of maintaining the overpressure. The airlock space is to be mechanically ventilated from a non-hazardous area and maintained at an overpressure with respect to the hazardous area Zone 1, in accordance with [4.3.2].

## **4.4 Ventilation of hazardous spaces**

**4.4.1** Hazardous spaces are to be fitted with extraction-type mechanical ventilation capable of providing at least 6 air changes per hour.

### **4.4.2 Ventilation**

*Enclosed hangar facilities or enclosed spaces containing refuelling installations are to be provided with mechanical ventilation as required by Ch 4, Sec 13, [2] for closed ro-ro spaces of cargo ships. Ventilation fans are to be of a non-sparking type (see Ch 4, Sec 1, [2.32]).*

**4.4.3** Filling stations, refuelling stations, fuel pump rooms and storage holds are to be fitted with mechanical ventilation of the extraction type, capable of providing at least 15 air changes per hour. A reduced rate of mechanical ventilation capacity may be considered for such spaces when they are of a semi-enclosed type.

**4.4.4** Any loss of the ventilating capacity required in [4.4.1] or [4.4.3] is to trigger a visual alarm at the entrance door of the considered space, an audible alarm inside the space and at the navigation bridge.

**4.4.5** Arrangements are to be provided to permit rapid shutdown and effective closure of the ventilation system from outside of the space in case of fire, taking into account the weather and sea conditions. It is to be possible to shut-off the ventilation of each compartment separately.

**4.4.6** The fans are to be non-sparking.

**4.4.7** Electrical equipment and wiring, if installed in an exhaust ventilation duct, are to be of a type approved for use in explosive petrol and air mixtures.

**4.4.8** *Electric motors driving fans of the ventilation systems of hazardous spaces are to be located outside of the ventilation ducting unless they are of a certified safe type.*

**4.4.9** Ducting used for the ventilation of hazardous spaces is to be separate from that used for the ventilation of non-hazardous spaces

**4.4.10** Air inlets for hazardous enclosed spaces are to be taken from areas which, in the absence of the considered inlet, would be non-hazardous.

**4.4.11** Air outlets for hazardous enclosed spaces are to be located in an open area which, in the absence of the considered outlet, would be of the same or lesser hazard than the ventilated space.

#### **4.5 Ventilation and door openings of non-hazardous spaces**

**4.5.1** Air inlets and door openings for non-hazardous enclosed spaces are to be taken from non-hazardous areas at least 1.5m from the limits of any hazardous area. Where the inlet duct passes through a hazardous area, the inlet duct is to have over-pressure in relation to this area unless the mechanical integrity and gas-tightness of the duct is considered by the Society to be such that no pressure differential is required to ensure that gases will not leak into the duct.

**4.5.2** Air outlets from non-hazardous enclosed spaces are to be located in a non-hazardous open area.

**4.5.3** Air outlets from high fire risk spaces are to be located at least 3 m away from fuel tanks, filling stations or refuelling stations located on the open deck or in semi-enclosed spaces.

Note 1: "High fire risk spaces" means machinery spaces of category A, ro-ro spaces, cargo holds where fixed fire-fighting systems are required (See Ch 4, Sec 6, [6.1]), galleys, pantries containing cooking appliances, laundry with drying equipment, spaces where oxygen is stored or produced, spaces in which flammable liquids or gases are stored, battery rooms and workshops.

# Section 12 Carriage of Dangerous Goods

## 1 General requirements

### 1.1 Application

**1.1.1** In addition to complying with the requirements of the other Sections of this Chapter, as appropriate, ship types and cargo spaces, referred to in [1.1.2], intended for the carriage of dangerous goods shall comply with the requirements of this Section, as appropriate, except when carrying dangerous goods in limited quantities and excepted quantities unless such requirements have already been met by compliance with the requirements elsewhere in this Chapter. The types of ships and modes of carriage of dangerous goods are referred to in [1.1.2] and in Tab 1, where the items of the list in [1.1.2] are referred to in the head of table. Cargo ships of less than 500 gross tonnage shall comply with this Section, but the Society may reduce the requirements and such reduced requirements shall be recorded in the document of compliance referred to in MSC/Circ. 642.

Note 1: "limited quantities" as per the IMO "International Maritime Dangerous Goods Code" (IMDG Code).

**1.1.2** The following ship types and cargo spaces shall govern the application of Tab 1 and Tab 2:

- a) Ships and cargo spaces not specifically designed for the carriage of freight containers, but intended for the carriage of dangerous goods in packaged form, including goods in freight containers and portable tanks
- b) Purpose-built container ships and cargo spaces intended for the carriage of dangerous goods in freight containers and portable tanks (see Note 1)
- c) Ro-ro ships and ro-ro spaces intended for the carriage of dangerous goods (see Note 2)
- d) Ships and cargo spaces intended for the carriage of solid dangerous goods in bulk, and
- e) Ships and cargo spaces intended for carriage of dangerous goods other than liquids and gases in bulk in shipborne barges.

Note 1: A purpose-built container space is a cargo space fitted with cell guides for stowage and securing of containers.

Note 2: Ro-ro spaces include special category spaces and vehicle spaces.

## 2 Special requirements

### 2.1 General

**2.1.1** Unless otherwise specified, the following requirements shall govern the application of Tab 1, Tab 2 and Tab 3 to both "on-deck" and "under-deck" stowage of dangerous goods where the numbers of following subarticles [2.2] to [2.11] are indicated in the first column of the tables.

### 2.2 Water supplies

**2.2.1** Arrangements shall be made to ensure immediate availability of a supply of water from the fire main at the required pressure either by permanent pressurisation or by suitably placed remote arrangements for the fire pumps.

**2.2.2** The quantity of water delivered shall be capable of supplying four nozzles of a size and at pressures as specified in Ch 4, Sec 6, [1.2.6], capable of being trained on any part of the cargo space when empty. This amount of water may be applied by equivalent means to the satisfaction of the Society.

Note 1: The number and position of hydrants should be such that at least two of the required four jets of water, when supplied by single lengths of hose, may reach any part of the cargo space when empty; and all four jets of water, each supplied by single lengths of hose may reach any part of ro-ro cargo spaces.

**2.2.3** Means shall be provided for effectively cooling the designated under-deck cargo space by at least 5 l/min per square metre of the horizontal area of cargo spaces, either by a fixed arrangement of spraying nozzles or by flooding the cargo space with water. Hoses may be used for this purpose in small cargo spaces and in small areas of larger cargo spaces at the discretion of the Society. However, the drainage and pumping arrangements shall be such as to prevent the build-up of free surfaces. The drainage system shall be sized to remove no less than 125% of the combined capacity of both the water spraying system pumps and the required number of fire hose nozzles. The drainage system valves shall be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells shall be of sufficient holding capacity and shall be arranged at the side shell of the ship at a distance from each other of not more than 40 m in each watertight compartment. If this is not possible, the adverse effect upon stability of the added weight and free surface of water shall be taken into account to the extent deemed necessary by the Society in its approval of the stability information.

**Table 1 : Application of the requirements to different modes of carriage of dangerous goods in ships and cargo spaces**

Requirements of Article [2]	Requirement [1.1.2]						
	Weather decks a) to e) inclusive	a) Not specifically designed	b) Container cargo spaces	c) Closed ro-ro spaces (5) Open ro-ro spaces		d) Solid dangerous goods in bulk	e) Shipborne barges
[2.2.1]	x	x	x	x	x	For application of requirements of Ch 4, Sec 12 to different classes of dangerous goods, see Tab 2	x
[2.2.2]	x	x	x	x	x		–
[2.2.3]	–	x	x	x	x		x
[2.2.4]	–	x	x	x	x		x
[2.3]	–	x	x	x	x		x (4)
[2.4]	–	x	x	x	–		x (4)
[2.5.1]	–	x	x (1)	x	–		x (4)
[2.5.2]	–	x	x (1)	x	–		x (4)
[2.6]	–	x	x (1)	x	–		–
[2.7.1]	x	x	x	x	x		–
[2.7.3]	x	x	x	x	x		–
[2.8]	x	x	–	–	x		–
[2.9]	x	x	x (2)	x	x		–
[2.10]	–	–	–	x (3)	x		–
[2.11.1]	–	–	–	x	–		–
[2.11.2]	–	–	–	x	–		–

x : Where “x” appears in the Table, it means that this requirement is applicable to all classes of dangerous goods as given in the appropriate line of Tab 3, except as indicated by the following notes.

- (1) For classes 4 and 5.1 solids, not applicable to closed freight containers. For classes 2, 3, 6.1 and 8 when carried in closed freight containers, the ventilation rate may be reduced to not less than two air changes per hour. For classes 4 and 5.1 liquids when carried in closed freight containers, the ventilation rate may be reduced to not less than two air changes per hour. For the purpose of this requirement, a portable tank is a closed freight container.
- (2) Applicable to decks only.
- (3) Applies only to closed ro-ro spaces, not capable of being sealed.
- (4) In the special case where the barges are capable of containing flammable vapours or, alternatively, if they are capable of discharging flammable vapours to a safe space outside the barge carrier compartment by means of ventilation ducts connected to the barges, these requirements may be reduced or waived to the satisfaction of the Society.
- (5) Special category spaces shall be treated as closed ro-ro spaces when dangerous goods are carried.

**Table 2 : Application of the requirements to different classes of dangerous goods for ships and cargo spaces carrying solid dangerous goods in bulk**

Requirements of Article [2]	Class						
	4.1	4.2	4.3 (1)	5.1	6.1	8	9
[2.2.1]	x	x	–	x	–	–	x
[2.2.2]	x	x	–	x	–	–	x
[2.3]	x	x (2)	x	x (3)	–	–	x (3)
[2.5.1]	–	x (2)	x	–	–	–	–
[2.5.2]	x (4)	x (2)	x	x (2) (4)	–	–	x (2) (4)
[2.5.3]	x	x	x	x	x	x	x
[2.7]	x	x	x	x	x	x	x
[2.9]	x	x	x	x (2)	–	–	x (5)

- (1) The hazards of substances in this class which may be carried in bulk are such that special consideration shall be given by the Society to the construction and equipment of the ship involved in addition to meeting the requirements enumerated in this Table.
- (2) Only applicable to Seedcake containing solvent extractions, to Ammonium nitrate and to Ammonium nitrate fertilizers.
- (3) Only applicable to Ammonium nitrate and to Ammonium nitrate fertilizers. However, a degree of protection in accordance with standards contained in the “International Electrotechnical Commission, publication 60079 - Electrical Apparatus for Explosive Gas Atmospheres” is sufficient.
- (4) Only suitable wire mesh guards are required.
- (5) The requirements of the “International Maritime Solid Bulk Cargoes (IMSBC) Code”, as amended, are sufficient.

Table 3 : Application of the requirements to different classes of dangerous goods except solid dangerous goods in bulk

Requirements of Article [2]	Class																								
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23

[2.11.1]	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	
[2.11.2]	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	

(1) When “mechanically-ventilated spaces” are required by the IMDG Code.  
 (2) Stow 3 m horizontally away from the machinery space boundaries in all cases.  
 (3) Refer to the IMDG Code.  
 (4) As appropriate for the goods to be carried.  
 (5) FP means flashpoint.  
 (6) Under the provisions of the IMDG Code, stowage of class 5.2 dangerous goods under deck or in enclosed ro-ro spaces is prohibited.  
 (7) Only applicable to dangerous goods evolving flammable vapour listed in the IMDG Code.  
 (8) Only applicable to dangerous goods having a flashpoint < 23°C listed in the IMDG Code.  
 (9) Only applicable to dangerous goods having a subsidiary risk class 6.1.  
 (10) Under the provisions of the IMDG Code, stowage of class 2.3 having subsidiary risk class 2.1 under deck or in enclosed ro-ro spaces is prohibited.  
 (11) Under the provisions of the IMDG Code, stowage of class 4.3 liquids having a flashpoint < 23°C under deck or in enclosed ro-ro spaces is prohibited.

**2.2.4** Provision to flood a designated under-deck cargo space with suitable specified media may be substituted for the requirements in [2.2.3].

A high expansion foam system complying with Ch 4, Sec 15 is acceptable unless cargoes react dangerously with water (see the IMO "International Maritime Dangerous Goods Code").

**2.2.5** The total required capacity of the water supply shall satisfy the requirements of [2.2.2] and [2.2.3], if applicable, simultaneously calculated for the largest designed cargo space. The capacity requirements of [2.2.2] shall be met by the total capacity of the main fire pump(s), not including the capacity of the emergency fire pump, if fitted. If a drencher system is used to satisfy the requirements of [2.2.3], the drencher pump shall also be taken into account in this total capacity calculation.

## **2.3 Sources of ignition**

**2.3.1** Electrical equipment and wiring shall not be fitted in enclosed cargo spaces or vehicle spaces unless it is essential for operational purposes in the opinion of the Society. However, if electrical equipment is fitted in such spaces, it shall be of a certified safe type for use in the dangerous environments to which it may be exposed unless it is possible to completely isolate the electrical system (e.g. by removal of links in the system, other than fuses). Cable penetrations of the decks and bulkheads shall be sealed against the passage of gas or vapour. Through runs of cables and cables within the cargo spaces shall be protected against damage from impact. Any other equipment which may constitute a source of ignition of flammable vapour shall not be permitted.

**2.3.2** The hazardous areas are to be defined in accordance with IEC 60092-506 standard, Special features - Ships carrying specific dangerous goods and materials hazardous only in bulk.

**2.3.3** In addition, when carrying flammable liquids having flashpoints less than 23°C as Class 3, 6.1 or 8 in cargo spaces, the bilge pipes with flanges, valves, pumps, etc. constitute a source of release and the enclosing spaces (e.g. pipe tunnels, bilge pump rooms, etc.) are to be classified as an extended hazardous area (comparable with Zone 2) unless these spaces are continuously mechanically ventilated with a capacity for at least six air changes per hour.

Except where the space is protected with redundant mechanical ventilation capable of starting automatically, equipment not certified for Zone 2 are to be automatically disconnected following loss of ventilation while essential systems such as bilge and ballast systems are to be certified for Zone 2.

Where redundant mechanical ventilation is employed, equipment and essential systems not certified for Zone 2 shall be interlocked so as to prevent inadvertent operation if the ventilation is not operational. Audible and visible alarms shall be provided at a manned station if failure occurs.

**2.3.4** For pipes having open ends (e.g. ventilation and bilge pipes, etc.) in a hazardous area, the pipe itself is to be classified as hazardous area.

## **2.4 Detection system**

**2.4.1** Ro-ro spaces shall be fitted with a fixed fire detection and fire alarm system complying with the requirements of Ch 4, Sec 15. All other types of cargo spaces shall be fitted with either a fixed fire detection and fire alarm system or a sample extraction smoke detection system complying with the requirements of Ch 4, Sec 15. If a sample extraction smoke detection system is fitted, particular attention shall be given to item c) of Ch 4, Sec 15, [9.1.1] in order to prevent the leakage of toxic fumes into occupied areas.

## **2.5 Ventilation arrangement**

**2.5.1** Adequate power ventilation shall be provided in enclosed cargo spaces. The arrangement shall be such as to provide for at least six air changes per hour in the cargo space, based on an empty cargo space, and for removal of vapours from the upper or lower parts of the cargo space, as appropriate.

**2.5.2** The fans shall be such as to avoid the possibility of ignition of flammable gas/air mixtures. Suitable wire mesh guards shall be fitted over inlet and outlet ventilation openings.

Exhaust fans are to be of non-sparking type.

Note 1: The purpose of "suitable wire mesh guards" is to prevent foreign objects from entering into the fan casing. The standard wire mesh guards should have a size of 13 mm x 13 mm.

**2.5.3** Natural ventilation shall be provided in enclosed cargo spaces intended for the carriage of solid dangerous goods in bulk, where there is no provision for mechanical ventilation.

**2.5.4** If adjacent spaces are not separated from cargo spaces by gastight bulkheads or decks, then they should be considered as part of the enclosed cargo space and the ventilation requirements should apply to the adjacent space as for the enclosed cargo space itself.

For open-top container ships, power ventilation should be required only for the lower part of the cargo hold for which purpose ducting is required. The ventilation capacity should be at least two air changes per hour, based on the empty hold volume below weather deck.

Note 1: Additional requirements are given in the IMO Circular MSC.1/Circ.1120, for cargoes liable to give off vapours or gases which can form an explosive mixture with air and for cargoes liable to spontaneous combustion.

## **2.6 Bilge pumping**

**2.6.1** *Where it is intended to carry flammable or toxic liquids in enclosed cargo spaces, the bilge pumping system shall be designed to protect against inadvertent pumping of such liquids through machinery space piping or pumps. Where large quantities of such liquids are carried, consideration shall be given to the provision of additional means of draining those cargo spaces. These means shall be to the satisfaction of the Society.*

**2.6.2** Cargo spaces intended for carriage of flammable liquids with flashpoint less than 23°C or toxic liquids are to be fitted with a fixed bilge drainage system independent of or separated from the bilge system in the machinery space and located outside such space.

If a single bilge drainage system completely independent of the machinery space is provided, the system is to comply with the requirements of Ch 1, Sec 10.

For open top container holds, bilge systems for cargo holds should be independent of the machinery space bilge system and be located outside of the machinery space.

**2.6.3** *If the bilge drainage system is additional to the system served by pumps in the machinery space, the capacity of the system shall be not less than 10 m<sup>3</sup>/h per cargo space served. If the additional system is common, the capacity need not exceed 25 m<sup>3</sup>/h. The additional bilge system need not be arranged with redundancy.*

**2.6.4** *Whenever flammable liquids with flashpoint less than 23°C or toxic liquids are carried, the bilge line into the machinery space shall be isolated either by fitting a blank flange or by a closed lockable valve.*

**2.6.5** *Enclosed spaces outside machinery spaces containing bilge pumps serving cargo spaces intended for carriage of flammable or toxic liquids shall be fitted with separate mechanical ventilation giving at least 6 air changes per hour. Electrical equipment in the space is to be in accordance with Part C, Chapter 2. If the space has access from another enclosed space, the door shall be self-closing.*

The reduced air changes per hour as per Note 1 of Tab 1 also apply when the bilge pump is located directly inside a container cargo space. In case several container cargo spaces are served by the same bilge pump, the bilge pump is to be installed in the container cargo hold with the highest ventilation rate, compared to the other container cargo spaces.

**2.6.6** Bilge drainage pipes are not to pass through the engine room unless they are made of steel with reinforced thickness as per Ch 1, Sec 10, Tab 6 and are joined only by welding.

**2.6.7** *If bilge drainage of cargo spaces is arranged by gravity drainage, the drainage shall be either led directly overboard or to a closed drain tank located outside the machinery spaces. The tank shall be provided with a vent pipe to a safe location on the open deck. Drainage from a cargo space into bilge wells in a lower space is only permitted if that space satisfies the same requirements as the cargo space above.*

## **2.7 Personnel protection**

**2.7.1** *Four sets of full protective clothing, resistant to chemical attack, shall be provided in addition to the fire-fighter's outfits required by SOLAS, chapter II-2, regulation 10.10 and shall be selected taking into account the hazards associated with the chemicals being transported and the standards developed by IMO according to the class and physical state. The protective clothing shall cover all skin, so that no part of the body is unprotected.*

**2.7.2** The required protective clothing, required in [2.7.1], is for emergency purposes.

For solid bulk cargoes the protective clothing is to satisfy the equipment requirements specified in Appendix 1 of the IMSBC Code for the individual substances. For packaged goods the protective clothing is to satisfy the equipment requirements specified in emergency procedures (EmS) of the Supplement to IMDG Code for the individual substances.

**2.7.3** *At least two self-contained breathing apparatuses additional to those required by SOLAS, chapter II-2, regulation 10 shall be provided. Two spare charges suitable for use with the breathing apparatus shall be provided for each required apparatus. Passenger ships carrying not more than 36 passengers and cargo ships that are equipped with suitably located means for fully recharging the air cylinders free from contamination need carry only one spare charge for each required apparatus.*

**2.7.4** For each of the breathing apparatuses required in [2.7.3], two complete sets of air bottles are required. These spare bottles are to be in addition to the spare bottles required for fire-fighter's outfit.

## **2.8 Portable fire extinguishers**

**2.8.1** *Portable fire extinguishers with a total capacity of at least 12 kg of dry powder or equivalent shall be provided for the cargo spaces. These extinguishers shall be in addition to any portable fire extinguishers required elsewhere in this Chapter.*

## **2.9 Insulation of machinery space boundaries**

**2.9.1** *Bulkheads forming boundaries between cargo spaces and machinery spaces of category A shall be insulated to A-60 class standard, unless the dangerous goods are stowed at least 3 m horizontally away from such bulkheads. Other boundaries between such spaces shall be insulated to A-60 class standard.*

**2.9.2** *In the case that a closed or semi-closed cargo space is located partly above a machinery space and the deck above the machinery space is not insulated, dangerous goods are prohibited in the whole of that cargo space. If the uninsulated deck above the machinery space is a weather deck, dangerous goods are prohibited only for the portion of the deck located above the machinery space.*

## **2.10 Water-spray system**

**2.10.1** *Each open ro-ro space having a deck above it and each space deemed to be a closed ro-ro space not capable of being sealed shall be fitted with an approved fixed pressure water-spraying system for manual operation which shall protect all parts of any deck and vehicle platform in the space, except that the Society may permit the use of any other fixed fire-extinguishing system that has been shown by full-scale test to be no less effective. However, the drainage and pumping arrangements shall be such as to prevent the build-up of free surfaces. The drainage system shall be sized to remove no less than 125% of the combined capacity of both the water-spraying system pumps and the required number of fire hose nozzles. The drainage system valves shall be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells shall be of sufficient holding capacity and shall be arranged at the side shell of the ship at a distance from each other of not more than 40 m in each watertight compartment. If this is not possible, the adverse effect upon stability of the added weight and free surface of water shall be taken into account to the extent deemed necessary by the Society in its approval of the stability information.*

## **2.11 Separation of ro-ro spaces**

**2.11.1** *In ships having ro-ro spaces, a separation shall be provided between a closed ro-ro space and an adjacent open ro-ro space. The separation shall be such as to minimise the passage of dangerous vapours and liquids between such spaces. Alternatively, such separation need not be provided if the ro-ro space is considered to be a closed cargo space over its entire length and fully complies with the relevant special requirements of this Section.*

**2.11.2** *In ships having ro-ro spaces, a separation shall be provided between a closed ro-ro space and the adjacent weather deck. The separation shall be such as to minimise the passage of dangerous vapours and liquids between such spaces. Alternatively, a separation need not be provided if the arrangements of the closed ro-ro spaces are in accordance with those required for the dangerous goods carried on adjacent weather decks.*

# Section 13 Protection of Vehicle, Special Category and Ro-ro Spaces

## 1 General requirements

### 1.1 Application

**1.1.1** *In addition to complying with the requirements of the other Sections of this Chapter, as appropriate, vehicle, special category and ro-ro spaces shall comply with the requirements of the present Section.*

**1.1.2** *On all ships, vehicles with fuel in their tanks for their own propulsion may be carried in cargo spaces other than vehicle, special category or ro-ro spaces, provided that all the following conditions are met:*

- *the vehicles do not use their own propulsion within the cargo spaces;*
- *the cargo spaces are in compliance with the appropriate requirements of Ch 4, Sec 12; and*
- *the vehicles are carried in accordance with the IMO IMDG Code.*

### 1.2 Basic principles for passenger ships

**1.2.1** *The basic principle underlying the provisions of this Section is that the main vertical zoning required by Ch 4, Sec 5, [1] may not be practicable in vehicle spaces of passenger ships and, therefore, equivalent protection must be obtained in such spaces on the basis of a horizontal zone concept and by the provision of an efficient fixed fire-extinguishing system. Based on this concept, a horizontal zone for the purpose of this Section may include special category spaces on more than one deck provided that the total overall clear height for vehicles does not exceed 10 m.*

**1.2.2** *The basic principle underlying the provisions of [1.2.1] is also applicable to ro-ro spaces.*

**1.2.3** *The requirements of ventilation systems, openings in A class divisions and penetrations in A class divisions for maintaining the integrity of vertical zones in this Chapter shall be applied equally to decks and bulkheads forming the boundaries separating horizontal zones from each other and from the remainder of the ship.*

## 2 Precaution against ignition of flammable vapours in closed vehicle spaces, closed ro-ro spaces and special category spaces

### 2.1 Ventilation systems

#### 2.1.1 Capacity of ventilation systems

*There shall be provided an effective power ventilation system sufficient to give at least the following air changes:*

a) *Passenger ships:*

- *Special category spaces: 10 air changes per hour*
- *Closed ro-ro and vehicle spaces other than special category spaces for ships carrying more than 36 passengers: 10 air changes per hour*
- *Closed ro-ro and vehicle spaces other than special category spaces for ships carrying not more than 36 passengers: 6 air changes per hour*

b) *Cargo ships: 6 air changes per hour.*

*The Society may require an increased number of air changes when vehicles are being loaded and unloaded.*

#### 2.1.2 Performance of ventilation systems

a) *In passenger ships, the power ventilation system shall be separate from other ventilation systems. The power ventilation system shall be operated to give at least the number of air changes required in [2.1.1] at all times when vehicles are in such spaces, except where an air quality control system in accordance with d) is provided. Ventilation ducts serving such cargo spaces capable of being effectively sealed shall be separated for each such space. The system shall be capable of being controlled from a position outside such spaces.*

b) *In cargo ships, the ventilation fans shall normally be run continuously and give at least the number of air changes required in [2.1.1] whenever vehicles are on board, except where an air quality control system in accordance with item d) is provided. Where this is impracticable, they shall be operated for a limited period daily as weather permits and in any case for a reasonable period prior to discharge, after which period the ro-ro or vehicle space shall be proved gas-free. One or more*

portable combustible gas detecting instruments shall be carried for this purpose. The system shall be entirely separate from other ventilation systems. Ventilation ducts serving ro-ro or vehicle spaces shall be capable of being effectively sealed for each cargo space. The system shall be capable of being controlled from a position outside such spaces.

- c) In passenger and cargo ships, the ventilation system shall be such as to prevent air stratification and the formation of air pockets.
- d) For all ships, where an air quality control system is provided based on the guidelines developed by IMO, the ventilation system may be operated at a decreased number of air changes and/or a decreased amount of ventilation. This relaxation does not apply to spaces to which at least ten air changes per hour is required by [2.2.2] and spaces subject to the requirements of [6] and Sec 11, [2.5.1].

Note 1: Refer to the Revised design guidelines and operational recommendations for ventilation systems in ro-ro cargo spaces (MSC/Circ.1515)

- e) Fans are to be of non-sparking type.

### **2.1.3 Indication of ventilation systems**

Means shall be provided on the navigation bridge to indicate any loss of the required ventilating capacity.

### **2.1.4 Closing appliances and ducts**

- a) Arrangements shall be provided to permit a rapid shut-down and effective closure of the ventilation system from outside of the space in case of fire, taking into account the weather and sea conditions.

For this purpose, the requirements of either 1) or 2) below are to be complied with:

- 1) The access routes to the controls for closure of the ventilation system are to be:
    - clearly marked and at least 600 mm clear width, and
    - provided with a single handrail or wire rope lifeline not less than 10 mm in diameter, supported by stanchions not more than 10 m apart in way of any route which involves traversing a deck exposed to weather, and
    - fitted with appropriate means of access (such as ladders or steps) to the closing devices of ventilators located in high positions (i.e. 1,8 m and above).
  - 2) Alternatively, remote closing and position indicator arrangements from the bridge or a fire control station for those ventilator closures is acceptable.
- b) Ventilation ducts, including dampers, within a common horizontal zone shall be made of steel. In passenger ships, ventilation ducts that pass through other horizontal zones or machinery spaces shall be A-60 class steel ducts constructed in accordance with Ch 4, Sec 5, [6.3.4], items a) and b).

### **2.1.5 Permanent openings**

Permanent openings in the side plating, the ends or deckhead of the space shall be so situated that a fire in the cargo space does not endanger stowage areas and embarkation stations for survival craft and accommodation spaces, service spaces and control stations in superstructures and deckhouses above the cargo spaces.

## **2.2 Electrical equipment and wiring**

- 2.2.1** Except as provided in [2.2.2], electrical equipment and wiring shall be of a type suitable for use in an explosive petrol and air mixture.

Electrical installations in vehicle, special category and ro-ro spaces are to comply with the requirements of Pt D, Ch 1, Sec 4 or Pt D, Ch 12, Sec 4 as applicable.

- 2.2.2** In case of other than special category spaces below the bulkhead deck, notwithstanding the provisions in [2.2.1], above a height of 450 mm from the deck and from each platform of vehicles, if fitted, except platforms with openings of sufficient size permitting penetration of petrol gases downwards, electrical equipment of a type so enclosed and protected as to prevent the escape of sparks shall be permitted as an alternative, on condition that the ventilation system is so designed and operated as to provide continuous ventilation of the cargo spaces at the rate of at least ten air changes per hour whenever vehicles are on board.

## **2.3 Electrical equipment and wiring in exhaust ventilation ducts**

- 2.3.1** Electrical equipment and wiring, if installed in an exhaust ventilation duct, shall be of a type approved for use in explosive petrol and air mixtures and the outlet from any exhaust duct shall be sited in a safe position, having regard to other possible sources of ignition.

## **2.4 Other ignition sources**

- 2.4.1** Other equipment which may constitute a source of ignition of flammable vapours shall not be permitted.

## **2.5 Scuppers and discharges**

- 2.5.1** Scuppers shall not be led to machinery or other spaces where sources of ignition may be present.

### 3 Detection and alarm

#### 3.1 Fixed fire detection and fire alarm systems

**3.1.1** There shall be provided a fixed fire detection and fire alarm system complying with the requirements of Ch 4, Sec 15. The fixed fire detection system shall be capable of rapidly detecting the onset of fire. The type of detectors and their spacing and location shall be to the satisfaction of the Society, taking into account the effects of ventilation and other relevant factors. After being installed, the system shall be tested under normal ventilation conditions and shall give an overall response time to the satisfaction of the Society.

Fire detectors are to be smoke detectors.

#### 3.2 Sample extraction smoke detection systems

**3.2.1** Except open ro-ro spaces, open vehicle spaces and special category spaces, a sample extraction smoke detection system complying with the requirements of Ch 4, Sec 15 may be used as an alternative for the fixed fire detection and fire alarm system required in [3.1].

#### 3.3 Special category spaces

**3.3.1** Manually operated call points shall be spaced so that no part of the space is more than 20 m from a manually operated call point, and one shall be placed close to each exit from such spaces.

### 4 Structural protection

#### 4.1 General

**4.1.1** Notwithstanding the provisions of Ch 4, Sec 5, [1.3], in passenger ships carrying more than 36 passengers, the boundary bulkheads and decks of special category spaces and ro-ro spaces shall be insulated to A-60 class standard. However, where a category (5), (9) or (10) space, as defined in Ch 4, Sec 5, [1.3.3] is on one side of the division, the standard may be reduced to A-0. Where fuel oil tanks are below a special category space or a ro-ro space, the integrity of the deck between such spaces may be reduced to A-0 standard.

### 5 Fire extinction

#### 5.1 Fixed fire-extinguishing systems

**5.1.1** Vehicle spaces and ro-ro spaces, which are not special category spaces and are capable of being sealed from a location outside of the cargo spaces, shall be fitted with one of the following fixed fire-extinguishing systems:

- a) a fixed gas fire-extinguishing system complying with the provisions of Ch 4, Sec 15
- b) a fixed high-expansion foam fire-extinguishing system complying with the provisions of Ch 4, Sec 15; or
- c) a fixed water-based fire fighting system for ro-ro spaces and special category spaces complying with the provisions of Ch 4, Sec 15.

**5.1.2** Vehicle spaces and ro-ro spaces not capable of being sealed and special category spaces shall be fitted with a fixed water-based fire-fighting system for ro-ro spaces and special category spaces complying with the provisions of Ch 4, Sec 15, which shall protect all parts of any deck and vehicle platform in such spaces.

Such a water-based fire-fighting system shall have:

- a pressure gauge on the valve manifold
- clear marking on each manifold valve indicating the spaces served
- instructions for maintenance and operation located in the valve room; and
- a sufficient number of drainage valves to ensure complete drainage of the system.

**5.1.3** The Society may permit the use of any other fixed fire-extinguishing system that has been shown, by a full-scale test in conditions simulating a flowing petrol fire in a vehicle space or a ro-ro space, to be not less effective in controlling fires likely to occur in such a space.

#### 5.2 Portable fire extinguishers

**5.2.1** Portable fire extinguishers shall be provided at each deck level in each hold or compartment where vehicles are carried, spaced not more than 20 m apart on both sides of the space. At least one portable fire extinguisher shall be located at each access to such a cargo space.

**5.2.2** In addition to the provision of [5.2.1], the following fire-extinguishing appliances shall be provided in vehicle, ro-ro and special category spaces intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion:

- a) at least three water-fog applicators, and
- b) one portable foam applicator unit complying with the provisions of Ch 4, Sec 15, provided that at least two such units are available in the ship for use in such spaces.

## **6 Vehicle carriers carrying motor vehicles with compressed hydrogen or natural gas in their tanks for their own propulsion**

### **6.1 Spaces intended for carriage of motor vehicles with compressed natural gas in their tanks**

#### **6.1.1 Electrical equipment and wiring**

All electrical equipment and wiring shall be of a certified safe type for use in an explosive methane and air mixture

Note 1: Refer to the recommendations of the International Electrotechnical Commission, in particular, publication IEC 60079.

#### **6.1.2 Ventilation arrangement**

- a) Electrical equipment and wiring, if installed in any ventilation duct, shall be of a certified safe type for use in explosive methane and air mixtures.
- b) The fans shall be such as to avoid the possibility of ignition of methane and air mixtures. Suitable wire mesh guards shall be fitted over inlet and outlet ventilation openings.

#### **6.1.3 Other ignition sources**

Other equipment which may constitute a source of ignition of methane and air mixtures shall not be permitted.

### **6.2 Spaces intended for carriage of motor vehicles with compressed hydrogen in their tanks**

#### **6.2.1 Electrical equipment and wiring**

All electrical equipment and wiring shall be of a certified safe type for use in an explosive hydrogen and air mixture

Note 1: Refer to the recommendations of the International Electrotechnical Commission, in particular, publication IEC 60079.

#### **6.2.2 Ventilation arrangement**

- a) Electrical equipment and wiring, if installed in any ventilation duct, shall be of a certified safe type for use in explosive hydrogen and air mixtures and the outlet from any exhaust duct shall be sited in a safe position, having regard to other possible sources of ignition.
- b) The fans shall be designed such as to avoid the possibility of ignition of hydrogen and air mixtures. Suitable wire mesh guards shall be fitted over inlet and outlet ventilation openings.

#### **6.2.3 Other ignition sources**

Other equipment which may constitute a source of ignition of hydrogen and air mixtures shall not be permitted.

### **6.3 Detection**

**6.3.1** When a vehicle carrier carries as cargo one or more motor vehicles with either compressed hydrogen or compressed natural gas in their tanks for their own propulsion, at least two portable gas detectors shall be provided. Such detectors shall be suitable for the detection of the gas fuel and be of a certified safe type for use in the explosive gas and air mixture.

# Section 14 Safety Centre on Passenger Ships

## 1 General

### 1.1 Application

1.1.1 *Passenger ships shall have on board a safety centre complying with the requirements of this Section.*

### 1.2 Location and arrangement

1.2.1 *The safety centre shall either be a part of the navigation bridge or be located in a separate space adjacent to and having direct access to the navigation bridge, so that the management of emergencies can be performed without distracting watch officers from their navigational duties.*

## 2 Layout and ergonomic design

### 2.1

2.1.1 *The layout and ergonomic design of the safety centre shall take into account the guidelines laid down in MSC.1/Circ.1368.*

## 3 Communications

### 3.1

3.1.1 *Means of communication between the safety centre, the central control station, the navigation bridge, the engine control room, the storage room(s) for fire extinguishing system(s) and fire equipment lockers shall be provided.*

## 4 Control and monitoring of safety systems

### 4.1

4.1.1 *Notwithstanding the requirements set out elsewhere in the Rules, the full functionality (operation, control, monitoring or any combination thereof, as required) of the safety systems listed below shall be available from the safety centre:*

- a) *all powered ventilation systems*
- b) *fire doors*
- c) *general emergency alarm system*
- d) *public address system*
- e) *electrically powered evacuation guidance systems*
- f) *watertight and semi-watertight doors*
- g) *indicators for shell doors, loading doors and other closing appliances*
- h) *water leakage of inner/outer bow doors, stern doors and any other shell door*
- i) *television surveillance system*
- j) *fire detection and alarm system*
- k) *fixed fire-fighting local application system(s)*
- l) *sprinkler and equivalent systems*
- m) *water-based systems for machinery spaces*
- n) *alarm to summon the crew*
- o) *atrium smoke extraction system*
- p) *flooding detection systems; and*
- q) *fire pumps and emergency fire pumps.*

# Section 15 Fire Safety Systems

## 1 General

### 1.1 Application

1.1.1 This Section applies to fire safety systems as referred to in the Rules

1.1.2 Piping systems included in fire safety systems covered by this Section are to comply with the requirements of Ch 1, Sec 10, unless otherwise specified in the present Section.

1.1.3 Pressure vessels included in fire safety systems covered by this Section are to comply with the requirements of Ch 1, Sec 3, unless otherwise specified in the present Section.

### 1.2 Use of toxic extinguishing media

1.2.1 The use of a fire-extinguishing medium which, in the opinion of the Society, either by itself or under expected conditions of use gives off toxic gases, liquids and other substances in such quantities as to endanger persons shall not be permitted.

## 2 International shore connections

### 2.1 Engineering specifications

#### 2.1.1 Standard dimensions

Standard dimensions of flanges for the international shore connection shall be in accordance with Tab 1.

**Table 1 : Standard dimensions of flanges for the international shore connection**

Description	Dimension
Outside diameter	178 mm
Inside diameter	64 mm
Bolt circle diameter	132 mm
Slots in flange	4 holes, 19 mm in diameter spaced equidistantly on a bolt circle of the above diameter, slotted to the flange periphery
Flange thickness	14,5 mm minimum
Bolts and nuts	4, each of 16 mm diameter, 50 mm in length

### **2.1.2 Materials and accessories**

*International shore connections shall be of steel or other equivalent material and shall be designed for 1,0 N/mm<sup>2</sup> services. The flange shall have a flat face on one side and, on the other side, it shall be permanently attached to a coupling that will fit the ship's hydrant and hose. The connection shall be kept aboard the ship together with a gasket of any material suitable for 1,0 N/mm<sup>2</sup> services, together with four bolts of 16 mm diameter and 50 mm in length, four 16 mm nuts and eight washers.*

## **3 Fire extinguishers**

### **3.1 Type approval**

**3.1.1** *All fire extinguishers shall be of approved types and designs.*

### **3.2 Engineering specifications**

#### **3.2.1 Fire extinguisher**

a) Safety requirements

Fire extinguishers containing an extinguishing medium which, in the opinion of the Society, either by itself or under the expected conditions of use gives off toxic gases in such quantities as to endanger persons or which is an ozone depleting substance shall not be permitted.

b) Quantity of medium

- 1) *Each powder or carbon dioxide extinguisher shall have a capacity of at least 5 kg and each foam extinguisher shall have a capacity of at least 9 l. The mass of all portable fire extinguishers shall not exceed 23 kg and they shall have a fire-extinguishing capability at least equivalent to that of a 9 l fluid extinguisher.*
- 2) *The Society shall determine the equivalents of fire extinguishers.*

#### **3.2.2 Portable foam applicators**

a) *A portable foam applicator unit shall consist of a foam nozzle/branch pipe, either of a self-inducing type or in combination with a separate inductor, capable of being connected to the fire main by a fire hose, together with a portable tank containing at least 20 l of foam concentrate and at least one spare tank of foam concentrate of the same capacity.*

b) System performance

- 1) *The nozzle/branch pipe and inductor shall be capable of producing effective foam suitable for extinguishing an oil fire, at a foam solution flow rate of at least 200 l/min at the nominal pressure in the fire main.*
- 2) *The foam concentrate shall be approved.*
- 3) *The values of the foam expansion and drainage time of the foam produced by the portable foam applicator unit shall not differ more than  $\pm 10\%$  of that determined in item 2).*
- 4) *The portable foam applicator unit shall be designed to withstand clogging, ambient temperature changes, vibration, humidity, shock, impact and corrosion normally encountered on ships.*

#### **3.2.3 Waterfog applicators**

A waterfog applicator might consist of a metal L-shaped pipe, the long limb being about 2 m in length capable of being fitted to a fire hose and the short limb being about 250 mm in length fitted with a fixed water fog nozzle or capable of being fitted with a water spray nozzle.

## **4 Fixed gas fire-extinguishing systems**

### **4.1 Engineering specifications**

#### **4.1.1 General**

a) Fire-extinguishing medium

- 1) *Where the quantity of the fire-extinguishing medium is required to protect more than one space, the quantity of medium available need not be more than the largest quantity required for any one space so protected. The system shall be fitted with normally closed control valves arranged to direct the agent into the appropriate space. Adjacent spaces with independent ventilation systems not separated by at least A-0 class divisions should be considered as the same space.*
- 2) *The volume of starting air receivers, converted to free air volume, shall be added to the gross volume of the machinery space when calculating the necessary quantity of the fire-extinguishing medium. Alternatively, a discharge pipe from the safety valves may be fitted and led directly to the open air.*
- 3) *Means shall be provided for the crew to safely check the quantity of the fire-extinguishing medium in the containers. It shall not be necessary to move the containers completely from their fixing position for this purpose. For carbon dioxide systems, hanging bars for a weighing device above each bottle row, or other means shall be provided. For other types of extinguishing media, suitable surface indicators may be used.*

- 4) Containers for the storage of fire-extinguishing medium, piping and associated pressure components shall be designed to pressure codes of practice to the satisfaction of the Society having regard to their locations and maximum ambient temperatures expected in service.

b) Installation requirements

- 1) The piping for the distribution of fire-extinguishing medium shall be arranged and discharge nozzles so positioned that a uniform distribution of the medium is obtained. System flow calculations shall be performed using a calculation technique acceptable to the Society.

In large cargo spaces, at least two distribution pipes are to be provided, one on the fore part, the second at the aft part.

In machinery spaces, the discharge nozzles are to be positioned in the upper and lower parts of these spaces.

- 2) Except as otherwise permitted by the Society, pressure containers required for the storage of the fire-extinguishing medium, other than steam, shall be located outside the protected spaces in accordance with Ch 4, Sec 6, [3.3].

- 3) The storage of the fire extinguishing medium is not permitted within spaces which may contain air/flammable gas mixtures.

- 4) In piping sections where valve arrangements introduce sections of closed piping, such sections shall be fitted with a pressure relief valve and the outlet of the valve shall be led to open deck.

- 5) All discharge piping, fittings and nozzles in the protected spaces shall be constructed of materials having a melting temperature which exceeds 925°C. The piping and associated equipment shall be adequately supported.

- 6) A fitting shall be installed in the discharge piping to permit the air testing as required in [4.1.3], item g)4).

c) System control requirements

- 1) The necessary pipes for conveying fire-extinguishing medium into the protected spaces shall be provided with control valves so marked as to indicate clearly the space to which the pipes are led. Suitable provision shall be made to prevent inadvertent release of the medium into the space. Where a cargo space fitted with a gas fire-extinguishing system is used as a passenger space, the gas connection shall be blanked during such use. The pipes may pass through accommodation areas provided that they are of substantial thickness and that their tightness is verified with a pressure test, after their installation, at a pressure head not less than 5 N/mm<sup>2</sup>. In addition, pipes passing through accommodation areas shall be joined only by welding and shall not be fitted with drains or other openings within such spaces. The pipes shall not pass through refrigerated spaces.

Control valves are to be capable of local operation.

The open or closed position of control valves is to be indicated.

Means are to be provided in order to permit the blowing through each branch line of the piping system downstream of the master (control) valves.

- 2) Means shall be provided for automatically giving audible and visual warning of the release of fire-extinguishing medium into any ro-ro spaces, container holds equipped with integral reefer containers, spaces accessible by doors or hatches, and other spaces in which personnel normally work or to which they have access. The audible alarms shall be located so as to be audible throughout the protected space with all machinery operating, and the alarms should be distinguished from other audible alarms by adjustment of sound pressure or sound patterns. The pre-discharge alarm shall be automatically activated (e.g. by opening of the release cabinet door). The alarm shall operate for the length of time needed to evacuate the space, but in no case less than 20 seconds before the medium is released.

Conventional cargo spaces and small spaces (such as compressor rooms, paint lockers, etc.) with only a local release need not be provided with such an alarm. However, ro-ro cargo spaces, holds in container ships equipped for integrated reefer containers and other spaces where personnel can be expected to enter and where the access is therefore facilitated by doors or manway hatches are to be provided with such an alarm.

Where audible alarms are fitted to warn of the release of fire-extinguishing medium into pump rooms, they may be of the pneumatic or electrical type:

- pneumatically operated alarms

Air operated alarms may be used provided the air supply is clean and dry.

- electrically operated alarms

When electrically operated alarms are used, the arrangements are to be such that the electrical actuating mechanism is located outside the pump room except where the alarms are certified intrinsically safe.

Electrically operated alarms are to be supplied with power from the main and an emergency source of power. They are to differ from other signals transmitted to the protected space.

- 3) The means of control of any fixed gas fire-extinguishing system shall be readily accessible, simple to operate and shall be grouped together in as few locations as possible at positions not likely to be cut off by a fire in a protected space. At each location there shall be clear instructions relating to the operation of the system having regard to the safety of personnel.
- 4) Automatic release of fire-extinguishing medium shall not be permitted, except as permitted by the Society.

#### **4.1.2 Carbon dioxide systems - General**

a) *Quantity of fire-extinguishing medium*

- 1) *For cargo spaces the quantity of carbon dioxide available shall, unless otherwise provided, be sufficient to give a minimum volume of free gas equal to 30% of the gross volume of the largest cargo space to be protected in the ship.*
- 2) *For vehicle spaces and ro-ro spaces which are not special category spaces, the quantity of carbon dioxide available shall be at least sufficient to give a minimum volume of free gas equal to 45% of the gross volume of the largest such cargo space which is capable of being sealed, and the arrangements shall be such as to ensure that at least two thirds of the gas required for the relevant space shall be introduced within 10 min. Carbon dioxide systems shall not be used for the protection of special category spaces.*
- 3) *For machinery spaces the quantity of carbon dioxide carried shall be sufficient to give a minimum volume of free gas equal to the larger of the following volumes, either:*
  - *40% of the gross volume of the largest machinery space so protected, the volume to exclude that part of the casing above the level at which the horizontal area of the casing is 40% or less of the horizontal area of the space concerned taken midway between the tank top and the lowest part of the casing, or*
  - *35% of the gross volume of the largest machinery space protected, including the casing.*

*In the calculation of 35% of the above-mentioned volume, the net volume of the funnel shall be considered up to a height equal to the whole casing height if the funnel space is in open connection with the machinery space without inter-position of closing means.*
- 4) *The percentages specified in item 3) above may be reduced to 35% and 30%, respectively, for cargo ships of less than 2000 gross tonnage.*

*In this case, where two or more machinery spaces are not entirely separate, they are to be considered as forming one space.*
- 5) *For the purpose of this item the volume of free carbon dioxide shall be calculated at 0,56 m<sup>3</sup>/kg.*
- 6) *For machinery spaces, the fixed piping system shall be such that 85% of the gas can be discharged into the space within 2 minutes.*
- 7) *For container and general cargo spaces (primarily intended to carry a variety of cargoes separately secured or packed) the fixed piping system shall be such that at least two thirds of the gas can be discharged into the space within 10 min. For solid bulk cargo spaces the fixed piping system shall be such that at least two thirds of the gas can be discharged into the space within 20 min. The system controls shall be arranged to allow one third, two thirds or the entire quantity of gas to be discharged based on the loading condition of the hold.*

b) *Controls*

- 1) *Carbon dioxide systems for the protection of ro-ro spaces, container holds equipped with integral reefer containers, spaces accessible by doors or hatches, and other spaces in which personnel normally work or to which they have access shall comply with the following requirements:*
  - *two separate controls shall be provided for releasing carbon dioxide into a protected space and to ensure the activation of the alarm. One control shall be used for opening the valve of the piping which conveys the gas into the protected space and a second control shall be used to discharge the gas from its storage containers. Positive means (see Note 1) shall be provided so they can only be operated in that order; and*
  - *the two controls shall be located inside a release box clearly identified for the particular space. If the box containing the controls is to be locked, a key to the box shall be in a break-glass-type enclosure conspicuously located adjacent to the box.*
- 2) *The pre-discharge alarm may be activated before the two separate system release controls are operated (e.g. by a micro-switch that activates the pre-discharge alarm upon opening the release cabinet door as per [4.1.1], item c) 2). Therefore, the two separate controls for releasing carbon dioxide into the protected space (i.e. one control to open the valve of the piping which conveys the gas into the protected space and a second control used to discharge the gas from its storage containers) as per item b) 1) above can be independent of the control for activating the alarm.*

*A single control for activation of the alarm is sufficient.*

*Note 1: The "positive means", referred to for the correct sequential operation of the controls, is to be achieved by a mechanical and/or electrical interlock that does not depend on any operational procedure to achieve the correct sequence of operation.*

*Note 2: The controls requirements detailed in item b) apply to the spaces identified in [4.1.1], item c) 2) to be provided with a pre-discharge alarm.*

#### **4.1.3 High-pressure carbon dioxide systems**

- a) *The system is to be designed for an ambient temperature range of 0°C/55°C, as a rule.*
- b) *Containers for the storage of the fire-extinguishing medium are to be designed and tested in accordance with the relevant requirements of Part C, Chapter 1.*
- c) *The filling ratio of carbon dioxide bottles is to be normally 0,67 kg/l, or less, of the total internal volume; however, for bottles to be fitted in ships which are to operate solely outside the tropical zone, the filling ratio may be 0,75 kg/l.*
- d) *Piping and accessories are to generally satisfy the relevant requirements of Part C, Chapter 1.*

- e) For systems where carbon dioxide is stored at ambient temperature, the thickness of steel pipes is not to be less than the values given in Tab 2.  
Slightly smaller thicknesses may be accepted provided they comply with national standards.  
The thickness of threaded pipes is to be measured at the bottom of the thread.
- f) Pipes are to be appropriately protected against corrosion. Steel pipes are to be, at least, zinc or paint coated, except those fitted in machinery spaces, with the reservation of the Society's acceptance.
- g) After mounting onboard, and in complement to tests and inspections at the Manufacturer's workshop, as per requirements of Part C, Chapter 1, carbon dioxide pipes and their accessories are to undergo the following tests:
  - 1) pipe lengths between bottles and master valves:  
a hydraulic test, at the workshop or on board, at 128 bar. When the hydraulic test is carried out at the workshop, at least test with inert gas or air, at 7 bar, is to be carried out on board
  - 2) pipe lengths between master valves and nozzles:  
a test on board with inert gas or air, at 7 bar
  - 3) master valves:  
a hydraulic test at 128 bar
  - 4) a test of the free air flow in all pipes and nozzles; and
  - 5) a functional test of the alarm equipment.

**Table 2 : Minimum wall thickness for steel pipes for CO<sub>2</sub> fire-extinguishing systems**

External diameter (mm)	Minimum wall thickness (mm)	
	between bottles and master valves	between master valves and nozzles
21,3 - 26,9	3,2	2,6
30,0 - 48,3	4,0	3,2
51,0 - 60,3	4,5	3,6
63,5 - 76,1	5,0	3,6
82,5 - 88,9	5,6	4,0
101,6	6,3	4,0
108,0 - 114,3	7,1	4,5
127,0	8,0	4,5
133,0 - 139,7	8,0	5,0
152,4 - 168,3	8,8	5,6

**4.1.4 Low-pressure carbon dioxide systems**

When carbon dioxide, instead of being contained in non-refrigerated high pressure bottles, is contained in refrigerated low pressure vessels, in addition to the requirements in [4.1.2] the following are to be complied with.

- a) General  
Except where different requirements are given in this item, the requirements of [4.1.3] for systems with carbon dioxide contained in high pressure bottles are generally to be complied with.
- b) Vessels and associated devices
  - 1) *The system control devices and the refrigerating plants are to be located within the same room where the pressure vessels are stored.*
  - 2) *The rated amount of liquid carbon dioxide is to be stored in vessels under the working pressure in the range of 1,8 MPa to 2,2 MPa. The normal liquid charge in the container is to be limited to provide sufficient vapour space to allow for expansion of the liquid under the maximum storage temperatures that can be obtained corresponding to the setting of the pressure relief valves, but is not to exceed 95% of the volumetric capacity of the container.*

- 3) The vessels are to be designed, constructed and tested in accordance with the requirements of Ch 1, Sec 3. For this purpose the design pressure is to be taken not less than the relief valve setting. In addition, for each vessel, *provision is to be made for:*
- a pressure gauge
  - a high pressure alarm: not more than the setting of the relief valve
  - a low pressure alarm: not less than 1,8 MPa
  - branch pipes with stop valves for filling the vessel
  - discharge pipes
  - a liquid CO<sub>2</sub> level indicator, fitted on the vessel
  - two safety relief valves arranged so that either valve can be shut off while the other is connected to the vessel. The setting of the relief valves is to be not less than 1,1 times the working pressure. The capacity of each valve is to be such that the vapours generated due to fire can be discharged with a pressure rise not more than 20% above the setting pressure. The discharge from the safety valves is to be led to the open.
- 4) The vessels and outgoing pipes permanently filled with carbon dioxide are to have thermal insulation preventing the operation of the safety valve for 24 hours after de-energising the plant, at ambient temperature of 45°C and an initial pressure equal to the starting pressure of the refrigeration unit. The insulating materials and their liners are to be to the satisfaction of the Society, bearing in mind, in particular, their fire resistance and mechanical properties, as well as protection against penetration of water vapours.

c) Refrigerating plant

- 1) The vessels are to be serviced by two automated completely independent refrigerating units solely intended for this purpose, each comprising a compressor and the associated prime mover, evaporator and condenser.
- 2) The refrigerating plant is to comply with the relevant requirements of Ch 1, Sec 16. The refrigerating capacity and the automatic control of each unit are to be such as to maintain the required temperature under conditions of continuous operation for 24 hours at a sea temperature up to 32°C and ambient air temperature up to 45°C.
- 3) In the event of failure of either one of the refrigerating units, the other is to be actuated automatically. Provision is to be made for local manual control of the refrigerating plant.
- 4) Each electrical refrigerating unit is to be supplied from the main switchboard busbars by a separate feeder.
- 5) The cooling water supply to the refrigerating plant (where required) is to be provided from at least two circulating pumps, one of which being used as a standby. The standby pump may be a pump used for other services so long as its use for cooling would not interfere with any other essential service of the ship. Cooling water is to be taken from not less than two sea connections, preferably one port and one starboard.

d) Pipes, valves and associated fittings

- 1) The pipes, valves and fittings are to be in accordance with the requirements of Ch 1, Sec 10 for a design pressure not less than the design pressure of the CO<sub>2</sub> vessels.
- 2) Safety relief devices are to be provided in each section of pipe that may be isolated by block valves and in which there could be a build up of pressure in excess of the design pressure of any of the components.
- 3) The piping system is to be designed in such a way that the CO<sub>2</sub> pressure at the nozzles should not be less than 1 Mpa.

e) Control of fire-extinguishing system operation

The machinery alarm system is to be equipped with audible and visual alarms activated when:

- 1) the pressure in the vessels reaches the low and the high values according to item b) 2) above
- 2) any one of the refrigerating units fails to operate
- 3) the lowest permissible level of the liquid in the vessels is reached.

f) Release control

- 1) The release of CO<sub>2</sub> is to be initiated manually.
- 2) If a device is provided which automatically regulates the discharge of the rated quantity of carbon dioxide into the protected spaces, it is also to be possible to regulate the discharge manually.
- 3) If the system serves more than one space, means for control of discharge quantities of CO<sub>2</sub> are to be provided, e.g. automatic timer or accurate level indicators located at the control positions or positions.

g) Testing

- 1) The pipes, valves and fittings and assembled system are to be tested to the satisfaction of the Society.
- 2) The pipes from the vessels to the release valves on the distribution manifold are to be subjected to a pressure test to not less than 1,5 times the set pressure of the safety relief valves.
- 3) The pipes from the release valves on the distribution manifold to the nozzles are to be tested for tightness and free flow of CO<sub>2</sub>, after having been assembled on board.
- 4) After having been fitted on board, the refrigerating plant is to be checked for its proper operation.
- 5) If deemed necessary by the Society, a discharge test may be required to check the fulfilment of the requirements of item d) 3) above.

## **4.2 Equivalent fixed gas fire-extinguishing systems**

**4.2.1** Fixed gas fire-extinguishing systems equivalent to those specified in [4.1] are to be specially considered by the Society.

## **4.3 Requirements of steam systems**

**4.3.1** *The boiler or boilers available for supplying steam are to have an evaporation of at least 1 kg of steam per hour for each 0,75 m<sup>3</sup> of the gross volume of the largest space so protected. In addition to complying with the foregoing requirements, the systems in all respects are to be as determined by, and to the satisfaction of, the Society.*

# **5 Fixed foam fire-extinguishing systems**

## **5.1 General**

### **5.1.1 Application**

The Article [5] details the specifications for fixed foam fire-extinguishing systems for:

- the protection of machinery spaces in accordance with Ch 4, Sec 6, [3.1.1], item b)
- cargo spaces in accordance with Ch 4, Sec 6, [6.1.1]
- cargo pump-rooms in accordance with Pt D, Ch 7, Sec 6, [4.2.2], item a) 2) and
- vehicle, special category and ro-ro spaces in accordance with Ch 4, Sec 13, [5.1.1].

This Article does not apply to cargo pump-rooms of chemical tankers carrying liquid cargoes, unless the Society specifically accepts the use of these systems based on additional tests with alcohol-based fuel and alcohol resistant foam.

### **5.1.2 Definitions**

- a) Design filling rate *is at least the minimum nominal filling rate used during the approval tests.*
- b) Foam *is the extinguishing medium produced when foam solution passes through a foam generator and is mixed with air.*
- c) Foam solution *is a solution of foam concentrate and water.*
- d) Foam concentrate *is a liquid which, when mixed with water in the appropriate concentration forms a foam solution.*
- e) Foam delivery ducts *are supply ducts for introducing high-expansion foam into the protected space from foam generators located outside the protected space.*
- f) Foam mixing ratio *is the percentage of foam concentrate mixed with water forming the foam solution.*
- g) Foam generators *are discharge devices or assemblies through which high-expansion foam solution is aerated to form foam that is discharged into the protected space. Foam generators using inside air typically consist of a nozzle or set of nozzles and a casing. The casing is typically made of perforated steel/stainless steel plates shaped into a box that enclose the nozzle(s). Foam generators using outside air typically consist of nozzles enclosed within a casing that spray onto a screen. An electric, hydraulic or pneumatically driven fan is provided to aerate the solution.*
- h) High-expansion foam fire-extinguishing systems *are fixed total flooding extinguishing systems that use either inside air or outside air for aeration of the foam solution. A high-expansion foam system consists of both the foam generators and the dedicated foam concentrate approved during the fire testing specified in [5.2.1], item c).*
- i) Inside air foam system *is a fixed high-expansion foam fire-extinguishing system with foam generators located inside the protected space and drawing air from that space.*
- j) Nominal flow rate *is the foam solution flow rate expressed in l/min.*
- k) Nominal application rate *is the nominal flow rate per area expressed in l/min/m<sup>2</sup>.*

- l) Nominal foam expansion ratio is the ratio of the volume of foam to the volume of foam solution from which it was made, under non-fire conditions, and at an ambient temperature of e.g. around 20°C.
- m) Nominal foam production is the volume of foam produced per time unit, i.e. nominal flow rate times nominal foam expansion ratio, expressed in m<sup>3</sup>/min.
- n) Nominal filling rate is the ratio of nominal foam production to the area, i.e. expressed in m/min.
- o) Nominal filling time is the ratio of the height of the protected space to the nominal filling rate, i.e. expressed in minutes.
- p) Outside air foam system is a fixed high-expansion foam system with foam generators installed outside the protected space that are directly supplied with fresh air.

## **5.2 Fixed high-expansion foam fire-extinguishing systems**

### **5.2.1 Principal performance**

- a) The system shall be capable of manual release, and shall be designed to produce foam at the required application rate within 1 minute of release. Automatic release of the system shall not be permitted unless appropriate operational measures or interlocks are provided to prevent any local application systems required by Ch 4, Sec 6, [4.7], from interfering with the effectiveness of the system.
  - b) The foam concentrates shall be approved by the Society based on IMO Circular MSC/Circ.670. Different foam concentrate types shall not be mixed in a high-expansion foam system.
  - c) The system shall be capable of fire extinction and manufactured and tested to the satisfaction of the Society based on IMO Circular MSC.1/Circ.1384.
  - d) The system and its components shall be suitably designed to withstand ambient temperature changes, vibration, humidity, shock, clogging and corrosion normally encountered on ships. Piping, fittings and related components inside the protected spaces (except gaskets) shall be designed to withstand 925°C.
  - e) System piping, foam concentrate storage tanks, components and pipe fittings in contact with the foam concentrate shall be compatible with the foam concentrate and be constructed of corrosion resistant materials such as stainless steel, or equivalent. Other system piping and foam generators shall be full galvanized steel or equivalent. Distribution pipework shall have self-draining capability.
  - f) Means for testing the operation of the system and assuring the required pressure and flow shall be provided by pressure gauges at both inlets (water and foam concentrate supply) and at the outlet of the foam proportioner. A test valve shall be installed on the distribution piping downstream of the foam proportioner, along with orifices which reflect the calculated pressure drop of the system. All sections of piping shall be provided with connections for flushing, draining and purging with air. All nozzles shall be able to be removed for inspection in order to prove clear of debris.
  - g) Means shall be provided for the crew to safely check the quantity of foam concentrate and take periodic control samples for foam quality.
  - h) Operating instructions for the system shall be displayed at each operating position.
  - i) Spare parts shall be provided based on the manufacturer's instruction.
  - j) If an internal combustion engine is used as a prime mover for the seawater pump for the system, the fuel oil tank to the prime mover shall contain sufficient fuel to enable the pump to run on full load for at least 3 h and sufficient reserves of fuel shall be available outside the machinery space of category A to enable the pump to be run on full load for an additional 15 h. If the fuel tank serves other internal combustion engines simultaneously, the total fuel tank capacity shall be adequate for all connected engines.
  - k) The arrangement of foam generators and piping in the protected space shall not interfere with access to the installed machinery for routine maintenance activities.
  - l) The system source of power supply, foam concentrate supply and means of controlling the system shall be readily accessible and simple to operate, and shall be arranged at positions outside the protected space not likely to be cut off by a fire in the protected space. All electrical components directly connected to the foam generators shall have at least an IP 54 rating.
  - m) The piping system shall be sized in accordance with a hydraulic calculation technique to ensure availability of flows and pressures required for correct performance of the system.
- Note 1: Where the Hazen-Williams method is used, the values of the friction factor C given in Tab 3 for different pipe types which may be considered should apply:
- n) The arrangement of the protected spaces shall be such that they may be ventilated as the space is being filled with foam. Procedures shall be provided to ensure that upper level dampers, doors and other suitable openings are kept open in case of a fire. For inside air foam systems, spaces below 500 m<sup>3</sup> need not comply with this requirement.
  - o) Onboard procedures shall be established to require personnel re-entering the protected space after a system discharge to wear breathing apparatus to protect them from oxygen deficient air and products of combustion entrained in the foam blanket.
  - p) Installation plans and operating manuals shall be supplied to the ship and be readily available on board. A list or plan shall be displayed showing spaces covered and the location of the zone in respect of each section. Instructions for testing and maintenance shall be available on board.

- q) All installation, operation and maintenance instructions/plans for the system shall be in the working language of the ship. If the working language of the ship is not English, French, nor Spanish, a translation into one of these languages shall be included.
- r) The foam generator room shall be ventilated to protect against overpressure, and shall be heated to avoid the possibility of freezing.
- s) The quantity of foam concentrate available shall be sufficient to produce a volume of foam equal to at least five times the volume of the largest protected space enclosed by steel bulkheads, at the nominal expansion ratio, or enough for 30 min of full operation for the largest protected space, whichever is greater.
- t) Machinery spaces, cargo pump-rooms, vehicle spaces, ro-ro spaces and special category spaces shall be provided with audible and visual alarms within the protected space warning of the release of the system. The alarms shall operate for the length of time needed to evacuate the space, but in no case less than 20 s.

**Table 3 : Friction factor C**

Pipe type	C
Black or galvanized mild steel	100
Copper or copper alloys	150
Stainless steel	150

**5.2.2 Inside air foam systems**

a) Systems for the protection of machinery spaces and cargo pump-rooms

- 1) The system shall be supplied by both main and emergency sources of power. The emergency power supply shall be provided from outside the protected space.
- 2) Sufficient foam-generating capacity shall be provided to ensure the minimum design filling rate for the system is met and in addition shall be adequate to completely fill the largest protected space within 10 min.

Where such a machinery space includes a casing (e.g. an engine casing in a machinery space of category A containing internal combustion machinery, and/or a boiler), the volume of such casing, above the level up to which foam shall be filled to protect the highest position of the fire risk objects within the machinery space, need not be included in the volume of the protected space.

The level up to which foam shall be filled to protect the highest positioned fire risk objects within the machinery space shall not be less than whichever is higher between 1 m above the highest point of any such object; and the lowest part of the casing.

Where such a machinery space does not include a casing, the volume of the largest protected space shall be that of the space in its entirety, irrespective of the location of any fire risk object therein.

Fire risk objects include, but may not be limited to, those listed in Ch 4, Sec 1, [2.29.1], and those defined in Ch 4, Sec 1, [2.33.1], although not referred to in those requirements, they may also include items having a similar fire risk such as exhaust gas boilers or oil fuel tanks.

- 3) The arrangement of foam generators shall in general be designed based on the approval test results. A minimum of two generators shall be installed in every space containing combustion engines, boilers, purifiers, and similar equipment. Small workshops and similar spaces may be covered with only one foam generator.
- 4) Foam generators shall be uniformly distributed under the uppermost ceiling in the protected spaces including the engine casing. The number and location of foam generators shall be adequate to ensure all high risk areas are protected in all parts and at all levels of the spaces. Extra foam generators may be required in obstructed locations. The foam generators shall be arranged with at least 1 m free space in front of the foam outlets, unless tested with less clearance. The generators shall be located behind main structures, and above and away from engines and boilers in positions where damage from an explosion is unlikely.

b) Systems for the protection of vehicle, ro-ro, special category and cargo spaces

- 1) The system shall be supplied by the ship's main power source. An emergency power supply is not required.
- 2) Sufficient foam-generating capacity shall be provided to ensure the minimum design filling rate for the system is met and in addition shall be adequate to completely fill the largest protected space within 10 min. However, for systems protecting vehicle and ro-ro spaces and special category spaces, with decks that are reasonably gas-tight and that have a deck height of 3 m or less, the filling rate shall be not less than two thirds of the design filling rate and in addition sufficient to fill the largest protected space within 10 min.
- 3) The system may be divided into sections, however, the capacity and design of the system shall be based on the protected space demanding the greatest volume of foam. Adjacent protected spaces need not be served simultaneously if the boundaries between the spaces are "A" class divisions.

- 4) *The arrangement of foam generators shall in general be designed based on the approval test results. The number of generators may be different, but the minimum design filling rate determined during approval testing shall be provided by the system. A minimum of two generators shall be installed in every space. The foam generators shall be arranged to uniformly distribute foam in the protected spaces, and the layout shall take into consideration obstructions that can be expected when cargo is loaded on board. As a minimum, generators shall be located on every second deck, including movable decks. The horizontal spacing of the generators shall ensure rapid supply of foam to all parts of the protected space. This shall be established on the basis of full scale tests.*
- 5) *The foam generators shall be arranged with at least 1 m free space in front of the foam outlets, unless tested with less clearance.*

### **5.2.3 Outside air foam systems**

- a) *Systems for the protection of machinery spaces and cargo pump-rooms*
  - 1) *The system shall be supplied by both main and emergency sources of power. The emergency power supply shall be provided from outside the protected machinery space.*
  - 2) *Sufficient foam-generating capacity shall be provided to ensure the minimum design filling rate for the system is met and in addition shall be adequate to completely fill the largest protected space within 10 min.*
  - 3) *The arrangement of foam delivery ducts shall in general be designed based on the approval test results. The number of ducts may be different, but the minimum design filling rate determined during approval testing shall be provided by the system. A minimum of two ducts shall be installed in every space containing combustion engines, boilers, purifiers, and similar equipment. Small workshops and similar spaces may be covered with only one duct.*
  - 4) *Foam delivery ducts shall be uniformly distributed under the uppermost ceiling in the protected spaces including the engine casing. The number and location of ducts shall be adequate to ensure all high risk areas are protected in all parts and at all levels of the spaces. Extra ducts may be required in obstructed locations. The ducts shall be arranged with at least 1 m free space in front of the foam delivery ducts, unless tested with less clearance. The ducts shall be located behind main structures, and above and away from engines and boilers in positions where damage from an explosion is unlikely.*
  - 5) *The arrangement of the foam delivery ducts shall be such that a fire in the protected space will not affect the foam-generating equipment. If the foam generators are located adjacent to the protected space, foam delivery ducts shall be installed to allow at least 450 mm of separation between the generators and the protected space, and the separating divisions shall be class "A-60" rated. Foam delivery ducts shall be constructed of steel having a thickness of not less than 5 mm. In addition, stainless steel dampers (single or multi-bladed) with a thickness of not less than 3 mm shall be installed at the openings in the boundary bulkheads or decks between the foam generators and the protected space. The dampers shall be automatically operated (electrically, pneumatically or hydraulically) by means of remote control of the foam generator related to them, and arranged to remain closed until the foam generators begin operating.*
  - 6) *The foam generators shall be located where an adequate fresh air supply can be arranged.*
- b) *Systems for the protection of vehicle and ro-ro spaces and special category and cargo spaces*
  - 1) *The system shall be supplied by the ship's main power source. An emergency power supply is not required.*
  - 2) *Sufficient foam-generating capacity shall be provided to ensure the minimum design filling rate for the system is met and in addition shall be adequate to completely fill the largest protected space within 10 min. However, for systems protecting vehicle and ro-ro spaces and special category spaces, with decks that are reasonably gas-tight and that have a deck height of 3 m or less, the filling rate shall be not less than two thirds of the design filling rate and in addition sufficient to fill the largest protected space within 10 min.*
  - 3) *The system may be divided into sections, however, the capacity and design of the system shall be based on the protected space demanding the greatest volume of foam. Adjacent protected spaces need not be served simultaneously if the boundaries between the spaces are "A" class divisions.*
  - 4) *The arrangement of foam delivery ducts shall in general be designed based on the approval test results. The number of ducts may be different, but the minimum design filling rate determined during approval testing shall be provided by the system. A minimum of two ducts shall be installed in every space. The foam generators shall be arranged to uniformly distribute foam in the protected spaces, and the layout shall take into consideration obstructions that can be expected when cargo is loaded on board. As a minimum, ducts shall be led to every second deck, including movable decks. The horizontal spacing of the ducts shall ensure rapid supply of foam to all parts of the protected space. This shall be established on the basis of full scale tests.*
  - 5) *The system shall be arranged with at least 1 m free space in front of the foam outlets, unless tested with less clearance.*
  - 6) *The arrangement of the foam delivery ducts shall be such that a fire in the protected space will not affect the foam-generating equipment. If the foam generators are located adjacent to the protected space, foam delivery ducts shall be installed to allow at least 450 mm of separation between the generators and the protected space, and the separating divisions shall be class "A-60" rated. Foam delivery ducts shall be constructed of steel having a thickness of not less than 5 mm. In addition, stainless steel dampers (single or multi-bladed) with a thickness of not less than 3 mm shall be installed at the openings in the boundary bulkheads or decks between the foam generators and the protected space. The dampers shall be automatically operated (electrically, pneumatically or hydraulically) by means of remote control of the foam generator related to them, and arranged to remain closed until the foam generators begin operating.*
  - 7) *The foam generators shall be located where an adequate fresh air supply can be arranged.*

### 5.2.4 Installation testing requirements

- a) After installation, the pipes, valves, fittings and assembled systems shall be tested to the satisfaction of the Society, including functional testing of the power and control systems, water pumps, foam pumps, valves, remote and local release stations and alarms. Flow at the required pressure shall be verified for the system using orifices fitted to the test line. In addition, all distribution piping shall be flushed with freshwater and blown through with air to ensure that the piping is free of obstructions.
- b) Functional tests of all foam proportioners or other foam mixing devices shall be carried out to confirm that the mixing ratio tolerance is within +30 to -0% of the nominal mixing ratio defined by the system approval. For foam proportioners using foam concentrates of Newtonian type with kinematic viscosity equal to or less than 100 cSt at 0°C and density equal to or less than 1,100 kg/m<sup>3</sup>, this test can be performed with water instead of foam concentrate. Other arrangements shall be tested with the actual foam concentrate.

### 5.2.5 Systems using outside air with generators installed inside the protected space

Systems using outside air but with generators located inside the protected space and supplied by fresh air ducts may be accepted by the Society provided that these systems have been shown to have performance and reliability equivalent to systems defined in [5.2.3]. For acceptance, the Society should consider the following minimum design features:

- lower and upper acceptable air pressure and flow rate in supply ducts;
- function and reliability of damper arrangements;
- arrangements and distribution of air delivery ducts including foam outlets; and
- separation of air delivery ducts from the protected space.

## 5.3 Fixed low-expansion foam fire-extinguishing systems

### 5.3.1 Quantity and foam concentrates

- a) The foam concentrates of low-expansion foam fire-extinguishing systems shall be approved by the Society based on IMO Circular MSC.1/Circ.1312. Different foam concentrate types shall not be mixed in a low-expansion foam system. Foam concentrates of the same type from different manufacturers shall not be mixed unless they are approved for compatibility.
- b) The system shall be capable of discharging through fixed discharge outlets, in no more than 5 min, a quantity of foam sufficient to produce an effective foam blanket over the largest single area over which oil fuel is liable to spread.

### 5.3.2 Installation requirements

- a) Means shall be provided for effective distribution of the foam through a permanent system of piping and control valves or cocks to suitable discharge outlets, and for the foam to be effectively directed by fixed sprayers onto other main fire hazards in the protected space. The means for effective distribution of the foam shall be proven acceptable to the Society through calculation or by testing.
- b) The means of control of any such systems shall be readily accessible and simple to operate and shall be grouped together in as few locations as possible at positions not likely to be cut off by a fire in the protected space.

## 6 Fixed pressure water-spraying and water-mist fire-extinguishing systems

### 6.1 Engineering specifications

#### 6.1.1 Fixed pressure water-spraying fire-extinguishing systems

Fixed-pressure water-spraying fire-extinguishing systems for machinery spaces and cargo pump-rooms shall be approved by the Society based on IMO Circular MSC.1/Circ.1165, as amended.

#### 6.1.2 Equivalent water-mist fire-extinguishing systems

Water-mist fire-extinguishing systems for machinery spaces and cargo pump rooms shall be approved by the Society based on IMO Circular MSC.1/Circ.1165, as amended.

#### 6.1.3 Fixed pressure water-spraying fire-extinguishing systems for cabin balconies

Fixed pressure water-spraying fire-extinguishing systems for cabin balconies shall be approved by the Society based on IMO Circular MSC.1/Circ.1268.

#### 6.1.4 Fixed water-based fire-fighting systems for ro-ro spaces, vehicle spaces and special category spaces

Fixed water-based fire-fighting systems for ro-ro spaces, vehicle spaces and special category spaces shall be approved by the Society based on IMO Circular MSC.1/Circ.1430, as amended.

#### 6.1.5 Fixed water-based local application fire-fighting systems

Fixed water-based local application fire-fighting systems are to be approved by the Society based on IMO Circular MSC.1/Circ.1387 as corrected by MSC.1/Circ.1387/Corr.1.

## 7 Automatic sprinkler, fire detection and fire alarm systems

### 7.1 Engineering specifications

#### 7.1.1 General

##### a) Type of sprinkler systems

The automatic sprinkler systems shall be of the wet pipe type, but small exposed sections may be of the dry pipe type where, in the opinion of the Society, this is a necessary precaution. Control stations, where water may cause damage to essential equipment, may be fitted with a dry pipe system or a pre-action system as permitted by regulation Pt C, Ch 4, Sec 6, [5.1.1]. Saunas shall be fitted with a dry pipe system, with sprinkler heads having an operating temperature up to 140°C.

##### b) Automatic sprinkler systems equivalent to those specified in [7.1.2] to [7.1.4] shall be approved by the Society, according to IMO Resolution A.800(19), as amended by MSC.265(84) and MSC.284(86).

#### 7.1.2 Sources of power supply

##### a) Passenger ships

There shall be not less than two sources of power supply for the sea water pump and automatic alarm and detection system. Where the sources of power for the pump are electrical, these shall be a main generator and an emergency source of power. One supply for the pump shall be taken from the main switchboard, and one from the emergency switchboard by separate feeders reserved solely for that purpose. The feeders shall be so arranged as to avoid galleys, machinery spaces and other enclosed spaces of high fire risk except in so far as it is necessary to reach the appropriate switchboards, and shall be run to an automatic change-over switch situated near the sprinkler pump. This switch shall permit the supply of power from the main switchboard so long as a supply is available therefrom, and be so designed that upon failure of that supply it will automatically change-over to the supply from the emergency switchboard. The switches on the main switchboard and the emergency switchboard shall be clearly labelled and normally kept closed. No other switch shall be permitted in the feeders concerned. One of the sources of power supply for the alarm and detection system shall be an emergency source. Where one of the sources of power for the pump is an internal combustion engine it shall, in addition to complying with the provisions of [7.1.4], item c), be so situated that a fire in any protected space will not affect the air supply to the machinery.

##### b) Cargo ships

There shall be not less than two sources of power supply for the sea water pump and automatic alarm and detection system. If the pump is electrically driven, it shall be connected to the main source of electrical power, which shall be capable of being supplied by at least two generators. The feeders shall be so arranged as to avoid galleys, machinery spaces and other enclosed spaces of high fire risk except in so far as it is necessary to reach the appropriate switchboards. One of the sources of power supply for the alarm and detection system shall be an emergency source. Where one of the sources of power for the pump is an internal combustion engine, it shall, in addition to complying with the provisions of [7.1.4], item c), be so situated that a fire in any protected space will not affect the air supply to the machinery.

#### 7.1.3 Component requirements

##### a) Sprinklers

The sprinklers shall be resistant to corrosion by the marine atmosphere. In accommodation and service spaces the sprinklers shall come into operation within the temperature range from 68°C to 79°C, except that in locations such as drying rooms, where high ambient temperatures might be expected, the operating temperature may be increased by not more than 30°C above the maximum deckhead temperature.

##### b) Pressure tanks

1) A pressure tank having a volume equal to at least twice that of the charge of water specified in this item shall be provided. The tank shall contain a standing charge of fresh water, equivalent to the amount of water which would be discharged in one minute by the pump referred to in item c) 2) below, and the arrangements shall be provided for maintaining an air pressure in the tank such as to ensure that where the standing charge of fresh water in the tank has been used the pressure will be not less than the working pressure of the sprinkler, plus the pressure exerted by a head of water measured from the bottom of the tank to the highest sprinkler in the system. Suitable means of replenishing the air under pressure and of replenishing the fresh water charge in the tank shall be provided. A glass gauge shall be provided to indicate the correct level of the water in the tank.

The tank is to be designed and built in compliance with the requirements for pressure vessels given in Ch 1, Sec 3.

2) Means shall be provided to prevent the passage of sea water into the tank.

##### c) Sprinkler pumps

1) An independent power pump shall be provided solely for the purpose of continuing automatically the discharge of water from the sprinklers. The pump shall be brought into action automatically by the pressure drop in the system before the standing fresh water charge in the pressure tank is completely exhausted.

2) The pump and the piping system shall be capable of maintaining the necessary pressure at the level of the highest sprinkler to ensure a continuous output of water sufficient for the simultaneous coverage of a minimum area of 280 m<sup>2</sup> at the application rate specified in [7.1.5], item b) 3). The hydraulic capability of the system shall be confirmed by the review of hydraulic calculations, followed by a test of the system, if deemed necessary by the Society.

- 3) *The pump shall have fitted on the delivery side a test valve with a short open-ended discharge pipe. The effective area through the valve and pipe shall be adequate to permit the release of the required pump output while maintaining the pressure in the system specified in item b) 1) above.*

#### **7.1.4 Installation requirements**

##### *a) General*

- 1) *Any parts of the system which may be subjected to freezing temperatures in service shall be suitably protected against freezing.*
- 2) *Special attention shall be paid to the specification of water quality provided by the system manufacturer to prevent internal corrosion of sprinklers and clogging or blockage arising from products of corrosion or scale-forming minerals.*

##### *b) Piping arrangements*

- 1) *Sprinklers shall be grouped into separate sections, each of which shall contain not more than 200 sprinklers. In passenger ships, any section of sprinklers shall not serve more than two decks and shall not be situated in more than one main vertical zone. However, the Society may permit such a section of sprinklers to serve more than two decks or be situated in more than one main vertical zone, if it is satisfied that the protection of the ship against fire will not thereby be reduced.*

*Sprinkler heads installed to fulfil the provisions of Ch 4, Sec 5, [3.2.3] are not required to be solely dedicated to the windows and sidescuttles they are to protect, provided that the sprinkler heads protecting the room and having a spraying density of 5 l/(m<sup>2</sup> min) are arranged such that the window or sidescuttle is covered with the same spraying density and the relevant area is considered in the calculation as per [7.1.5].*

- 2) *Each section of sprinklers shall be capable of being isolated by one stop-valve only. The stop-valve in each section shall be readily accessible in a location outside of the associated section or in cabinets within stairway enclosures. The valve's location shall be clearly and permanently indicated. Means shall be provided to prevent the operation of the stop-valves by any unauthorized person.*
- 3) *A test valve shall be provided for testing the automatic alarm for each section of sprinklers by a discharge of water equivalent to the operation of one sprinkler. The test valve for each section shall be situated near the stop-valve for that section.*
- 4) *The sprinkler system shall have a connection from the ship's fire main by way of a lockable screw-down non-return valve at the connection which will prevent a backflow from the sprinkler system to the fire main.*

*The automatic sprinkler fire detection and fire alarm system shall be an independent unit and therefore no other piping system shall be connected to it, except for the following:*

- *connections for feeding the system from shoreside sources, fitted with adjacent stop valves and non-return valves*
- *connection from the fire main as required above.*

*The valves on the shore filling connection and on the fire main connection shall be fitted with clear and permanent labels indicating their service. These valves shall be capable of being locked in the "closed" position.*

- 5) *A gauge indicating the pressure in the system shall be provided at each section stop-valve and at a central station.*
- 6) *The sea inlet to the pump shall, wherever possible, be in the space containing the pump and shall be so arranged that when the ship is afloat it will not be necessary to shut off the supply of sea water to the pump for any purpose other than the inspection or repair of the pump.*

##### *c) Location of systems*

*The sprinkler pump and tank shall be situated in a position reasonably remote from any machinery space of category A and shall not be situated in any space required to be protected by the sprinkler system.*

#### **7.1.5 System control requirements**

##### *a) Ready availability*

- 1) *Any required automatic sprinkler, fire detection and fire alarm system shall be capable of immediate operation at all times and no action by the crew shall be necessary to set it in operation.*
- 2) *The automatic sprinkler system shall be kept charged at the necessary pressure and shall have provision for a continuous supply of water as required in this Section.*

##### *b) Alarm and indication*

- 1) *Each section of sprinklers shall include means for giving a visual and audible alarm signal automatically at one or more indicating units whenever any sprinkler comes into operation. Such alarm systems shall be such as to indicate if any fault occurs in the system. Such units shall indicate in which section served by the system a fire has occurred and shall be centralized on the navigation bridge or in the continuously-manned central control station and, in addition, visible and audible alarms from the unit shall also be placed in a position other than on the aforementioned spaces to ensure that the indication of fire is immediately received by the crew.*
- 2) *Switches shall be provided at one of the indicating positions referred to in the previous item 1) which will enable the alarm and the indicators for each section of sprinklers to be tested.*

- 3) *Sprinklers shall be placed in an overhead position and spaced in a suitable pattern to maintain an average application rate of not less than 5 l/m<sup>2</sup>/minute over the nominal area covered by the sprinklers. For this purpose, nominal area shall be taken as the gross horizontal projection of the area to be covered. However, the Society may permit the use of sprinklers providing such an alternative amount of water suitably distributed as has been shown, to the satisfaction of the Society, to be not less effective.*
  - 4) *A list or plan shall be displayed at each indicating unit showing the spaces covered and the location of the zone in respect of each section. Suitable instructions for testing and maintenance shall be available.*
- c) *Testing*  
*Means shall be provided for testing the automatic operation of the pump on reduction of pressure in the system.*

## **8 Fixed fire detection and fire alarm systems**

### **8.1 Definitions**

- 8.1.1** *Section means a group of fire detectors and manually operated call points as reported in the indicating unit(s).*
- 8.1.2** *Section identification capability means a system with the capability of identifying the section in which a detector or manually operated call point has activated.*
- 8.1.3** *Individually identifiable means a system with the capability to identify the exact location and type of detector or manually activated call point which has activated, and which can differentiate the signal of that device from all others.*

### **8.2 Engineering specifications**

#### **8.2.1 General requirements**

- a) *Any required fixed fire detection and fire alarm system with manually operated call points shall be capable of immediate operation at all times (this does not require a backup control panel). Notwithstanding this, particular spaces may be disconnected, for example, workshops during hot work and ro-ro spaces during on and off-loading. The means for disconnecting the detectors shall be designed to automatically restore the system to normal surveillance after a predetermined time that is appropriate for the operation in question. The space shall be manned or provided with a fire patrol when detectors required by regulation are disconnected. Detectors in all other spaces shall remain operational.*
- b) *The fire detection system shall be designed to:*
- 1) *control and monitor input signals from all connected fire and smoke detectors and manual call points;*
  - 2) *provide output signals to the navigation bridge, continuously manned central control station or onboard safety centre to notify the crew of fire and fault conditions;*
  - 3) *monitor power supplies and circuits necessary for the operation of the system for loss of power and fault conditions; and*
  - 4) *the system may be arranged with output signals to other fire safety systems including:*
    - *paging systems, fire alarm or public address systems*
    - *fan stops (See Note 1)*
    - *fire doors*
    - *fire dampers (See Note 1)*
    - *sprinkler systems*
    - *smoke extraction systems*
    - *low-location lighting systems*
    - *fixed local application fire-extinguishing systems*
    - *closed circuit television (CCTV) systems, and*
    - *other fire safety systems.*

*Note 1: The ventilation fans and the fire dampers serving a machinery room equipped with internal combustion engines taking their combustion air directly inside the room are not to be automatically stopped or closed in case of fire detection, in order to prevent depressurization of the room.*

- c) *The fire detection system may be connected to a decision management system provided that:*
- 1) *the decision management system is proven to be compatible with the fire detection system;*
  - 2) *the decision management system can be disconnected without losing any of the functions required by this chapter for the fire detection system; and*
  - 3) *any malfunction of the interfaced and connected equipment should not propagate under any circumstance to the fire detection system.*
- d) *Detectors and manual call points shall be connected to dedicated sections of the fire detection system. Other fire safety functions, such as alarm signals from the sprinkler valves, may be permitted if in separate sections.*

- e) *The system and equipment shall be suitably designed to withstand supply voltage variation and transients, ambient temperature changes, vibration, humidity, shock, impact and corrosion normally encountered in ships. All electrical and electronic equipment on the bridge or in the vicinity of the bridge shall be tested for electromagnetic compatibility, taking into account IMO Resolution A.813(19).*
- f) *Fixed fire detection and fire alarm systems with individually identifiable fire detectors shall be so arranged that:*
  - 1) *means are provided to ensure that any fault (e.g. power break, short circuit, earth, etc.) occurring in the section will not prevent the continued individual identification of the remainder of the connected detectors in the section;*
  - 2) *all arrangements are made to enable the initial configuration of the system to be restored in the event of failure (e.g. electrical, electronic, informatics, etc.);*
  - 3) *the first initiated fire alarm will not prevent any other detector from initiating further fire alarms; and*
  - 4) *no section will pass through a space twice. When this is not practical (e.g. for large public spaces), the part of the section which by necessity passes through the space for a second time shall be installed at the maximum possible distance from the other parts of the section.*
- g) *In passenger ships, the fixed fire detection and fire alarm system shall be capable of remotely and individually identifying each detector and manually operated call point. Fire detectors fitted in passenger ship cabins, when activated, shall also be capable of emitting, or cause to be emitted, an audible alarm within the space where they are located. In cargo ships and on passenger ship cabin balconies the fixed fire detection and fire alarm system shall, as a minimum, have section identification capability.*
- h) *In cargo ships and on passenger ship cabin balconies, where an individually identifiable system is fitted, notwithstanding the provisions in item f)1), isolator modules need not be provided at each fire detector if the system is arranged in such a way that the number and location of individually identifiable fire detectors rendered ineffective due to a fault would not be larger than an equivalent section in a section identifiable system, arranged in accordance with [8.2.4], item a).*

### **8.2.2 Sources of power supply**

- a) *There shall be not less than two sources of power supply for the electrical equipment used in the operation of the fixed fire detection and fire alarm system, one of which shall be an emergency source of power. The supply shall be provided by separate feeders reserved solely for that purpose. Such feeders shall run to an automatic change-over switch situated in, or adjacent to, the control panel for the fire detection system. The change-over switch shall be arranged such that a fault will not result in the loss of both power supplies. The main (respective emergency) feeder shall run from the main (respective emergency) switchboard to the change-over switch without passing through any other distributing switchboard.*
- b) *The operation of the automatic changeover switch or a failure of one of the power supplies shall not result in loss of fire detection capability. Where a momentary loss of power would cause degradation of the system, a battery of adequate capacity shall be provided to ensure continuous operation during change-over.*
- c) *There shall be sufficient power to permit the continued operation of the system with all detectors activated, but not more than 100 if the total exceeds this figure.*
- d) *The emergency source of power specified in item a) above may be supplied by accumulator batteries or from the emergency switchboard. The power source shall be sufficient to maintain the operation of the fire detection and fire alarm system for the periods required under Pt C, Ch 2, Sec 3 for cargo ships, Pt D, Ch 11, Sec 5 for passenger ships and Pt D, Ch 12, Sec 4 for ro-ro passenger ships and, at the end of that period, shall be capable of operating all connected visual and audible fire alarm signals for a period of at least 30 min.*
- e) *Where the system is supplied from accumulator batteries, they shall be located in or adjacent to the control panel for the fire detection system, or in another location suitable for use in an emergency. The rating of the battery charge unit shall be sufficient to maintain the normal output power supply to the fire detection system while recharging the batteries from a fully discharged condition.*

### **8.2.3 Component requirements**

- a) *Detectors*
  - 1) *Detectors shall be operated by heat, smoke or other products of combustion, flame, or any combination of these factors. Detectors operated by other factors indicative of incipient fires may be considered by the Society provided that they are no less sensitive than such detectors.*
  - 2) *Smoke detectors required in all stairways, corridors and escape routes within accommodation spaces shall be certified to operate before the smoke density exceeds 12,5% obscuration per metre, but not until the smoke density exceeds 2% obscuration per metre, when tested according to standards EN 54:2001 and IEC 60092-504. Alternative testing standards may be used as determined by the Society. Smoke detectors to be installed in other spaces shall operate within sensitivity limits to the satisfaction of the Society having regard to the avoidance of detector insensitivity or oversensitivity.*
  - 3) *Heat detectors shall be certified to operate before the temperature exceeds 78°C but not until the temperature exceeds 54°C, when the temperature is raised to those limits at a rate less than 1°C per minute, when tested according to standards EN 54:2001 and IEC 60092-504. Alternative testing standards may be used as determined by the Society. At higher rates of temperature rise, the heat detector shall operate within temperature limits to the satisfaction of the Society having regard to the avoidance of detector insensitivity or oversensitivity.*

- 4) *The operation temperature of heat detectors in drying rooms and similar spaces of a normal high ambient temperature may be up to 130°C, and up to 140°C in saunas.*
  - 5) *Flame detectors shall be tested according to standards EN 54-10:2001 and IEC 60092-504. Alternative testing standards may be used as determined by the Society.*
  - 6) *All detectors shall be of a type such that they can be tested for correct operation and restored to normal surveillance without the renewal of any component.*
  - 7) *Fixed fire detection and fire alarm systems for cabin balconies shall be approved by the Society, based on IMO Circular MSC.1/Circ.1242.*
  - 8) *Detectors fitted in hazardous areas shall be tested and approved for such service. Detectors required by Ch 4, Sec 12, [3] and installed in spaces that comply with regulation Ch 4, Sec 12, [2.2.2] need not be suitable for hazardous areas. Detectors fitted in spaces carrying dangerous goods, required in Ch 4, Sec 11, Tab 3 to comply with Ch 4, Sec 11, [2.3], shall be suitable for hazardous areas.*
- b) *Control panel*  
*The control panel for the fire detection system shall be tested according to standards EN 54-2:1997, EN 54-4:1997 and IEC 60092-504:2001. Alternative standards may be used as determined by the Society.*
- c) *Cables*  
*Cables used in the electrical circuits shall be flame retardant according to standard IEC 60332-1. On passenger ships, cables routed through other main vertical zones that they serve, and cables to control panels in an unattended fire control station shall be fire resisting according to standard IEC 60331, unless duplicated and well separated.*

#### **8.2.4 Installation requirements**

- a) *Sections*
- 1) *Detectors and manually operated call points shall be grouped into sections.*
  - 2) *A section of fire detectors which covers a control station, a service space or an accommodation space shall not include a machinery space of category A or a ro-ro space. A section of fire detectors which covers a ro-ro space shall not include a machinery space of category A. For fixed fire detection systems with remotely and individually identifiable fire detectors, a section covering fire detectors in accommodation, service spaces and control stations shall not include fire detectors in machinery spaces of category A or ro-ro spaces.*
  - 3) *Where the fixed fire detection and fire alarm system does not include means of remotely identifying each detector individually, no section covering more than one deck within accommodation spaces, service spaces and control stations shall normally be permitted except a section which covers an enclosed stairway. In order to avoid delay in identifying the source of fire, the number of enclosed spaces included in each section shall be limited as determined by the Society. If the detection system is fitted with remotely and individually identifiable fire detectors, the sections may cover several decks and serve any number of enclosed spaces.*
  - 4) *In passenger ships, a section of detectors and manually operated call points shall not be situated in more than one main vertical zone, except on cabin balconies.*
- b) *Positioning of detectors*
- 1) *Detectors shall be located for optimum performance. Positions near beams and ventilation ducts, or other positions where patterns of air flow could adversely affect performance, and positions where impact or physical damage is likely, shall be avoided. Detectors shall be located on the overhead at a minimum distance of 0,5 m away from bulkheads, except in corridors, lockers and stairways.*
  - 2) *The maximum spacing of detectors shall be in accordance with Tab 4. The Society may require or permit other spacing based upon test data which demonstrate the characteristics of the detectors. Detectors located below moveable ro-ro decks shall be in accordance with Tab 4.*
  - 3) *Detectors in stairways shall be located at least at the top level of the stair and at every second level beneath.*
  - 4) *When fire detectors are installed in freezers, drying rooms, saunas, parts of galleys used to heat food, laundries and other spaces where steam and fumes are produced, heat detectors may be used.*
  - 5) *Where a fixed fire detection and fire alarm system is required by regulation Ch 4, Sec 3, [4], spaces having little or no fire risk need not be fitted with detectors. Such spaces include void spaces with no storage of combustibles, private bathrooms, public toilets, fire-extinguishing medium storage rooms, cleaning gear lockers (in which flammable liquids are not stowed), open deck spaces and enclosed promenades having little or no fire risk and that are naturally ventilated by permanent openings.*
- c) *Arrangement of cables*
- 1) *Cables which form part of the system shall be so arranged as to avoid galleys, machinery spaces of category A and other enclosed spaces of high fire risk except where it is necessary to provide for fire detection or fire alarms in such spaces or to connect to the appropriate power supply.*
  - 2) *A section with individually identifiable capability shall be arranged so that it cannot be damaged at more than one point by a fire.*

Table 4 : Spacing of detectors

Type of detector	Maximum floor area per detector	Maximum distance apart between centres	Maximum distance away from bulkheads
Heat	37 m <sup>2</sup>	9 m	4,5 m
Smoke	74 m <sup>2</sup>	11 m	5,5 m

### 8.2.5 System control requirements

#### a) Visual and audible fire signals

- 1) The activation of any detector or manually operated call point shall initiate a visual and audible fire detection alarm signal at the control panel and indicating units. If the signals have not been acknowledged within 2 minutes, an audible fire alarm shall be automatically sounded throughout the crew accommodation and service spaces, control stations and machinery spaces of category A. This alarm sounder system need not be an integral part of the detection system.

The alarm sounder system utilized by the fixed fire detection and fire alarm system should be powered from no less than two sources of power, one of which should be an emergency source of power.

For ships provided with a transitional source of emergency electrical power, as required by:

- Pt D, Ch 11, Sec 5, [2],
- Ch 2, Sec 3, [2], and
- Ch 2, Sec 3, [3],

the alarm sounder system should also be powered from this power source.

- 2) In passenger ships, the control panel shall be located in the onboard safety centre. In cargo ships, the control panel shall be located on the navigation bridge or in the fire control station.
- 3) In passenger ships, an indicating unit that is capable of individually identifying each detector that has been activated or manually operated call point that has operated shall be located on the navigation bridge. In cargo ships, an indicating unit shall be located on the navigation bridge if the control panel is located in the fire control station. In ships with a cargo control room, an additional indicating unit shall be located in the cargo control room. In cargo ships and on passenger cabin balconies, indicating units shall, as a minimum, denote the section in which a detector has activated or manually operated call point has been operated.

A space in which a cargo control console is installed, but does not serve as a dedicated cargo control room (e.g. ship's office, machinery control room), should be regarded as a cargo control room for the purposes of this requirement and therefore be provided with an additional indicating unit.

- 4) Clear information shall be displayed on or adjacent to each indicating unit about the spaces covered and the location of the sections.
- 5) Power supplies and electric circuits necessary for the operation of the system shall be monitored for loss of power and fault conditions, as appropriate, including:
  - a single open or power break fault caused by a broken wire;
  - a single ground fault caused by the contact of a wiring conductor to a metal component; and
  - a single wire to wire fault caused by the contact of two or more wiring conductors.

Occurrence of a fault condition shall initiate a visual and audible fault signal at the control panel which shall be distinct from a fire signal.

- 6) Means to manually acknowledge all alarm and fault signals shall be provided at the control panel. The audible alarm sounders on the control panel and indicating units may be manually silenced. The control panel shall clearly distinguish between normal, alarm, acknowledged alarm, fault and silenced conditions.
- 7) The system shall be arranged to automatically reset to the normal operating condition after alarm and fault conditions are cleared.
- 8) When the system is required to sound a local audible alarm within the cabins where the detectors are located, a means to silence the local audible alarms from the control panel shall not be permitted.
- 9) In general, audible alarm sound pressure levels at the sleeping positions in the cabins and 1 m from the source shall be at least 75 dB(A) and at least 10 dB(A) above ambient noise levels existing during normal equipment operation with the ship under way in moderate weather. The sound pressure level should be in the 1/3 octave band about the fundamental frequency. Audible alarm signals shall not exceed 120 dB(A).

#### b) Testing

Suitable instructions and component spares for testing and maintenance shall be provided. Detectors shall be periodically tested using equipment suitable for the types of fires to which the detector is designed to respond. Detectors installed within cold spaces such as refrigerated compartments shall be tested using procedures having due regard for such locations. Ships with self-diagnostic systems that have in place a cleaning regime for areas where heads may be prone to contamination may carry out testing in accordance with the requirements of the Society.

## 9 Sample extraction smoke detection systems

### 9.1 Engineering specifications

#### 9.1.1 General requirements

- a) Wherever in the text of Article [9] the word “system” appears, it shall mean “sample extraction smoke detection system”.  
A sample extraction smoke detection system consists of the following main components:
- 1) *smoke accumulators: air collection devices installed at the open ends of the sampling pipes in each cargo hold that perform the physical function of collecting air samples for transmission to the control panel through the sampling pipes, and may also act as discharge nozzles for the fixed-gas fire-extinguishing system, if installed;*
  - 2) *sampling pipes: a piping network that connects the smoke accumulators to the control panel, arranged in sections to allow the location of the fire to be readily identified;*
  - 3) *three-way valves: if the system is interconnected to a fixed-gas fire-extinguishing system, three-way valves are used to normally align the sampling pipes to the control panel and, if a fire is detected, the three-way valves are re-aligned to connect the sampling pipes to the fire-extinguishing system discharge manifold and isolate the control panel; and*
  - 4) *control panel: the main element of the system which provides continuous monitoring of the protected spaces for indication of smoke. It typically may include a viewing chamber or smoke sensing units. Extracted air from the protected spaces is drawn through the smoke accumulators and sampling pipes to the viewing chamber, and then to the smoke sensing chamber where the airstream is monitored by electrical smoke detectors. If smoke is sensed, the repeater panel (normally on the bridge) automatically sounds an alarm (not localized). The crew can then determine at the smoke sensing unit which cargo hold is on fire and operate the pertinent three-way valve for discharge of the extinguishing agent.*
- b) Any required system shall be capable of continuous operation at all times except that systems operating on a sequential scanning principle may be accepted, provided that the interval between scanning the same position twice gives a maximum allowable interval determined as follows:  
The interval ( $I$ ) should depend on the number of scanning points ( $N$ ) and the response time of the fans ( $T$ ), with a 20% allowance:  
$$I = 1,2 T N$$
  
However, the maximum allowable interval should not exceed 120 s ( $I_{max} = 120$  s).
- c) The system shall be designed, constructed and installed so as to prevent the leakage of any toxic or flammable substances or fire-extinguishing media into any accommodation and service space, control station or machinery space.
- d) The system and equipment shall be suitably designed to withstand supply voltage variations and transients, ambient temperature changes, vibration, humidity, shock, impact and corrosion normally encountered in ships and to avoid the possibility of ignition of a flammable gas-air mixture.
- e) The system shall be of a type that can be tested for correct operation and restored to normal surveillance without the renewal of any component.
- f) An alternative power supply for the electrical equipment used in the operation of the system shall be provided.

#### 9.1.2 Component requirements

- a) The sensing unit shall be certified to operate before the smoke density within the sensing chamber exceeds 6,65% obscuration per metre.
- b) Duplicate sample extraction fans shall be provided. The fans shall be of sufficient capacity to operate with the normal conditions or ventilation in the protected area and the connected pipe size shall be determined with consideration of fan suction capacity and piping arrangement to satisfy the conditions of [9.1.4], item b) 2). Sampling pipes shall be a minimum of 12 mm internal diameter. The fan suction capacity should be adequate to ensure the response of the most remote area within the time criteria required in [9.1.4], item b) 2). Means to monitor airflow shall be provided in each sampling line.
- c) The control panel shall permit observation of smoke in the individual sampling pipes.
- d) The sampling pipes shall be so designed as to ensure that, as far as practicable, equal quantities of airflow are extracted from each interconnected accumulator.
- e) Sampling pipes shall be provided with an arrangement for periodically purging with compressed air.
- f) The control panel for the smoke detection system shall be tested according to standards EN 54-2 (1997), EN 54-4 (1997) and IEC 60092-504 (2001). Alternative standards may be used as determined by the Society.

#### 9.1.3 Installation requirements

- a) *Smoke accumulators*
- 1) *At least one smoke accumulator shall be located in every enclosed space for which smoke detection is required. However, where a space is designed to carry oil or refrigerated cargo alternatively with cargoes for which a smoke sampling system is required, means may be provided to isolate the smoke accumulators in such compartments for the system. Such means shall be to the satisfaction of the Society.*

- 2) *Smoke accumulators shall be located on the overhead or as high as possible in the protected space and shall be spaced so that no part of the overhead deck area is more than 12 m measured horizontally from an accumulator. Where systems are used in spaces which may be mechanically ventilated, the position of the smoke accumulators shall be considered having regard to the effects of ventilation. At least one additional smoke accumulator is to be provided in the upper part of each exhaust ventilation duct. An adequate filtering system shall be fitted at the additional accumulator to avoid dust contamination.*
  - 3) *Smoke accumulators shall be positioned where impact or physical damage is unlikely to occur.*
  - 4) *Sampling pipe networks shall be balanced to ensure compliance with [9.1.2], item d). The number of accumulators connected to each sampling pipe shall ensure compliance with [9.1.4], item b) 2).*
  - 5) *Smoke accumulators from more than one enclosed space shall not be connected to the same sampling pipe.*
  - 6) *In cargo holds where non-gastight "tween deck panels" (movable stowage platforms) are provided, smoke accumulators shall be located in both the upper and lower parts of the holds.*
- b) *Sampling pipes*
- 1) *The sampling pipe arrangements shall be such that the location of the fire can be readily identified.*
  - 2) *Sampling pipes shall be self-draining and suitably protected from impact or damage from cargo working.*

#### **9.1.4 System control requirements**

- a) *Visual and audible fire signals*
- 1) *The detection of smoke or other products of combustion shall initiate a visual and audible signal at the control panel and indicating units.*
  - 2) *The control panel shall be located on the navigation bridge or in the fire control station. An indicating unit shall be located on the navigation bridge if the control panel is located in the fire control station.*  
the control panel can be located in the CO<sub>2</sub> room provided that an indicating unit is located on the navigation bridge. Indicating unit has the same meaning as repeater panel and observation of smoke should be made either by electrical means or by visual on repeater panel.
  - 3) *Clear information shall be displayed on, or adjacent to, the control panel and indicating units designating the spaces covered.*
  - 4) *Power supplies necessary for the operation of the system shall be monitored for loss of power. Any loss of power shall initiate a visual and audible signal at the control panel and the navigating bridge which shall be distinct from a signal indicating smoke detection.*
  - 5) *Means to manually acknowledge all alarm and fault signals shall be provided at the control panel. The audible alarm sounders on the control panel and indicating units may be manually silenced. The control panel shall clearly distinguish between normal, alarm, acknowledged alarm, fault and silenced conditions.*
  - 6) *The system shall be arranged to automatically reset to the normal operating condition after alarm and fault conditions are cleared.*
- b) *Testing*
- 1) *Suitable instructions and component spares shall be provided for the testing and maintenance of the system.*
  - 2) *After installation, the system shall be functionally tested using smoke generating machines or equivalent as a smoke source. An alarm shall be received at the control unit in not more than 180 s for vehicle decks, and not more than 300 s for container and general cargo holds, after smoke is introduced at the most remote accumulator.*

## **10 Low-location lighting systems**

### **10.1 Application**

**10.1.1** *This Article details the specifications for low-location lighting systems as required by Ch 4, Sec 8.*

### **10.2 Engineering specification**

#### **10.2.1 General requirements**

*Any required low-location lighting systems shall be approved by the Society based on IMO resolution A.752(18) and on the Recommendations by the International Organization for Standardization, in particular, publication ISO 15370 on Low-location lighting on passenger ships.*

## **11 Fixed emergency fire pumps**

### **11.1 Engineering specifications**

#### **11.1.1 Type of emergency fire pumps**

*The emergency fire pump shall be a fixed independently driven power-operated pump.*

**11.1.2 Component requirements**

a) *Emergency fire pumps*

1) *Capacity of the pump*

*The capacity of the pump shall not be less than 40% of the total capacity of the fire pumps required by Ch 4, Sec 6, [1.3.4] and in any case not less than the following:*

- *for passenger ships of less than 1000 gross tonnage and for cargo ships of 2000 gross tonnage and upwards: 25 m<sup>3</sup>/h, and*
- *for cargo ships of less than 2000 gross tonnage: 15 m<sup>3</sup>/h.*

*The emergency pump is to be capable of supplying two jets of water to the satisfaction of the Society and the amount of water needed for any fixed fire-extinguishing system provided to protect the space where the main fire pumps are located.*

*On board cargo ships designed to carry five or more tiers of containers on or above the weather deck, the total capacity of the emergency fire pump need not exceed 72 m<sup>3</sup>/h.*

2) *Pressure at hydrants*

*When the pump is delivering the quantity of water required by item 1) above, the pressure at any hydrants shall be not less than the minimum pressure required in Ch 4, Sec 6, [1.2.6].*

3) *Suction heads*

*The total suction head and the net positive suction head of the pump shall be determined having due regard to the requirements of Ch 4, Sec 6 and the present Article on the pump capacity and on the hydrant pressure under all conditions of list, trim, roll and pitch likely to be encountered in service. The ballast condition of a ship on entering or leaving a dry dock need not be considered a service condition.*

4) *Arrangement of the sea suction of the emergency fire pump*

- *The sea suction for the pump is to be fitted at a safe depth below the waterline at any draught under all trim and heeling conditions; the ballast condition of a ship on entering or leaving a dry dock need not be considered a service condition. The emergency fire pump is to be of the self-priming type. The location of the pump is to be such that it is capable of pumping at any draught under all trim and heeling conditions. The sea valve is to be capable of being operated from a position near the pump.*
- *Where it is found necessary to locate the emergency fire pump sea suction in the space containing the main fire pumps, the sea valve is to be operable from a readily accessible position not likely to be affected by a fire in the space containing the main fire pumps.*

b) *Diesel engines and fuel tank*

1) *Starting of diesel engine*

*Any diesel-driven power source for the pump shall be capable of being readily started in its cold condition down to the temperature of 0°C by hand (manual) cranking. Where ready starting cannot be assured, if this is impracticable, or if lower temperatures are likely to be encountered, and if the room for the diesel driven power source is not heated, electric heating of the diesel engine cooling water or lubricating oil system shall be fitted, to the satisfaction of the Society. If hand (manual) starting is impracticable, the Society may permit compressed air, electricity, or other sources of stored energy, including hydraulic power or starting cartridges to be used as a means of starting. These means shall be such as to enable the diesel-driven power source to be started at least six times within a period of 30 minutes and at least twice within the first 10 minutes.*

2) *Fuel tank capacity*

*Any service fuel tank shall contain sufficient fuel to enable the pump to run on full load for at least 3 hours and sufficient reserves of fuel shall be available outside the machinery space of category A to enable the pump to be run on full load for an additional 15 hours.*

c) *Prime mover and source of power of the emergency fire pump*

1) *The emergency fire pump and its prime mover are to be to the satisfaction of the Society.*

2) *The emergency fire pump prime mover is to be so arranged that an immediate start is possible under all prevailing temperature conditions. Diesel engines exceeding 15 kW are to be equipped with an approved auxiliary starting device, e.g. starting battery, independent hydraulic system or independent starting air system, having a capacity sufficient for at least six starts of the fire emergency pump. For diesel engines of 15 kW and smaller, manual means of starting are sufficient.*

3) *For the operation of the emergency fire pump, fuel is to be available from outside the main machinery space for at least 18h operation.*

4) *When the emergency fire pump is electrically driven, the power is to be supplied by a source other than that supplying the main fire pumps and to be located outside the engine room, and separated from it by an A class division, and the relevant electrical cables are not to pass through the compartment containing the main fire pump.*

d) *Testing of the emergency fire pump and its prime mover*

1) *Upon completion of the installation of the emergency fire pump, a running test is to be carried out to the satisfaction of the Society.*

- 2) The emergency generator and its prime mover and any emergency accumulator battery are to be so arranged as to ensure that they will function at full rated power when the ship is upright and when inclined at any angle of list up to and including 22,5° either way or up to and including 10° inclination either way in the fore and aft direction. The above angles of list and trim are to be considered to occur simultaneously in their most unfavourable combination (see also Ch 1, Sec 1, [2.4]).

## 12 Arrangement of means of escape

### 12.1 Passenger ships

#### 12.1.1 Width of stairways

##### a) Basic requirements for stairway widths

Stairways shall not be less than 900 mm in clear width. The minimum clear width of stairways shall be increased by 10 mm for every one person provided for in excess of 90 persons. The total number of persons to be evacuated by such stairways shall be assumed to be two thirds of the crew and the total number of passengers in the areas served by such stairways. The width of the stairways shall not be inferior to those determined by item b) hereafter.

##### b) Calculation method of stairway widths

###### 1) Basic principles of the calculation

- This calculation method determines the minimum stairway width at each deck level, taking into account the consecutive stairways leading into the stairway under consideration.
- It is the intention that the calculation method shall consider evacuation from enclosed spaces within each main vertical zone individually and take into account all of the persons using the stairway enclosures in each zone, even if they enter that stairway from another vertical zone.
- For each main vertical zone the calculation shall be completed for the night-time (case 1) and daytime (case 2) and the largest dimension from either case used for determining the stairway width for each deck under consideration.
- The calculation of stairway widths shall be based upon the crew and passenger load on each deck. Occupant loads shall be rated by the designer for passenger and crew accommodation spaces, service spaces, control spaces and machinery spaces. For the purpose of the calculation the maximum capacity of a public space shall be defined by either of the following two values: the number of seats or similar arrangements, or the number obtained by assigning 2 m<sup>2</sup> of gross deck surface area to each person.

###### 2) Calculation method for minimum value

- Basic formulae

In considering the design of stairway widths for each individual case which allow for the timely flow of persons evacuating to the assembly stations from adjacent decks above and below, the following calculation methods shall be used (see Fig 2 and Fig 1):

- when joining two decks:

$$W = (N1 + N2) \times 10 \text{ mm}$$

- when joining three decks:

$$W = (N1 + N2 + 0,5 N3) \times 10 \text{ mm}$$

- when joining four decks:

$$W = (N1 + N2 + 0,5 N3 + 0,25 N4) \times 10 \text{ mm}$$

- when joining five decks or more decks, the width of the stairways shall be determined by applying the above formula for four decks to the deck under consideration and to the consecutive deck,

where:

$W$  : The required tread width between handrails of the stairway.

The calculated value of  $W$  may be reduced where available landing area  $S$  is provided in stairways at the deck level defined by subtracting  $P$  from  $Z$ , such that:

$$P = S \times 3,0 \text{ persons/m}^2; \text{ and } P_{\text{max}} = 0,25 Z$$

where:

$Z$  : The total number of persons expected to be evacuated on the deck being considered

$P$  : The number of persons taking temporary refuge on the stairway landing, which may be subtracted from  $Z$  to a maximum value of  $P = 0,25 Z$  (to be rounded down to the nearest whole number)

$S$  : The surface area (m<sup>2</sup>) of the landing, minus the surface area necessary for the opening of doors and minus the surface area necessary for accessing the flow on stairs (see Fig 2)

$N$  : The total number of persons expected to use the stairway from each consecutive deck under consideration;  $N1$  is for the deck with the largest number of persons using that stairway;  $N2$  is taken for the deck with the next highest number of persons directly entering the stairway flow such that when sizing the stairway width at each deck level:

$N1 > N2 > N3 > N4$  (see Fig 1). These decks are assumed to be on or up-stream (i.e. away from the embarkation deck) of the deck being considered.

- **Distribution of persons**

The dimensions of the means of escape shall be calculated on the basis of the total number of persons expected to escape by the stairway and through doorways, corridors and landings (see Fig 3). Calculations shall be made separately for the two cases of occupancy of the spaces specified below. For each component part of the escape route, the dimension taken shall not be less than the largest dimension determined for each case:

Case 1:

- passengers in cabins with maximum berthing capacity fully occupied
- members of the crew in cabins occupied to 2/3 of maximum berthing capacity, and
- service spaces occupied by 1/3 of the crew.

Case 2:

- passengers in public spaces occupied to 3/4 of maximum capacity,
- 1/3 of the crew distributed in public spaces
- service spaces occupied by 1/3 of the crew, and
- crew accommodation occupied by 1/3 of the crew.

The maximum number of persons contained in a main vertical zone, including persons entering stairways from another main vertical zone, shall not be assumed to be higher than the maximum number of persons authorized to be carried on board for the calculation of stairway widths only.

c) **Prohibition of decrease in width in the direction to the assembly station**

The stairway shall not decrease in width in the direction of evacuation to the assembly station. Where several assembly stations are in one main vertical zone, the stairway width shall not decrease in the direction of the evacuation to the most distant assembly station.

**Figure 1 : Minimum stairway width (W) calculation example**

$Z$  (pers) = number of persons expected to evacuate through the stairway

$N$  (pers) = number of persons directly entering the stairway flow from a given deck

$W$  (mm) =  $(N1 + N2 + 0,5 N3 + 0,25 N4) \times 10$  = calculated width of stairway

$D$  (mm) = width of exit doors

$N1 > N2 > N3 > N4$  where:

$N1$  (pers) = the deck with the largest number of persons  $N$  entering directly the stairway

$N2$  (pers) = the deck with the next largest number of persons  $N$  entering directly the stairway, etc.

Note: The doors to the assembly station shall have aggregate widths of 11355 mm.

**12.1.2 Details of stairways**

a) *Handrails*

Stairways shall be fitted with handrails on each side. The maximum clear width between handrails shall be 1800 mm.

b) *Alignment of stairways*

All stairways sized for more than 90 persons shall be aligned fore and aft.

c) *Vertical rise and inclination*

Stairways shall not exceed 3,5 m in vertical rise without the provision of a landing and shall not have an angle of inclination greater than 45°.

d) *Landings*

With the exception of intermediate landings, landings at each deck level shall be not less than 2 m<sup>2</sup> in area and shall increase by 1 m<sup>2</sup> for every 10 persons provided for in excess of 20 persons, but need not exceed 16 m<sup>2</sup>, except for those landings servicing public spaces having direct access onto the stairway enclosure. Intermediate landings shall be sized in accordance with [12.1.3], item a).

**12.1.3 Doorways and corridors**

a) *Doorways and corridors and intermediate landings included in means of escape shall be sized in the same manner as stairways.*

b) *The aggregate width of stairway exit doors to the assembly station shall not be less than the aggregate width of stairways serving this deck.*

**Figure 2 : Landing calculation for stairway width reduction**

$P = S \times 3 \text{ persons/m}^2 =$  the number of persons taking refuge on the landing to a maximum of  $P = 0,25 Z$

$N = Z - P =$  the number of persons directly entering the stairway flow from a given deck

$Z =$  number of persons to be evacuated from the deck considered

$S =$  available landing area (m<sup>2</sup>) after subtracting the surface area necessary for movement and subtracting the space taken by the door swing area. Landing area is a sum of flow area, credit area and door area

$D =$  width of exit doors to the stairway landing area (mm).

#### **12.1.4 Evacuation routes to the embarkation deck**

a) *Assembly station*

*It shall be recognized that the evacuation routes to the embarkation deck may include an assembly station. In this case, consideration shall be given to the fire protection requirements and sizing of corridors and doors from the stairway enclosure to the assembly station and from the assembly station to the embarkation deck, noting that evacuation of persons from assembly stations to embarkation positions will be carried out in small controlled groups.*

b) *Routes from the assembly station to the survival craft embarkation position*

*Where the passengers and crew are held at an assembly station which is not at the survival craft embarkation position, the dimension of stairway width and doors from the assembly station to this position shall be based on the number of persons in the controlled group. The width of these stairways and doors need not exceed 1500 mm unless larger dimensions are required for evacuation of these spaces under normal conditions.*

#### **12.1.5 Means of escape plans**

*Means of escape plans shall be provided indicating the following:*

- a) *the number of crew and passengers in all normally occupied spaces*
- b) *the number of crew and passengers expected to escape by stairway and through doorways, corridors and landings*
- c) *assembly stations and survival craft embarkation positions*
- d) *primary and secondary means of escape, and*
- e) *width of stairways, doors, corridors and landing areas.*

*Means of escape plans shall be accompanied by detailed calculations for determining the width of escape stairways, doors, corridors and landing areas (see also Ch 4, Sec 8, [2.2.3], item g)).*

### **12.2 Cargo ships**

**12.2.1** *Stairways and corridors used as means of escape shall be not less than 700 mm in clear width and shall have a handrail on one side. Stairways and corridors with a clear width of 1800 mm and over shall have handrails on both sides. Clear width is considered the distance between the handrail and the bulkhead on the other side or between the handrails. The angle of inclination of stairways should be, in general, 45°, but not greater than 50°, and in machinery spaces and small spaces not more than 60°. Doorways which give access to a stairway shall be of the same size as the stairway.*

## **13 Inert gas systems**

### **13.1 Definitions**

**13.1.1** *For the purposes of this Article:*

- a) *Cargo tanks means those cargo tanks, including slop tanks, which carry cargoes, or cargo residues, having a flashpoint not exceeding 60°C.*
- b) *Inert gas system includes inert gas systems using flue gas, inert gas generators, and nitrogen generators and means the inert gas plant and inert gas distribution together with means for preventing backflow of cargo gases to machinery spaces, fixed and portable measuring instruments and control devices.*
- c) *Gas-safe space is a space in which the entry of gases would produce hazards with regard to flammability or toxicity.*
- d) *Gas-free is a condition in a tank where the content of hydrocarbon or other flammable vapour is less than 1% of the lower flammable limit (LFL), the oxygen content is at least 21%, and no toxic gases are present.*

*Note 1: Refer to the Revised recommendations for entering enclosed spaces aboard ships (IMO resolution A.1050(27)).*

### **13.2 Requirements for all systems**

#### **13.2.1 General**

- a) *The inert gas systems shall be designed, constructed and tested to the satisfaction of the Society. It shall be designed to be capable of rendering and maintaining the atmosphere of the relevant cargo tanks non-flammable.*

*Note 1: Refer to the Revised standards for the design, testing and locating of devices to prevent the passage of flame into cargo tanks in tankers (MSC/Circ.677, as amended by MSC/Circ.1009 and MSC.1/Circ.1324) and the Revised factors to be taken into consideration when designing cargo tank venting and gas-freeing arrangements (MSC/Circ.731).*

b) *The system shall be capable of:*

- 1) *inerting empty cargo tanks and maintaining the atmosphere in any part of the tank with an oxygen content not exceeding 8% by volume and at a positive pressure in port and at sea except when it is necessary for such a tank to be gas-free;*
- 2) *eliminating the need for air to enter a tank during normal operations except when it is necessary for such a tank to be gas-free;*
- 3) *purging empty cargo tanks of hydrocarbon or other flammable vapours, so that subsequent gas-freeing operations will at no time create a flammable atmosphere within the tank;*
- 4) *delivering inert gas to the cargo tanks at a rate of at least 125% of the maximum rate of discharge capacity of the ship expressed as a volume. For chemical tankers and chemical/product tankers, the Society may accept inert gas systems having a lower delivery capacity provided that the maximum rate of discharge of cargoes from cargo tanks being protected by the system is restricted to not more than 80% of the inert gas capacity; and*
- 5) *delivering inert gas with an oxygen content of not more than 5% by volume to the cargo tanks at any required rate of flow.*

c) *Materials used in inert gas systems shall be suitable for their intended purpose. In particular, those components which may be subjected to corrosive action of the gases and/or liquids are to be either constructed of corrosion-resistant material or lined with rubber, glass fibre epoxy resin or other equivalent coating material.*

d) *The inert gas supply may be:*

- 1) *treated flue gas from main or auxiliary boilers, or*
- 2) *gas from an oil or gas-fired gas generator, or*
- 3) *gas from nitrogen generators.*

*The Society may accept systems using inert gases from one or more separate gas generators or other sources or any combination thereof, provided that an equivalent level of safety is achieved. Such systems shall, as far as practicable, comply with the requirements of this article. Systems using stored carbon dioxide shall not be permitted unless the Administration is satisfied that the risk of ignition from generation of static electricity by the system itself is minimized.*

### **13.2.2 Safety measures**

- a) *The inert gas system shall be so designed that the maximum pressure which it can exert on any cargo tank will not exceed the test pressure of any cargo tank.*
- b) *Automatic shutdown of the inert gas system and its components parts shall be arranged on predetermined limits being reached, taking into account the provisions of [13.2.4], [13.3.3] and [13.4.3].*

The automatic shutdown of the inert gas system and its components should involve the following:

- shutdown of fans and closing of regulating valve for the following:
  - high water level in scrubber (not applicable for N<sub>2</sub>);
  - low pressure/flow to scrubber (not applicable for N<sub>2</sub>); or
  - high-high temperature of inert gas supply.
- closing of regulating valve in the event of:
  - high oxygen content (in excess of 5% by volume); or
  - failure of blowers/fans or N<sub>2</sub> compressors.
- activation of double-block and bleed arrangement upon:
  - loss of inert gas supply (for ships with double block and bleed replacing water seal); or
  - loss of power.

- c) *Suitable shutoff arrangements shall be provided on the discharge outlet of each generator plant.*
- d) *The system shall be designed to ensure that if the oxygen content exceeds 5% by volume, the inert gas shall be automatically vented to atmosphere.*
- e) *Arrangements shall be provided to enable the functioning of the inert gas plant to be stabilized before commencing cargo discharge. If blowers are to be used for gas-freeing, their air inlets shall be provided with blanking arrangements.*
- f) *Where a double block and bleed valve is installed, the system shall ensure upon loss of power, the block valves are automatically closed and the bleed valve is automatically open.*

### **13.2.3 System components**

a) *Non-return devices*

- 1) *At least two non-return devices shall be fitted in order to prevent the return of vapour and liquid to the inert gas plant, or to any gas-safe spaces.*

- 2) *The first non-return device shall be a deck seal of the wet, semi-wet, or dry type or a double-block and bleed arrangement. Two shut-off valves in series with a venting valve in between, may be accepted provided:*
    - *the operation of the valve is automatically executed. Signal(s) for opening/closing is (are) to be taken from the process directly, e.g. inert gas flow or differential pressure; and*
    - *alarm for faulty operation of the valves is provided, e.g. the operation status of “blower stop” and “supply valve(s) open” is an alarm condition.*
  - 3) *The second non-return device shall be a non-return valve or equivalent capable of preventing the return of vapours and liquids and fitted between the deck water seal (or equivalent device) and the first connection from the inert gas main to a cargo tank. It shall be provided with positive means of closure. As an alternative to positive means of closure, an additional valve having such means of closure may be provided between the non-return valve and the first connection to the cargo tanks to isolate the deck water seal, or equivalent device, from the inert gas main to the cargo tanks.*
  - 4) *A water seal, if fitted, shall be capable of being supplied by two separate pumps, each of which shall be capable of maintaining an adequate supply at all times. The audible and visual alarm on the low level of water in the water seal shall operate at all times.*
  - 5) *The arrangement of the water seal, or equivalent devices, and its associated fittings shall be such that it will prevent backflow of vapours and liquids and will ensure the proper functioning of the seal under operating conditions.*
  - 6) *Provision shall be made to ensure that the water seal is protected against freezing, in such a way that the integrity of seal is not impaired by overheating.*
  - 7) *A water loop or other approved arrangement shall also be fitted to each associated water supply and drain pipe and each venting or pressure-sensing pipe leading to gas-safe spaces. Means shall be provided to prevent such loops from being emptied by vacuum.*
  - 8) *Any water seal, or equivalent device, and loop arrangements shall be capable of preventing return of vapours and liquids to an inert gas plant at a pressure equal to the test pressure of the cargo tanks.*
  - 9) *The non-return devices shall be located in the cargo area on deck.*
- b) *Inert gas lines*
- 1) *The inert gas main may be divided into two or more branches downstream of the non-return devices required by [13.2.3], item a).*
  - 2) *The inert gas main shall be fitted with branch piping leading to the cargo tank. Branch piping for inert gas shall be fitted with either stop valves or equivalent means of control for isolating each tank. Where stop valves are fitted, they shall be provided with locking arrangements. The control system shall provide unambiguous information of the operational status of such valves to at least the control panel required in [13.2.4].*

Unambiguous information of the operational status of stop valves in branch piping leading from the inert gas main to cargo tanks means position indicators providing open/intermediate/closed status information in the control panel required in [13.2.4]. Limit switches should be used to positively indicate both open and closed positions. Intermediate position status should be indicated when the valve is in neither open nor closed position.
  - 3) *Each cargo tank not being inerted shall be capable of being separated from the inert gas main by:*
    - *removing spool-pieces, valves or other pipe sections, and blanking the pipe ends; or*
    - *arrangement of two spectacle flanges in series with provisions for detecting leakage into the pipe between the two spectacle flanges; or*
    - *equivalent arrangements to the satisfaction of the Society, providing at least the same level of protection.*
  - 4) *Means shall be provided to protect cargo tanks against the effect of overpressure or vacuum caused by thermal variations and/or cargo operations when the cargo tanks are isolated from the inert gas mains.*
  - 5) *Piping systems shall be so designed as to prevent the accumulation of cargo or water in the pipelines under all normal conditions.*
  - 6) *Arrangements shall be provided to enable the inert gas main to be connected to an external supply of inert gas. The arrangements shall consist of a 250 mm nominal pipe size bolted flange, isolated from the inert gas main by a valve and located downstream of the non-return valve. The design of the flange should conform to the appropriate class in the standards adopted for the design of other external connections in the ship's cargo piping system.*
  - 7) *If a connection is fitted between the inert gas main and the cargo piping system, arrangements shall be made to ensure an effective isolation having regard to the large pressure difference which may exist between the systems. This shall consist of two shutoff valves with an arrangement to vent the space between the valves in a safe manner or an arrangement consisting of a spool-piece with associated blanks.*
  - 8) *The valve separating the inert gas main from the cargo main and which is on the cargo main side shall be a non-return valve with a positive means of closure.*
  - 9) *Inert gas piping systems shall not pass through accommodation, service and control station spaces.*
  - 10) *In combination carriers, the arrangement to isolate the slop tanks containing oil or oil residues from other tanks shall consist of blank flanges which will remain in position at all times when cargoes other than oil are being carried except as provided for in the relevant section of IMO Circular MSC/Circ.353, as amended by IMO Circular MSC/Circ.387.*

### **13.2.4 Indicators and alarms**

a) *The operation status of the inert gas system shall be indicated in a control panel.*

The operational status of the inert gas system is to be based on indication that inert gas is being supplied downstream of the gas regulating valve and on the pressure or flow of the inert gas mains downstream of the non-return devices. However, the operational status of the inert gas system is not to be considered to require additional indicators and alarms other than those specified in this requirement and [13.3.3] or [13.4.3], as appropriate.

b) *Instrumentation shall be fitted for continuously indicating and permanently recording, when inert gas is being supplied:*

- 1) *the pressure of the inert gas mains downstream of the non-return devices; and*
- 2) *the oxygen content of the inert gas.*

c) *The indicating and recording devices shall be placed in the cargo control room where provided. But where no cargo control room is provided, they shall be placed in a position easily accessible to the officer in charge of cargo operations.*

d) *In addition, meters shall be fitted:*

- 1) *in the navigating bridge to indicate at all times the pressure referred to in item b) 1) and the pressure in the slop tanks of combination carriers, whenever those tanks are isolated from the inert gas main; and*
- 2) *in the machinery control room or in the machinery space to indicate the oxygen content referred to in item b) 2).*

e) *Audible and visual alarms*

1) *Audible and visual alarms shall be provided, based on the system designed, to indicate:*

- *oxygen content in excess of 5% by volume (see also item e) 2));*
- *failure of the power supply to the indicating devices as referred to in item b);*
- *gas pressure less than 100 mm water gauge. The alarm arrangement shall be such as to ensure that the pressure in slop tanks in combination carriers can be monitored at all times (see also item e) 2));*
- *high-gas pressure; and*
- *failure of the power supply to the automatic control system (see also item e) 2)).*

2) *The alarms required in item e) 1) for:*

- *oxygen content*
- *gas pressure less than 100 mm water gauge, and*
- *failure of the power supply to the automatic control system,*

*shall be fitted in the machinery space and cargo control room, where provided, but in each case in such a position that they are immediately received by responsible members of the crew.*

3) *An audible alarm system independent of that required in item e) 1) for gas pressure less than 100 mm water gauge, or automatic shutdown of cargo pumps shall be provided to operate on predetermined limits of low pressure in the inert gas main being reached.*

The term "alarm system independent" means that a second pressure sensor, independent of the sensor serving the alarms for low pressure, high pressure and pressure indicator/recorder should be provided. Notwithstanding the above, a common programmable logic controller (PLC) should, however, be accepted for the alarms in the control system. The independent sensor should not be required if the system is arranged for the shutdown of cargo pumps. If a system for shutdown of cargo pumps is arranged, an automatic system shutting down all cargo pumps should be provided. The shutdown should be alarmed at the control station. The shutdown should not prevent the operation of ballast pumps or pumps used for bilge drainage of a cargo pump room.

4) *Two oxygen sensors shall be positioned at appropriate locations in the space or spaces containing the inert gas system. If the oxygen level falls below 19%, these sensors shall trigger alarms, which shall be both visible and audible inside and outside the space or spaces and shall be placed in such a position that they are immediately received by responsible members of the crew.*

### **13.2.5 Instruction manuals**

*Detailed instruction manuals shall be provided on board, covering the operations, safety and maintenance requirements and occupational health hazards relevant to the inert gas system and its application to the cargo tank system.*

*Note 1: Refer to the Revised Guidelines for inert gas systems (MSC/Circ.353), as amended by MSC/Circ.387.*

*The manuals shall include guidance on procedures to be followed in the event of a fault or failure of the inert gas system.*

## **13.3 Requirements for flue gas and inert gas generator systems**

### **13.3.1 Application**

*In addition to the provisions in [13.2], for inert gas systems using flue gas or inert gas generators, the provisions of this sub-article shall apply.*

### **13.3.2 System requirements**

a) *Inert gas generators*

- 1) *Two fuel oil pumps shall be fitted to the inert gas generator. Suitable fuel in sufficient quantity shall be provided for the inert gas generators.*
- 2) *The inert gas generators shall be located outside the cargo tank area. Spaces containing inert gas generators shall have no direct access to accommodation service or control station spaces, but may be located in machinery spaces. If they are not located in machinery spaces, such a compartment shall be separated by a gastight steel bulkhead and/or deck from accommodation, service and control station spaces. Adequate positive-pressure-type mechanical ventilation shall be provided for such a compartment.*

b) *Gas regulating valves*

- 1) *A gas regulating valve shall be fitted in the inert gas main. This valve shall be automatically controlled to close, as required in [13.2.2], item b). It shall also be capable of automatically regulating the flow of inert gas to the cargo tanks unless means are provided to automatically control the inert gas flow rate.*
- 2) *The gas regulating valve shall be located at the forward bulkhead of the forward most gas-safe space through which the inert gas main passes.*

c) *Cooling and scrubbing arrangement*

- 1) *Means shall be fitted which will effectively cool the volume of gas specified in [13.2.1], item b) and remove solids and sulphur combustion products. The cooling water arrangements shall be such that an adequate supply of water will always be available without interfering with any essential services on the ship. Provision shall also be made for an alternative supply of cooling water.*
- 2) *Filters or equivalent devices shall be fitted to minimize the amount of water carried over to the inert gas blowers.*

d) *Blowers*

- 1) *At least two inert gas blowers shall be fitted and be capable of delivering to the cargo tanks at least the volume of gas required by [13.2.1], item b). For systems fitted with inert gas generators the Society may permit only one blower if that system is capable of delivering the total volume of gas required by [13.2.1], item b) to the cargo tanks, provided that sufficient spares for the blower and its prime mover are carried on board to enable any failure of the blower and its prime mover to be rectified by the ship's crew.*
- 2) *Where inert gas generators are served by positive displacement blowers, a pressure relief device shall be provided to prevent excess pressure being developed on the discharge side of the blower.*
- 3) *When two blowers are provided, the total required capacity of the inert gas system shall be divided evenly between the two and in no case is one blower to have a capacity less than 1/3 of the total required.*

e) *Inert gas isolating valves*

*For systems using flue gas, flue gas isolating valves shall be fitted in the inert gas mains between the boiler uptakes and the flue gas scrubber. These valves shall be provided with indicators to show whether they are open or shut, and precautions shall be taken to maintain them gastight and keep the seatings clear of soot. Arrangements shall be made to ensure that boiler soot blowers cannot be operated when the corresponding flue gas valve is open.*

f) *Prevention of flue gas leakage*

- 1) *Special consideration shall be given to the design and location of scrubber and blowers with relevant piping and fittings in order to prevent flue gas leakages into enclosed spaces.*
- 2) *To permit safe maintenance, an additional water seal or other effective means of preventing flue gas leakage shall be fitted between the flue gas isolating valves and scrubber or incorporated in the gas entry to the scrubber.*

### **13.3.3 Indicators and alarms**

- a) *In addition to the requirements in [13.2.4], item b), means shall be provided for continuously indicating the temperature of the inert gas at the discharge side of the system, whenever it is operating.*
- b) *In addition to the requirements [13.2.4], item e), audible and visual alarms shall be provided to indicate:*
  - *insufficient fuel oil supply to the oil-fired inert gas generator;*
  - *failure of the power supply to the generator;*
  - *low water pressure or low water flow rate to the cooling and scrubbing arrangement;*
  - *high water level in the cooling and scrubbing arrangement;*
  - *high gas temperature;*
  - *failure of the inert gas blowers; and*
  - *low water level in the water seal.*

## **13.4 Requirements for nitrogen generator systems**

### **13.4.1 Application**

*In addition to the provisions in [13.2], for inert gas systems using nitrogen generators, the provisions of [13.4.2] and [13.4.3] shall apply.*

### **13.4.2 System requirements**

- a) *The system shall be provided with one or more compressors to generate enough positive pressure to be capable of delivering the total volume of gas required by [13.2.1], item b).*
- b) *A feed air treatment system shall be fitted to remove free water, particles and traces of oil from the compressed air.*
- c) *The air compressor and nitrogen generator may be installed in the engine-room or in a separate compartment. A separate compartment and any installed equipment shall be treated as an "Other machinery space" with respect to fire protection. Where a separate compartment is provided for the nitrogen generator, the compartment shall be fitted with an independent mechanical extraction ventilation system providing six air changes per hour. The compartment is to have no direct access to accommodation spaces, service spaces and control stations.*
- d) *Where a nitrogen receiver or a buffer tank is installed, it may be installed in a dedicated compartment, in a separate compartment containing the air compressor and the generator, in the engine room, or in the cargo area. Where the nitrogen receiver or a buffer tank is installed in an enclosed space, the access shall be arranged only from the open deck and the access door shall open outwards. Adequate, independent mechanical ventilation, of the extraction type, shall be provided for such a compartment.*

### **13.4.3 Indicators and alarms**

- a) *In addition to the requirements in [13.2.4], item b), instrumentation is to be provided for continuously indicating the temperature and pressure of air at the suction side of the nitrogen generator.*
- b) *In addition to the requirements in [13.2.4], item e), audible and visual alarms shall be provided to include:*
  - *failure of the electric heater, if fitted;*
  - *low feed-air pressure or flow from the compressor;*
  - *high-air temperature; and*
  - *high condensate level at automatic drain of water separator.*

## **14 Helicopter facility foam firefighting appliances**

### **14.1 Application**

**14.1.1** *This Article details the specifications for foam firefighting appliances for the protection of helidecks and helicopter landing areas as required by Ch 4, Sec 10.*

### **14.2 Definitions**

**14.2.1** *D-value means the largest dimension of the helicopter used for assessment of the helideck when its rotors are turning. It establishes the required area of foam application.*

**14.2.2** *Deck integrated foam nozzles are foam nozzles recessed into or edge mounted on the helideck.*

**14.2.3** *Foam-making branch pipes are air-aspirating nozzles in tube shape for producing and discharging foam, usually in straight stream only.*

**14.2.4** *Hose reel foam station is a hose reel fitted with a foam-making branch pipe and non-collapsible hose, together with fixed foam proportioner and fixed foam concentrate tank, mounted on a common frame.*

**14.2.5** *Monitor foam station is a foam monitor, either self-inducing or together with separate fixed foam proportioner, and fixed foam concentrate tank, mounted on a common frame.*

**14.2.6** *Obstacle free sector is the take-off and approach sector which totally encompasses the safe landing area and extends over a sector of at least 210°, within which only specified obstacles are permitted.*

**14.2.7** *Limited obstacle sector is a 150° sector outside the take-off and approach sector that extends outward from a helideck where objects of limited height are permitted.*

### **14.3 Engineering specifications for helidecks and helicopter landing areas**

**14.3.1** *The system shall be capable of manual release, and may be arranged for automatic release.*

**14.3.2** *For helidecks the foam system shall contain at least two fixed foam monitors or deck integrated foam nozzles. In addition, at least two hose reels fitted with a foam-making branch pipe and non-collapsible hose sufficient to reach any part of the helideck shall be provided. The minimum foam system discharge rate shall be determined by multiplying the D-value area by 6 l/min/m<sup>2</sup>. The minimum foam system discharge rate for deck integrated foam nozzle systems shall be determined by multiplying the overall helideck area by 6 l/min/m<sup>2</sup>. Each monitor shall be capable of supplying at least 50% of the minimum foam system discharge rate, but not less than 500 l/min. The minimum discharge rate of each hose reel shall be at least 400 l/min.*

*The quantity of foam concentrate shall be adequate to allow operation of all connected discharge devices for at least 5 min.*

**14.3.3** Where foam monitors are installed, the distance from the monitor to the farthest extremity of the protected area shall be not more than 75% of the monitor throw in still air conditions.

**14.3.4** For helicopter landing areas, at least two portable foam applicators or two hose reel foam stations shall be provided, each capable of discharging a minimum foam solution discharge rate, in accordance with Tab 5.

The quantity of foam concentrate shall be adequate to allow operation of all connected discharge devices for at least 10 min. For tankers fitted with a deck foam system, the Society may consider an alternative arrangement, taking into account the type of foam concentrate to be used.

**Table 5 : Foam discharge rates**

Cat.	Helicopter overall length (D-value)	Minimum foam solution discharge rate, in l/min
H1	up to but not including 15 m	250
H2	from 15 m up to but not including 24 m	500
H3	from 24 m up to but not including 35 m	800

**14.3.5** Manual release stations capable of starting necessary pumps and opening required valves, including the fire main system, if used for water supply, shall be located at each monitor and hose reel. In addition, a central manual release station shall be provided at a protected location. The foam system shall be designed to discharge foam with nominal flow and at design pressure from any connected discharge devices within 30 s of activation.

**14.3.6** Activation of any manual release station shall initiate the flow of foam solution to all connected hose reels, monitors, and deck integrated foam nozzles.

**14.3.7** The system and its components shall be designed to withstand ambient temperature changes, vibration, humidity, shock impact and corrosion normally encountered on the open deck, and shall be manufactured and tested to the satisfaction of the Society.

**14.3.8** A minimum nozzle throw of at least 15 m shall be provided with all hose reels and monitors discharging foam simultaneously. The discharge pressure, flow rate and discharge pattern of deck integrated foam nozzles shall be to the satisfaction of the Society, based on tests that demonstrate the nozzle's capability to extinguish fires involving the largest size helicopter for which the helideck is designed.

**14.3.9** Monitors, foam-making branch pipes, deck integrated foam nozzles and couplings shall be constructed of brass, bronze or stainless steel. Piping, fittings and related components, except gaskets, shall be designed to withstand exposure to temperatures up to 925°C.

**14.3.10** The foam concentrate shall be demonstrated effective for extinguishing aviation fuel spill fires and is to be approved based on IMO Circular MSC.1/Circ.1312 or International Civil Aviation Organization - Airport Services Manual, Part 1 - Rescue and Firefighting, Chapter 8 - Extinguishing Agent Characteristics, Paragraph 8.1.5 - Foam Specifications Table 8-1, Level "B" foam. Where the foam storage tank is on the exposed deck, freeze protected foam concentrates shall be used, if appropriate, for the area of operation.

**14.3.11** Any foam system equipment installed within the take-off and approach obstacle-free sector shall not exceed a height of 0.25 m. Any foam system equipment installed in the limited obstacle sector shall not exceed the height permitted for objects in this area.

**14.3.12** All manual release stations, monitor foam stations, hose reel foam stations, hose reels and monitors shall be provided with a means of access that does not require travel across the helideck or helicopter landing area.

**14.3.13** Oscillating monitors, if used, shall be pre-set to discharge foam in a spray pattern and have a means of disengaging the oscillating mechanism to allow rapid conversion to manual operation.

**14.3.14** If a foam monitor with flow rate up to 1000 l/min is installed, it shall be equipped with an air-aspirating nozzle. If a deck integrated nozzle system is installed, then the additionally installed hose reel shall be equipped with an air-aspirating handline nozzle (foam branch pipes). Use of non-air-aspirating foam nozzles (on both monitors and the additional hose reel) is permitted only where foam monitors with a flow rate above 1000 l/min are installed. If only portable foam applicators or hose reel stations are provided, these shall be equipped with an air-aspirating handline nozzle (foam branch pipes).

## Chapter 8 Chemical Tankers

### Section 1 General

1	General	226
1.1	Application	
1.2	IBC Code requirements and the Society's rules	
2	Additional requirements	227
2.1	Emergency towing arrangement	
2.2	Steering gear	
3	Documentation to be submitted	227
3.1		

### Section 2 Ship Survival Capability and Location of Cargo Tanks

1	Freeboard and intact stability	229
1.1	Intact stability	
2	Conditions of loading	229
2.1	Additional loading conditions for ships where additional class notation SDS is requested	
3	Location of cargo tanks	229
3.1	Minimum distance of cargo tanks from shell	
3.2	Suction wells	
4	Flooding assumptions for ships where additional class notation SDS is requested	229
4.1	Tunnels, ducts and pipes in the damaged zone	
5	Standard of damage for ships where additional class notation SDS is requested	230
5.1	Damage to stepped machinery space forward bulkhead	
5.2	Longitudinal extension of damage to superstructure	
6	Survival requirements for ships where additional class notation SDS is requested	230
6.1	General	
6.2	Intermediate stages of flooding	
6.3	Definition of range of positive stability	
6.4	Survival criterion	
6.5	Type 3 ships less than 125 m in length	

### Section 3 Ship Arrangement

1	Cargo segregation	232
1.1	Segregation of cargoes mutually reacting	
1.2	Cargo piping arrangement	
2	Accommodation, service and machinery spaces and control stations	233
2.1	Location of paint lockers	
2.2	Air intakes and other openings to accommodation spaces	
2.3	Windows, sidescuttles and doors to accommodation spaces	
2.4	Access to the bow	
3	Cargo pump rooms	233
3.1	General requirement	
3.2	Machinery driven by shafting passing through pump room bulkheads	

# Table of Content

	<b>4</b>	<b>Access to spaces in the cargo area</b>	<b>234</b>
	4.1	General	
	4.2	Horizontal openings	
	4.3	Vertical openings

## Section 6 Materials of Construction and Quality Control

1	Definitions	354
	1.1	
2	Scope and general requirements	354
	2.1	
3	General test requirements and specifications	354
	3.1 Tensile test	
	3.2 Toughness test	
	3.3 Bend test	
	3.4 Section observation and other testing	
4	Requirements for metallic materials	356
	4.1 General requirements for metallic materials	
5	Welding of metallic materials and non-destructive testing	361
	5.1 General	
	5.2 Welding consumables	
	5.3 Welding procedure tests for cargo tanks and process pressure vessels	
	5.4 Welding procedure tests for piping	
	5.5 Production weld tests	
	5.6 Non-destructive testing	
6	Other requirements for construction in metallic materials	363
	6.1 General	
	6.2 Independent tank	
	6.3 Secondary barriers	
	6.4 Semi-membrane tanks	
	6.5 Membrane tanks	
7	Non-metallic materials	364
	7.1 General	

## Section 7 Cargo Pressure / Temperature Control

1	Methods of control	365
	1.1 General	
2	Design of systems	365
	2.1 General	
3	Reliquefaction of cargo vapours	365
	3.1	
	3.2 Refrigerating installation components	
	3.3 Refrigerants	
4	Thermal oxidation of vapours	366
	4.1 General	
	4.2 Thermal oxidation systems	
	4.3 Burners	
	4.4 Safety	
5	Pressure accumulation systems	367
	5.1 General	
6	Liquid cargo cooling	367
	6.1 General	
7	Segregation	367
	7.1 General	
8	Availability	367
	8.1 General	

# Table of Content

<b>Section 8</b>	<b>Vent Systems for Cargo Containment</b>	
1	General	369
	1.1	
2	Pressure relief systems	369
	2.1 General	
3	Vacuum protection systems	372
	3.1 General	
4	Sizing of pressure relieving system	372
	4.1 Sizing of pressure relief valves	
	4.2 Sizing of vent pipe system	
	4.3 Upstream pressure losses	
	4.4 Downstream pressure losses	
	4.5 Blow-down	
<b>Section 9</b>	<b>Cargo Containment System Atmosphere Control</b>	
1	General	375
	1.1 Atmosphere control within the cargo containment system	
	1.2 Atmosphere control within the hold spaces (cargo containment systems other than type C independent tanks)	
	1.3 Environmental control of spaces surrounding type C independent tanks	
	1.4 Inerting	
	1.5 Inert gas production on board	
	1.6 Engineering specifications for nitrogen / inert gas systems	
<b>Section 10</b>	<b>Electrical Installations</b>	
1	General	378
	1.1 Application	
	1.2 Documentation to be submitted	
	1.3 Definitions	
	1.4 General requirements	
	1.5 System of supply	
	1.6 Earth detection	
	1.7 Mechanical ventilation of hazardous spaces	
2	Hazardous locations and types of equipment	381
	2.1 Electrical equipment permitted in gas-dangerous spaces and zones	
	2.2 Submerged cargo pumps	
3	Product classification	381
	3.1 Temperature class and explosion group	
<b>Section 11</b>	<b>Fire Protection and Extinction</b>	
1	General	383
	1.1 Fire safety requirements	
	1.2 Fire mains and hydrants	
	1.3 Water-spray system	
	1.4 Dry chemical powder fire-extinguishing systems	
	1.5 Enclosed spaces containing cargo handling equipment	
	1.6 Firefighter's outfits	
<b>Section 12</b>	<b>Artificial Ventilation in the Cargo Area</b>	
1	General	388
	1.1 Scope	
	1.2 Spaces required to be entered during normal cargo handling operations	
	1.3 Spaces not normally entered

## 1 Application

### 1.1

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of one of the service notation **ro-ro cargo ship, PCTC** or **PCC**, as defined in Pt A, Ch 1, Sec 2, [4.2.3] and Pt A, Ch 1, Sec 2, [4.2.4].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules,
- NR216 Materials and Welding.
- applicable requirements according to Tab 1.

**1.1.3** Additional guidance for arrangement and structural assessment is provided in NI640 Guidance Note for Structural Assessment of Passenger Ships and Ro-ro Ships.

**Table 1 : Applicable requirements**

# Section 2 Hull and Stability

## 1 General

### 1.1 Application

1.1.1 The requirements of this Section apply to multi-deck ships with double bottom and, in some cases, with wing tanks up to the lowest deck above the full load waterline, intended for the carriage of:

- vehicles which embark and disembark on their own wheels, and/or goods in or on pallets or containers which can be loaded and unloaded by means of wheeled vehicles
- railway cars, on fixed rails, which embark and disembark on their own wheels.

### 1.2 Documents to be submitted

1.2.1 In addition to the documentation requested in Part B, the following documents are to be submitted:

- operating and maintenance manual of bow, side and stern doors and ramps (see Pt B, Ch 11, Sec 6 and Pt B, Ch 11, Sec 7)
- plan of design loads on deck
- plan of arrangement of motor vehicles, railway cars and/or other types of vehicles which are intended to be carried, indicating securing and load bearing arrangements
- characteristics of motor vehicles, railways cars and/or other types of vehicles which are intended to be carried: (as applicable) axle load, axle spacing, number of wheels per axle, wheel spacing, size of tyre print.

## 2 Stability

### 2.1 Damage stability requirements for ship where additional class notation SDS is required

2.1.1 A **ro-ro cargo ship, PCTC or PCC**, equal to or greater than 80 m in length where additional class notation **SDS** is required (see Pt A, Ch 1, Sec 2, [6.17.1]) is to comply with the subdivision and damage stability criteria in Pt B, Ch 3, App 3.

## 3 Structure design principles

### 3.1 Wood sheathing

3.1.1 Wood sheathing is recommended for caterpillar trucks and unusual vehicles.

It is recommended that a piece of wood of suitable thickness is provided under each crutch in order to distribute the mass over the plate and the nearest stiffeners.

## 4 Design loads

### 4.1 Load combinations for direct strength analysis

4.1.1 The load combinations defined in NI640, App 1, [4] are to be considered for direct strength analysis.

## 5 Global strength

### 5.1 Hull girder strength

5.1.1 In addition to the requirements in Pt B, Ch 6, Sec 1, [1.3] and Pt B, Ch 7, Sec 6, [1.1.2], the contribution of the hull structures up to the strength deck to the longitudinal strength is to be assessed through a finite element analysis of the whole ship in the following cases:

- when the size of openings in side shell and/or longitudinal bulkheads located below the strength deck decreases significantly the capability of the plating to transmit shear forces to the strength deck
- when the ends of superstructures which are required to contribute to longitudinal strength may be considered not effectively connected to the hull structures.

### 5.2 Global transverse strength

5.2.1 The behaviour of the ship primary structural members under racking effects due to transverse forces induced by transverse accelerations is to be investigated according to Pt B, Ch 7, App 1, or by means of a complete ship model according to NI 640.

## 6 Construction and testing

### 6.1 Special structural details

**6.1.1** The specific requirements in Pt B, Ch 13, Sec 5, [2] for ships with the service notation **ro-ro cargo ship, PCTC or PCC**, are to be complied with.

## Section 3 Machinery and Systems

### 1 Scuppers and sanitary discharges

#### 1.1 Drainage of ro-ro cargo spaces, intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion

##### 1.1.1 Prevention of build-up of free surfaces

In cargo spaces intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion and fitted with a fixed pressure water-spraying fire-extinguishing system, the drainage arrangement is to be such as to prevent the build-up of free surfaces. If this is not possible, the adverse effect upon stability of the added weight and free surface of water is to be taken into account to the extent deemed necessary by the Society in its approval of the stability information.

##### 1.1.2 Scupper draining

Scuppers from cargo spaces intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion are not to be led to machinery or other places where sources of ignition may be present.

# Section 4 Electrical Installations

## 1 General

### 1.1 Applicable requirements

**1.1.1** In addition to the relevant requirements of Part C, Chapter 2 and those contained in this Section, electrical installations in spaces intended for the carriage of motor vehicles with fuel in their tanks for their propulsion are to comply with those of Part C, Chapter 4.

### 1.2 Documentation to be submitted

**1.2.1** In addition to the documentation requested in Pt C, Ch 2, Sec 1, Tab 1, the following is to be submitted for approval:

- a) plan of hazardous areas
- b) document giving details of types of cables and safety characteristics of the equipment installed in hazardous areas.

**Table 1 : Electrical equipment permitted in closed ro-ro cargo spaces**

No.	Space description	Electrical equipment	Hazardous area
1	Closed ro-ro cargo spaces except areas under item 3	Electrical equipment complying with one of the following types of protection may be considered: <ol style="list-style-type: none"> <li>a) any type that may be considered for zone 0</li> <li>b) certified intrinsically safe apparatus Ex(ib)</li> <li>c) simple electrical apparatus and components (e.g. thermocouples, photocells, strain gauges, junction boxes, switching devices), included in intrinsically-safe circuits of category "ib" not capable of storing or generating electrical power or energy in excess of limits stated in the relevant rules, and acceptable to the appropriate authority</li> <li>d) certified flameproof Ex(d)</li> <li>e) certified pressurised Ex(p)</li> <li>f) certified increased safety Ex(e)</li> <li>g) certified encapsulated Ex(m)</li> <li>h) certified sand filled Ex(q)</li> <li>i) certified specially Ex(s)</li> <li>j) cables sheathed with at least one of the following:               <ul style="list-style-type: none"> <li>• a non-metallic impervious sheath in combination with braiding or other metallic covering</li> <li>• copper or stainless steel sheath (for mineral-insulated cables only)</li> </ul> </li> </ol>	Zone 1
2	Exhaust ventilation ducts	As stated under item 1	Zone 1
3	On condition that the ventilation system is so designed and operated as to provide continuous ventilation of the cargo spaces at the rate of at least 10 air changes per hour whenever vehicles are on board: <ul style="list-style-type: none"> <li>• areas above a height of 450 mm from the deck</li> <li>• areas above a height of 450 mm from each platform for vehicles, if fitted, without openings of sufficient size permitting penetration of petrol gases downward</li> <li>• areas above platforms for vehicles, if fitted, with openings of sufficient size permitting penetration of petrol gases downward</li> </ul>	Electrical equipment complying with one of the following types of protection may be considered: <ol style="list-style-type: none"> <li>a) any type that may be considered for zone 1</li> <li>b) tested specially for zone 2 (e.g. type "n" protection)</li> <li>c) pressurised, and acceptable to the appropriate authority</li> <li>d) encapsulated, and acceptable to the appropriate authority</li> <li>e) the type which ensures the absence of sparks and arcs and of "hot spots" during its normal operation (minimum class of protection IP55)</li> <li>f) cables sheathed with at least a non-metallic external impervious sheath</li> </ol>	Zone 2

### **1.3 Safety characteristics**

**1.3.1** The explosion group and temperature class of electrical equipment of a certified safe type for use with explosive petrol-air mixtures are to be at least IIA and T3.

## **2 Installation**

### **2.1 Installations in closed ro-ro cargo spaces**

**2.1.1** Except as provided for in [2.1.2], electrical equipment is to be of a certified safe type as stated in Pt C, Ch 2, Sec 3, [10.1.6] and electrical cables are to be as stated in Pt C, Ch 2, Sec 3, [10.3.2].

**2.1.2** Above a height of 450 mm from the deck and from each platform for vehicles, if fitted, except platforms with openings of sufficient size permitting penetration of petrol gases downwards, electrical equipment as stated in Pt C, Ch 2, Sec 3, [10.1.7] and electrical cables as stated in Pt C, Ch 2, Sec 3, [10.3.3] are permitted, on condition that the ventilation system is so designed and operated as to provide continuous ventilation of the cargo spaces at the rate of at least 10 air changes per hour whenever vehicles are on board.

**2.1.3** Electrical equipment and cables in an exhaust ventilation duct are to be as stated in [2.1.1].

**2.1.4** The requirements in this item are summarised in Tab 1.

### **2.2 Installations in cargo spaces other than ro-ro cargo spaces but intended for the carriage of motor vehicles**

**2.2.1** The provisions of [2.1] apply.

**2.2.2** All electric circuits terminating in cargo holds are to be provided with multipole linked isolating switches located outside the holds. Provision is to be made for locking in the off position.

This requirement does not apply to safety installations such as fire, smoke or gas detection systems.

## **3 Type approved components**

### **3.1**

**3.1.1** Alarm systems for closing devices of openings and water leakage detection systems if of electronic type, as well as television surveillance systems, are to be type approved or in accordance with [3.1.2].

**3.1.2** Case-by-case approval based on submission of adequate documentation and execution of tests may also be granted at the discretion of the Society.

# Part D

## Service Notations

---

## CHAPTER 2

# CONTAINER SHIPS

---

- Section 1      General
- Section 2      Hull and Stability
- Section 3      Machinery and Systems

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **container ship**, as defined in Pt A, Ch 1, Sec 2, [4.2.6].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1

and the requirements of Pt F, Ch 12, Sec 6, for open-top container ships, as defined in [1.2.1].

**1.1.3** Ships assigned the additional service feature **equipped for carriage of containers** are to comply with the requirements of Ch 2, Sec 2 except Ch 2, Sec 2, [4.2]; Ch 2, Sec 2, [7] and Ch 2, Sec 2, [10].

### 1.2 Definition

#### 1.2.1 Open-top container ships

An "open-top containership" is defined as container ship especially designed so that one or more of the cargo holds need not be fitted with hatch covers.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT
Ship arrangement	L ≥ 65 m	• Part B	• NR566
	L < 65 m	• NR600	• NR566

**Note 1:**

NR566: Hull Arrangement, Stability and Systems for Ships less than 500 GT.

NR600: Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m.

# Section 2 Hull and Stability

## Symbols

For symbols not defined in this Section, refer to Pt B, Ch 1, Sec 3.

$M_{sw-min}$  : Minimum permissible still water bending moment as defined in Pt B, Ch 5, Sec 4, [2.2.1].

$M_{sw-max}$  : Maximum permissible still water bending moment as defined in Pt B, Ch 5, Sec 4, [2.2.1].

$Q_{sw-min}$  : Minimum permissible still water shear force as defined in Pt B, Ch 5, Sec 4, [2.3.1].

$Q_{sw-max}$  : Maximum permissible still water shear force as defined in Pt B, Ch 5, Sec 4, [2.3.1].

## 1 General

### 1.1 Application

**1.1.1** The requirements of this Section apply to double bottom ships of double or single side skin construction, intended to carry containers in holds or on decks.

#### 1.1.2 Open-top container ships

In addition to the requirements of this Section, open-top container ships are to comply with the requirements of Pt F, Ch 12, Sec 6.

### 1.2 Documents and information

#### 1.2.1 Documents to be submitted

Documents are to be submitted as required in Pt B, Ch 1, Sec 4. In addition, the following documents are to be submitted to the Society for review:

- container stowage plan, describing the arrangement of containers in hold, on deck and on hatch covers; the plan shall also include the gross weight of containers and the maximum design weight of container stacks
- list and/or plan of all fixed securing devices as requested in [14]
- fixed cell guides arrangement and scantlings.

#### 1.2.2 Information to be submitted

The following additional information is to be included in the relevant documents:

- the distributions of still water permissible vertical bending moments, vertical shear forces, and the maximum torsional moment in seagoing and harbour conditions, as defined in Pt B, Ch 5, Sec 4, are to be included in the loading manual
- the permissible stack weights for 20' and 40' containers stacks in hold and on deck, as defined in [5.2.2], are to be included on the midship section drawing and in the loading manual

## 2 Stability

### 2.1 Intact stability

#### 2.1.1 General

The stability for the loading conditions defined in Pt B, Ch 3, App 2, [1.2.4] is to be in compliance with the requirements of Pt B, Ch 3, Sec 2.

#### 2.1.2 Additional criteria

In addition to [2.1.1], the initial metacentric height is to be equal to or greater than 0,20 m.

#### 2.1.3 Alternative criteria for ships greater than 100 m in length

For ships greater than 100 m in length, the Society may apply the following criteria instead of those in Pt B, Ch 3, Sec 2:

- the area under the righting lever curve (GZ curve), in  $m\cdot rad$ , is to be not less than  $0,009/C$  up to an angle of heel of  $30^\circ$ , and not less than  $0,016/C$  up to  $40^\circ$  or the angle of flooding  $\theta_f$  if this angle is less than  $40^\circ$
- the area under the righting lever curve (GZ curve), in  $m\cdot rad$ , between the angles of heel of  $30^\circ$  and  $40^\circ$  or between  $30^\circ$  and  $\theta_f$  if this angle is less than  $40^\circ$ , is to be not less than  $0,006/C$
- the righting lever  $GZ$ , in  $m$ , is to be at least  $0,033/C$  at an angle of heel equal to or greater than  $30^\circ$
- the maximum righting lever  $GZ$ , in  $m$ , is to be at least  $0,042/C$
- the total area under the righting lever curve (GZ curve), in  $m\cdot rad$ , up to the angle of flooding  $\theta_f$  is not to be less than  $0,029/C$  where:

$C$  : Coefficient defined by:

$$C = \sqrt{\frac{T}{KG}} \sqrt{\frac{100}{L} \left(\frac{C_B}{C_W}\right)^2 \frac{TD'}{B_m^2}}$$

$T$  : Mean draught, in m

$KG$  : Height of the centre of mass above base, in m, corrected for free surface effect, not be taken as less than  $T$

$C_B$  : Block coefficient

$C_W$  : Waterplane coefficient

$D'$  : Moulded depth, in m, corrected for defined parts of volumes within the hatch coamings obtained from the following formula:

$$D' = D + \left(\frac{2b - B_D}{B_D}\right) \left(\frac{2\sum \ell_H}{L}\right) h$$

$h$  : Mean height, in m, of hatch coamings within  $L/4$  forward and aft from amidships (see Fig 1)

$b$  : Mean width, in m, of hatch coamings within  $L/4$  forward and aft from amidships (see Fig 1)

$B_m, B_D$  : Breadths, in m, defined in Fig 1

$\ell_H$  : Length, in m, of each hatch coaming within  $L/4$  forward and aft from amidships (see Fig 2).

**2.2 Damage stability requirements for ships where the additional class notation SDS is required**

**2.2.1 General**

Any type of container ship with a length equal to or greater than 80 m is to comply with the subdivision and damage stability criteria of Pt B, Ch 3, App 3.

**Figure 1 : Definition of dimensions**

**Figure 2 : Definition of dimensions**

### 3 Structure design principles

#### 3.1 Ship structure

##### 3.1.1 Design

The ship structure is to be longitudinally or transversely framed with full transverse bulkheads and intermediate web frames.

When single side skin construction is adopted, a torsion box girder at the topsides or an equivalent structure is to be fitted. Typical midship sections are shown in Fig 3 and Fig 4.

**Figure 3 : Container ship of double side skin construction**

**Figure 4 : Container ship of single side skin construction**

#### 3.2 Material

**3.2.1** The material classes required for the strength deck plating, the sheerstrake and the torsion box girder structure within 0,4 L amidships are to be maintained in way of the entire cargo hold region.

**3.2.2** When steel plates of thickness greater than 50 mm, made of material with specified minimum yield stress equal to 460 N/mm<sup>2</sup> are used in the upper deck region (for upper deck plating, hatch top and side coaming or their attached longitudinals stiffeners), the material grade is at least to be EH.

##### 3.2.3 Prevention of brittle crack propagation

This requirement applies to ships for which steel with minimum specified yield stress  $R_{eH}$  of 390 or 460 N/mm<sup>2</sup> is used for hatch coaming plating.

It gives measures, to be applied in cargo hold region, for prevention of propagation of brittle cracks initiating in block-to-block butt joints of upper deck and hatch side coaming (including top plating and their attached longitudinals).

- a) For plating with as-built thickness greater than 50 mm but not greater than 100 mm, measures are to be taken as specified in Tab 1, in which minimum specified yield stress  $R_{eH}$  and thickness  $t$  refer to hatch coaming top and side platings (not upper deck).

Measures are defined as follows:

- Measure 1: measure for prevention of brittle crack propagation along block-to-block butt joints, and deviation from butt joints into base metal
- Measure 2: measure for prevention of brittle crack propagation from weld areas other than butt joints considered in Measure 1, such as fillets and attachment welds.

When brittle crack arrest steels are used, the minimum specified yield stress of the upper deck is to be not higher than 390. Otherwise other means for preventing the crack initiation and propagation shall be agreed by the Society.

- b) For plating with as-built thickness greater than 100 mm, appropriate measures are to be considered on a case-by-case basis by the Society.
- c) If the as-built thickness of the hatch coaming structure is equal to or less than 50 mm, measures are not necessary, regardless of the as-built thickness and yield stress of the upper deck.

The following is considered to be an acceptable example of preventive Measure 1:

- a) use of brittle crack arrest steel for upper deck plating, in a way suitable to prevent transmission of crack propagating from hatch coaming to the structure below, and
- b) use of brittle crack arrest steel for hatch side coaming plating, and
- c) one of the following arrangements, aiming at creating a discontinuity in weld line:
  - shifting block-to-block butt welds of the hatch side coaming and those of the upper deck. This shift is to be not less than 300 mm (see Fig 5)
  - providing crack arrest holes in way of the block-to-block butt welds at the region where hatch side coaming weld meets the deck weld. In this case, the fatigue strength of the lower end of the butt weld is to be assessed (see Fig 6)
  - including arrest insert plates, of brittle crack arrest steel in way of the block-to-block butt welds at the region where hatch side coaming weld meets the deck weld (see Fig 7).

As an alternative to items b) and c), the shipbuilder may apply enhanced non-destructive testing (particularly time-of-flight diffraction technique) to all block-to-block butt joints over their full length, using stricter defect acceptance criteria, in lieu of ultrasonic testing.

The procedure and the acceptance criteria of non destructive (NDT) and ultrasonic testing (UT) are to be in accordance with Pt B, Ch 13, Sec 4.

The use of brittle crack arrest steel for upper deck plating, in a way suitable to prevent transmission of crack propagating from hatch coaming to the structure below, is considered to be an acceptable example of preventive Measure 2.

The brittle crack arrest steels used in Measure 1 and Measure 2 are to be selected according to Tab 2 where suffixes CAS1 and CAS2 are defined in NR216 Materials and Welding.

When brittle crack arrest steels are used, the weld joints between the hatch coaming side and the upper deck are to be partial penetration. In the vicinity of ship block joints, alternative weld may be used for the deck and hatch coaming side connection provided additional means for preventing the crack propagation are implemented and agreed by the Society.

**Table 1 : Measures to prevent propagation of brittle cracks**

$R_{eH}$ , in N/mm <sup>2</sup>	As-built thickness, in mm	Measures
390	$50 < t \leq 85$	N.A.
	$85 < t \leq 100$	Measure 1 <b>(1)</b> and Measure 2
460 Flux cored arc welding	$50 < t \leq 100$	Measure 1 <b>(1)</b> and Measure 2
460 Electrogas welding	$50 < t \leq 100$	Measure 1 and Measure 2
<b>(1)</b> As an alternative to Measure 1, the shipbuilder may apply enhanced non-destructive testing (particularly time-of-flight diffraction technique) to all block-to-block butt joints over their full length, using stricter defect acceptance criteria, in lieu of ultrasonic testing.		

**Table 2 : Brittle crack arrest steel selection**

Structural members plating <b>(1)</b>	Thickness (mm)	Brittle crack arrest steel
Upper deck	$50 < t \leq 100$	EH36CAS1 / FH36CAS1 EH40CAS1 / FH40CAS1
Hatch coaming side	$50 < t \leq 80$	EH40CAS1 / FH40CAS1 EH47CAS1 / FH47CAS1
	$80 < t \leq 100$	EH40CAS2 / FH40CAS2 EH47CAS2 / FH47CAS2
<b>(1)</b> Excluding their attached longitudinals		

**Figure 5 :**

Figure 6 :

Figure 7 :

### 3.3 Net scantling approach

#### 3.3.1 Net thickness approach

The applied corrosion is to be taken equal to  $0 t_c$  in the following cases:

- calculations of stresses based on cargo hold model (standard mesh, or 3-D beam models) or complete ship model
- calculations of stresses based on local fine mesh or very fine mesh

### 3.4 Strength principles

#### 3.4.1 Reinforcement under container corners and in way of fixed cargo securing devices and cell guides

Local reinforcement of the hull structure and hatch covers is to be provided under container corners and in way of fixed cargo securing devices and cell guides, if fitted.

The forces applying on the fixed cargo securing devices are to be indicated by the designer. When one of the additional class notations **LASHING** or **LASHING-RSSA( )** is assigned, these forces may be determined by the Society.

### 3.5 Bottom structure

#### 3.5.1 Floor spacing

Generally, the floor spacing is to be such that floors are located in way of the container corners. Floors are also to be fitted in way of the watertight bulkheads.

The floor spacing is generally not to be greater than 3,5 m or four times the transverse frame spaces, whichever is the smaller.

#### 3.5.2 Cell guides

The structure of the bottom and inner bottom on which cell guides rest is to be adequately stiffened with doublers, brackets or other equivalent reinforcements.

### 3.6 Deck structure

#### 3.6.1 Longitudinal hatch coaming

The width of the longitudinal hatch coaming flanges is to be such as to accommodate the hatch covers and their securing arrangements.

The end connections of the longitudinal hatch coamings are to ensure a proper transmission of stresses from the hatch coaming to the supporting structure.

### 3.6.2 Hatch corners

The stress concentrations in way of the hatch corners are to be checked, in particular in the top part (hatch coaming, upper deck and stringers under deck).

### 3.6.3 Deck and hatch cover reinforcements

The deck and hatch cover structures are to be reinforced taking into account the loads transmitted by the container corners and cell guides.

## 3.7 Bulkheads

### 3.7.1 Transverse torsion box structures in way of transverse bulkheads

Transverse torsion box structures are generally to be provided at the top part of the transverse bulkheads.

They are to be provided with sufficient strength to sustain stress resulting from the shear forces induced at their ends by hull girder torsion effects.

Similar boxes might as well be provided at the bottom part of the transverse bulkheads.

### 3.7.2 Primary supporting members

The vertical primary supporting members of the transverse bulkheads are to be fitted in line with bottom girders.

Their flanges are to be in line with a double bottom floor.

The strength of the connection between these members and the bottom structure is to be assessed.

### 3.7.3 Reinforcements in way of cell guides

When cell guides are fitted on transverse or longitudinal bulkheads which form boundaries of the hold, such structures are to be reinforced, taking into account the loads transmitted by the cell guides.

## 4 Design loads

### 4.1 Still water hull girder loads

#### 4.1.1 Permissible torsional still water moment in seagoing condition

The permissible torsional still water moment  $M_{sw-t}$ , in kN·m, induced by a non-uniform distribution of cargo, consumable liquids and ballast in seagoing condition, is to be considered.

When no specific data is provided by the designer, as a guidance at a preliminary stage,  $M_{sw-t}$  may be obtained, from the following formula:

$$M_{sw-t} = 0,04 L B (S_h T_h + S_d T_d)$$

where:

- $S_h$  : Number of container stacks over the breadth B in cargo hold amidships
- $T_h$  : Number of container tiers in cargo hold amidships
- $S_d$  : Number of container stacks over the breadth B on deck amidships
- $T_d$  : Number of container tiers on deck amidships.

#### 4.1.2 Permissible torsional still water moment in harbour/sheltered water

The permissible torsional still water moment  $M_{sw-t-h}$ , in kN·m, induced by a non-uniform distribution of cargo, consumable liquids and ballast in the harbour/sheltered water condition, is to be considered.

This value is defined as a constant value over the ship length.

When no specific data is provided by the designer, a preliminary value for  $M_{sw-t-h}$  may be taken equal to the permissible torsional still water moment in seagoing condition  $M_{sw-t}$  as defined in [4.1.1].

#### 4.1.3 Torsional still water moment for direct calculations in seagoing condition

For direct calculation analysis, the torsional still water moment in seagoing condition  $M_{sw-t-LC}$ , in kN·m, is to be taken, at any longitudinal position for the considered dynamic load case, as follows:

- For  $C_{WT} \geq 0$   
 $M_{sw-t-LC} = |f_{ip}| M_{sw-t} (f_{q-a} + f_{q-i})$
- For  $C_{WT} < 0$   
 $M_{sw-t-LC} = -|f_{ip}| M_{sw-t} (f_{q-a} + f_{q-i})$

where:

- $C_{WT}$  : Load combination factor for wave torsional moment, to be taken as specified in Pt B, Ch 5, Sec 2, for the considered dynamic load case.
- $f_{ip}$  : Factor depending on the longitudinal position, as defined in Pt B, Ch 5, Sec 2

$f_{q-a}$ ,  $f_{q-f}$  : Distribution factors, as defined in Pt B, Ch 5, Sec 4, [3.4.1]

$M_{sw-t}$  : Permissible torsional still water moment in seagoing condition, as defined in [3.1.1].

#### 4.1.4 Torsional still water moment for direct calculations in harbour/sheltered water

For direct calculation analysis, the torsional still water moment in the harbour/sheltered water condition  $M_{sw-t-p}$ , in kN.m, is to be taken, at any longitudinal position, as follows:

$$M_{sw-t-p} = f_{ip} M_{sw-t-h} (f_{q-a} + f_{q-f})$$

where:

$f_{ip}$  : Factor depending on the longitudinal position, as defined in Pt B, Ch 5, Sec 2

$M_{sw-t-h}$  : Permissible torsional still water moment in harbour/sheltered water, as defined in [4.1.2]

$f_{q-a}$ ,  $f_{q-f}$  : Distribution factors, as defined in Pt B, Ch 5, Sec 4, [3.4.1].

## 4.2 Dynamic hull girder loads

### 4.2.1 Vertical wave bending moments for strength assessment

The vertical wave bending moments  $M_{wv-h}$  and  $M_{wv-s}$ , in kN.m, at any longitudinal position, are to be taken as:

- in hogging condition:

$$M_{wv-h} = 1,5 f_R f_S f_{nl-h} f_{m-h} H L^3 C_W f_{BL}^{0,8}$$

- in sagging condition:

$$M_{wv-s} = -1,5 f_R f_S f_{nl-s} f_{m-s} H L^3 C_W f_{BL}^{0,8}$$

where:

$f_R$  : Routing factor as defined in Pt B, Ch 5, Sec 3

$f_S$  : Speed effect coefficient as defined in Pt B, Ch 5, Sec 3

$f_{nl-h}$  : Coefficient considering non-linear effects applied to hogging, to be taken equal to:

$$f_{nl-h} = 1 + n \cdot \left( 0,3 \frac{C_B}{C_W} \sqrt{T_{SC}} - 1 \right)$$

without being taken greater than 1,1

$f_{nl-s}$  : Coefficient considering non-linear effects applied to sagging, to be taken equal to:

$$f_{nl-s} = 1 + n \cdot \left( 4,5 \frac{1 + 0,2 f_{Bow}}{C_W \sqrt{C_B}} L^{0,3} - 1 \right)$$

without being taken less than 1,0

$f_{Bow}$  : Bow flare shape coefficient, to be taken equal to:

$$f_{Bow} = \frac{A_{DK} - A_{WL}}{0,2 L Z_f}$$

$A_{DK}$  : Projected area to the horizontal plane of deck, in m<sup>2</sup>, including the forecastle deck, extending from 0,8 L forward (see Fig 10)

$A_{WL}$  : Waterplane area, in m<sup>2</sup>, at scantling draught  $T_{SC}$ , extending from 0,8 L forward

$f_{m-h}$  : Distribution factor for vertical wave bending moment in hogging condition along the ship's length, to be taken as follows (see Fig 8):

- $f_{m-h} = 0,0$  for  $x \leq 0$
- $f_{m-h} = 0,15$  for  $x = 0,1 L$
- $f_{m-h} = 1,00$  for  $0,35 L \leq x \leq 0,55 L$
- $f_{m-h} = 0,25$  for  $x = 0,8 L$
- $f_{m-h} = 0,0$  for  $x \geq L$

Intermediate values of  $f_{m-h}$  are to be obtained by linear interpolation

Figure 8 : Distribution factor  $f_{m-h}$

$f_{m-s}$  : Distribution factor for vertical wave bending moment in sagging condition along the ship's length, to be taken as follows (see Fig 9):

- $f_{m-s} = 0,0$  for  $x \leq 0$
- $f_{m-s} = 1,0$  for  $0,35 L \leq x \leq 0,6 L$
- $f_{m-s} = 0,0$  for  $x \geq L$

Intermediate values of  $f_{m-s}$  are to be obtained by linear interpolation

$z_f$  : Vertical distance, in m, from the waterline at scantling draught  $T_{sc}$  to the deck (or forecastle deck), measured at FE (see Fig 10)

$H$  : Wave parameter, as defined in Pt B, Ch 5, Sec 3, for a reference length  $L_{ref}$  calculated with:

$$\alpha = \frac{315}{486} \cdot \frac{1}{C_w^{1,3}}$$

$$f_\alpha = 1,0$$

Figure 9 : Distribution factor  $f_{m-s}$

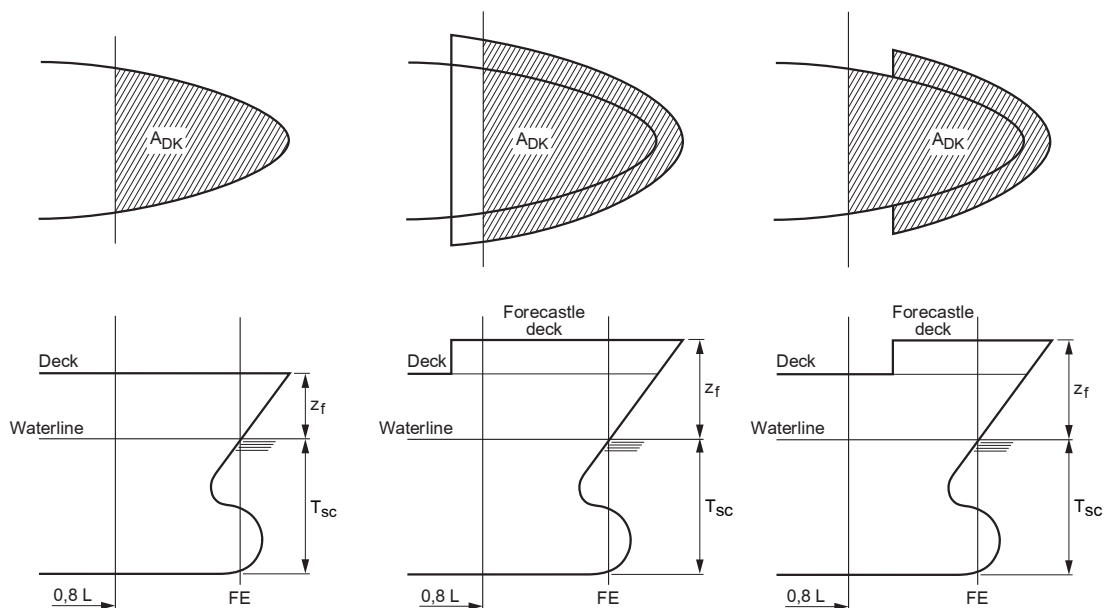

Figure 10 : Projected area  $A_{DK}$  and vertical distance  $z_f$

**4.2.2 Vertical wave shear forces for strength assessment**

The vertical wave shear forces  $Q_{wv-pos}$  and  $Q_{wv-neg}$ , in kN, at any longitudinal position, are to be taken as follows:

$$Q_{wv-pos} = f_R f_S f_{q-pos} H L^2 C_W f_{BL}^{0,8}$$

$$Q_{wv-neg} = - f_R f_S f_{q-neg} H L^2 C_W f_{BL}^{0,8}$$

where:

$f_R$  : Routing factor as defined in Pt B, Ch 5, Sec 3

$f_S$  : Speed effect coefficient as defined in Pt B, Ch 5, Sec 3

$f_{q-pos}$  : Distribution factor along the ship length for positive wave shear force, to be taken as (see Fig 11):

- $f_{q-pos} = 0,0$  for  $x \leq 0$
- $f_{q-pos} = 5,2 (0,3 + 0,7f_{nl-h})$  for  $0,15L \leq x \leq 0,3L$
- $f_{q-pos} = 4,0$  for  $0,4L \leq x \leq 0,55L$
- $f_{q-pos} = 5,7 (0,25 + 0,75f_{nl-s})$  for  $0,65L \leq x \leq 0,85L$
- $f_{q-pos} = 0,0$  for  $x \geq L$

Intermediate values of  $f_{q-pos}$  are to be obtained by linear interpolation

**Figure 11 : Distribution factor  $f_{q-pos}$**

$f_{q-neg}$  : Distribution factor along the ship length for negative wave shear force, to be taken as (see Fig 12):

- $f_{q-neg} = 1,3 (0,3 + 0,7f_{nl-s})$  for  $x \leq 0$
- $f_{q-neg} = 5,2 (0,3 + 0,7f_{nl-s})$  for  $0,15L \leq x \leq 0,3L$
- $f_{q-neg} = 4,0$  for  $0,4L \leq x \leq 0,50L$
- $f_{q-neg} = 5,7 f_{nl-h}$  for  $0,6L \leq x \leq 0,75L$
- $f_{q-neg} = 0,0$  for  $x \geq L$

Intermediate values of  $f_{q-neg}$  are to be obtained by linear interpolation

**Figure 12 : Distribution factor  $f_{q-neg}$**

$f_{nl-h}$ ,  $f_{nl-s}$  : Coefficients considering non-linear effects and defined in [4.2.1]

H : Wave parameter, as defined in Pt B, Ch 5, Sec 3, for a reference length  $L_{ref}$  calculated with:

$$\alpha = \frac{330}{486} \cdot \frac{1}{C_W^{1,3}}$$

$$f_\alpha = 1,0$$

## 5 Load combinations for direct strength analysis based on partial three-dimensional model

### 5.1 General

5.1.1 The loading conditions to be considered for three-dimensional analysis are given in:

- [5.3] for strength check of cargo holds
- [5.4] for strength check of fuel oil tanks when deep fuel oil tanks are located in the cargo hold area.

These loading conditions may be adjusted if deemed relevant by the Society.

5.1.2 The load cases to be considered for three-dimensional analysis are given in [5.5].

### 5.2 Container weight

#### 5.2.1 Maximum number of tiers

It corresponds to the maximum number of tiers on deck and in hold as provided on the container stowage plan.

On a case-by-case basis, for tiers on deck, the maximum number of tiers as provided among all the loading conditions as described in the loading manual might be used, upon agreement by the Society.

#### 5.2.2 Permissible stack weight

The permissible stack weights in hold and on deck, for 20' and 40' containers as referred to in [5.2.3] to [5.2.6], are to be defined in the loading manual and on the midship section, as required in [1.2.2].

#### 5.2.3 Heavy cargo in hold

a) 40' containers

Heavy cargo weight of 40' containers in hold is to be calculated as the permissible stack weight, as defined in [5.2.2], divided by the maximum number of tiers, as defined in [5.2.1].

Note 1: At preliminary stage when the permissible stack weight is not available, the heavy cargo weight of 40' containers in hold may be taken equal to 30,5 T.

b) 20' containers

Heavy cargo weight of 20' containers in hold is to be calculated as the permissible stack weight, as defined in [5.2.2], divided by the maximum number of tiers, as defined in [5.2.1].

A specific value of uniform permissible stack weight of 20' containers might be specified in loading manual and midship section, used for FE calculation. This value should be at least equal to the maximum stack weight of 20' container stacks provided among the different loading conditions of the loading manual.

#### 5.2.4 Heavy cargo on deck

a) 40' containers

Heavy cargo weight of 40' containers on deck is to be calculated as the permissible stack weight, as defined in [5.2.2], divided by the maximum number of tiers, as defined in [5.2.1].

b) 20' containers

Heavy cargo weight of 20' containers on deck is to be calculated as the permissible stack weight, as defined in [5.2.2], divided by the maximum number of tiers, as defined in [5.2.1].

#### 5.2.5 Light cargo in hold

a) 40' containers

Light cargo weight of 40' containers in hold is to be taken as 55% of its related heavy cargo weight, as defined in [5.2.3], not exceeding 16,5 T per container.

b) 20' containers

Light cargo weight of 20' containers in hold is to be taken as the minimum stack weight in holds, selected among homogeneous conditions provided in the loading manual considering the holds filled up to the top, divided by the maximum number of tiers as defined in [5.2.1], without exceeding 8 T per container.

#### 5.2.6 Light cargo on deck

Light cargo weight of 40' containers on deck is to be taken equal to 90% of its related heavy cargo weight, without exceeding 17 T per container.

### 5.3 Loading conditions for cargo holds strength check

5.3.1 The loading conditions to be considered for cargo hold strength check are given in [5.3.4] to [5.3.8] and are summarized in Tab 3.

Table 3 : Loading conditions for cargo hold strength check

Loading condition	Description	Loading pattern	Container loading (1)	Draught	SWBM	SWSF
BL-1	Ballast		Not loaded	$T_{BAL}$	from LM	$Q_{sw}$
HH	Homogeneous (heavy)		Heavy cargo 40'	$T_{SC}$	$M_{sw-max}$	$Q_{sw}$
HL	Homogeneous (light)		Light cargo 40'	$T_{SC}$	$M_{sw-max}$	$Q_{sw}$
HR	Homogeneous (reduced draught)		Heavy cargo 20' If mixed stowage on deck is applicable: Max 20' and 40' stack weight	$\leq 0,9T_{SC}$	$M_{sw-min}$	$Q_{sw}$
DL	Maximum deck load		Heavy cargo 20' on deck If mixed stowage on deck is applicable: Max 20, and 40' stack weight. Light cargo 20' in hold	$0,9 T_{SC}$	$M_{sw-min} (2)$	$Q_{sw}$
OB-1	One bay empty		Heavy cargo 40' One bay empty in hold and on deck (3)	$T_{SC}$	$M_{sw-max}$	$Q_{sw}$
FD	Flooding		Heavy cargo 40' Any cargo hold flooded	$T_{FL}$	-	-

(1) Container weights are defined in [5.2]. Each stack is to be loaded with the maximum number of tiers, as defined in [5.2.1].  
 (2) The minimum vertical still water bending moment taken from all the homogeneous loading conditions in the loading manual may be used.  
 (3) A minimum list of loading patterns is defined in Tab 4.

5.3.2 For the loading conditions given in [5.3.5] to [5.3.8], all ballast and fuel oil tanks in way of cargo hold model are to be empty.

5.3.3 If deemed necessary by the Society, specific static harbour conditions may have to be considered in addition to the loading conditions given in [5.3.4] to [5.3.8], using permissible hull girder loads for harbour conditions.

5.3.4 Ballast loading condition

Ballast 1 (BL-1):

- all cargo holds to be empty, ballast tanks to be full
- the draught value is to be taken as the minimum ballast draught provided in the loading manual (LM) and the still water bending moment is to be taken from the same condition.

5.3.5 Homogeneous loading conditions

Homogeneous heavy (HH):

- homogeneous 40' containers loaded on deck and in holds
- heavy cargo weight of 40' containers is to be considered as defined in [5.2.3] and [5.2.4]
- scantling draught is to be considered together with the maximum design still water bending moment in hogging.

Homogeneous light (HL):

- homogeneous 40' containers loaded on deck and in holds
- light cargo weight of 40' containers is to be considered as defined in [5.2.5] and [5.2.6]
- scantling draught is to be considered together with the maximum design still water bending moment in hogging.

Homogeneous reduced draught (HR):

- homogeneous 20' containers loaded on deck and in holds. Reduced draught is to be considered together with the minimum design still water bending moment
- reduced draught corresponds to the expected draught amidships when heavy cargo is loaded in the considered holds while lighter cargo is loaded in the other holds.  
Reduced draught is not to be taken more than 90% of the scantling draught
- heavy cargo weight of 20' containers is to be considered as defined in [5.2.3].

**5.3.6 Maximum deck load loading condition**

Maximum deck load (DL):

- maximum stack load of 20' containers on deck and minimum stack load of 20' containers in holds
- light cargo weight of 20' containers in hold is to be taken as defined in [5.2.5]
- heavy cargo weight of 20' containers on deck is to be taken as defined in [5.2.3]
- scantling draught is to be considered together with the minimum still water bending moment, selected among all homogeneous loading conditions described in the loading manual.

**5.3.7 One bay empty loading condition**

One bay empty 1 (OB-1):

- homogeneous loading is to be considered similarly to HH, as defined in [5.3.5], except one bay to be kept empty in hold and on deck. A minimum list of loading patterns is defined in Tab 4
- scantling draught is to be considered together with the maximum design still water bending moment in hogging.

**Table 4 : One bay empty loading condition**

Container ship arrangement		Bays to be considered as being empty
Design	Number of bays per hold	
Twin islands	2	Bay located immediately aft of the fore island
		One of the two bays of the second cargo hold aft of the fore island
	3	Bay located immediately aft of the fore island
		Two forward bays in the second cargo hold aft of the fore island <b>(1)</b>
Single island	2	One bay among those located within 0,3 L to 0,7 L
	3	One bay among those located within 0,3 L to 0,7 L and adjacent to a watertight bulkhead
		One bay among those located within 0,3 L to 0,7 L, in the middle of the hold
<b>(1)</b> Two different loading conditions are to be checked, each of them with one of the bays to be considered empty.		

**5.3.8 Flooding**

Flooding (FD):

- homogeneous loading is to be considered similarly to HH, as defined in [5.3.5]. Dynamic loads and hull girder loads are disregarded
- draught  $T_{FL}$  is to be considered up to the deepest equilibrium waterline in damaged condition (obtained from applicable damage stability calculations). If this information is not available at design stage, the draught might be considered up to the freeboard deck. It is to be checked at a later stage that the deepest equilibrium waterline remains below the freeboard deck
- the structural analysis is only carried out on the transverse watertight bulkheads.

**5.4 Loading conditions for fuel oil tanks**

**5.4.1** The loading conditions to be considered for fuel oil tank strength check are given in [5.4.3] to [5.4.6] and are summarized in Tab 5.

**5.4.2** The actual density of the fuel oil is to be used in the calculation.

If any deckhouse or superstructure is fitted above the fuel oil tanks, inertial loads induced by such structures are to be modelled.

**Table 5 : Loading conditions for fuel oil tanks strength check**

Loading condition	Description	Container loading (1)	FOT loading	Draught	SWBM	SWSF
BL-2	Ballast	Not loaded	Full	$T_{BAL}$	from LM	$Q_{sw}$
BL-3			Alternate			
SL-1	Maximum stack load	Heavy cargo 40'	Empty	$T_{SC}$	$M_{sw-min}$	$Q_{sw}$
SL-2			Alternate			
OB-2	One bay empty	Heavy cargo 40' One bay adjacent to HFO empty (2)	Empty	$T_{SC}$	$M_{sw-max}$	$Q_{sw}$
OB-3			Alternate			
OB-4			Full	$T_L (3)$	$M_{sw-min}$	
OB-5			Alternate			
TS	Testing	Not loaded	Testing	$T_{BAL}$	from LM	$Q_{sw}$

(1) Container weights are defined in [5.2]. Each stack is to be loaded with the maximum number of tiers as defined in [5.2.1].  
 (2) If the arrangement and scantling of the bays forward and aft of the FOT are symmetrical, either bay is to be empty and the other to be full. Otherwise, both conditions are to be considered.  
 (3) The lightest load draught taken from the loading manual.

**5.4.3 Normal ballast loading conditions**

Ballast 2 (BL-2):

- cargo holds are to be empty. All fuel oil tanks are to be fully loaded
- the draught is to be taken as the minimum ballast draught provided in the loading manual.

Ballast 3 (BL-3):

- cargo holds are to be empty. Fuel oil tanks are to be loaded alternately
- the draught is to be taken as the minimum ballast draught provided in the loading manual.

**5.4.4 Maximum stack load loading conditions**

Maximum stack load 1 (SL-1):

- cargo holds are to be loaded as per HH condition described in [5.3.5]. Fuel oil tanks are to be empty
- scantling draught is to be considered together with the minimum still water bending moment, selected among all homogeneous loading conditions described in the loading manual.

Maximum stack load 2 (SL-2):

- cargo holds are to be loaded as per HH condition described in [5.3.5]. Fuel oil tanks are to be loaded alternately through ship's breadth
- Scantling draught is to be considered together with the minimum still water bending moment, selected among all homogeneous loading conditions described in the loading manual.

**5.4.5 One bay empty loading conditions**

One bay empty 2 (OB-2):

- cargo holds are to be loaded as per HH condition described in [5.3.5] except one bay adjacent to the fuel oil tanks to be kept empty. Fuel oil tanks are to be empty
- scantling draught is to be considered together with the maximum design still water bending moment in hogging.

One bay empty 3 (OB-3):

- cargo holds are to be loaded as per HH condition described in [5.3.5] except one bay adjacent to the fuel oil tanks to be kept empty. Fuel oil tanks are to be loaded alternately
- scantling draught is to be considered together with the maximum design still water bending moment in hogging.

One bay empty 4 (OB-4):

- cargo holds are to be loaded as per HH condition described in [5.3.5] except one bay adjacent to the fuel oil tanks to be kept empty. All fuel oil tanks are to be fully loaded
- the draught is to be taken as the lightest load draught provided in loading manual.

One bay empty 5 (OB-5):

- cargo holds are to be loaded as per HH condition described in [5.3.5] except one bay adjacent to the fuel oil tanks to be kept empty. Fuel oil tanks are to be loaded alternately
- the draught is to be taken as the lightest load draught provided in loading manual, without being taken greater than 0,75 D.

**5.4.6 Testing loading conditions**

Testing (TS):

- fuel oil tank testing condition is to be checked considering the test pressure as defined for deep tanks in Pt B, Ch 5, Sec 6, [10]. No dynamic pressure is to be considered. Each tank is to be filled separately
- the draught is to be taken as the minimum ballast draught from the loading manual, and the still water bending moment is to be taken from the same condition.

**5.5 Load cases**

**5.5.1** To obtain the FE load combinations as defined in Pt B, Ch 8, App 1, [3], each loading condition is to be associated with all dynamic load cases as given in Pt B, Ch 5, Sec 2, [2] except the BP load cases.

**6 Load combinations for direct strength analysis based on full length model**

**6.1 Loading condition**

**6.1.1** A single loading condition complying with the following criteria is to be selected from the loading manual:

- the resulting draught is equal to the scantling draught, as far as practicable
- the resulting still water bending moment is at least equal to 95% of the maximum permissible still water bending moment ( $M_{sw-max}$ )
- the ship is homogeneously loaded, as far as practicable
- the cargo holds are loaded up to their top, as far as practicable
- the minimum ballast water is carried.

**6.1.2** The full length model is generally to be loaded with 40' containers; 20' containers might be used to fill holds that cannot be entirely filled in with 40' containers.

The selection criteria for the loading condition generally leads to a nominal container weight of 28 t / FEU (14 t / TEU). Any significant deviation to this value shall be discussed with the Society.

Note 1:

TEU : Twenty-foot Equivalent Unit, used to define a standard container of 20 feet in length

FEU : Forty-foot Equivalent Unit, used to define a standard container of 40 feet in length

**6.2 Load cases**

**6.2.1 Load case definition**

The wave heading  $\beta$ , in deg, which maximises each dominant load effect is specified in Tab 6.

The peak period  $T_p$ , in s, which maximises each dominant load effect is to be taken as:

$$T_p = (T_0)^{0.5} \left( \frac{2\pi L_c}{g} \right)^{0.25}$$

where:

$T_0$  : Wave period providing the maximum RAO, in s, to be taken as:

$$T_0 = 2,2 \left( \frac{L}{\alpha g} \right)^{0.5}$$

$L_c$  : Length, in m, as defined in Pt B, Ch 5, Sec 3

$\alpha$  : Parameter for the considered load case, as defined in Tab 6.

**6.2.2 Design value of dominant load effect**

The design values of dominant load effects are specified in Tab 6.

When deemed relevant by the Society, the design values may be derived on the basis of a direct long-term linear seakeeping analysis. The long-term value for vertical bending moment is to be corrected for Froude-Krylov non-linearities. Long-term values are to be derived for a return period of 25 years, considering a North-Atlantic scatter diagram. The routing factor as defined in Pt B, Ch 5, Sec 3 is also to be considered.

**6.2.3 Combined load effects**

When the design value of the dominant load effect is not based on the rule value, the heading and amplitude of waves is to be selected such that the amplitude of the other combined load effects is not to exceed their rule reference value multiplied by a factor  $C_{max}$  given in Tab 7.

**Table 6 : Load cases definition**

Load case	EDW (1)	Dominant load effect	Location	Wave heading $\beta$ (2)	$\alpha$	Reference of design value D
1	HVM	Vertical wave bending moment $M_{wv-h}$ or $M_{wv-s}$	Midship section	180°	$0,65 C_{W-LC}^{-1,3}$	$M_{wv-h}$ and $M_{wv-s}$ defined in [4.2.1]
2	FVM	Vertical wave bending moment $M_{wv-h}$ or $M_{wv-s}$	Vicinity of 0,25L	0°	$0,65 C_{W-LC}^{-1,3}$	
3	BR	Roll motion $\theta$	Midship section	90°	$4,60 T_R^{-2}$	$\theta$ defined in Pt B, Ch 5, Sec 3, [2.1.1]
4	BP	Wave pressure at the waterline $P_W$	Midship section	90°	$0,55 f_{TL}^{-0,4}$	$P_W$ defined in Pt B, Ch 5, Sec 5, [1.3.1] for BP
5	OHM	Horizontal wave bending moment $M_{wh}$	Midship section	120°	$0,65 f_{TL}^{-0,3}$	$M_{wh}$ defined in Pt B, Ch 5, Sec 4, [3.3]
6	OHS	Horizontal wave shear force $Q_{wh}$ and torsion $M_{wt}$	Vicinity of 0,75L	60°	$0,68 f_{TL}^{-0,3}$	$Q_{wh}$ defined in Pt B, Ch 5, Sec 4, [3.4] $M_{wt}$ defined in Pt B, Ch 5, Sec 4, [3.5]
7	OVA	Vertical acceleration $a_z$	Vicinity of L	120°	$0,24 f_{BL}^{-0,8}$	$a_z$ defined in Pt B, Ch 5, Sec 3, [3.2.4]

(1) Equivalent Design Wave as defined in Pt B, Ch 5, Sec 2

(2) The forward ship speed is to be taken equal to 5 knots

**Note 1:**

$C_{W-LC}$  : Waterplane coefficient at considered loading condition draught  $T_{LC}$

$T_R$  : Dimensionless roll period as defined in Pt B, Ch 5, Sec 2

$f_{TL}$  : Ratio between draught at the considered loading condition and rule length as defined in Pt B, Ch 5, Sec 3

$f_{BL}$  : Ratio between moulded breadth and rule length as defined in Pt B, Ch 5, Sec 3

**Table 7 : Values of factor  $C_{max}$**

Load component	$C_{max}$
Wave bending moments and wave torque	1,10
Wave shear forces	1,40
Roll angle, vertical and horizontal accelerations	1,10
Wave pressure	1,20

## 7 Hull girder strength assessment

### 7.1 Section modulus and moment of inertia

#### 7.1.1 Minimum net moment of inertia

For both hogging and sagging conditions, the net moment of inertia  $I_{y-n50}$ , in  $m^4$ , of the hull transverse section is to be not less than  $I_{y-min}$ , obtained from the following formula:

$$I_{y-min} = 1,55 L |M_{sw} + M_{wv}| 10^{-7}$$

7.1.2 Within the longitudinal extend as defined in Pt B, Ch 6, Sec 1, [3.2.1], the scantlings of all continuous longitudinal members are to be maintained based on the modulus requirement at the midship.

## 8 Cargo hold structural strength analysis

### 8.1 General

8.1.1 As an alternative to Pt B, Ch 8, App 1, [1.1.3], the extent of the cargo hold structural analysis may be limited to the midship area at the discretion of the Society.

## 9 Local structural strength analysis

### 9.1 Screening criteria

9.1.1 The screening criteria, as defined in Pt B, Ch 8, App 2, [1.2.3], is to be checked with a screening factor  $\lambda_{sc}$  and a permissible screening factor  $\lambda_{scperm}$  defined in Tab 8

**Table 8 : Screening factors and permissible screening factors**

Type of details	Screening factors $\lambda_{sc}$	Permissible screening factors $\lambda_{scperm}$	
		AC-2 (1)	AC-1 (1)
Bracket toes of primary supporting members	Tab 9	1,50	1,20
Connection of stringers and double bottom girders with transverse bulkheads	$2,00 \lambda_y$	1,50	1,20
Hatch corner area	$\lambda_y$	0,95 $\lambda_{yperm}$	

(1) See Pt B, Ch 8, Sec 1, [4] for acceptance criteria definition.

**Note 1:**  
 $\lambda_y$  : Standard mesh yield utilisation factor, as defined in Pt B, Ch 8, App 1, [5.2.3]  
 $\lambda_{yperm}$  : Standard mesh permissible yield utilisation factor, as defined in Pt B, Ch 8, App 1, [5.2.3].

**Table 9 : Screening factor for bracket toes of primary supporting members**

$\lambda_{sc}$  : Screening factor taken as:

$$\lambda_{sc} = C_a \left[ 0,68 \sqrt{\frac{b_2}{b_1}} \sigma_{vm} + 0,50 \sqrt{\frac{A_{beam-n50}}{b_1 t_{n50}}} \cdot |\sigma_{beam}| \right] \frac{k}{235}$$

$C_a$  : Coefficient taken as:

$$C_a = 1,0 - 0,2 \left( \frac{R_a}{1400} \right)^2$$

$b_1, b_2$  : Heights of shell element in way of bracket toe in cargo hold FE model, in mm  
 $A_{beam-n50}$  : Sectional area of beam or rod element in cargo hold FE model representing the face plate of bracket, in mm<sup>2</sup>  
 $\sigma_{beam}$  : Beam or rod element axial stress determined from cargo hold FE analysis, in N/mm<sup>2</sup>  
 $\sigma_{vm}$  : Von Mises stress of shell element in way of bracket toe determined from cargo hold FE analysis, in N/mm<sup>2</sup>  
 $t_{n50}$  : Net thickness of shell element in way of bracket toe, in mm  
 $R_a$  : Leg length, in mm, not to be taken greater than 1400 mm.

## 10 Buckling

### 10.1 Load cases

10.1.1 HVM and FVM load cases are replaced by S11A1 and S11A2 head sea load cases, where all load components are to be applied simultaneously with the hull girder still water load values as defined in Tab 10 and the load combination factors (LCF) for the hull girder wave loads and accelerations as defined in Tab 11.

**Table 10 : Hull girder still water loads for buckling strength assessment**

Load component	S11A1		S11A2		
	Hogging	Sagging	Hogging	Sagging	
Hull girder still water loads	$M_{sw}$	$M_{sw-max}$	$M_{sw-min}$	$0,7 M_{sw-max}$	$0,7 M_{sw-min}$
	$Q_{sw}$	$0,7 Q_{hog}$	$0,7 Q_{sag}$	$Q_{hog}$	$Q_{sag}$
	$M_{sw-t}$	0	0	0	0

**Note 1:**

- For  $x/L \leq 0,5$  :  $Q_{hog} = Q_{sw-max}$  and  $Q_{sag} = Q_{sw-min}$
- For  $x/L > 0,5$  :  $Q_{hog} = Q_{sw-min}$  and  $Q_{sag} = Q_{sw-max}$

**Table 11 : Load combination factors for buckling strength assessment**

Load component		LCF	S11A1		S11A2	
			Hogging	Sagging	Hogging	Sagging
Hull girder wave loads	$M_{wv}$	$C_{wv}$	1,0	-1,0	0,7	-0,7
	$Q_{wv}$	$C_{Qv}$	$0,7 f_{lq}$	$-0,7 f_{lq}$	$f_{lq}$	$-f_{lq}$
	$M_{wh}$	$C_{wh}$	0	0	0	0
	$Q_{wh}$	$C_{QH}$	0	0	0	0
	$M_{wt}$	$C_{wt}$	0	0	0	0
Longitudinal accelerations	$a_{surge}$	$C_{XS}$	$10 f_{TL} - 0,60$	$0,60 - 10 f_{TL}$	$10 f_{TL} - 0,60$	$0,60 - 10 f_{TL}$
	$a_{pitch-x}$	$C_{XP}$	0,38	-0,38	0,38	-0,38
	$a_{yaw-x}$	$C_{XY}$	0	0	0	0
	$g \sin\phi$	$C_{XG}$	-0,36	0,36	-0,36	0,36
Transverse accelerations	$a_{sway}$	$C_{YS}$	0	0	0	0
	$a_{roll-y}$	$C_{YR}$	0	0	0	0
	$a_{yaw-y}$	$C_{YY}$	0	0	0	0
	$g \sin\theta$	$C_{YG}$	0	0	0	0
Vertical accelerations	$a_{heave}$	$C_{ZH}$	$-0,10 - 5,70 f_{TL}$	$0,10 + 5,70 f_{TL}$	$-0,10 - 5,70 f_{TL}$	$0,10 + 5,70 f_{TL}$
	$a_{roll-z}$	$C_{ZR}$	0	0	0	0
	$a_{pitch-z}$	$C_{ZP}$	0,38	-0,38	0,38	-0,38
<p><b>Note 1:</b>  <math>f_{lq} = 1</math> for <math>x/L \leq 0,5</math> and <math>f_{lq} = -1</math> for <math>x/L &gt; 0,5</math>  <math>f_{TL}</math> : Ratio between draught at the considered loading condition and rule length, to be taken as <math>f_{TL} = T_{LC} / L</math>  <math>T_{LC}</math> : Draught amidships, in m, at the considered loading condition</p>						

## 11 Fatigue

### 11.1 Corrosion model

11.1.1 The following values of stress correction factor as defined in NI611 are to be considered:

- a) for analytical approach for longitudinal stiffeners:
  - $f_{c-a} = 0,95$
  - $f_{c-b} = 1,0$
- b) for FEA calculations:
  - $f_{c-FEA} = 1,0$

### 11.2 Design loading condition for fatigue assessment

11.2.1 A single loading condition at  $0,85 T_{SC}$  is to be considered for fatigue analysis.

When a finite element analysis is requested, the design fatigue loading condition is to be selected according to the criteria defined in [6.1], in particular with respect to the minimum value for still water bending moment, except for the resulting draught to be taken equal to  $0,85 T_{SC}$ . Loading conditions based on deeper draught may also be accepted.

11.2.2 For spectral fatigue analysis a second loading condition may be requested if deemed necessary. This loading condition takes into account the effect of specific local loads, typically for large fuel tanks (oil or gas).

This second loading condition is to be taken similar to the one described in [11.2.1], with only an adjustment on the local loads as necessary.

When a second loading condition is considered, the contribution to the global damage of each loading condition is to be adjusted as relevant.

## 12 Fixed cell guides

### 12.1 General

12.1.1 Containers may be secured within fixed cell guides, permanently connected by welding to the hull structure, which prevent horizontal sliding and tipping.

**12.1.2** When containers are secured by fixed cell guides, the scantlings of such cell guides and supports are to comply with the criteria in [12.2] and [12.3].

**12.2 Arrangement of fixed cell guides**

**12.2.1** Vertical guides generally consist of sections with equal sides, not less than 12 mm in thickness, extended over a height sufficient to give uniform support to containers.

**12.2.2** Guides are to be connected to each other and to the supporting structures of the hull by means of cross-ties and longitudinal members such as to prevent deformation due to the action of the forces transmitted by containers.

In general, the spacing between cross-ties connecting the guides may not exceed 5 metres and their position is to coincide as nearly as possible with that of the container corners (see Fig 13).

Cross-ties are to be longitudinally restrained at one or more points so that their elastic deformation due to the action of the longitudinal thrust of containers does not exceed 20 mm at any point.

**12.2.3** The upper end of the guides is to be fitted with a block to facilitate entry of the containers. Such appliance is to be of robust construction so as to withstand impact and chafing.

**Figure 13 : Typical structure of cell guides**

**12.3 Strength criteria**

**12.3.1** The local stresses in the elements of cell guides, transverse and longitudinal cross-ties, and connections with the hull structure are to be less than the following values:

- normal stress:  $150/k \text{ N/mm}^2$
- shear stress:  $100/k \text{ N/mm}^2$
- Von Mises equivalent stress:  $175/k \text{ N/mm}^2$ ,

where:

k : Material factor, defined in Pt B, Ch 4, Sec 1, [2.2].

**13 Lashing bridge**

**13.1 General**

**13.1.1 Container securing**

Containers on deck may be secured by means of lashing bridges permanently connected by welding to the ship structure. Lashing bridges allow lashing at a higher level.

**13.1.2 Material**

Materials used are to comply with Pt B, Ch 4, Sec 1. The manufacturing processes and testing are to comply with the applicable requirements of NR216 Materials and Welding.

**13.1.3 Strength verification**

Drawings of the lashing bridge structure and details of the supporting structure are to be submitted to the Society for approval together with details on the calculations carried out.

**13.1.4 Structural modelling**

Calculations are to be based at least on three-dimensional beam analysis or on finite element analysis.

A finite element model is to be used in all cases where a beam model is deemed insufficient, in particular when vertical plain bulkheads are fitted.

A finite element model is to be built in accordance with relevant requirements from Pt B, Ch 8, App 1, [2.3] and Pt B, Ch 8, App 1, [2.4].

The finite element mesh size is to be adjusted in accordance with Pt B, Ch 8, App 1, [2.4.3] in order to properly model the displacements and resulting stresses in the lashing bridge structure. At least 3 elements are to be used along the width of horizontal deck strips and vertical webs (sizes from 200 mm by 200 mm to 250 mm by 250 mm are generally adequate mesh sizes).

Adjacent ship structure is to be included in the model, vertically down to the second deck level and horizontally up to one web frame fore and aft of the transverse bulkhead.

Recommended boundary conditions are given in Tab 12.

Calculations are to be based on gross scantlings.

The connection of the lashing equipment to the lashing bridge is to be located in way of high stiffness structure. The Society may require a detailed finite element analysis in case of lashing equipment attached to a structure with limited stiffness.

**Table 12 : Boundary conditions for FE model of lashing bridge**

Location	Translation			Rotation		
	$\delta_x$	$\delta_y$	$\delta_z$	$\theta_x$	$\theta_y$	$\theta_z$
End of the model (e.g. top part of the hull, from second deck to hatch coaming)	fix	–	–	–	fix	fix
Elements linked to continuous vertical plating (e.g. linked to vertical frames of a bulkhead or to the inner hull and side shell)	–	fix	fix	–	–	–

**Note 1:** [–] means no constraint applied (free).

**13.1.5 Arrangement**

Overall stiffness of the lashing bridge is to be sufficient to sustain the lashing loads. Stiffness reinforcement such as shear plates or diagonal bars are recommended below the level where the lashing rods can be attached.

Structural continuity is to be ensured at the connections of the vertical supports of the lashing bridge to the ship structure.

**13.2 Design load**

**13.2.1 Forces applied on lashing bridge**

The lashing bridge is to be loaded by forces corresponding to 70% of the SWL (Safe Working Load) of the container lashing equipment, taken as 250 kN.

The forces defined in Tab 13 are to be applied to lashing eyes loaded by a lashing device in maximum tension, with an assumed displacement of the stacks towards portside.

A lashing device in external or internal lashing is considered in maximum tension when the device restrains both the container racking and lifting (see Fig 14).

**Table 13 : Forces towards portside**

Longitudinal direction	Transverse direction	Upward
20 kN (fore bay) -20 kN (aft bay)	119 kN	126 kN

**Figure 14 : Loaded lashing eye**

### 13.2.2 Loading conditions

The following loading conditions are to be considered for the calculation of lashing bridges:

- a) both fore and aft bays of the lashing bridge are loaded with containers
- b) fore bay of the lashing bridge is loaded with containers while the aft bay is empty
- c) aft bay of the lashing bridge is loaded with containers while the fore bay is empty.

Loading condition a) is intended to maximize vertical and transverse forces acting on the lashing bridge. Loading conditions b) and c) are intended to maximize the longitudinal forces acting on the lashing bridge.

## 13.3 Strength assessment

### 13.3.1 Allowable stress

Allowable stresses for the design loads as defined in [13.2]] are to be in accordance with:

- Pt B, Ch 7, Sec 6, [5.1.4] for beam analysis
- Pt B, Ch 8, App 1, [5.2.3] or Pt B, Ch 8, App 2, [4.1.3] for finite element analysis.

### 13.3.2 Lashing bridge stiffness

In order to sustain the loads transmitted by the lashing devices and to have enough rigidity with limited deformations, the lashing bridge stiffness is to be assessed.

The displacement in the transverse direction at each lashing level  $i$  of the lashing bridge is to satisfy the following criteria:

$$(d_{\text{trans},i} - d_{\text{bot}}) \leq 1,85 h_i$$

where:

$i$  : Lashing level depending on the vertical location of attachment of the lashing device to the lashing bridge. The level of reference (level 0) is defined as the lowest level where it is possible to attach the lashing devices over the full width of the lashing bridge (see Pt F, Ch 12, Sec 5)

$d_{\text{trans},i}$  : Average transverse displacement, in mm, of the lashing eyes for the considered lashing level  $i$

$d_{\text{bot}}$  : Average transverse displacement, in mm, of the lashing bridge at the bottom of the stack

$h_i$  : Average height, in m, of the lashing eyes with regard to the bottom of the stack, for the considered lashing level  $i$

When the lashing bridge is not compliant with the above criteria, standard values for the effective stiffness factors of lashing devices as defined in Pt F, Ch 12, Sec 5, are to be replaced by values obtained with direct calculations.

## 14 Lashing items

### 14.1 Fixed cargo securing devices

14.1.1 A list and/or a plan of all the fixed securing devices, indicating their location on board, is to be provided.

14.1.2 For each type of fixed securing device, the following information is to be provided:

- identification of the device (name and model type)
- sketch of the device and material quality
- value of Safe Working Load (also named Maximum Securing Load)
- value of the minimum breaking load.

14.1.3 The deck stanchions are to be checked according to the criteria for pillars defined in Pt B, Ch 7, Sec 6, [2.6] with design loads submitted by the manufacturer.

### 14.2 Lashing software

14.2.1 If installed on board a ship, a lashing software is to be approved, following the provisions of Pt F, Ch 12, Sec 5.

## Section 3 Machinery and Systems

### 1 Open-top container ships

#### 1.1

1.1.1 Open-top container ships are to comply with the requirements of Pt F, Ch 12, Sec 6.

# Section 1                      General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **livestock carrier**, as defined in Pt A, Ch 1, Sec 2, [4.2.6].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

### 1.2 Summary table

**1.2.1** Requirements applicable to ships having the service notation **livestock carrier** are summarized in Tab 1.

**Table 1 : Applicable requirements**

### 1 General

#### 1.1 Documents to be submitted

1.1.1 In addition to the documentation requested in Part B, the following documents are to be submitted for information:

- livestock arrangement
- distribution of fodder and consumable liquid on the various decks and platforms.

### 2 General arrangement

#### 2.1 Livestock arrangement

2.1.1 The livestock are to be kept in pens. The dimensions of these pens are to be suitable for the livestock carried. In general, the breadth and the length of the pen may not be greater than 4,5 m and 9 m, respectively.

The livestock may not be carried on hatch covers unless the latter are effectively protected.

#### 2.2 Arrangement of spaces dedicated to the carriage of livestock

##### 2.2.1 General

The requirements of this item apply to the arrangement of the spaces dedicated to the carriage of livestock. When deemed necessary by the Society, such spaces may need to be adapted or complemented depending on the species of animals which are to be carried.

##### 2.2.2 Protection of livestock

Arrangements for protecting the livestock from injury, avoidable suffering and exposure to weather, sea or hot parts are to be provided.

##### 2.2.3 Livestock arrangement

Livestock may not be carried, or loaded for carriage, in any part of a ship where the livestock, livestock fittings, livestock equipment or carrying arrangements may:

- obstruct access to any accommodation space or working space necessary for the safe running of the ship, or the means of egress from any hold or under deck space
- interfere with life-saving or fire-fighting appliances
- interfere with the tank sounding equipment or bilge pumping
- interfere with the operation of closing appliances
- interfere with the operation of freeing ports
- interfere with the lighting or ventilation of other parts of the ships
- interfere with the proper navigation of the ship.

#### 2.3 Means of escape and access

##### 2.3.1 General

In each space in which livestock is carried, not less than two means of escape for persons are to be fitted, widely separated and giving access to an open deck.

Access to livestock space for persons is to be safe. Where it is combined with a ramp used for moving livestock between decks, it is to be separated from the livestock ramp by protective fencing.

##### 2.3.2 Closing arrangement

Pens, stalls and similar fittings are to be provided with a means of access for persons with secure closing arrangement which structural strength is to be considered by the Society on a case-by-case basis.

##### 2.3.3 Passageway width

If access between a ship side and a pen, stall or similar fitting is required for purposes of safe and proper operation of ship, a passageway not less than 550 mm wide is to be provided between the ship's rail or bulwark and the rails or receptacles of the pen, stall or fitting.

### 3 Stability

#### 3.1 Intact stability

##### 3.1.1 General

The stability of the ship for the loading conditions reported in the trim and stability booklet is to be in compliance with the requirements of Pt B, Ch 3, Sec 2.

##### 3.1.2 Additional requirements

Where national or international rules apply, the Society reserves the right to adopt the rules in force in the country in which the ship is registered or in which the ship trades.

### 4 Design loads

#### 4.1 Local loads

##### 4.1.1 Cargo deck

The static pressure  $P_{dl-sr}$ , in kN/m<sup>2</sup>, due to livestock on decks to be considered for the assessment of plating and stiffeners is to be defined by the Designer.

When no value is specified, the following may be considered:

- 15 kN/m<sup>2</sup> for cattle, horses and camels
- 8 kN/m<sup>2</sup> for sheep, goats and pigs.

For the assessment of primary supporting members,  $P_{dl-s}$  is to be taken equal to 0,3 times the value defined above for plating and stiffeners.

#### 4.2 Load combinations for direct strength analysis

##### 4.2.1 Loading condition

One loading condition is to be selected among those presented in the loading manual considering the following criteria:

- it represents the maximum draught
- it results in the highest vertical bending moment.

##### 4.2.2 Load cases

The loading condition defined in [4.2.1] is to be associated to the following dynamic load cases:

- HVM
- FVM
- OVA1
- BP2
- OHM
- OHS
- BR1

### 5 Hull girder strength

#### 5.1 Application

##### 5.1.1 Strength deck

In addition to the requirements in Pt B, Ch 6, Sec 1, [1.3], the contribution of the hull structures up to the strength deck to the longitudinal strength is to be assessed through a finite element analysis of the whole ship in the following cases:

- when the size of openings in the side shell and/or longitudinal bulkheads located below the deck assumed by the Designer as the strength deck decrease significantly the capability of the plating to transmit shear forces to the strength deck.
- when the ends of superstructures which are required to contribute to longitudinal strength may be considered not effectively connected to the hull structures in way.

Alternatively, finite element analysis may be replaced by beam analysis on a case-by-case basis.

#### 5.2 Global transverse strength

**5.2.1** The behaviour of the ship primary structural members under racking effects due to transverse forces induced by transverse accelerations is to be investigated according to Pt B, Ch 7, App 1, or by means of a complete ship model according to Pt B, Ch 8, App 3.

## **6 Hull scantlings**

### **6.1 Scantlings of plating, ordinary stiffeners and primary supporting members**

#### **6.1.1 Movable or collapsible structural elements above the strength deck**

In general, the movable or collapsible structural elements used for the stocking and the distribution of livestock on decks or platform decks are not considered for classification purpose.

Nevertheless, where deemed necessary by the shipyard they may be designed and constructed according to the criteria in Part B, Chapter 7. In this case, the scantlings of the barriers surrounding each pen are to take into account the loads applied by the livestock as a result of roll and pitch of the ship.

# Section 3 Systems serving Livestock Spaces

## 1 General

### 1.1 Application

1.1.1 The provisions of this Section cover the systems installed on ships having the service notation **livestock carrier** and intended for:

- the supply of food, water and fresh air to the livestock
- the cleaning of the livestock spaces
- the draining of the sewage effluents produced by the livestock.

### 1.2 Documents to be submitted

1.2.1 The documents listed in Tab 1 are to be submitted for approval.

**Table 1 : Documents to be submitted**

Item No.	Description of the document (1)
1	Diagram of the ventilation system, with indication of the gross volume of the enclosed spaces
2	Diagram of storage and distribution systems for fodder and water
3	Diagram of the water cleaning system
4	Diagram of the drainage system
(1) Diagrams are also to include, where applicable: <ul style="list-style-type: none"> <li>• the (local and remote) control and monitoring systems and automation systems</li> <li>• the instructions for the operation and maintenance of the piping system concerned (for information).</li> </ul>	

## 2 Design of the systems

### 2.1 General

2.1.1 The piping systems covered by this Section are to be designed, constructed and tested in accordance with the applicable provisions of Pt C, Ch 1, Sec 10.

### 2.2 Ventilation system

#### 2.2.1 General

Mechanical ventilation is to be provided for the following spaces containing livestock:

- enclosed spaces
- partially closed spaces arranged with pens on more than one deck level and having a breadth greater than 20 m.

#### 2.2.2 Capacity of the mechanical ventilation

The capacity of the mechanical ventilation is not to be less than:

- 20 air changes per hour of each enclosed space
- 15 air changes per hour of each partially closed space,

based on the gross volume of the space, deduced, if possible, from the volume of any tank or trunk within that space.

Note 1: Where the clear height of the space is less than 2,30 m, the Society may require higher air change rates, with a maximum of:

- 30 changes per hour for enclosed spaces
- 22,5 changes per hour for partially closed spaces.

#### 2.2.3 Fans

- Ventilation circuits are to be supplied by at least two independent fans of such a capacity as to maintain normal ventilation of all the spaces with one fan out of action.
- Fans driven by electric motors are to be considered as essential auxiliaries. Their electrical supply is to comply with the provisions of Pt C, Ch 2, Sec 3.

## **2.3 Fodder and fresh water systems**

### **2.3.1 General**

- a) Spaces intended for livestock are to be provided with receptacles for feeding and watering the animals concerned.
- b) The capacity of the receptacles is not to be less than 33% of the daily consumption of the animals concerned, except when the feed system is automatic.

### **2.3.2 Fresh water system**

- a) The fresh water system serving the livestock spaces is to be totally independent from the fresh water system serving the spaces intended for the crew.
- b) All livestock spaces are to be provided with fresh water service.
- c) The fresh water system is to include at least:
  - one main supply pump, of a capacity sufficient to continuously supply fresh water to the livestock
  - one standby pump of at least the same capacity.

Note 1: When the water supply system is not automatic, the standby pump may be replaced by a portable pump ready to be connected to at least one fresh water tank.

- d) When the water supply is automatic, water receptacles are to be fitted with:
  - means of automatic water level control
  - devices to avoid the return of water from the receptacle to the fresh water tank.

## **2.4 Washing system**

**2.4.1** A water washing system is to be provided with appropriate connections to wash the livestock spaces.

## **2.5 Drainage system**

### **2.5.1 General**

- a) Each space intended for the livestock is to be fitted with a pipe or gutter of sufficient size to drain the sewage and the washing effluents.
- b) The drainage system serving the livestock spaces is to be independent from any piping system serving the other spaces of the ship, and in particular from the bilge system.

### **2.5.2 Materials**

The pipes and other components of the draining system are to be made of a material resistant to the corrosion due to the effluents.

### **2.5.3 Draining pipes and discharges**

- a) Discharges from livestock spaces are to comply with the provisions of Pt C, Ch 1, Sec 10, [8].
- b) Where necessary, drainage gutters and upper parts of the draining pipes are to be covered by a strainer plate.
- c) Draining pipes from livestock spaces are to discharge into a holding tank, wells or overboard.

Note 1: Overboard discharge is subject to the provisions of MARPOL Annex IV - Regulations for the Prevention of Pollution by Sewage.

- d) Means are to be provided to stop the overboard discharge when the ship is in port.

### **2.5.4 Drainage tanks**

- a) Drainage tanks are to be fitted with means to indicate visually the amount of their content.
- b) Drainage tanks and wells are to be accessible from outside livestock pens for inspection and cleaning.

### **2.5.5 Pumps and ejectors**

Pumps and ejectors serving the drainage tanks or wells are to be capable of conveying semi-solid matter.

## **2.6 Lighting system**

**2.6.1** Permanently fixed adequate lighting is to be provided to give a sufficient level of illumination in passage ways between pens and access routes between or from those parts.

**2.6.2** An emergency permanently fixed lighting system is to be provided in case of failure of the main electrical system required in [2.6.1]. This lighting system is to comply with the requirements in Part C, Chapter 2 for emergency lighting.

**2.6.3** In addition to those required in [2.6.1], fixed or portable lightings are to be provided to give a sufficient level of illumination so that livestock can be inspected in each pen.

# Section 4 Fire-Fighting Systems in Livestock Spaces

## 1 General

### 1.1 Application

**1.1.1** This Section provides, for ships having the service notation **livestock carrier**, specific requirements for fire-fighting in the livestock spaces.

Such requirements supplement those given in Part C, Chapter 4.

### 1.2 Documents to be submitted

**1.2.1** The documents listed in Tab 1 are to be submitted for approval.

**Table 1 : Documents to be submitted**

No.	Description of the document
1	Drawing showing the location of the fire-fighting appliances fitted in the livestock spaces
2	Specification of the fire-fighting appliances

## 2 Fire-fighting appliances

### 2.1 Fire hoses

**2.1.1** The number and position of the hydrants are to be such that at least two jets of water not emanating from the same hydrant may reach any part of the spaces intended for the livestock. At least one of these jets is to be from a single length of hose.

**2.1.2** Fire hoses are to be provided for:

- each hydrant located in an enclosed space, and
- for each 50 m length, or part thereof, of open deck spaces.

**2.1.3** Fire hoses are to be located in conspicuous locations, near the hydrants and close to the entrances or access to the spaces.

### 2.2 Additional fire-fighting means

#### 2.2.1 Livestock spaces containing hay or straw

If hay or straw is carried or used in a livestock space, one of the following fire-fighting means is to be provided:

- a fixed water fire-fighting system, or
- portable water extinguishers spaced no more than 18 m apart, one of these extinguishers being positioned at the entrance of the space concerned.

#### 2.2.2 Livestock spaces containing electrical equipment other than lighting systems

If electrical equipment other than that referred to in Ch 3, Sec 3, [2.6] is located in an enclosed livestock space, suitable fire-fighting means are to be provided in this respect.

Section 1	General
Section 2	Ship Arrangement
Section 3	Hull and Stability
Appendix 1	Intact Stability Criteria for Grain Loading
Appendix 2	Hold Mass Curves

# Section 1 General

## 1 General

### 1.1 Application

1.1.1 Ships complying with the requirements of this Chapter are eligible for the assignment of one of the service notations:

- **bulk carrier ESP, bulk carrier CSR ESP, bulk carrier CSR BC-A ESP, bulk carrier CSR BC-B ESP or bulk carrier CSR BC-C ESP**, as defined in Pt A, Ch 1, Sec 2, [4.3.2]
- **Self-unloading bulk carrier ESP**, as defined in Pt A, Ch 1, Sec 2, [4.3.6]
- **bulk carrier**, as defined in Pt A, Ch 1, Sec 2, [4.3.1].

1.1.2 Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**Table 1 : Applicable requirements**

## Section 2 Ship Arrangement

### 1 General arrangement design

#### 1.1 General

##### 1.1.1 Forecastle

Ships with the service notation **bulk carrier ESP** or **bulk carrier** are to be fitted with an enclosed forecastle on the freeboard deck, with its aft bulkhead fitted in way or aft of the forward bulkhead of the foremost hold, as shown in Fig 1.

However, if this requirement hinders hatch cover operation, the aft bulkhead of the forecastle may be fitted forward of the forward bulkhead of the foremost cargo hold provided the forecastle length is not less than 7% of ship length abaft the forward perpendicular where the ship length and forward perpendicular are defined in the International Convention on Load Lines 1966 and its Protocol 1988.

The forecastle height  $H_F$  above the main deck is to be not less than:

- the standard height of a superstructure as specified in Pt B, Ch 1, Sec 3, [2.2]
- $H_C + 0,5$  m, where  $H_C$  is the height of the forward transverse hatch coming of the foremost cargo hold, i.e. cargo hold No. 1, whichever is the greater.

All points of the aft edge of the forecastle deck are to be located at a distance  $l_F$ :

$$l_F \leq 5\sqrt{H_F - H_C}$$

from the hatch coming plate in order to apply the reduced loading to the No. 1 forward transverse hatch coaming and No. 1 hatch cover in applying Pt B, Ch 11, Sec 9, [4.1.3], and Pt B, Ch 11, Sec 9, [8.3.9].

A breakwater is not to be fitted on the forecastle deck with the purpose of protecting the hatch coaming or hatch covers. If fitted for other purposes, it is to be located such that its upper edge at centre line is not less than  $H_B / \tan 20^\circ$  forward of the aft edge of the forecastle deck, where  $H_B$  is the height of the breakwater above the forecastle (see Fig 1).

Figure 1 : Forecastle arrangement

### 2 Access arrangement

#### 2.1 Access arrangement to double bottom and pipe tunnel

##### 2.1.1 Means of access

Adequate means of access to the double bottom and the pipe tunnel are to be provided.

##### 2.1.2 Manholes in the inner bottom, floors and girders

Manholes cut in the inner bottom are to be located at a minimum distance of one floor spacing from the lower stool, or transverse bulkhead if no stool is fitted.

The location and size of manholes in floors and girders are to be determined to facilitate the access to double bottom structures and their ventilation. However, they are to be avoided in the areas where high shear stresses may occur.

## 2.2 Access arrangement to and within spaces in, and forward of, the cargo area

### 2.2.1 Means of access

Ships with the service notation **bulk carrier CSR ESP**, **bulk carrier CSR BC-A ESP**, **bulk carrier CSR BC-B ESP**, **bulk carrier CSR BC-C ESP**, are to comply with the relevant requirements of NR606 Common structural rules for bulk carriers and oil tankers.

Ships with the service notation **bulk carrier ESP** or **bulk carrier** of less than 150 m in length and of 20,000 gross tonnage and over, are to comply with SOLAS, Ch II-1, Reg 3-6.

Ships with the service notation **bulk carrier ESP** or **bulk carrier** are to comply with [2.2.2] and [2.2.3]. In addition, as far as practicable, permanent or movable means of access stored on board are to be provided to ensure proper survey and maintenance of cargo holds and, in particular, of the lower part of cargo hold side frames.

### 2.2.2 Hatches of cargo holds

*If separate hatches are used as access to the ladders as required in [2.2.3], each hatch is to have a clear opening of at least 600 mm x 600 mm.*

*When the access to the cargo hold is arranged through the cargo hatch, the top of the ladder is to be placed as close as possible to the hatch coaming.*

*Accesses and ladders are to be so arranged that personnel equipped with self-contained breathing apparatus may readily enter and leave the cargo hold.*

*Access hatch coamings having a height greater than 900 mm are also to have steps on the outside in conjunction with cargo hold ladders.*

### 2.2.3 Ladders within cargo holds

*Each cargo hold is to be provided with at least two ladders as far apart as practicable longitudinally. If possible these ladders are to be arranged diagonally, e.g. one ladder near the forward bulkhead on the port side, the other one near the aft bulkhead on the starboard side, from the ship's centreline.*

*Ladders are to be so designed and arranged that the risk of damage from the cargo handling gear is minimised.*

*Vertical ladders may be permitted provided they are arranged above each other in line with other ladders to which they form access and resting positions are provided at not more than 9 metres apart.*

*Tunnels passing through cargo holds are to be equipped with ladders or steps at each end of the hold so that personnel may get across such tunnels.*

*Where it may be necessary for work to be carried out within a cargo hold preparatory to loading, consideration is to be given to suitable arrangements for the safe handling of portable staging or movable platforms.*

## Section 3 Hull and Stability

### Symbols

- $D_p$  : Propeller diameter, in m
- $L_{LL}$  : Load line length, in m, defined in Pt B, Ch 1, Sec 3, [2.1.2]
- $\ell$  : Span, in m, of side frames; see [2.2.2]
- $M_{Full}$ ,  $M_H$ ,  $M_{HD}$  : Cargo mass, in t, in a cargo hold, as defined in Pt B, Ch 5, Sec 6
- $t_c$  : Corrosion addition, in mm, defined in Pt B, Ch 4, Sec 2, [1.1.1]
- $\ell_p$  : Distance from propeller centreline to the waterline, in m.
- $P$  : Design pressure in  $\text{kN/m}^2$ , for the design load set being considered according to Pt B, Ch 7, Sec 2, [2] and calculated at the load calculation point defined in Pt B, Ch 4, Sec 6, [3.2].

## 1 Stability

### 1.1 Definitions

#### 1.1.1 Grain

The term grain covers wheat, maize (corn), oats, rye, barley, rice, pulses, seeds and processed forms thereof, whose behaviour is similar to that of grain in its natural state.

#### 1.1.2 Filled compartment trimmed

The term filled compartment trimmed refers to any cargo space in which, after loading and trimming as specified in Ch 4, App 1, the bulk grain is at its highest possible level.

#### 1.1.3 Filled compartment untrimmed

The term filled compartment untrimmed refers to a cargo space which is filled to the maximum extent possible in way of the hatch opening but which has not been trimmed outside the periphery of the hatch opening.

#### 1.1.4 Partially filled compartment

The term partly filled compartment refers to any cargo space where the bulk grain is not loaded in the manner prescribed in [1.1.2] or [1.1.3].

#### 1.1.5 Stowage factor

The term stowage factor, for the purposes of calculating the grain heeling moment caused by a shift of grain, means the volume per unit weight of the cargo as attested by the loading facility, i.e. no allowance is to be made for lost space when the cargo space is nominally filled.

#### 1.1.6 Specially suitable compartment

The term specially suitable compartment refers to a cargo space which is constructed with at least two vertical or sloping, longitudinal, grain-tight divisions which are coincident with the hatch side girders or are so positioned as to limit the effect of any transverse shift of grain. If sloping, the divisions are to have an inclination of not less than  $30^\circ$  to the horizontal.

## 1.2 Intact stability

### 1.2.1 General

The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.5] is to be in compliance with the requirements of Pt B, Ch 3, Sec 2. In addition, the requirements in [1.2.2] and [1.2.3] are to be complied with.

1.2.2 Grain Loading Manual

Information in printed booklet form is to be provided on board to enable the Master to ensure that the ship complies with the stability requirements reported in the Rules when carrying grain in bulk. This booklet is commonly referred to as Grain Loading Manual and is to include the following information:

- ship's particulars
- lightship displacement and the vertical distance from the intersection of the moulded base line and midship section to the centre of gravity (KG)
- table of liquid free surface corrections
- capacities and centres of gravity
- curve or table of angle of flooding, where less than 40°, at all permissible displacements
- curves or tables of hydrostatic properties suitable for the range of operating drafts
- cross curves of stability which are sufficient for the purpose of the requirements in [1.2.3] and which include curves at 12° and 40°
- curves or tables of volumes, vertical centres of volumes, and assumed volumetric heeling moments for every hold, filled or partly filled, or combination thereof, including the effects of temporary fittings
- tables or curves of maximum permissible heeling moments for varying displacements and varying vertical centres of gravity to allow the Master to demonstrate compliance with the requirements specified in [1.2.3]
- loading instructions in the form of notes summarising the requirements of these Rules
- a worked example for the guidance of the Master
- typical loaded service departure and arrival conditions and, where necessary, intermediate worst service conditions.

It is recommended that loading conditions should be provided for at least three representative stowage factors.

The Grain Loading Manual may be drawn up in the official language or languages of the Administration of the issuing country; if the language used is neither English nor French, the text is to include a translation into one of these languages.

1.2.3 Intact stability criteria for grain loading

The intact stability characteristics of any ship carrying bulk grain are to be shown to meet, throughout the voyage, at least the following criteria after taking into account in the manner described in Ch 4, App 1 and in Fig 1, the heeling moments due to grain shift:

- the angle of heel due to the shift of grain is to be not greater than 12° or the angle at which the deck edge is immersed, whichever is the lesser
- in the statical stability diagram, the net or residual area between the heeling arm curve and the righting arm curve up to the angle of heel of maximum difference between the ordinates of the two curves, or 40° or the angle of flooding, whichever is the least, is in all conditions of loading to be not less than 0,075 m·rad
- the initial metacentric height, after correction for the free surface effects of liquids in tanks, as specified in Pt B, Ch 3, Sec 2, [4], is to be not less than 0,30 m.

After loading, the Master is to ensure that the ship is upright before proceeding to sea.

Figure 1 : Stability curve

### **1.3 Damage stability requirements for ships where additional class notation SDS is required**

#### **1.3.1 General**

Ships with the service notation **bulk carrier ESP, bulk carrier CSR ESP, bulk carrier CSR BC-A ESP, bulk carrier CSR BC-B ESP, bulk carrier CSR BC-C ESP** or **bulk carrier** where additional class notation **SDS** is required (see Pt A, Ch 1, Sec 2, [6.17.1]), equal to or greater than 80 m in length, are subjected to the probabilistic approach reported in Pt B, Ch 3, Sec 3, [2.1.3] and are to comply with the requirements in Pt B, Ch 3, App 3.

#### **1.3.2 Freeboard reduction**

Ships with the service notation **bulk carrier CSR ESP, bulk carrier CSR BC-A ESP, bulk carrier CSR BC-B ESP, bulk carrier CSR BC-C ESP** or **bulk carrier** greater than 100 m in length which have been assigned reduced freeboard as permitted by Regulation 27 of the International Convention on Load Lines, 1966, as referenced in Pt B, Ch 3, Sec 3, [2.1.2] are to comply with the requirements specified in Pt B, Ch 3, App 4. Therefore, compliance with the requirements in [1.3.1] is not required.

#### **1.3.3 Additional requirements for single side skin bulk carriers equal to or greater than 150 m in length**

The requirements specified in [1.3.4] to [1.3.6] apply to single side skin bulk carriers, where additional class notation **SDS** is required, equal to or greater than 150 m in length, intended for the carriage of bulk cargoes having dry bulk density of 1.0 t/m<sup>3</sup>, or above.

Ships complying with the requirements in [1.3.2] are not required to comply with those in [1.3.4] to [1.3.6].

#### **1.3.4 Flooding of cargo holds**

*Bulk carriers specified in [1.3.3], when loaded to the summer load line, are to be able to withstand flooding of any one cargo hold in all loading conditions and remain afloat in satisfactory condition as specified in [1.3.5].*

#### **1.3.5 Flooding criteria**

*After flooding, the vessel is to comply with the requirements laid down in Pt B, Ch 3, App 4.*

*The assumed flooding need only take into account flooding of the cargo hold space, considering the permeability values specified in [1.3.6].*

#### **1.3.6 Flooding assumptions**

*The permeability of a loaded hold is to be assumed as 0,9, unless a permeability relevant to a particular cargo is assumed for the volume of a flooded hold occupied by cargo and a permeability of 0,95 is assumed for the remaining empty volume of the hold. In the latter case, the permeabilities and the corresponding cargo densities specified in [3.2.2] are to be assumed.*

The permeability of an empty hold is to be assumed as 0,95.

## **2 Structure design principles**

### **2.1 Double bottom structure**

#### **2.1.1 Longitudinally framed double bottom**

In ships greater than 120 m in length, the double bottom and the sloped bulkheads of hopper tanks are to be longitudinally framed.

The girder spacing is to be not greater than 4 times the spacing of bottom or inner bottom ordinary stiffeners and the floor spacing is to be not greater than 3 frame spaces.

Greater spacing may be accepted by the Society, depending on the results of the analysis carried out according to Part B, Chapter 8 for the primary supporting members in the cargo holds.

#### **2.1.2 Transversely framed double bottom**

The double bottom and the sloped bulkheads of hopper tanks may be transversely framed in ships equal to or less than 120 m in length, when this is deemed acceptable by the Society on a case-by-case basis. In this case, however, the floor spacing is to be not greater than 2 frame spaces.

#### **2.1.3 Floors in way of transverse bulkheads**

The thickness and material properties of the supporting floors and pipe tunnel beams are to be not less than those required for the bulkhead plating or, when a stool is fitted, of the stool side plating.

### **2.2 Single side structure**

#### **2.2.1 Frame spacing**

In general, the frame spacing in cargo holds bounded by the side shell only is to be not greater than the values obtained, in m, from the following formulae:

$$s = 0,6 + \frac{L}{320} \quad \text{for } L < 90\text{m}$$

$$s = 0,9 + 1,25 \left( \frac{L}{100} \right)^{0,25} \quad \text{for } L \geq 90\text{m}$$

**2.2.2 Frame span and web height**

Frame span  $\ell$  and web height  $d$  are to be measured as indicated in Fig 2.

**2.2.3 Symmetrical frame sections**

Frames are to be fabricated symmetrical sections with integral upper and lower brackets and are to be arranged with soft toes.

The web depth to thickness ratio is to be not greater than  $60 k^{0.5}$ . The outstanding flange is to be not greater than  $10 k^{0.5}$  times the flange thickness. The end of the flange is to be sniped.

The frame flange is to be curved (not knuckled) at the connection with the end brackets. The radius of curvature (see Fig 2) is to be not less than the value obtained, in mm, from the following formula:

$$r = \frac{0,4b_f^2}{t_f}$$

where  $b_f$  and  $t_f$  are, in mm, the flange width and thickness, respectively.

**2.2.4 Asymmetrical frame sections**

In ships less than 190 m in length, mild steel frames may be asymmetrical and fitted with overlapped welded brackets. The face plate or flange of the bracket is to be sniped at both ends. Brackets are to be arranged with soft toes.

The web to thickness ratio is to be not greater than  $50 k^{0.5}$ . The outstanding flange is to be not greater than  $10 k^{0.5}$  times the flange thickness.

**2.2.5 Lower and upper end brackets**

The section modulus of the frame end bracket or integral bracket, calculated, with an attached side plating according to Pt B, Ch 4, Sec 6, [1.3], at the end sections of the span  $\ell$  (sections AA and BB in Fig 2), is to be not less than twice the section modulus required for the frame midspan area according to Pt B, Ch 7, Sec 6 or NR600, as applicable.

The dimensions of the lower and upper end brackets are to be not less than those shown in Fig 2.

**Figure 2 : Frame and end bracket geometry**

**2.2.6 Connecting brackets within hopper and topside tanks**

Structural continuity with the upper and lower end connections of side frames is to be ensured within hopper and topside tanks by connecting brackets as shown in Fig 3.

The net connection area of the lower or upper connecting bracket to the supporting longitudinal stiffener is to comply with the following formula:

$$\sum_i A_i d_i R_{eH, bkt-i} \geq 0,02 \alpha_T P S \ell_{SF}^2 10^{-3}$$

The net section modulus of the:

- Side shell and hopper tank longitudinals supporting the lower connecting brackets.
- Side shell and topside tank longitudinals supporting the upper connecting brackets.

is to comply with the following formula:

$$\sum_{i=1}^n Z_{pli} d_i \geq \alpha_T \frac{P \ell_{SF}^2 \ell_1^2}{16 R_{eH}}$$

where:

- $A_i$  : The offered net connection area of the bracket connecting with the i-th longitudinal stiffener, in cm<sup>2</sup>.
- $d_i$  : Distance, in m, of the above i-th longitudinal stiffener from the intersection point of the side shell and hopper/topside tank.
- $\ell_1$  : Spacing, in m, of transverse supporting webs in hopper/topside tank, as applicable.
- $\ell_{SF}$  : Side frame span, in m, not to be taken less than 0,25 D.
- $n$  : Number of the longitudinal stiffeners on the side shell and hopper/topside tank supporting the lower/upper end connecting bracket of the side frame, as applicable.
- $R_{eH}$  : Lowest value of specified yield stress, in N/mm<sup>2</sup>, among the materials of the longitudinal stiffeners of side shell and hopper/topside tanks that support the lower/upper end connecting bracket of the side frame.
- $R_{eH,bkt-i}$  : The specified minimum yield stress of the bracket connecting with the i-th longitudinal stiffener, in N/mm<sup>2</sup>.
- $Z_{pli}$  : Net plastic section modulus, in cm<sup>3</sup>, of the i-th longitudinal stiffener on the side shell or hopper/topside tank supporting the lower/upper end connecting bracket of the side frame, as applicable.
- $\alpha_T$  : Coefficient taken as:
  - $\alpha_T = 150$  for the longitudinal stiffeners supporting the lower connecting brackets.
  - $\alpha_T = 75$  for the longitudinal stiffeners supporting the upper connecting brackets.
- $s$  : Spacing between side frames, in m.

Figure 3 : Connection with bracket within hopper and topside tanks

### 2.2.7 Tripping brackets

In way of the foremost cargo hold, side frames of asymmetrical section are to be fitted with sloped tripping brackets every two frames, as shown in Fig 4.

In way of the other holds, side frames of asymmetrical sections are to be fitted with sloped tripping brackets every two frames where the web height  $d$  is greater than 600 mm or the span  $\ell$  is greater than 6 m.

Figure 4 : Tripping brackets

## 2.3 Double side structure

### 2.3.1 Side primary supporting members

The spacing of transverse side primary supporting members is to be not greater than 3 frame spaces.

Greater spacing may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Part B, Chapter 8 for the primary supporting members in the cargo holds.

In any case, transverse side primary supporting members are to be fitted in line with web frames in hopper and topside tanks.

## 2.4 Deck structure

### 2.4.1 Topside tank sloping plates

The spacing of web frames in topside tanks is to be not greater than 6 frame spaces.

Greater spacing may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Part B, Chapter 8 for the primary supporting members in the cargo holds.

### 2.4.2 Deck between hatches

The cross decks between hatches are generally to be transversely framed.

Connection of the strength deck at side with the deck between hatches is to be ensured by a plate of intermediate thickness.

### 2.4.3 Connection of hatch end beams with deck structures

The connection of hatch end beams with deck structures is to be properly ensured by fitting inside the topside tanks additional web frames or brackets.

### 2.4.4 Topside tank structure

Topside tank structures are to extend as far as possible within the machinery spaces and are to be adequately tapered.

## 3 Design loads

### 3.1 Loading conditions for longitudinal strength assessment

#### 3.1.1 Seagoing conditions

In addition to the loading conditions specified in Pt B, Ch 5, Sec 8, the following seagoing loading conditions are to be included, as a minimum, in the loading manual:

- a) Cargo loading conditions defined in [3.1.2], as applicable.
- b) Ballast conditions with all ballast tanks 100% full,
- c) Heavy ballast condition, mandatory only for ships assigned the navigation notation **unrestricted navigation**, where:
  - the ballast tanks may be full, partially full or empty. Where ballast tanks are partially full, the conditions in Pt B, Ch 5, Sec 8, [3.1.1] are to be complied with
  - at least one cargo hold adapted for the carriage of water ballast at sea, where required or provided, is to be full
  - The propeller immersion  $\ell_p / D_p$  is to be at least 60%
  - The trim is to be by the stern and is not to exceed  $0,015L_{LL}$
  - The moulded forward draught is not to be taken less than the smaller of  $0,03L_{LL}$  or 8 m.

#### 3.1.2 Cargo loading conditions

- Homogeneous cargo loaded condition where the cargo density corresponds to all cargo holds, including hatchways, being 100% full at scantling draught with all ballast tanks empty.
- Homogeneous cargo loaded condition where the cargo density is taken equal to  $3,0 \text{ t/m}^3$ , and all cargo holds are taken with the same filling ratio (cargo mass/hold cubic capacity) in all cargo holds at scantling draught with all ballast tanks empty.  
In cases where the cargo density applied for this design loading condition is different from  $3,0 \text{ t/m}^3$ , the maximum density of the cargo that the ship is allowed to carry is to be indicated.
- Non-homogeneous cargo loaded condition, for ships which service notation is completed by the additional service feature **nonhomload**. These conditions are to include cases where some holds may be empty, at a draught up to the scantling draught, if such conditions are intended to be operated.

### 3.2 Hull girder loads in flooded conditions

#### 3.2.1 Application

These requirements apply to all types of bulk carriers of length greater than or equal to 150 m intended for the carriage of bulk cargoes having dry bulk cargo density of  $1,0 \text{ t/m}^3$  or above and having the service notation **bulk carrier** or **self-unloading bulk carrier ESP** where the unloading system maintains the watertightness during seagoing operations.

### 3.2.2 Flooding assumptions

Each cargo hold is to be considered individually flooded up to the equilibrium waterline. For ships assigned the service notation **self-unloading bulk carrier ESP** and equipped with unloading systems that do not maintain watertightness, the longitudinal strength in the flooded conditions are to be considered using the extent to which the flooding may occur.

Appropriate permeabilities and bulk densities are to be used for any cargo carried. For iron ore, a minimum permeability of 0,3 with a corresponding bulk density of 3,0 t/m<sup>3</sup> is to be used. For cement, a minimum permeability of 0,3 with a corresponding bulk density of 1,3 t/m<sup>3</sup> is to be used. In this respect, "permeability" for dry bulk cargo means the ratio of the floodable volume between the particles, granules or any larger pieces of the cargo, to the gross volume of the bulk cargo.

The permeability of empty cargo spaces and volume left in loaded cargo spaces above any cargo is to be taken equal to 0,95.

For packed cargo conditions (such as in the case of steel mill products), the actual density of the cargo is to be used with a permeability of zero.

### 3.2.3 Still water hull girder loads

The permissible still water loads  $M_{sw,f}$  and  $Q_{sw,f}$  in flooded conditions are to be calculated for each of the cargo and ballast conditions considered in the intact longitudinal strength calculations, as specified in [3.1] except that harbour conditions, docking condition afloat, loading and unloading transitory conditions in port and loading conditions encountered during ballast water exchange need not be considered.

### 3.2.4 Wave hull girder loads

The wave loads in flooded conditions are taken as follows:

- $M_{ww,f}$  : Vertical wave bending moment, in kN.m, in flooded conditions, at the hull transverse section under consideration, to be taken equal to 0,8  $M_{ww}$
- $M_{ww}$  : Vertical wave bending moment in seagoing operation, in kN.m, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 4, [3.1.1]
- $Q_{ww,f}$  : Vertical wave shear force, in kN, in flooded conditions, at the hull transverse section under consideration, to be taken equal to 0,8  $Q_{ww}$
- $Q_{ww}$  : Vertical wave shear force in seagoing condition, in kN, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 4, [3.2.1].

## 3.3 Load combinations for direct strength analysis

### 3.3.1 Applicable general load combinations

The following loading conditions are to be considered for direct strength analysis:

- Full load and scantling draught  $T_{SC}$ , the loaded holds being completely filled with cargo.  
Unless otherwise specified, this loading condition is to be associated with the BP dynamic load cases
- Full load, the cargo density taken equal to 3 t/m<sup>3</sup> unless otherwise specified in the loading manual, and scantling draught  $T_{SC}$ .  
Unless otherwise specified, this loading condition is to be associated with the BP dynamic load cases
- Heavy ballast condition and minimum design heavy ballast draught  $T_{BAL-H}$ .  
Unless otherwise specified, this loading condition is to be associated with the HVM, FVM and BR dynamic load cases
- Multi-port (MP) loading conditions, if allowed by the loading manual, and draught amidships corresponding to these conditions in the loading manual.  
Unless otherwise specified, these loading conditions are to be associated with the all the dynamic load cases
- Alternate loading conditions, if allowed by the loading manual, and draught amidships corresponding to these conditions in the loading manual.  
Unless otherwise specified, these loading conditions are to be associated with the all dynamic load cases

In addition, harbour conditions covering the loading/unloading sequences and associated draughts amidships as defined in the loading manual are to be considered.

## 4 Hull girder strength

### 4.1 Hull girder yield strength in flooded conditions

#### 4.1.1 Application

These requirements apply to all types of bulk carriers of length greater than or equal to 150 m intended for the carriage of bulk cargoes having dry bulk cargo density of 1,0 t/m<sup>3</sup> or above.

Such ships are also to have their hull girder strength checked for the flooded conditions specified in [3.2].

The damaged structure is assumed to remain fully effective in resisting the applied loads.

**4.1.2 Stresses**

The normal stresses in flooded conditions  $\sigma_{L,f}$  at any point are to be obtained, in N/mm<sup>2</sup>, according to the requirements given in Pt B, Ch 6, Sec 1, [2.1.1], in which  $M_{sw}$  and  $M_{wv}$  are to be replaced respectively by  $M_{sw,f}$  and  $M_{wv,f}$  as defined in [3.2].

The shear stresses  $\tau_{L,f}$  of the side shell and the inner hull (longitudinal bulkhead) if any, at any point, are to be obtained, in N/mm<sup>2</sup>, according to the requirements given in Pt B, Ch 6, Sec 1, [2.2.1], in which  $Q_{sw}$  and  $Q_{wv}$  are to be replaced respectively by  $Q_{sw,f}$  and  $Q_{wv,f}$  as defined in [3.2].

The equivalent Von Mises stresses  $\sigma_{eq,f}$  are to be obtained, in N/mm<sup>2</sup>, according to the requirements given in Pt B, Ch 6, Sec 1, [3.5.1], in which  $\sigma_L$  and  $\tau_L$  are to be replaced respectively by  $\sigma_{L,f}$  and  $\tau_{L,f}$ .

**4.1.3 Checking criteria**

It is to be checked that the equivalent Von Mises stresses  $\sigma_{eq,f}$  calculated according to [4.1.2] is in compliance with the acceptance criteria Pt B, Ch 6, Sec 1, [3.5.1] for seagoing operations.

**5 Hull scantlings of bulk carriers**

**5.1 Plating**

**5.1.1 Minimum net thickness of side plating**

The net thickness of the side plating located between hopper and topside tanks is to be not less than the value obtained, in mm, from the following formula:  $t_{MIN} = L^{0.5} - t_C$

**5.2 Ordinary stiffeners**

**5.2.1 Minimum net thicknesses of side frames**

The net thicknesses of side frames and their brackets, in way of cargo holds, are to be not less than the values given in Tab 1.

**Table 1 : Minimum net thicknesses of side frames**

Item	Minimum net thickness, in mm
Side frame webs	$C_L (7,0 + 0,03L_1) - t_C$
Lower end bracket	The greater of: <ul style="list-style-type: none"> <li><math>C_L (7,0 + 0,03L_1) + 2 - t_C</math></li> <li>as fitted net thickness of side frame web</li> </ul>
Upper end bracket	The greater of: <ul style="list-style-type: none"> <li><math>C_L (7,0 + 0,03L_1) - t_C</math></li> <li>as fitted net thickness of side frame web</li> </ul>
<b>Note 1:</b>	
$C_L$	: Coefficient equal to: <ul style="list-style-type: none"> <li>1,15 for side frames in way of the foremost cargo hold</li> <li>1,0 for side frames in way of other cargo holds</li> </ul>
$L_1$	: Ship's length, in m, defined in Pt B, Ch 1, Sec 3, Tab 1.

**5.2.2 Scantlings of side frames abaft the collision bulkhead**

The net moment of inertia  $I$ , in cm<sup>4</sup>, of the three side frames located immediately abaft the collision bulkhead is not to be taken less than:

$$I = 0,18 \frac{P_{SF}^4}{n}$$

where:

$n$  : Frame number of considered side frame counted from the collision bulkhead to the frame in question, taken equal to 1, 2 or 3.

As an alternative, supporting structures, such as horizontal stringers, are to be fitted between the collision bulkhead and a side frame which is in line with transverse webs fitted in both the topside tank and hopper tank, maintaining the continuity of the forepeak stringers within the foremost hold.

**5.2.3 Hopper and topside tank ordinary stiffeners**

These requirements apply to the ordinary stiffeners of side and sloped longitudinal bulkheads, within hopper and topside tanks, which support the connecting brackets fitted in way of the side frame brackets, according to [2.2.6].

The scantlings of these ordinary stiffeners are to be determined according to Pt B, Ch 7, Sec 4, with their span measured according to Pt B, Ch 4, Sec 6, [1.1] between hopper or topside tank primary supporting members.

Alternative arrangements may be considered by the Society on a case-by-case basis. In these cases, the scantlings of the above ordinary stiffeners are to be determined for the purpose of effectively supporting the connecting brackets.

### **5.3 Buckling check in flooded conditions**

#### **5.3.1 Application**

These requirements apply to all types of bulk carriers of length greater than or equal to 150 m intended for the carriage of bulk cargoes having dry bulk cargo density 1,0 t/m<sup>3</sup> or above.

#### **5.3.2 General**

The following elements are to be checked in the flooded conditions specified in [3.2] according to Pt B, Ch 9, Sec 1, considering the hull girder stresses defined in [4.1.2]:

- Plating and ordinary stiffeners contributing to the hull girder longitudinal strength
- Web plate of transverse corrugated bulkhead.

## **6 Protection of hull metallic structures**

### **6.1 Protection of cargo holds**

#### **6.1.1 Coating**

It is the responsibility of the shipbuilder and of the Owner to choose coatings suitable for the intended cargoes, in particular for the compatibility with the cargo, and to see that they are applied in accordance with the Manufacturer's requirements.

#### **6.1.2 Application**

All internal and external surfaces of hatch coamings and hatch covers and all internal surfaces of cargo holds (side and transverse bulkheads) are to have an efficient protective coating, of an epoxy type or equivalent, applied in accordance with the Manufacturer's recommendations.

The side (single and double skin) and transverse bulkhead areas to be coated are specified in [6.1.3] to [6.1.5].

#### **6.1.3 Single side areas to be coated**

The areas to be coated are:

- the internal surfaces of the side plating
- the side frames with end brackets
- the internal surfaces of the topside tank sloping plates and, for a distance of 300 mm below, of the hopper tank sloping plates.

These areas are shown in Fig 5.

#### **6.1.4 Double side areas to be coated**

The areas to be coated are the internal surfaces of:

- the inner side plating
- the internal surfaces of the topside tank sloping plates and the hopper tank sloping plates for a distance of 300 mm below their upper ends.

These areas are shown in Fig 6.

#### **6.1.5 Transverse bulkhead areas to be coated**

The areas to be coated are the upper parts down to 300 mm below the top of the lower stool. Where there is no lower stool, the area to be coated is the whole transverse bulkhead.

These areas are shown in Fig 7.

Figure 5 : Single side - Areas to be coated

Figure 6 : Double side - Areas to be coated

Figure 7 : Transverse bulkheads - Areas to be coated

## 7 Construction and testing

### 7.1 Welding and weld connections

7.1.1 The weld factors for some hull structural connections are specified in Tab 2. These weld factors are to be used, in lieu of the corresponding factors specified in Pt B, Ch 13, Sec 3, Tab 1, to calculate the leg length of fillet weld T connections according to Pt B, Ch 13, Sec 3, [3.2].

7.1.2 For the connections in Tab 2, continuous fillet welding is to be adopted.

### 7.2 Special structural details

7.2.1 The specific requirements in Pt B, Ch 13, Sec 5, [2] are to be complied with.

**Table 2 : Weld factor  $w_F$**

Hull area	Connection		Weld factor $w_F$	
	of	to		
Double bottom in way of cargo holds	girders	bottom and inner bottom plating	0,48	
		floors (interrupted girders)		
	floors	bottom and inner bottom plating		
		girders (interrupted floors)		
Side	web of side frames and brackets	side plating, hopper and topside tank sloping plates, face plates	in zone "a" (1)	0,63 (2)
			in zone "b" (1)	0,56 (2)

(1) Zones "a" and "b" are defined in Fig 8.  
 (2) Where the hull form is such as to prohibit an effective fillet weld, the Society may require edge preparation of the web of side frame and bracket to be carried out in order to ensure the same efficiency as the required weld connections.

**Figure 8 : Zones "a" and "b" of weld connections of side frames**

# Appendix 1 Intact Stability Criteria for Grain Loading

## 1 Calculation of assumed heeling moments due to cargo shifting

### 1.1 Stowage of bulk grain

#### 1.1.1 General

All necessary and reasonable trimming is to be performed to level all free grain surfaces and to minimise the effect of grain shifting.

#### 1.1.2 Filled compartment trimmed

In any filled compartment trimmed, as defined in Ch 4, Sec 3, [1.1.2], the bulk grain is to be trimmed so as to fill all spaces under the decks and hatch covers to the maximum extent possible.

#### 1.1.3 Filled compartment untrimmed

In any filled compartment untrimmed, as defined in Ch 4, Sec 3, [1.1.3], the bulk grain is to be filled to the maximum extent possible in way of the hatch opening but may be at its natural angle of repose outside the periphery of the hatch opening. A filled compartment may qualify for this classification if it falls into one of the following categories:

- a) the Society may, under [1.7], grant dispensation from trimming in those cases where the underdeck void geometry resulting from free flowing grain in a compartment, which may be provided with feeder ducts, perforated decks or other similar means, is taken into account when calculating the void depths, or
- b) the compartment is "specially suitable" as defined in Ch 4, Sec 3, [1.1.6], in which case dispensation may be granted from trimming the ends of that compartment.

#### 1.1.4 Grain in partially filled compartments

If there is no bulk grain or other cargo above a lower cargo space containing grain, the hatch covers are to be secured in an approved manner having regard to the mass and permanent arrangements provided for securing such covers.

When bulk grain is stowed on top of closed 'tweendeck hatch covers which are not grain-tight, such covers are to be made grain-tight by taping the joints, covering the entire hatchway with tarpaulins or separation cloths, or other suitable means.

After loading, all free grain surfaces in partly filled compartments are to be level.

#### 1.1.5 Cargo securing

Unless account is taken of the adverse heeling effect due to the grain shift according to these Rules, the surface of the bulk grain in any partly filled compartment is to be secured so as to prevent a grain shift by overstowing as described in [1.9.1] to [1.9.3]. Alternatively, in partly filled compartments, the bulk grain surface may be secured by strapping or lashing as described in [1.9.4] or [1.9.5].

Lower cargo spaces and 'tweendeck spaces in way thereof may be loaded as one compartment provided that, in calculating transverse heeling moments, proper account is taken of the flow of grain into the lower spaces.

#### 1.1.6 Longitudinal division

In filled compartments trimmed, filled compartments untrimmed and partly filled compartments, longitudinal divisions may be installed as a device to reduce the adverse heeling effect of grain shift provided that:

- a) the division is grain-tight,
- b) the construction meets the requirements in Part B for longitudinal bulkheads; if no particular requirement is foreseen see MSC Res. 23(59)sect 11-14); and
- c) in 'tweendecks, if fitted, the division extends from deck to deck and in other cargo spaces the division extends downwards from the underside of the deck or hatch covers, as described in [1.3.2] a) (second bullet), Note 2, [1.3.2] b), Note 7, or [1.6.1] b), as applicable.

## 1.2 General assumptions

### 1.2.1 Voids in spaces loaded with grain

For the purpose of calculating the adverse heeling moment due to a shift of cargo surface in ships carrying bulk grain it is to be assumed that:

- a) in filled compartments which have been trimmed in accordance with [1.1.2], a void exists under all boundary surfaces having an inclination to the horizontal less than 30° and that void is parallel to the boundary surface having an average depth calculated according to the formula:

$$V_d = V_{d1} + 0,75 (d - 600)$$

where:

$V_d$  : Average void depth, in mm

$V_{d1}$  : Standard void depth, in mm, from Tab 1

$d$  : Actual girder depth, in mm.

In any case,  $V_d$  is to be assumed equal to or greater than 100 mm.

- b) within filled hatchways and in addition to any open void within the hatch cover there is a void of average depth of 150 mm measured down to the grain surface from the lowest part of the hatch cover or the top of the hatch side coaming, whichever is the lower.
- c) in a filled compartment untrimmed which is exempted from trimming outside the periphery of the hatchway by the provisions of [1.1.3] a), it is to be assumed that the surface of the grain after loading will slope into the void space underdeck, in all directions, at an angle of 30° to the horizontal from the edge of the opening which establishes the void.
- d) In a filled compartment untrimmed which is exempted from trimming in the ends of the compartment under the provisions of [1.1.3] b), it is to be assumed that the surface of the grain after loading will slope in all directions away from the filling area at an angle of 30° from the lower edge of the hatch end beam. However, if feeding holes are provided in the hatch end beams in accordance with Tab 2, then the surface of the grain after loading is to be assumed to slope in all directions, at an angle of 30° from a line on the hatch end beam which is the mean of the peaks and valleys of the actual grain surface as shown in Fig 1.

The description of the pattern of grain surface behaviour to be assumed in partly filled compartments is contained in [1.6].

**Table 1 : Standard void depth**

Distance, in m, from hatch end or hatch side to boundary of compartment	Standard void depth $V_{d1}$ in mm
0,5	570
1,0	530
1,5	500
2,0	480
2,5	450
3,0	440
3,5	430
4,0	430
4,5	430
5,0	430
5,5	450
6,0	470
6,5	490
7,0	520
7,5	550
8,0	590

**Note 1:** For boundary distances greater than 8,0 m, the standard void depth  $V_{d1}$  is to be linearly extrapolated with 80 mm increases for each 1,0 m increase in length.

**Note 2:** In the corner area of a compartment, the boundary distance is to be the perpendicular distance from the line of the hatch side girder or the line of the hatch end beam to the boundary of the compartment, whichever is the greater. The girder depth  $d$  is to be taken as the depth of the hatch side girder or the hatch end beam, whichever is the lesser.

**Note 3:** Where there is a raised deck clear of the hatchway, the average void depth measured from the underside of the raised deck is to be calculated using the standard void depth in association with a girder depth of the hatch end beam plus the height of the raised deck.

**Table 2 : Requirements for feeding holes**

Minimum diameter, in mm	Area, in cm <sup>2</sup>	Maximum spacing, in m
90	63,6	0,60
100	78,5	0,75
110	95,0	0,90
120	113,1	1,07
130	133,0	1,25
140	154,0	1,45
150	177,0	1,67
160	201,0	1,90
170 or above	227,0	2,00

Figure 1 : Effective grain surface to be assumed

**1.2.2 Assumptions in filled compartments trimmed**

For the purpose of demonstrating compliance with the stability criteria specified in Ch 4, Sec 3, [1.2.3], the ship's stability calculations are normally to be based upon the assumption that the centre of gravity of cargo in a filled compartment trimmed is at the volumetric centre of the whole cargo space. In those cases where the Society authorises account to be taken of the effect of assumed underdeck voids on the vertical position of the centre of gravity of the cargo in filled compartments trimmed, it is necessary to compensate for the adverse effect of the vertical shift of grain surfaces by increasing the assumed heeling moment due to the transverse shift of grain as follows:

$$M_{H,T} = 1,06 M_{H,C}$$

where:

$M_{H,T}$  : Total heeling moment, in t.m

$M_{H,C}$  : Calculated transverse heeling moment, in t.m.

In all cases the weight of cargo in a filled compartment trimmed is to be the volume of the whole cargo space divided by the stowage factor.

**1.2.3 Assumptions in filled compartments untrimmed**

The centre of gravity of cargo in a filled compartment untrimmed is to be taken to be the volumetric centre of the whole cargo compartment with no account being allowed for voids. In all cases the weight of cargo is to be the volume of the cargo (resulting from the assumptions stated in [1.2.1] c) or [1.2.1] d)) divided by the stowage factor.

**1.2.4 Assumptions in partially filled compartments**

In partly filled compartments the adverse effect of the vertical shift of grain surfaces is to be taken into account as follows:

$$M_{H,T} = 1,12 M_{H,C}$$

where  $M_{H,T}$  and  $M_{H,C}$  are defined in [1.2.2].

**1.2.5 Equivalent methods**

Any other equally effective method may be adopted to make the compensation required in [1.2.2] and [1.2.4].

**1.3 Assumed volumetric heeling moment of a filled compartment trimmed**

**1.3.1 General**

The pattern of grain surface movement relates to a transverse section across the portion of the compartment being considered and the resultant heeling moment is to be multiplied by the length to obtain the total moment for that portion.

The assumed transverse heeling moment due to grain shifting is a consequence of final changes of shape and position of voids after grain has moved from the high side to the low side.

The resulting grain surface after shifting is to be assumed to be at 15° to the horizontal.

In calculating the maximum void area that can be formed against a longitudinal structural member, the effects of any horizontal surfaces, e.g. flanges or face bars, are to be ignored.

The total areas of the initial and final voids are to be equal.

Longitudinal structural members which are grain-tight may be considered effective over their full depth except where they are provided as a device to reduce the adverse effect of grain shift, in which case the provisions of [1.1.6] are to apply.

A discontinuous longitudinal division may be considered effective over its full length.

1.3.2 Assumptions

In the following paragraphs it is assumed that the total heeling moment for a compartment is obtained by adding the results of separate consideration of the following portions:

- a) before and abaft hatchways:
  - if a compartment has two or more main hatchways through which loading may take place, the depth of the underdeck void for the portion or portions between such hatchways is to be determined using the fore and aft distance to the mid-point between the hatchways
  - after the assumed shift of grain the final void pattern is to be as shown in Fig 2.
- b) In and abreast of hatchways without longitudinal division, after the assumed shift of grain the final void pattern is to be as shown in Fig 3 or Fig 4.

Figure 2 : Final void pattern

Note 1: If the maximum void area which can be formed against the girder at B is less than the initial area of the void under AB, i.e.  $AB \cdot Vd$ , the excess area is to be assumed to transfer to the final void on the high side.

Note 2: If, for example, the longitudinal division at C is one which has been provided in accordance with [1.1.6], it is to extend to at least 0,6 m below D or E, whichever gives the greater depth.

Figure 3 : Final void pattern

Note 3: AB: Any area in excess of that which can be formed against the girder at B is to transfer to the final void area in the hatchway.

Note 4: CD: Any area in excess of that which can be formed against the girder at E is to transfer to the final void area on the high side.

Figure 4 : Final void pattern

Note 5: The excess void area from AB is to transfer to the low side half of the hatchway in which two separate final void areas are formed: one against the centreline division and the other against the hatch side coaming and girder on the high side.

Note 6: If a bagged saucer or bulk bundle is formed in a hatchway it is to be assumed for the purpose of calculating the transverse heeling moment that such a device is at least equivalent to the centreline division.

Note 7: If the centreline division is one which has been provided in accordance with [1.1.6], it is to extend to at least 0,6 m below H or J, whichever gives the greater depth.

### **1.3.3 Compartment loaded in combination**

The following paragraphs describe the patterns of void behaviour which are to be assumed when compartments are loaded in combination:

a) without effective centreline divisions:

- under the upper deck:  
as for the single deck arrangement described in [1.3.2] a) (second bullet) and [1.3.2] b).
- under the second deck (if applicable):  
the area of void available for transfer from the low side, i.e. original void area less area against the hatch side girder, is to be assumed to transfer as follows: one half to the upper deck hatchway and one quarter each to the high side under the upper and second deck.
- under the third and lower decks (if applicable):  
the void areas available for transfer from the low side of each of these decks are to be assumed to transfer in equal quantities to all the voids under the decks on the high side and the void in the upper deck hatchway.

b) with effective centreline divisions which extend into the upper deck hatchway:

- at all deck levels abreast of the division the void areas available for transfer from the low side are to be assumed to transfer to the void under the low side half of the upper deck hatchway
- at the deck level immediately below the bottom of the division the void area available for transfer from the low side is to be assumed to transfer as follows: one half to the void under the low side half of the upper deck hatchway and the remainder in equal quantities to the voids under the decks on the high side
- at deck levels lower than those described above, the void area available for transfer from the low side of each of those decks is to be assumed to transfer in equal quantities to the voids in each of the two halves of the upper deck hatchway on each side of the division and the voids under the decks on the high side.

c) with effective centreline divisions which do not extend into the upper deck hatchway:

Since no horizontal transfer of voids may be assumed to take place at the same deck level as the division, the void area available for transfer from the low side at this level is to be assumed to transfer above the division to voids on the high side in accordance with the principles of a) and b).

## **1.4 Assumed volumetric heeling moment of a filled compartment untrimmed**

### **1.4.1 General**

All the provisions for filled compartments trimmed set forth in [1.3] are to also apply to filled compartments untrimmed, except as reported in [1.4.2].

### **1.4.2 Additional requirements**

In filled compartments untrimmed which are exempted from trimming outside the periphery of the hatchway under the provisions of [1.1.3] a), the following assumptions apply:

- a) The resulting grain surface after shifting is to be assumed to be at an angle of 25° to the horizontal. However, if in any section of the compartment, forward, aft, or abreast of the hatchway the mean transverse area of the void in that section is equal to or less than the area which would be obtained by application of [1.2.1] a), then the angle of grain surface after shifting in that section is to be assumed to be 15° to the horizontal.
- b) The void area at any transverse section of the compartment is to be assumed to be the same both before and after the grain shift, i.e. it is to be assumed that additional feeding does not occur at the time of the grain shift.

In filled compartments untrimmed which are exempted from trimming in the ends, forward and aft of the hatchway, under the provisions of [1.1.3] b), the following assumptions apply:

- a) the resulting grain surface abreast of the hatchway after shifting is to be assumed to be at an angle of 15° to the horizontal
- b) the resulting grain surface in the ends, forward and aft of the hatchway after shifting is to be assumed to be at an angle of 25° to the horizontal.

## **1.5 Assumed volumetric heeling moments in trunks**

**1.5.1** After the assumed shift of grain the final void pattern is to be as shown in Fig 5.

Note 1: If the wing spaces in way of the trunk cannot be properly trimmed in accordance with [1.1], it is to be assumed that a 25° surface shift takes place.

## 1.6 Assumed volumetric heeling moment of a partly filled compartment

### 1.6.1

- When the free surface of the bulk grain has not been secured in accordance with [1.9.1] to [1.9.3], [1.9.4], or [1.9.5], it is to be assumed that the grain surface after shifting is at 25° to the horizontal.
- In a partly filled compartment, a division, if fitted, is to extend from one eighth of the maximum breadth of the compartment above the level of the grain surface and to the same distance below the grain surface.
- In a compartment in which the longitudinal divisions are not continuous between the transverse boundaries, the length over which any such divisions are effective as devices to prevent full width shifts of grain surfaces is to be taken to be the actual length of the portion of the division under consideration less two sevenths of the greater of the transverse distances between the division and its adjacent division or ship side. This correction does not apply in the lower compartments of any combination loading in which the upper compartment is either a filled compartment or a partly filled compartment.

Figure 5 : Assumed volumetric heeling moment in trunks

## 1.7 Other assumptions

1.7.1 The Society may authorise departure from the assumptions contained in these Rules in those cases where it considers this to be justified having regard to the provisions for loading or the structural arrangements, provided the stability criteria in Ch 4, Sec 3, [1.2.3] are met.

Where such authorisation is granted under this regulation, particulars shall be included in the grain loading manual.

These particulars include the additional calculation of heeling moments for filled holds with untrimmed ends, an example of which is reported in [2.1].

## 1.8 Saucers

1.8.1 For the purpose of reducing the heeling moment a saucer may be used in place of a longitudinal division in way of a hatch opening only in a filled trimmed compartment as defined in Ch 4, Sec 3, [1.1.2], except in the case of linseed and other seeds having similar properties, where a saucer may not be substituted for a longitudinal division. If a longitudinal division is provided, it is to meet the requirements of [1.1.6].

1.8.2 The depth of the saucer, measured from the bottom of the saucer to the deck line, is to be as follows:

- for ships with a moulded breadth of up to 9,1 m, not less than 1,2 m
- for ships with a moulded breadth of 18,3 m or more, not less than 1,8 m
- for ships with a moulded breadth between 9,1 m and 18,3 m, the minimum depth of the saucer is to be calculated by interpolation.

1.8.3 The top (mouth) of the saucer is to be formed by the underdeck structure in way of the hatchway, i.e. hatch side girders or coamings and hatch end beams. The saucer and hatchway above are to be completely filled with bagged grain or other suitable cargo laid down on a separation cloth or its equivalent and stowed tightly against adjacent structure so as to have a bearing contact with such structure to a depth equal to or greater than one half of the depth specified in [1.8.2].

If hull structure to provide such bearing surface is not available, the saucer is to be fixed in position by steel wire rope, chain, or double steel strapping as specified in [1.9.4] d) and spaced not more than 2,4 m apart.

**1.8.4** As an alternative to filling the saucer in a filled trimmed compartment with bagged grain or other suitable cargo, a bundle of bulk grain may be used provided that:

- a) the dimensions and means for securing the bundle in place are the same as specified for a saucer in [1.8.2] and [1.8.3]
- b) the saucer is lined with a material acceptable to the Society having a tensile strength of not less than 2,687 N per 5 cm strip and which is provided with suitable means for securing at the top
- c) as an alternative to b), a material acceptable to the Society having a tensile strength of not less than 1,344 N per 5 cm strip may be used if the saucer is constructed as follows:
  - athwartship lashings acceptable to the Society are to be placed inside the saucer formed in the bulk grain at intervals of not more than 2,4 m. These lashings are to be of sufficient length to permit being drawn up tight and secured at the top of the saucer.
  - dunnage not less than 25 mm in thickness or other suitable material of equal strength and between 150 mm and 300 mm in width is to be placed fore and aft over these lashings to prevent the cutting or chafing of the material which is to be placed thereon to line the saucer
- d) the saucer is to be filled with bulk grain and secured at the top except that when using material approved under c) further dunnage is to be laid on top after lapping the material before the saucer is secured by setting up the lashings
- e) if more than one sheet of material is used to line the saucer they are to be joined at the bottom either by sewing or by a double lap
- f) the top of the saucer is to be coincidental with the bottom of the beams when these are in place and suitable general cargo or bulk grain may be placed between the beams on top of the saucer.

## **1.9 Overstowing arrangements and securing**

### **1.9.1 Bagged grain**

Where bagged grain or other suitable cargo is utilised for the purpose of securing partly filled compartments, the free grain surface is to be level and is to be covered with a separation cloth or equivalent or by a suitable platform. Such platform is to consist of bearers spaced not more than 1,2 m apart and 25 mm boards laid thereon spaced not more than 100 mm apart. Platforms may be constructed of other materials provided they are deemed by the Society to be equivalent.

### **1.9.2 Separating platform**

The platform or separation cloth is to be topped off with bagged grain tightly stowed and extending to a height of not less than one sixteenth of the maximum breadth of the free grain surface or 1,2 m, whichever is the greater.

### **1.9.3 Equivalent cargo**

The bagged grain is to be carried in sound bags which are to be well filled and securely closed.

Instead of bagged grain, other suitable cargo tightly stowed and exerting at least the same pressure as bagged grain stowed in accordance with [1.9.2] may be used.

### **1.9.4 Strapping or lashing**

When, in order to eliminate heeling moments in partly filled compartments, strapping or lashing is utilised, the securing is to be accomplished as follows:

- a) the grain is to be trimmed and levelled to the extent that it is very slightly crowned and covered with burlap separation cloths, tarpaulins or the equivalent
- b) the separation cloths and/or tarpaulins are to overlap by at least 1,8 m
- c) two solid floors of rough 25 mm by 150 mm to 300 mm lumber are to be laid with the top floor running longitudinally and nailed to an athwartship bottom floor. Alternatively, one solid floor of 50 mm lumber, running longitudinally and nailed over the top of a 50 mm bottom bearer not less than 150 mm wide, may be used. The bottom bearers are to extend the full breadth of the compartment and are to be spaced not more than 2,4 m apart. Arrangements utilising other materials and deemed by the Society to be equivalent to the foregoing may be accepted.
- d) Steel wire rope (19 mm diameter or equivalent), double steel strapping (50 mm x 1,3 mm and having a breaking load of at least 49 kN), or chain of equivalent strength, each of which is to be set tightly by means of a 32 mm turnbuckle, may be used for lashings. A winch tightener, used in conjunction with a locking arm, may be substituted for the 32 mm turnbuckle when steel strapping is used, provided suitable wrenches are available for setting up as necessary.

When steel strapping is used, not less than three crimp seals are to be used for securing the ends. When wire is used, not less than four clips are to be used for forming eyes in the lashings.
- e) Prior to the completion of loading the lashings are to be positively attached to the framing at a point approximately 450 mm below the anticipated final grain surface by means of either a 25 mm shackle or beam clamp of equivalent strength
- f) the lashings are to be spaced not more than 2,4 m apart and each is to be supported by a bearer nailed over the top of the fore and aft floor. This bearer is to consist of lumber of not less than 25 mm by 150 mm or its equivalent and is to extend the full breadth of the compartment.
- g) During the voyage the strapping is to be regularly inspected and set up where necessary.

### **1.9.5 Securing with wire mesh**

When, in order to eliminate grain heeling moments in partly filled compartments, strapping or lashing is utilised, the securing may, as an alternative to the method described in [1.9.4], be accomplished as follows:

- a) the grain is to be trimmed and levelled to the extent that it is very slightly crowned along the fore and aft centreline of the compartment
- b) the entire surface of the grain is to be covered with burlap separation cloths, tarpaulins, or the equivalent. The covering material is to have a tensile strength of not less than 1,344 N per 5 cm strip.
- c) Two layers of wire reinforcement mesh are to be laid on top of the burlap or other covering. The bottom layer is to be laid athwartship and the top layer is to be laid longitudinally. The lengths of wire mesh are to be overlapped at least 75 mm. The top layer of mesh is to be positioned over the bottom layer in such a manner that the squares formed by the alternate layer measure approximately 75 mm by 75 mm. The wire reinforcement mesh is the type used in reinforced concrete construction. It is fabricated of 3 mm diameter steel wire having a breaking strength of not less than 52 kN/cm<sup>2</sup>, welded in 150 mm x 150 mm squares. Wire mesh having mill scale may be used but mesh having loose, flaking rust may not be used.
- d) The boundaries of the wire mesh, at the port and starboard side of the compartment, are to be retained by wood planks 150 mm x 50 mm,
- e) hold-down lashings, running from side to side across the compartment, are to be spaced not more than 2,4 m apart except that the first and the last lashing are not to be more than 300 mm from the forward or after bulkhead, respectively. Prior to the completion of the loading, each lashing is to be positively attached to the framing at a point approximately 450 mm below the anticipated final grain surface by means of either a 25 mm shackle or beam clamp of equivalent strength. The lashing is to be led from this point over the top of the boundary plank described in d), which has the function of distributing the downward pressure exerted by the lashing. Two layers of 150 mm x 25 mm planks are to be laid athwartship centred beneath each lashing and extending the full breadth of the compartment.
- f) The hold-down lashings are to consist of steel wire rope (19 mm diameter or equivalent), double steel strapping (50 mm x 1,3 mm and having a breaking load of at least 49 kN), or chain of equivalent strength, each of which is to be set tight by means of a 32 mm turnbuckle. A winch tightener, used in conjunction with a locking arm, may be substituted for the 32 mm turnbuckle when steel strapping is used, provided suitable wrenches are available for setting up as necessary. When steel strapping is used, not less than three crimp seals are to be used for securing the ends. When wire rope is used, not less than four clips are to be used for forming eyes in the lashings.
- g) During the voyage the hold-down lashings are to be regularly inspected and set up where necessary.

## **2 Dispensation from trimming ends of holds in certain ships**

### **2.1 Calculation example**

#### **2.1.1 General**

As a result of the provisions in [1.1.3] and [1.7.1], dispensation may be granted from trimming the ends of holds in specially suitable ships, when requested, provided that an additional entry of heeling moments for filled holds with untrimmed ends is approved and included in the grain loading manual required in Ch 4, Sec 3, [1.2.2]. Untrimmed ends are to be treated as partly filled spaces and, accordingly, the grain surface in these portions of the hold is to be assumed to shift to an angle of 25° from the horizontal.

After taking into account the heeling moments due to the shift of grain in the untrimmed ends, dispensation may be granted provided the ship meets the stability criteria specified in Ch 4, Sec 3, [1.2.3].

This dispensation may be granted only to ships which are arranged with sloping bulkheads, port and starboard forming the longitudinal inner boundaries of topside tanks and which slope at an angle of 30° or more to the horizontal.

When calculating the geometry of the void beyond the hatch end, allowance may be made for feeding holes in the hatch and beam provided they meet the requirements reported in Tab 2.

The effective depth is to be taken as the distance from the underside of the deck to a horizontal line on the hatch end beam which is the mean between the peaks and valleys of the actual grain surface as shown in Fig 1.

#### **2.1.2 Assumptions**

In performing the calculation of the volumetric heeling moment, the grain in the hatchway is assumed to be filled to the maximum and the resulting surface shifted to an angle of 15° to the horizontal.

In the untrimmed end the surface of the grain will slope in all directions away from the filling area at an angle of 30° to the horizontal from the lower edge of the hatch end beam or, in certain cases from a higher level where feeding holes are provided.

The sum of the moments calculated for the ends and the moments for the hatchway give the total volumetric heeling moment for the compartment "filled - ends not trimmed" and is to be listed for any such compartment in the grain loading manual.

The information concerning full holds assumed to be trimmed and partly filled holds is to remain the same as at present.

#### **2.1.3 Calculation of void areas**

In ships having sloping topside tanks in each hold, the grain surface leans against topside tank bulkheads if its slope is equal to or greater than 30° to the horizontal; in this case no void occurs.

In the zone forward and abaft the hatch, the grain surface is located so as that the standard void depth  $V_d$  increases with the distance from the hatch.

For the void depth calculation, three different transversal sections, AA, BB and CC are taken into account, and for each of these sections, three different points ( $A_1, A_2, A_3, B_1, B_2, B_3$  and  $C_1, C_2, C_3$ ) are to be considered, as illustrated in Fig 6.

The distance between the points  $C_3$  and  $B_2$ , in m, is as follows:

$$C_3B_2 = \sqrt{(3^2 + 2^2)} = 3,61$$

and the void depth  $V_{d2}$ , in m, measured in  $B_2$  is:

$$V_{d2} = 3,61 \tan 30^\circ + 0,60 = 2,68$$

The topside tank area  $A_W$ , in  $m^2$ , (I + II) is as follows:

$$A_W = (6 \cdot 0,60) + \frac{6(\tan 30^\circ)6}{2} = 13,98$$

The void depth  $V_{d3}, V_{d2}, V_{d1}$ , in m, relevant to points  $A_3, A_2, A_1$  of section AA is:

$$V_{d3} = 4 \tan 30^\circ + 0,60 = 2,91$$

$$V_{d2} = (\sqrt{3^2 + 4^2}) \tan 30^\circ + 0,60 = 3,49$$

$$V_{d1} = (\sqrt{6^2 + 4^2}) \tan 30^\circ + 0,60 = 4,76$$

The area  $A_{V,AA}$ , in  $m^2$ , of the void in transversal section AA (calculated according to Simpson's integration rule) is as follows:

$$A_{V,AA} = \frac{A_3 \cdot A_2}{3} \cdot (V_{d3} + 4 \cdot V_{d2} + V_{d1}) = 21,63$$

With reference to Fig 7 and Fig 8 the following areas are calculated:

- area  $A_{A_1A_3C_3G_1}$  (which is the area  $A_{V,AA}$  calculated above), in  $m^2$ , equal to: 21,63
- topside tank area  $A_W$ , in  $m^2$ , equal to: 13,98
- area  $A_{V,I}$ , in  $m^2$ , relevant to void I, equal to:  
 $A_{V,I} = 21,63 - 13,98 = 7,65$
- area  $A_{V,II}$ , in  $m^2$ , relevant to void II, equal to:  
 $A_{V,II} = 5 \cdot 2,91 = 14,55$
- total area  $A_{T,AA}$  of void, port and starboard, in  $m^2$ , in section AA, equal to:  
 $A_{T,AA} = 2 (7,65 + 14,55) = 44,40$

With the same procedure the void relevant to the BB section is calculated, as follows:

- total area  $A_{T,BB}$  of void, port and starboard, in  $m^2$ , in section BB:  
 $A_{T,BB} = 22,98$
- total area  $A_{T,CC}$  of void, port and starboard, in  $m^2$ , in section CC:  
 $A_{T,CC} = 2 (5 \cdot 0,60) = 6,00$

**Figure 6 : Geometry for void depth calculation**

Figure 7 : Geometry for void depth calculation

Figure 8 : Geometry for void depth calculation

2.1.4 Calculation of areas and area moments

Finding the surface at each station after shift which establishes a void area exactly equal to that at the station before shift is a complicated calculation if done directly.

However, if the areas and corresponding area moments are calculated for random shifts from the horizontal to 25°, and a plot is made of areas versus area moments, then by entering the plot with the actual void area at any position before shift, a close approximation to the area moment after shift can be obtained. Such a plot is provided in Fig 9.

Another advantage of this method lies in the fact that while the lengths of the end sections may vary, the cross-sectional dimensions are usually uniform throughout most of the ship. Therefore the same plot of areas versus area moments can be used for several locations.

Figure 9 : Plot of areas versus area moments

With reference to Fig 10, the areas relevant to the zones 1, 2, 3 are as follows:

- area  $A_1$ , in  $m^2$ , relevant to zone 1:

$$A_1 = \frac{8,74(\tan 25^\circ)8,74}{2} - 13,98 = 3,83$$

- area  $A_2$ , in  $m^2$ , relevant to zone 2:

$$A_2 = \frac{13(\tan 25^\circ)13}{2} - 13,98 = 25,41$$

- area  $A_3$ , in  $m^2$ , relevant to zone 3:

$$A_3 = \frac{16(\tan 25^\circ)16}{2} - 13,98 = 45,70$$

**Figure 10 : Geometry for void depth calculation**

The area moments  $M_1$ ,  $M_2$ ,  $M_3$ , in  $m^3$ , relevant to areas  $A_1$ ,  $A_2$ ,  $A_3$ , referred to the centreline are as follows:

- area moment  $M_1$ :

$$M_1 = 17,81\left(\frac{2}{3} \cdot 8,74 + 2,26\right) - 3,6(3 + 5) - 10,38\left(\frac{2}{3} \cdot 6 + 5\right) = 21,80$$

- area moment  $M_2$ :

$$M_2 = 39,39\left(\frac{2}{3} \cdot 13 - 2\right) - 3,6(3 + 5) - 10,38\left(\frac{2}{3} \cdot 6 + 5\right) = 140,38$$

- area moment  $M_3$ :

$$M_3 = 59,68\left(\frac{2}{3} \cdot 16 - 5\right) - 3,6(3 + 5) - 10,38\left(\frac{2}{3} \cdot 6 + 5\right) = 215,97$$

A summary of the values obtained is reported in Tab 3.

**Table 3 : Areas and area moments**

Zone	Area, in $m^2$	Area moment in $m^3$
1	3,83	21,80
2	25,41	140,38
3	45,70	215,97

**2.1.5 Calculation of volumetric heeling moment**

- a) Volumetric heeling moment in untrimmed end

Tab 4 gives the values of areas and area moments derived from the plot in Fig 9.

Therefore, the longitudinal distance between points A, B, C being equal to 2 m, the volumetric heeling moment in the untrimmed end  $M^I$ , in  $m^4$ , is as follows:

$$M^I = \frac{2}{3}[1 \cdot 34 + 4 \cdot 128 + 1 \cdot 212] = 505,33$$

b) Volumetric heeling moment in hatch

The following calculation is valid for void spaces within the hatch (see Fig 11):

- void area  $A_H$ , in  $m^2$ :

$$A_H = 10(0,4 + 0,15) = 5,5$$

- centre of gravity  $x$ , in m, relevant to  $A_H$ :

$$x = \frac{\sqrt{5,5 \cdot 2}}{\tan 15^\circ} = 6,41$$

- area moment  $M_H$ , in  $m^3$ :

$$M_H = 5,5 \left( 5 - \frac{6,41}{3} \right) = 15,75$$

The hatch length being equal to 15 m, the volumetric heeling moment in hatch  $M^H$ , in  $m^4$ , is as follows:

$$M^H = 17,75 \cdot 15 = 236,25$$

In addition, the possible void relevant to a longitudinal deck girder as described in Fig 12, as well as the possible void relevant to the topside tank geometry as described in Fig 13, are to be taken into account; on the contrary, the possible void relevant to topside tank longitudinal stiffeners as described in Fig 14 may not be taken into account.

c) Volumetric heeling moment

The total volumetric heeling moment in a hold, as reported in Tab 4, is the sum of the contribution of a) and b) above.

**Figure 11 : Volumetric heeling moment in hatch**

**Figure 12 : Possible void relevant to a longitudinal deck girder**

# Appendix 2      Hold Mass Curves

## Symbols

$h$	: Vertical distance from the top of inner bottom plating to the lowest point of the upper deck plating at the ship's centreline, in m
$h_a$	: Vertical distance from the top of inner bottom plating to the lowest point of the upper deck plating at the ship's centreline of the aft cargo hold of two adjacent cargo holds, in m
$h_f$	: Vertical distance from the top of inner bottom plating to the lowest point of the upper deck plating at the ship's centreline of the fore cargo hold of two adjacent cargo holds, in m
$M_H$	: Cargo mass, in t, as defined in Pt B, Ch 5, Sec 6.
$M_{Full}$	: Cargo mass, in t, as defined in Pt B, Ch 5, Sec 6.
$M_{HD}$	: Cargo mass, in t, as defined in Pt B, Ch 5, Sec 6
$M_{BLK}$	: The maximum cargo mass in a cargo hold of two adjacent cargo holds according to the block loading condition in the loading manual, in t
$T_i$	: In loading condition No. i, draught, in m, at mid-hold position of single cargo hold length or at mid-length of the two adjacent cargo holds considered
$T_{min}$	: 0,75 $T_{SC}$ or draught in ballast conditions with the two adjacent cargo holds empty, whichever is greater, in m
$T_{H1}$	: Minimum permissible draught, in m, in harbour condition with $M_{Full}$ in each of the two adjacent holds to be taken as defined in Tab 1
$T_{H2}$	: Minimum permissible draught, in m, in harbour condition with $M_{Full}$ in holds intended to be empty in alternate loading conditions or in any hold of ships always loaded homogeneously, to be taken as defined in Tab 1
$T_{H3}$	: Minimum permissible draught, in m, in harbour condition in case of block loading with $M_{BLK}$ in each of the two adjacent holds of ships intended to be loaded in alternate conditions, to be taken as defined in Tab 1
$T_{H4}$	: Minimum permissible draught, in m, in harbour condition with $M_{HD}$ in holds intended to be full in alternate conditions, to be taken as defined in Tab 1
$V_H$	: Volume in $m^3$ , as defined in Pt B, Ch 5, Sec 6
$V_a$	: Volume of the after cargo hold of two adjacent cargo holds excluding volume of the hatchway part, in $m^3$
$V_f$	: Volume of the forward cargo hold of two adjacent cargo holds excluding volume of the hatchway part, in $m^3$
$\Sigma$	: The sum of masses of two adjacent cargo holds.

## 1 General

### 1.1 Application

**1.1.1** The requirements of this Appendix apply to bulk carriers of 150 m in length L and above.

**1.1.2** This appendix describes the procedure to be used for determination of:

- The maximum and minimum mass of cargo in each cargo hold as a function of the draught at mid-hold position of cargo hold.
- The maximum and minimum mass of cargo in any two adjacent holds as a function of the draught at mid-length of these two adjacent cargo holds.

Results of these calculations are to be included in the reviewed Loading Manual which has also to indicate the maximum permissible mass of cargo at scantling draught in each hold or in any two adjacent holds, as obtained from the design review.

#### 1.1.3 General

The cargo mass curves of single cargo hold or of two adjacent cargo holds in seagoing and harbour conditions as defined in Tab 2 to Tab 9 are based on the loading conditions considered in Ch 4, Sec 3, [3.3]. However if the ship structure is checked for more severe loading conditions, the minimum required cargo mass and the maximum allowable cargo mass can be based on those corresponding loading conditions.

#### 1.1.4 Loading/unloading conditions in harbour

For any bulk carrier, the maximum permissible cargo mass and the minimum required cargo mass of single cargo hold or of two adjacent cargo holds, corresponding to draught for loading/unloading conditions in harbour may be increased or decreased by 15% of the maximum permissible mass at the maximum draught for the cargo hold in seagoing condition. However, maximum permissible mass is in no case to be greater than the maximum permissible cargo mass at designed maximum load draught for each cargo hold.

**1.1.5 Maximum and minimum permissible mass expression**

The maximum and minimum permissible mass in seagoing conditions, ( $W_{\max}(T_i)$ ,  $W_{\min}(T_i)$ ) and in harbour condition ( $W_{\max H}(T_i)$ ,  $W_{\min H}(T_i)$ ) at various draughts ( $T_i$ ) are obtained, in t, by the following formulae given in Tab 2 to Tab 9 for the followings cases:

- ships intended to be loaded in alternate conditions not completed by the **(No MP)** indication
- ships intended to be loaded in alternate conditions completed by the **(No MP)** indication
- ships always loaded homogeneously not completed by the **(No MP)** indication
- ships always loaded homogeneously completed by the **(No MP)** indication.

**2 Hold mass curves**

**2.1 General**

**2.1.1 Maximum permissible mass and minimum required mass of single cargo hold**

See Tab 2 to Tab 5.

**2.1.2 Maximum permissible mass and minimum required mass of two adjacent holds**

See Tab 6 to Tab 9.

**Table 1 : Minimum permissible draught, in m**

	For ships having <b>(No MP)</b> notation assigned	For ships not having <b>(No MP)</b> notation assigned
$T_{H1}$	$T_{H1} = \min \left\{ \begin{array}{l} 0,67T_{SC} \\ T_{SC} - \frac{0,15 \sum M_{Full}}{1,025 \left( \frac{V_f}{h_f} + \frac{V_a}{h_a} \right)} \end{array} \right.$	$T_{H2} = 0,67T_{SC} - \frac{0,15M_{Full}}{1,025 \frac{V_H}{h}}$
$T_{H2}$	$T_{H2} = \min \left\{ \begin{array}{l} 0,67T_{SC} \\ T_{SC} - \frac{0,15M_{Full}}{1,025 \frac{V_H}{h}} \end{array} \right.$	$T_{H2} = 0,67T_{SC} - \frac{0,15M_{Full}}{1,025 \frac{V_H}{h}}$
$T_{H3}$	$T_{H3} = T_{SC} - \frac{\sum (0,15M_{BLK} + 0,1M_H)}{1,025 \left( \frac{V_f}{h_f} + \frac{V_a}{h_a} \right)}$	
$T_{H4}$	$T_{H4} = \min \left\{ \begin{array}{l} 0,67T_{SC} \\ T_{SC} - \frac{0,15M_{HD} + 0,1M_H}{1,025 \frac{V_H}{h}} \end{array} \right.$

- Section 2      Ship Arrangement
- Section 3      Hull and Stability

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **ore carrier**, as defined in Pt A, Ch 1, Sec 2, [4.3.3].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- Tab 1.

**Table 1 : Applicable requirements**

## Section 2 Ship Arrangement

### 1 General

#### 1.1 Application

1.1.1 The requirements of Ch 5, Sec 2 and Ch 5, Sec 3 apply to single deck ships with two longitudinal bulkheads and a double bottom throughout the cargo region and intended to carry dry cargoes in bulk, including ore cargo, in the centre holds only. A typical midship section is shown in Fig 1.

The application of these requirements to other ship types is to be considered by the Society on a case-by-case basis.

Figure 1 : Ore carrier

### 2 General arrangement design

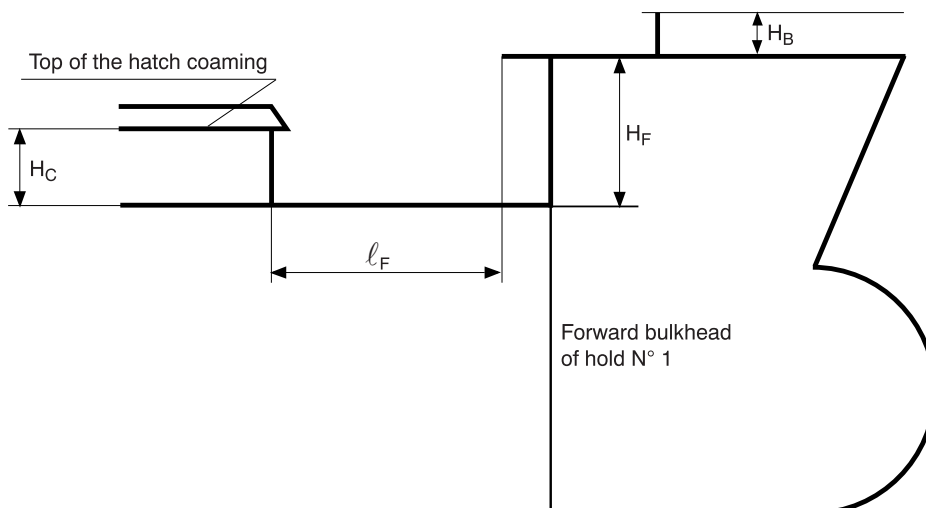

#### 2.1 General

##### 2.1.1 Forecastle

Ships with the service notation **ore carrier ESP** are to be fitted with an enclosed forecastle on the freeboard deck, with its aft bulkhead fitted in way or aft of the forward bulkhead of the foremost hold, as shown in Fig 2.

However, if this requirement hinders hatch cover operation, the aft bulkhead of the forecastle may be fitted forward of the forward bulkhead of the foremost cargo hold provided the forecastle length is not less than 7% of ship length abaft the forward perpendicular where the ship length and forward perpendicular are defined in the International Convention on Load Lines 1966 and its Protocol 1988.

Figure 2 : Forecastle arrangement

The forecastle height  $H_F$  above the main deck is to be not less than:

- the standard height of a superstructure as specified in Pt B, Ch 1, Sec 3, [2.2]
- $H_C + 0,5$  m, where  $H_C$  is the height of the forward transverse hatch coaming of the foremost cargo hold, i.e. cargo hold No. 1, whichever is the greater.

All points of the aft edge of the forecastle deck are to be located at a distance  $\ell_F$ :

$$\ell_F \leq 5\sqrt{H_F - H_C}$$

from the hatch coaming plate in order to apply the reduced loading to the No. 1 forward transverse hatch coaming and No. 1 hatch cover in applying Pt B, Ch 11, Sec 9, [4.1.3], and Pt B, Ch 11, Sec 9, [8.3.9].

A breakwater is not to be fitted on the forecastle deck with the purpose of protecting the hatch coaming or hatch covers. If fitted for other purposes, it is to be located such that its upper edge at centre line is not less than  $H_B / \tan 20^\circ$  forward of the aft edge of the forecastle deck, where  $H_B$  is the height of the breakwater above the forecastle (see Fig 2).

### 3 Access arrangement

#### 3.1 Access arrangement to double bottom and pipe tunnel

##### 3.1.1 Means of access

Adequate means of access to the double bottom and pipe tunnel are to be provided.

##### 3.1.2 Manholes in the inner bottom, floors and girders

Manholes cut in the inner bottom are to be located at a minimum distance of one floor spacing from the lower stool.

The location and size of manholes in floors and girders are to be determined to facilitate the access to double bottom structures and their ventilation. However, they are to be avoided in the areas where high shear stresses may occur.

#### 3.2 Access arrangement to and within spaces in, and forward of, the cargo area

##### 3.2.1 Means of access

Ships with the service notation **ore carrier ESP**, of 20,000 gross tonnage and over, are to comply with the International Convention for the Safety of Life at Sea, 1974, as amended, Chapter II-1, Part A-1, Regulation 3-6, for details and arrangements of openings and attachments to the hull structure.

Ships with the service notation **ore carrier ESP**, of less than 20,000 gross tonnage, are to comply with [3.2.2] and [3.2.3]. In addition, as far as practicable, permanent or movable means of access stored on board are to be provided to ensure proper survey and maintenance of cargo holds.

##### 3.2.2 Hatches of large cargo holds

*If separate hatches are used as access to the ladders as required in [3.2.3], each hatch is to have a clear opening of at least 600 mm x 600 mm.*

*When the access to the cargo hold is arranged through the cargo hatch, the top of the ladder is to be placed as close as possible to the hatch coaming.*

*Accesses and ladders are to be so arranged that personnel equipped with self-contained breathing apparatus may readily enter and leave the cargo hold.*

*Access hatch coamings having a height greater than 900 mm are also to have steps on the outside in conjunction with cargo hold ladders.*

##### 3.2.3 Ladders within large cargo holds

*Each cargo hold is to be provided with at least two ladders as far apart as practicable longitudinally. If possible these ladders are to be arranged diagonally, e.g. one ladder near the forward bulkhead on the port side, the other one near the aft bulkhead on the starboard side, from the ship's centreline.*

*Ladders are to be so designed and arranged that the risk of damage from the cargo handling gear is minimised.*

*Vertical ladders may be permitted provided they are arranged above each other in line with other ladders to which they form access and resting positions are provided at not more than 9 metres apart.*

*Tunnels passing through cargo holds are to be equipped with ladders or steps at each end of the hold so that personnel may get across such tunnels.*

*Where it may be necessary for work to be carried out within a cargo hold preparatory to loading, consideration is to be given to suitable arrangements for the safe handling of portable staging or movable platforms.*

# Section 3 Hull and Stability

## Symbols

- $R_{eH}$  : Minimum yield stress, in N/mm<sup>2</sup>, of the material  
 $k$  : Material factor for steel, defined in Pt B, Ch 4, Sec 1, [2.2]  
 $E$  : Young's modulus, in N/mm<sup>2</sup>, to be taken equal to:
  - $E = 2,06 \cdot 10^5$  N/mm<sup>2</sup> for steels in general
  - $E = 1,95 \cdot 10^5$  N/mm<sup>2</sup> for stainless steels. $b$  : Breadth of plate panel, in mm, as defined in Pt B, Ch 4, Sec 6, [2.1.1].

## 1 General

### 1.1 Loading manual and loading instruments

1.1.1 The specific requirements in Pt B, Ch 1, Sec 5 for ships with the service notation **ore carrier ESP** and equal to or greater than 150 m in length are to be complied with.

## 2 Stability

### 2.1 Intact stability

#### 2.1.1 General

The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.5] is to be in compliance with the requirements in Pt B, Ch 3, Sec 2. Where the ship is intended also for the carriage of grain, the requirements in Ch 4, Sec 3, [1.2.2] and Ch 4, Sec 3, [1.2.3] are to be complied with.

### 2.2 Damage stability requirements for ships where additional class notation SDS has been required

#### 2.2.1 General

Ore carriers equal to or greater than 80 m in length are subjected to the probabilistic approach reported in Pt B, Ch 3, Sec 3, [2.1.3] and are to comply with the requirements in Pt B, Ch 3, App 3.

#### 2.2.2 Freeboard reduction

Ore carriers greater than 100 m in length which have been assigned reduced freeboard as permitted by Regulation 27 of the International Convention on Load Lines, 1966, as referenced in Pt B, Ch 3, Sec 3, [2.1.2] are to comply with the requirement specified in Pt B, Ch 3, App 4. Therefore, compliance with the requirements in [2.2.1] is not required.

## 3 Structure design principles

### 3.1 Double bottom structure

3.1.1 The double bottom is to be longitudinally framed.

The girder spacing is to be not greater than 4 times the spacing of bottom or inner bottom ordinary stiffeners and the floor spacing is to be not greater than 3 frame spaces.

Solid floors are to be fitted in line with the transverse primary supporting members in wing tanks and intermediate floors are to be added at mid-span between primary supporting members.

3.1.2 Other arrangements may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Pt B, Ch 8, Sec 1 for the primary supporting members in the cargo holds.

3.1.3 Scarfing of the double bottom structure into the wing tanks is to be properly ensured. The inner bottom plating is generally to be prolonged within the wing tanks by adequately sized horizontal brackets in way of floors.

### 3.2 Side structure

3.2.1 In ships greater than 120 m in length, the side shell is to be longitudinally framed.

In general, the spacing of vertical primary supporting members is to be not greater than 6 times the frame spacing.

**3.2.2** Other arrangements may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Pt B, Ch 8, Sec 1 for the primary supporting members in the cargo hold.

### **3.3 Deck structure**

**3.3.1** The deck outside the line of hatches is to be longitudinally framed.

**3.3.2** The cross decks between hatches are generally to be transversely framed.

**3.3.3** The connection of hatch end beams with deck structures is to be properly ensured by fitting inside the wing tanks additional web frames or brackets.

### **3.4 Longitudinal bulkhead structure**

**3.4.1** Longitudinal bulkheads are to be plane, but they may be knuckled in the upper and lower parts to form a hopper. In such cases, the design of the knuckles and the adjacent structures is to be considered by the Society on a case-by-case basis.

**3.4.2** In ships greater than 120 m in length, longitudinal bulkheads are to be longitudinally framed.

**3.4.3** Other arrangements may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Pt B, Ch 8, Sec 1 for the primary supporting members in the cargo hold.

### **3.5 Transverse bulkhead structure**

**3.5.1** Where the structural arrangement of transverse bulkheads in wing tanks is different from that in centre holds, arrangements are to be made to ensure continuity of the transverse strength through the longitudinal bulkheads.

## **4 Design loads**

### **4.1 Hull girder loads**

#### **4.1.1 Still water loads**

In addition to the requirements in Pt B, Ch 5, Sec 4, [2.1.1], still water loads are to be calculated for the following loading conditions, subdivided into departure and arrival conditions as appropriate:

- alternate light and heavy cargo loading conditions at maximum draught
- homogeneous light and heavy cargo loading conditions at maximum draught
- ballast conditions. Partial filling of the peak tanks is not acceptable in the design ballast conditions, unless effective means are provided to prevent accidental overfilling.
- short voyage conditions where the ship is to be loaded to maximum draught but with a limited amount of bunkers
- Multi-port (MP) loading/unloading conditions, if allowed by the loading manual (see definition in Pt B, Ch 1, Sec 3, [2.6.1])
- deck cargo conditions, where applicable
- typical loading sequences where the ship is loaded from commencement of cargo loading to reaching full deadweight capacity, for homogeneous conditions, relevant part load conditions and alternate conditions where applicable. Typical unloading sequences for these conditions are also to be included. The typical loading/unloading sequences are also to be developed so as not to exceed applicable strength limitations. The typical loading sequences are also to be developed paying due attention to the loading rate and deballasting capability.
- typical sequences for change of ballast at sea, where applicable.

### **4.2 Load combinations for direct strength analysis**

**4.2.1** The following sea-going loading conditions are to be considered for direct strength analysis:

- full load and scantling draught T, the loaded holds being completely filled with cargo
- full load, the cargo density being the maximum obtained from the loading booklet, but taken not less than 3 t/m<sup>3</sup>, and scantling draught T
- ballast condition and ballast draught corresponding to this condition in the loading manual, or the lesser value of 0,04 L and 10 m
- Multi-Port (MP) loading conditions, if allowed by the loading manual, at draught amidships considered in the loading manual.

Unless otherwise specified, these loading conditions are to be associated with the HVM and FVM dynamic load cases.

In addition, harbour conditions covering the loading/ unloading sequences as defined in the loading manual are to be considered.

## 5 Hull scantlings

### 5.1 Corrosion addition

#### 5.1.1 Value of corrosion addition for tank top

The corrosion addition for tank top of void/dry spaces is to be taken equal to 0 mm.

### 5.2 Additional requirements

#### 5.2.1 Minimum net thicknesses

The net thickness of the inner bottom plating in holds is to be not less than the value given in Tab 1.

**Table 1 : Minimum net thickness of the inner bottom plating in holds**

Plating	Minimum net thickness, in mm	
	Inner bottom in holds	Longitudinal framing
Transverse framing		$2,35 (L^{1/3} k^{1/6}) + 0,0045 b$

## 6 Construction and testing

### 6.1 Welding and weld connections

**6.1.1** The weld factors for some hull structural connections are specified in Tab 2. These weld factors are to be used in lieu of the corresponding factors specified in Pt B, Ch 13, Sec 3, Tab 1 to calculate T connections fillet weld leg length according to Pt B, Ch 13, Sec 3, [3.2.6]. For the connections in Tab 2, continuous fillet welding is to be adopted.

### 6.2 Special structural details

**6.2.1** The specific requirements in Pt B, Ch 13, Sec 5, [2] for ships with the service notation **ore carrier ESP** are to be complied with.

**Table 2 : Weld factor  $w_F$**

Hull area	Connection		$w_F$
	of	to	
Double bottom in way of cargo holds	girders	bottom and inner bottom plating	0,48
		floors (interrupted girders)	
	floors	bottom and inner bottom plating	
		girders (interrupted floors)	
Bulkheads in cargo holds	structures of watertight bulkheads	longitudinal bulkheads

- Section 2      Ship Arrangement
- Section 3      Hull and Stability
- Section 4      Machinery and Cargo Systems

# Section 1                      General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **combination carrier**, as defined in Pt A, Ch 1, Sec 2, [4.3.4] and Pt A, Ch 1, Sec 2, [4.3.5].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules,
- NR216 Materials and Welding,
- applicable requirements according to Tab 1.

**Table 1 : Applicable requirements**

## Section 2 Ship Arrangement

### 1 General arrangement design

#### 1.1 General

##### 1.1.1 Forecastle

Ships with the service notation **combination carrier/OBO ESP** or **combination carrier/OOC ESP** are to be fitted with an enclosed forecastle on the freeboard deck, with its aft bulkhead fitted in way or aft of the forward bulkhead of the foremost hold, as shown in Fig 1.

However, if this requirement hinders hatch cover operation, the aft bulkhead of the forecastle may be fitted forward of the forward bulkhead of the foremost cargo hold provided the forecastle length is not less than 7% of ship length abaft the forward perpendicular where the ship length and forward perpendicular are defined in the International Convention on Load Lines 1966 and its Protocol 1988.

The forecastle height  $H_F$  above the main deck is to be not less than:

- the standard height of a superstructure as specified in Pt B, Ch 1, Sec 3, [2.2.9]
- $H_C + 0,5$  m, where  $H_C$  is the height of the forward transverse hatch coaming of the foremost cargo hold, i.e. cargo hold No. 1, whichever is the greater.

All points of the aft edge of the forecastle deck are to be located at a distance  $l_F$ :

$$l_F \leq 5\sqrt{H_F - H_C}$$

from the hatch coaming plate in order to apply the reduced loading to the No. 1 forward transverse hatch coaming and No. 1 hatch cover in applying Pt B, Ch 11, Sec 9, [4.1.3], and Pt B, Ch 11, Sec 9, [8.3.9].

A breakwater is not to be fitted on the forecastle deck with the purpose of protecting the hatch coaming or hatch covers. If fitted for other purposes, it is to be located such that its upper edge at centre line is not less than  $H_B / \tan 20^\circ$  forward of the aft edge of the forecastle deck, where  $H_B$  is the height of the breakwater above the forecastle (see Fig 1).

**Figure 1 : Forecastle arrangement**

##### 1.1.2 Cofferdams

A cofferdam or similar compartment of width not less than 760 mm is to be provided at the aft end of the oil cargo tank area. Its bulkheads are to extend from keel to deck across the full breadth of the ship.

For the purpose of this requirement, the term "cofferdam" is intended to mean an isolating compartment between two adjacent steel bulkheads or decks. The minimum distance between the two bulkheads or decks is to be sufficient for safe access and inspection.

For continuity reason, in the particular case when a corner-to-corner situation occurs, welding a diagonal plate across the corner may be accepted.

Cofferdams are also to be constructed so as to enable adequate ventilation.

### **1.1.3 Cargo segregation**

Unless expressly provided otherwise, tanks containing oil cargoes or oil cargo residues are to be segregated from accommodation, service and machinery spaces, drinking water and stores for human consumption by means of a cofferdam, or any other similar compartment.

Where accommodation and service compartments are arranged immediately above the compartments containing flammable liquids, the cofferdam may be omitted only where the deck is not provided with access openings and is coated with a layer of material recognised as suitable by the Society. The cofferdam may also be omitted where such compartments are adjacent to a passageway, subject to the following conditions:

- the thicknesses of common boundary plates of adjacent tanks are increased with respect to those obtained from the applicable requirements in Part B and Ch 6, Sec 3, by 2 mm in the case of tanks carrying fresh water or boiler feed water, and by 1 mm in all other cases
- the sum of the throats of the weld fillets at the edges of such plates is not less than the thickness of the plates themselves
- the hydrostatic test is carried out with a head increased by 1 m with respect to that required in Pt B, Ch 13, Sec 6.

*Combination carriers of 600 t deadweight and above are not allowed to carry oil in any compartment extending forward of a collision bulkhead located in accordance with Pt B, Ch 2, Sec 1, [3].*

### **1.1.4 Location of fuel tanks in cargo area**

On ships carrying liquid cargoes having a flashpoint not exceeding 60°C, fuel tanks located with a common boundary to cargo or slop tanks are not to be situated within, nor extend partly into, the cargo tank block as defined in Ch 7, Sec 1, [1.2.4]. Such tanks may, however, be situated aft and/or forward of the cargo tank block. They may be accepted when located as independent tanks on open deck in the cargo area subject to spill and fire safety considerations.

The arrangement of independent fuel tanks and associated fuel piping systems, including the pumps, may be as for fuel tanks and associated fuel piping systems located in the machinery spaces. For electrical equipment, requirements applicable to hazardous area classification must however be met.

### **1.1.5 Slop tanks**

*The slop tanks are to be surrounded by cofferdams except where the boundaries of the slop tanks are part of the hull, main cargo deck, cargo pump room bulkhead or fuel oil bunker tank. These cofferdams are not to be open to a double bottom, pipe tunnel, pump room or other enclosed space, nor they are to be used for cargo or ballast and they are not to be connected to piping systems serving oil cargo or ballast. Means are to be provided for filling the cofferdams with water and for draining them.*

*Where the boundary of a slop tank is part of the cargo pump room bulkhead, the pump room is not to be open to the double bottom, pipe tunnel or other enclosed space; however, openings provided with gas-tight bolted covers may be permitted.*

### **1.1.6 Deck spills**

*Means are to be provided to keep deck spills away from the accommodation and service areas. This may be accomplished by providing a permanent continuous coaming of a height of at least 300 mm, extending from side to side.*

Where gutter bars are installed on the weather decks of combination carriers in way of cargo manifolds and are extended aft as far as the aft bulkhead of superstructures for the purpose of containing cargo spills on deck during loading and discharge operations, the free surface effects caused by containment of a cargo spill during liquid transfer operations or of boarding seas while underway are to be considered with respect to the vessel's available margin of positive initial stability ( $GM_0$ ).

Where the gutter bars installed are higher than 300 mm, they are to be treated as bulwarks with freeing ports arranged in accordance with Pt B, Ch 11, Sec 12, [6] and provided with effective closures for use during loading and discharge operations. Attached closures are to be arranged in such a way that jamming is prevented while at sea, enabling the freeing ports to remain effective.

An assessment of the initial stability ( $GM_0$ ) for compliance with the relevant intact stability requirements taking into account the free surface effect caused by liquids contained by the gutter bars is to be undertaken on:

- tankers having cargo tanks exceeding 60% of the vessel's maximum beam at midships regardless of gutter bar height
- ships without deck camber
- ships where the height of the installed gutter bars exceeds the camber.

### **1.1.7 Piping**

*Oil cargo lines below deck are to be placed in special ducts.*

### **1.1.8 Opening in watertight bulkheads and decks**

Openings intended to be used for dry cargo handling are not permitted in bulkheads and decks separating oil cargo tanks from other compartments not designed and equipped for the carriage of oil cargoes unless such openings are equipped with alternative means approved by the Society to ensure an equivalent integrity.

**1.1.9 Tank cleaning openings**

Hatches and tank cleaning openings to slop tanks are only permitted on the open deck and are to be fitted with closing arrangements.

Except where they consist of bolted plates with bolts at watertight spacing, these closing arrangements are to be provided with locking arrangements which are to be under the control of the responsible ship's officer.

**1.2 Double bottom tanks or compartments**

**1.2.1 General**

Double bottom tanks adjacent to cargo tanks are not to be used as fuel oil tanks.

**1.2.2 Combination carriers of 5000 t deadweight and above**

At any cross-section, the depth of each double bottom tank or compartment is to be such that the distance  $h$  between the bottom of the cargo tanks and the moulded line of the bottom shell plating measured at right angles to the bottom shell plating, as shown in Fig 2, is not less than  $B/15$ , in m, or 2,0 m, whichever is the lesser.  $h$  is to be not less than 1,0 m.

**1.2.3 Combination carriers of less than 5000 t but at least 600 t deadweight**

At any cross-section, the depth of each double bottom tank or compartment is to be such that the distance  $h$  between the bottom of the cargo tanks and the moulded line of the bottom shell plating measured at right angles to the bottom shell is not less than  $B/15$ , in m, with a minimum value of 0,76 m.

In the turn of the bilge area and at locations without a clearly defined turn of the bilge, the cargo tank boundary line is to run parallel to the line of the midship flat bottom as shown in Fig 3.

**1.3 Navigation position**

**1.3.1** When it is proven necessary to provide a navigation station above the cargo area, such station is to be for navigation purposes only and is to be separated from the cargo tank deck by an open space of at least 2 m in height.

**Figure 2 : Cargo tank boundary lines**

**Figure 3 : Cargo tank boundary lines**

## 2 Size and arrangement of cargo tanks and slop tanks

### 2.1 Cargo tanks

**2.1.1** Cargo tanks of combination carriers are to be of such size and arrangements that the hypothetical outflow  $O_C$  or  $O_S$  calculated in accordance with the provisions of [2.2] anywhere in the length of the ship does not exceed:

- 30000 m<sup>3</sup>, or
- $400\sqrt[3]{DW}$

where  $DW$  is the deadweight, in t,

whichever is the greater, but subject to a maximum of 40000 m<sup>3</sup>.

**2.1.2** The length of each cargo tank is not to exceed 10 metres or one of the values of Tab 1, as applicable, whichever is the greater.

**Table 1 : Length of cargo tanks**

Longitudinal bulkhead arrangement	Condition (1)	Length of cargo tanks, in m
No bulkhead ( <b>combination carrier/OBO ESP</b> )	–	$(0,5 b_i / B + 0,1) L_{LL}$ (2)
Two bulkheads ( <b>combination carrier/OOC ESP</b> )	$b_i / B \geq 1/5$	0,2 $L_{LL}$
	$b_i / B < 1/5$	$(0,5 b_i / B + 0,1) L_{LL}$
(1) $b_i$ is the minimum distance from the ship side to the outer longitudinal bulkhead of the -th tank, measured inboard at right angles to the centreline at the level corresponding to the assigned summer freeboard.		
(2) Not to exceed 0,2 $L_{LL}$ .		

### 2.1.3 Cargo transfer system

In order not to exceed the volume limits established by [2.1.1] and irrespective of the accepted type of cargo transfer system installed, when such system interconnects two or more cargo tanks, valves or other similar closing devices are to be provided for separating the tanks from each other.

### 2.1.4 Piping through cargo tanks

Lines of piping which run through oil cargo tanks in a position less than  $t_c$  from the ship side or less than  $v_c$  from the ship's bottom are to be fitted with valves or similar closing devices at the point at which they open into any cargo tank. These valves are to be kept closed at sea at any time when the tanks contain cargo oil, except that they may be opened only for cargo transfer needed for the purpose of trimming of the ship.

$t_c$  and  $v_c$  are, respectively, the transverse and the vertical extent of side damage as defined in Ch 6, Sec 3, [2.3.2].

### 2.1.5 Suction wells in cargo tanks

Suction wells in cargo tanks may protrude into the double bottom below the boundary line defined by the distance  $h$  in [1.2.2] or [1.2.3], as applicable, provided that such wells are as small as practicable and the distance between the well bottom and bottom shell plating is not less than 0,5  $h$ .

## 2.2 Oil outflow

### 2.2.1 General

In order to limit the oil pollution from combination carriers due to side and bottom damages, the hypothetical oil outflows  $O_C$  and  $O_S$  as referred to in [2.1.1] are to be calculated by the formulae of [2.2.2] with respect to compartments breached by damage to all conceivable locations along the length of the ship to the extent as defined in Ch 6, Sec 3, [2.3.2].

In calculating the hypothetical oil outflows, the following is to be considered:

- the volume of an oil cargo tank is to include the volume of the hatchway up to the top of the hatchway coamings, regardless of the construction of the hatch, but may not include the volume of any hatch cover; and
- for the measurement of the volume to moulded lines, no deduction is to be made for the volume of internal structures.

### 2.2.2 General calculation of oil outflow

The oil outflow for side and bottom damages is calculated by the following formulae:

a) for side damages:

$$O_C = \Sigma W_i + \Sigma K_i C_i$$

b) for bottom damages:

$$O_S = \frac{1}{3}(\Sigma Z_i W_i + \Sigma Z_i C_i)$$

where:

- $W_i$  : Volume of a wing tank in cubic metres assumed to be breached by the damage as specified in Ch 6, Sec 3, [2.3.2];  $W_i$  for a segregated ballast tank may be taken equal to zero
- $C_i$  : Volume of a centre tank in cubic metres assumed to be breached by the damage as specified in Ch 6, Sec 3, [2.3.2];  $C_i$  for a segregated ballast tank may be taken equal to zero
- $K_i$  : Coefficient defined as:
- $1 - b_i / t_c$  for  $b_i < t_c$
  - $0$  for  $b_i \geq t_c$
- $Z_i$  : Coefficient defined as:
- $1 - h_i / v_s$  for  $h_i < v_s$
  - $0$  for  $h_i \geq v_s$
- $b_i$  : Width, in m, of wing tank under consideration measured inboard from the ship side at right angles to the centreline at the level corresponding to the assigned summer freeboard. In a case where the width  $b_i$  is not constant along the length of a particular wing tank, the smallest  $b_i$  value in the tank is to be used for the purposes of assessing the hypothetical outflows of oil  $O_c$  and  $O_s$
- $h_i$  : Minimum depth, in m, of the double bottom under consideration; where no double bottom is fitted,  $h_i$  is to be taken equal to zero
- $t_c$  : Transverse extent of side damage as defined in Ch 6, Sec 3, [2.3.2]
- $v_s$  : Vertical extent of bottom damage as defined in Ch 6, Sec 3, [2.3.2].

**2.2.3 Bottom damage involving simultaneously four centre tanks**

In the case where bottom damage simultaneously involves four centre tanks, the value of  $O_s$  may be calculated according to the formula:

$$O_s = \frac{1}{4}(\sum Z_i W_i + \sum Z_i C_i)$$

where  $Z_i$ ,  $W_i$  and  $C_i$  are defined in [2.2.2].

**2.2.4 Assumptions**

For the purpose of calculating  $O_s$ , credit is only to be given in respect of double bottom tanks which are either empty or carrying clean water when cargo is carried in the tanks above.

Suction wells may be neglected in the determination of the value  $h_i$  provided such wells are not excessive in area and extend below the tank for a minimum distance and in no case more than half the height of the double bottom. If the depth of such a well exceeds half the height of the double bottom,  $h_i$  is to be taken equal to the double bottom height minus the well height.

Piping serving such wells if installed within the double bottom is to be fitted with valves or other closing arrangements located at the point of connection to the tank served to prevent oil outflow in the event of damage to the piping.

**2.2.5 Reduction of oil outflow**

The Society may credit as reducing oil outflow in the event of bottom damage, an installed cargo transfer system having an emergency high suction in each cargo oil tank, capable of transferring from a breached tank or tanks to segregated ballast tanks or to available cargo tankage if it can be ensured that such tanks will have sufficient ullage. Credit for such a system would be governed by ability to transfer in two hours of operation oil equal to one half of the largest of the breached tanks involved and by availability of equivalent receiving capacity in ballast or cargo tanks. The credit is to be confined to permitting calculation of  $O_s$  according to the formula in [2.2.3]. The pipes for such suctions are to be installed at least at a height not less than the vertical extent of the bottom damage  $v_s$ .

$v_s$  is the vertical extent of bottom damage as defined in Ch 6, Sec 3, [2.3.2].

**2.2.6 Alternative methods for calculating oil outflow**

As an alternative to the formulae indicated in [2.2.2] or [2.2.3], the probabilistic methodology for calculating oil outflow as described in IMO Resolution MEPC.110(49) may be applied.

**2.3 Slop tanks****2.3.1 Combination carriers of 150 gross tonnage and above**

The arrangements of the slop tank or combination of slop tanks are to have a capacity necessary to retain the slop generated by tank washings, oil residues and dirty ballast residues. The total capacity of the slop tank or tanks is to be not less than 3 per cent of the oil carrying capacity of the ships, except that the Society may accept:

- 2% for such combination carriers where the tank washing arrangements are such that once the slop tank or tanks are charged with washing water, this water is sufficient for tank washing and, where applicable, for providing the driving fluid for ejectors, without the introduction of additional water into the system
- 2% where segregated ballast tanks are provided in accordance with Article [4]. This capacity may be further reduced to 1,5% for such combination carriers where the tank washing arrangements are such that once the slop tank or tanks are charged

with washing water, this water is sufficient for tank washing and, where applicable, for providing the driving fluid for ejectors, without the introduction of additional water into the system.

- 1% for combination carriers where oil cargo is only carried in tanks with smooth walls. This capacity may be further reduced to 0,8% where the tank washing arrangements are such that once the slop tank or tanks are charged with washing water, this water is sufficient for tank washing and, where applicable, for providing the driving fluid for ejectors, without the introduction of additional water into the system.

The term "tanks with smooth walls" includes the main oil cargo tanks of combination carriers which may be constructed with vertical framing of a small depth. Vertically corrugated bulkheads are considered smooth walls.

### **2.3.2 Combination carriers of 70000 t deadweight and above**

Combination carriers of 70000 t deadweight and above are to be provided with at least two slop tanks.

## **3 Size and arrangement of protective ballast tanks or compartments**

### **3.1 General**

**3.1.1** This requirement applies to combination carriers of 600 t deadweight and above.

### **3.2 Size and arrangement of ballast tanks or compartments**

#### **3.2.1 General**

The entire oil cargo tank length is to be protected by ballast tanks or compartments other than oil cargo and fuel oil tanks as indicated in [3.2.2] to [3.2.5] for combination carriers of 5000 t deadweight and above, or [3.2.6] for combination carriers less than 5000 t deadweight.

#### **3.2.2 Wing tanks or compartments**

Wing tanks or compartments are to extend either for the full depth of the ship side or from the top of the double bottom to the uppermost deck, disregarding a rounded gunwale where fitted. They are to be arranged such that the oil cargo tanks are located inboard of the moulded line of the side shell plating, nowhere less than the distance  $w$  which, as shown in Fig 2, is measured at any cross-section at right angles to the side shell, as specified below:

- $w = 0,5 + DW / 20000$ , or
- $w = 2,0$  m

whichever is the lesser.

The value of  $w$  is to be at least 1,0 m.

#### **3.2.3 Double bottom tanks or compartments**

The requirements of [1.2.1] and [1.2.2] apply.

#### **3.2.4 Aggregate capacity of ballast tanks**

On combination carriers of 20000 t deadweight and above, the aggregate capacity of wing tanks, double bottom tanks, fore peak tanks and after peak tanks is to be not less than the capacity of segregated ballast tanks necessary to meet the requirements of [4]. Wing tanks or compartments and double bottom tanks used to meet the requirements of [4] are to be located as uniformly as practicable along the oil cargo tank length. Additional segregated ballast capacity provided for reducing longitudinal hull girder bending stress, trim, etc., may be located anywhere within the ship.

In calculating the aggregate capacity, the following is to be taken into account:

- the capacity of engine-room ballast tanks is to be excluded from the aggregate capacity of ballast tanks
- the capacity of ballast tanks located inboard of double hull is to be excluded from the aggregate capacity of ballast tanks (see Fig 4)
- spaces such as void spaces located in the double hull within the cargo tank length should be included in the aggregate capacity of ballast tanks

Any ballast carried in localised inboard extensions, indentation or recesses of the double hull, such as bulkhead stools, should be considered as excess ballast above the minimum requirement for segregated ballast capacity according to [4].

#### **3.2.5 Alternative methods of design and construction**

Other methods of design and construction of combination carriers may also be accepted as alternatives to the requirements prescribed in [3.2.2] to [3.2.4], provided that such methods ensure at least the same level of protection against oil pollution in the event of collision or stranding. Such methods are to be acceptable to the Society.

Note 1: The Society considers the method described in IMO Resolution MEPC.110(49) as being acceptable.

#### **3.2.6 Combination carriers of less than 5000 t deadweight**

Combination carriers of less than 5000 t deadweight are to comply with [1.2.3].

Figure 4 : Segregated ballast tanks located inboard of double hull

## 4 Size and arrangement of segregated ballast tanks (SBT)

### 4.1 General

4.1.1 Every combination carrier of 20000 t deadweight and above is to be provided with segregated ballast tanks and to comply with [4.2].

### 4.2 Capacity of SBT

#### 4.2.1 Combination carriers equal to or greater than 150 m in length

The capacity of the segregated ballast tanks is to be so determined that the ship may operate safely on ballast voyages without recourse to the use of oil cargo tanks for water ballast. In all cases, however, the capacity of segregated ballast tanks is to be at least such that, in any ballast condition at any part of the voyage, including the conditions consisting of lightweight plus segregated ballast only, the ship's draughts and trim can meet each of the following requirements:

- the moulded draught amidships,  $d_m$  in metres (without taking into account any ship's deformation), is to be not less than  $2,0 + 0,02 L_{LL}$
- the draughts at the forward and after perpendicular are to correspond to those determined by the draught amidships  $d_m$  as specified above, in association with the trim by the stern of not greater than  $0,015 L_{LL}$
- in any case the draught at the after perpendicular is to be not less than that which is necessary to obtain full immersion of the propeller(s)
- in no case is ballast water to be carried in oil cargo tanks, except:
  - on those rare voyages when weather conditions are so severe that, in the opinion of the Master, it is necessary to carry additional ballast water in oil cargo tanks for the safety of the ship
  - in exceptional cases where the particular character of the operation of a combination carrier renders it necessary to carry ballast water in excess of the quantity required to comply with the requirements above, provided that such operation of the combination carrier falls under the category of exceptional cases.

#### 4.2.2 Combination carriers less than 150 m in length

The capacity of the segregated ballast tanks is to be considered by the Society on a case-by-case basis.

## 5 Access arrangement

### 5.1 Access to double bottom and pipe tunnel

#### 5.1.1 Means of access

Adequate means of access to the double bottom and the pipe tunnel are to be provided.

### **5.1.2 Manholes in the inner bottom, floors and girders**

Manholes are not to be cut in the inner bottom in way of oil cargo holds; access to the double bottom is, in general, to be provided by trunks leading to the upper deck.

The location and size of manholes in longitudinal girders and floors are determined to facilitate the access to double bottom structures and their ventilation. However, they are to be avoided in the areas where high shear stresses may occur.

### **5.1.3 Access to pipe tunnels under oil cargo tanks**

The pipe tunnel in the double bottom under oil cargo tanks is to comply with the following requirements:

- it is not to communicate with the engine room
- provision is to be made for at least two exits to the open deck arranged at a maximum distance from each other. One of these exits fitted with a watertight closure may lead to the cargo pump room.

### **5.1.4 Doors between pipe tunnel and main pump room**

Where there is a permanent access from a pipe tunnel to the main pump room, a watertight door is to be fitted complying with the requirements in Pt B, Ch 2, Sec 1, [6.3.1]. In addition the following is to be complied with:

- in addition to bridge operation, the watertight door is to be capable of being manually closed from outside the main pump room entrance
- the watertight door is to be kept closed during normal operations of the ship except when access to the pipe tunnel is required. A notice is to be affixed to the door to this effect.

## **5.2 Access arrangement to and within spaces in, and forward of, the cargo area**

### **5.2.1 Means of access**

Ships with the service notation **combination carrier/OBO ESP** or **combination carrier/OOC ESP** of 20,000 gross tonnage and over, are to comply with provisions of [5.5] and with the International Convention for the Safety of Life at Sea, 1974, as amended, Chapter II-1, Part A-1, Regulation 3-6, as amended, Chapter II-1, Part A-1, Regulation 3-6, for details and arrangements of openings and attachments to the hull structure.

Ships with the service notation **combination carrier/OBO ESP** or **combination carrier/OOC ESP** of less than 20,000 gross tonnage, are to comply with [5.3], [5.4] and [5.5].

## **5.3 Access to dry cargo holds**

### **5.3.1 Means of access**

As far as practicable, permanent or movable means of access stored on board are to be provided to ensure proper survey and maintenance of dry cargo holds.

### **5.3.2 Hatches of large cargo holds**

When the access to the dry cargo hold is arranged through the cargo hatch, the top of the ladder, as required in [5.3.3], is to be placed as close as possible to the hatch coaming.

Accesses and ladders are to be so arranged that personnel equipped with self-contained breathing apparatus may readily enter and leave the dry cargo hold.

Access hatch coamings having a height greater than 900 mm are also to have steps on the outside in conjunction with dry cargo hold ladders.

### **5.3.3 Ladders within large cargo holds**

Each dry cargo hold is to be provided with at least two ladders as far apart as practicable longitudinally. If possible these ladders are to be arranged diagonally, e.g. one ladder near the forward bulkhead on the port side, the other one near the aft bulkhead on the starboard side, from the ship's centreline.

Ladders are to be so designed and arranged that the risk of damage from the cargo handling gear is minimised.

Vertical ladders may be permitted provided they are arranged above each other in line with other ladders to which they form access and resting positions are provided at not more than 9 metres apart.

Tunnels passing through dry cargo holds are to be equipped with ladders or steps at each end of the hold so that personnel may get across such tunnels.

Where it may be necessary for work to be carried out within a dry cargo hold preparatory to loading, consideration is to be given to suitable arrangements for the safe handling of portable staging or movable platforms.

## **5.4 Access to compartments in the oil cargo area**

### **5.4.1 General**

Access to cofferdams, ballast tanks, dry cargo holds, oil cargo tanks and other compartments in the oil cargo area is to be direct from the open deck and such as to ensure their complete inspection.

**5.4.2 Access through horizontal openings**

*For access through horizontal openings the dimensions are to be sufficient to allow a person wearing a self-contained, air-breathing apparatus and protective equipment to ascend or descend any ladder without obstruction and also to provide a clear opening to facilitate the hoisting of an injured person from the bottom of the compartment. The minimum clear opening is to be not less than 600 mm by 600 mm.*

**5.4.3 Access through vertical openings**

*For access through vertical openings the minimum clear opening is to be not less than 600 mm by 800 mm at a height of not more than 600 mm from the bottom shell plating unless gratings or other footholds are provided.*

**5.5 Access to the bow**

**5.5.1** *Combination carriers are to be provided with the means to enable the crew to gain safe access to the bow even in severe weather conditions. Such means are to be accepted by the Society.*

Note 1: The Society considers means in compliance with the Guidelines adopted by the Maritime Safety Committee of IMO with Resolution MSC.62(67) on 5/12/1996 as being acceptable.

## Section 3 Hull and Stability

### 1 General

#### 1.1 Loading manual and loading instrument

1.1.1 The specific requirements in Pt B, Ch 1, Sec 5 for ships with either of the service notations **combination carrier /OBO ESP** or **combination carrier /OOC ESP** and equal to or greater than 150 m in length are to be complied with.

### 2 Stability

#### 2.1 Intact stability

##### 2.1.1 General

The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.5] is to be in compliance with the requirements in Pt B, Ch 3, Sec 2. Where the ship is intended also for the carriage of grain, the requirements in Ch 4, Sec 3, [1.2.2] and Ch 4, Sec 3, [1.2.3] are to be complied with.

In addition, for the carriage of liquids, the requirements in [2.1.3] are to be complied with.

##### 2.1.2 Liquid transfer operations

Ships with certain internal subdivision may be subjected to lolling during liquid transfer operations such as loading, unloading or ballasting. In order to reduce the effect of lolling, the design of combination carriers of 5000 t deadweight and above is to be such that the following criteria are complied with:

- a) *The intact stability criteria reported in b) are to be complied with for the worst possible condition of loading and ballasting as defined in c), consistent with good operational practice, including the intermediate stages of liquid transfer operations. Under all conditions the ballast tanks are to be assumed slack.*
- b) *The initial metacentric height  $GMo$ , in m, corrected for free surface measured at  $0^\circ$  heel, is to be not less than 0,15. For the purpose of calculating  $GMo$ , liquid surface corrections are to be based on the appropriate upright free surface inertia moment.*
- c) *The vessel is to be loaded with:*
  - *all cargo tanks filled to a level corresponding to the maximum combined total of vertical moment of volume plus free surface inertia moment at  $0^\circ$  heel, for each individual tank*
  - *cargo density corresponding to the available cargo deadweight at the displacement at which transverse KM reaches a minimum value*
  - *full departure consumable*
  - *1% of the total water ballast capacity. The maximum free surface moment is to be assumed in all ballast tanks.*

##### 2.1.3 Alternative requirements for liquid transfer operation

As an alternative to the requirements in [2.1.2], simple supplementary operational procedures are to be followed when the ship is carrying oil cargoes or during liquid transfer operations.

*Simple supplementary operational procedures for liquid transfer operations means written procedures made available to the Master which:*

- *are approved by the Society,*
- *indicate those cargo and ballast tanks which may, under any specific condition of liquid transfer and possible range of cargo densities, be slack and still allow the stability criteria to be met. The slack tanks may vary during the liquid transfer operations and be of any combination provided they satisfy the criteria,*
- *are to be readily understandable to the officer-in-charge of liquid transfer operations,*
- *provide for planned sequences of cargo/ballast transfer operations,*
- *allow comparisons of attained and required stability using stability performance criteria in graphical or tabular form,*
- *require no extensive mathematical calculations by the officer-in-charge,*
- *provide for corrective actions to be taken by the officer-in-charge in the event of departure from the recommended values and in case of emergency situations, and*
- *are prominently displayed in the approved trim and stability booklet and at the cargo/ballast transfer control station and in any computer software by which stability calculations are performed.*

**2.2 Damage stability - dry cargoes or ballast loading conditions - for ships where additional class notation SDS is requested**

**2.2.1 General**

Combination carriers equal to or greater than 80 m in length are subjected to the probabilistic approach reported in Pt B, Ch 3, Sec 3, [2.1.3] and are to comply with the requirements in Pt B, Ch 3, App 3, for the loading conditions which entail the carriage of dry cargoes or ballast, unless they comply with the requirements in [2.2.2] or [2.3].

**2.2.2 Freeboard reduction**

Combination carriers greater than 100 m in length which have been assigned reduced freeboard as permitted by Regulation 27 of the International Convention on Load Lines, 1966, as referenced in Pt B, Ch 3, Sec 3, [2.1.2] are to comply with the requirement specified in Pt B, Ch 3, App 4. Therefore, compliance with the requirements in Ch 5, Sec 3, [2.2.1] is not required.

**2.3 Damage stability - oil cargoes - for ships where additional class notation SDS is requested**

**2.3.1 General**

In the loading conditions which entail the carriage of oil cargoes, combination carriers are to comply with the subdivision and damage stability criteria as specified in [2.3.8], after the assumed side or bottom damage as specified in [2.3.2], for the standard of damage described in [2.3.3], and for any operating draught reflecting actual partial or full load conditions consistent with trim and strength of the ship as well as specific gravities of the cargo.

The actual partial or full load conditions to be considered are those specified in Pt B, Ch 3, App 2, [1.2.6], but ballast conditions where the ship is not carrying oil in cargo tanks, excluding any oil residues, are not to be considered.

**2.3.2 Damage dimensions**

The assumed extent of damage is to be as defined in Tab 1.

The transverse extent of damage is measured inboard the ship side at right angles to the centreline at the level of the summer load line.

The vertical extent of damage is measured from the moulded line of the bottom shell plating at centreline.

For the purpose of determining the extent of assumed damage, suction wells may be neglected, provided such wells are not excessive in areas and extend below the tank for a minimum distance and in no case more than half the height of the double bottom.

If any damage of a lesser extent than the maximum extent of damage specified in Tab 1 would result in a more severe condition, such damage is to be considered.

**Table 1 : Extent of damage**

Damage		Longitudinal extent	Transverse extent	Vertical extent
Side		<ul style="list-style-type: none"> <li><math>l_c = 1/3 L_{LL}^{2/3}</math> or</li> <li>14,5 m</li> </ul> whichever is the lesser	$t_c = B/5$ 11,5 m whichever is the lesser	$v_c =$ without limit
Bottom	for 0,3 $L_{LL}$ from the forward perpendicular	<ul style="list-style-type: none"> <li><math>l_s = 1/3 L_{LL}^{2/3}</math></li> <li>14,5 m</li> </ul> whichever is the lesser	<ul style="list-style-type: none"> <li><math>t_s = B/6</math></li> <li>10 m</li> </ul> whichever is the lesser	<ul style="list-style-type: none"> <li><math>v_s = B/15</math></li> <li>6 m</li> </ul> whichever is the lesser
	any other part	<ul style="list-style-type: none"> <li><math>l_s = 1/3 L_{LL}^{2/3}</math></li> <li>5 m</li> </ul> whichever is the lesser	<ul style="list-style-type: none"> <li><math>t_s = B/6</math></li> <li>5 m</li> </ul> whichever is the lesser	<ul style="list-style-type: none"> <li><math>v_s = B/15</math></li> <li>6 m</li> </ul> whichever is the lesser

**2.3.3 Standard of damage**

The damage in [2.3.2] is to be applied to all conceivable locations along the length of the ship, according to Tab 2.

**Table 2 : Standard of damage**

Ship's length, in m	Damage anywhere in ship's length	Damage between transverse bulkheads	Machinery space flooded alone
$L_{LL} \leq 100$	No	Yes (1) (2)	No
$100 < L_{LL} \leq 150$	No	Yes (1)	No
$150 < L_{LL} \leq 225$	Yes	No	Yes
$L_{LL} > 225$	Yes	No	No

(1) Machinery space not flooded.  
 (2) Exemptions from the requirements of [2.3.8] may be accepted by the Society on a case-by-case basis.

**2.3.4 Calculation method**

The metacentric heights (GM), the stability levers (GZ) and the centre of gravity positions (KG) for judging the final survival conditions are to be calculated by the constant displacement method (lost buoyancy).

**2.3.5 Flooding assumptions**

The requirements of [2.3.8] are to be confirmed by calculations which take into consideration the design characteristics of the ship, the arrangements, configuration and contents of the damaged compartments and the distribution, specific gravities and free surface effect of liquids.

Where the damage involving transverse bulkheads is envisaged as specified in [2.3.3], transverse watertight bulkheads are to be spaced at least at a distance equal to the longitudinal extent of assumed damage specified in [2.3.2] in order to be considered effective. Where transverse bulkheads are spaced at a lesser distance, one or more of these bulkheads within such extent of damage is to be assumed as non-existent for the purpose of determining flooded compartments.

Where the damage between adjacent transverse watertight bulkheads is envisaged as specified in [2.3.3], no main transverse bulkhead bounding side tanks or double bottom tanks is to be assumed damaged, unless:

- the spacing of the adjacent bulkheads is less than the longitudinal extent of assumed damage specified in [2.3.2] or,
- there is a step or a recess in a transverse bulkhead of more than 3,05 metres in length, located within the extent of penetration of assumed damage. The step formed by the after peak bulkhead and after peak tank top is not to be regarded as a step.

**2.3.6 Progressive flooding**

If pipes, ducts or tunnels are situated within the assumed extent of damage penetration as defined in [2.3.2], arrangements are to be made so that progressive flooding cannot thereby extend to compartments other than those assumed to be floodable in the calculation for each case of damage.

**2.3.7 Permeabilities**

The specific gravity of cargoes carried, as well as any outflow of liquid from damaged compartments, are to be taken into account for any empty or partially filled tank.

The permeability of compartments assumed to be damaged is to be as indicated in Tab 3.

**Table 3 : Permeability**

Compartments	Permeability
Appropriated for stores	0,60
Occupied by accommodation	0,95
Occupied by machinery	0,85
Void compartments	0,95
Intended for consumable liquids	0 to 0,95 <b>(1)</b>
Intended for other liquids	0 to 0,95 <b>(1)</b>

**(1)** The permeability of partially filled compartments is to be consistent with the amount of liquid carried in the compartment.

**2.3.8 Survival requirements**

Combination carriers, in the damage case of [2.3], are to be regarded as complying with the damage stability criteria if the requirements of [2.3.9] and [2.3.10] are met.

**2.3.9 Final stage of flooding**

- The final waterline, taking into account sinkage, heel and trim, is to be below the lower edge of any opening through which progressive flooding may take place. The progressive flooding is to be considered in accordance with Pt B, Ch 3, Sec 3, [3.3].
- The angle of heel due to unsymmetrical flooding may not exceed 25°, except that this angle may be increased up to 30° if no deck edge immersion occurs.
- The stability is to be investigated and may be regarded as sufficient if the righting lever curve has at least a range of 20° beyond the position of equilibrium in association with a maximum residual righting lever, in m, of at least 0,1 within the 20° range; the area, in m-rad, under the curve within this range is to be not less than 0,0175.

**2.3.10 Intermediate stage of flooding**

The Society is to be satisfied that the stability is sufficient during the intermediate stages of flooding. To this end the Society applies the same criteria relevant to the final stage of flooding also during the intermediate stages of flooding.

**2.3.11 Bottom raking damage**

This requirement applies to combination carriers of 20000 t deadweight and above.

The damage assumptions relative to the bottom damage prescribed in [2.3.2] are to be supplemented by the assumed bottom raking damage of Tab 4.

The requirements of [2.3.8] are to be complied with for the assumed bottom raking damage.

Table 4 : Bottom damage extent

Deadweight	Longitudinal extent	Transverse extent	Vertical extent
< 75000 t	0,4 L <sub>LL</sub> (1)	B/3	(2)
≥ 75000 t	0,6 L <sub>LL</sub> (1)	B/3	(2)
(1) Measured from the forward perpendicular.			
(2) Breach of the outer hull.			

### 2.3.12 Equalisation arrangements

Equalisation arrangements requiring mechanical aids such as valves or cross levelling pipes, if fitted, may not be considered for the purpose of reducing an angle of heel or attaining the minimum range of residual stability to meet the requirements of [2.3.9] and sufficient residual stability is to be maintained during all stages where equalisation is used. Compartments which are linked by ducts of a large cross-sectional area may be considered to be common.

### 2.3.13 Information to the Master

The Master of every combination carrier is to be supplied in an approved form with:

- information relative to loading and distribution of cargo necessary to ensure compliance with the requirements relative to stability, and
- data on the ability of the ship to comply with damage stability criteria as determined in [2.3.8] including the effect of relaxation that may have been allowed as specified in Tab 2.

## 3 Structure design principles of ships with the service notation combination carrier / OBO ESP

### 3.1 Double bottom structure

#### 3.1.1 Longitudinally framed double bottom

In ships greater than 120 m in length, the double bottom and the sloped bulkheads of hopper tanks are to be longitudinally framed.

The girder spacing is to be not greater than 4 times the spacing of bottom or inner bottom ordinary stiffeners and the floor spacing is to be not greater than 3 frame spaces.

Greater spacing may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Pt B, Ch 7, Sec 6 for the primary supporting members in the cargo holds.

#### 3.1.2 Transversely framed double bottom

The double bottom and the sloped bulkheads of hopper tanks may be transversely framed in ships less than or equal to 120 m in length, when this is deemed acceptable by the Society on a case-by-case basis. In this case, however, the floor spacing is to be not greater than 2 frame spaces.

#### 3.1.3 Floors in way of transverse bulkheads

The thickness and material properties of the supporting floors and pipe tunnel beams are to be not less than those required for the bulkhead plating or, when a stool is fitted, of the stool side plating.

### 3.2 Double side structure

#### 3.2.1 General

The side within the hopper and topside tanks is, in general, to be longitudinally framed. It may be transversely framed when this is accepted for the double bottom and the deck according to [3.1.2] and [3.3.1], respectively.

#### 3.2.2 Side primary supporting members

The spacing of transverse side primary supporting members is to be not greater than 3 frame spaces.

Greater spacing may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Pt B, Ch 7, Sec 6 for the primary supporting members in the cargo holds.

In any case, transverse side primary supporting members are to be fitted in line with transverse primary supporting members in hopper and topside tanks.

### 3.3 Deck structure

#### 3.3.1 Deck outside the line of hatches and topside tank sloping plates

In ships greater than 120 m in length, the deck outside the line of hatches and the topside tank sloping plates are to be longitudinally framed.

The spacing of transverse primary supporting members in topside tanks is to be not greater than 6 frame spaces.

Greater spacing may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Pt B, Ch 7, Sec 6 for the primary supporting members in the cargo holds.

### **3.3.2 Deck between hatches**

The cross decks between hatches are generally to be transversely framed.

### **3.3.3 Connection of hatch end beams with deck structures**

The connection of hatch end beams with deck structures is to be properly ensured by fitting inside the topside tanks additional web frames or brackets.

### **3.3.4 Topside tank structure**

Topside tank structures are to extend as far as possible within the machinery space and are to be adequately tapered.

## **4 Structure design principles of ships with the service notation combination carrier / OOC ESP**

### **4.1 Double bottom structure**

**4.1.1** The double bottom is to be longitudinally framed.

The girder spacing is to be not greater than 4 times the spacing of bottom or inner bottom ordinary stiffeners and the floor spacing is to be not greater than 3 frame spaces.

Solid floors are to be fitted in line with the transverse primary supporting members in wing tanks and intermediate floors are to be added at mid-span between primary supporting members.

**4.1.2** Other arrangements may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Pt B, Ch 7, Sec 6 for the primary supporting members in the cargo holds.

**4.1.3** Scarfing of the double bottom structure into the wing tanks is to be properly ensured. The inner bottom plating is generally to be prolonged within the wing tanks by adequately sized horizontal brackets in way of floors.

### **4.2 Side structure**

**4.2.1** In ships greater than 120 m in length, the side shell is to be longitudinally framed.

In general, the spacing of vertical primary supporting members is to be not greater than 6 times the frame spacing.

**4.2.2** Other arrangements may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Pt B, Ch 7, Sec 6 for the primary supporting members in the cargo hold.

### **4.3 Deck structure**

**4.3.1** The deck outside the line of hatches is to be longitudinally framed.

**4.3.2** The cross decks between hatches are generally to be transversely framed.

**4.3.3** The connection of hatch end beams with deck structures is to be properly ensured by fitting inside the wing tanks additional web frames or brackets.

### **4.4 Longitudinal bulkhead structure**

**4.4.1** Longitudinal bulkheads are to be plane, but they may be knuckled in the upper part and in the lower part to form a hopper. In these cases, the design of the knuckles and the adjacent structures is to be considered by the Society on a case-by-case basis.

**4.4.2** In ships greater than 120 m in length, longitudinal bulkheads are to be longitudinally framed.

**4.4.3** Other arrangements may be accepted by the Society, on a case-by-case basis, depending on the results of the analysis carried out according to Pt B, Ch 7, Sec 6 for the primary supporting members in the cargo hold.

### **4.5 Transverse bulkhead structure**

**4.5.1** Where the structural arrangement of transverse bulkheads in wing tanks is different from that in centre holds, arrangements are to be made to ensure continuity of the transverse strength through the longitudinal bulkheads.

## 5 Design loads

### 5.1 Loading conditions for longitudinal strength assessment

5.1.1 In addition to the requirements in Pt B, Ch 5, Sec 4, [2.1.1], still water loads are to be calculated for the following loading conditions, subdivided into departure and arrival conditions as appropriate:

- alternate light and heavy cargo (dry or oil) loading conditions at maximum draught, where applicable
- homogeneous light and heavy cargo (dry or oil) loading conditions at maximum draught
- ballast conditions. For ships having ballast holds adjacent to topside wing, hopper and double bottom tanks, it may be acceptable in terms of strength that the ballast holds are filled when the topside wing, hopper and double bottom tanks are empty. Partial filling of the peak tanks is not acceptable in the design ballast conditions, unless effective means are provided to prevent accidental overfilling
- short voyage conditions where the ship is to be loaded to maximum draught but with a limited amount of bunkers
- Multi-port (MP) loading/unloading conditions, if allowed by the loading manual (see Pt B, Ch 1, Sec 5, [2])
- deck cargo conditions, where applicable
- typical loading sequences where the ship is loaded from commencement of cargo loading to reaching full deadweight capacity, for homogeneous conditions, relevant part load conditions and alternate conditions where applicable.  
Typical unloading sequences for these conditions are also to be included. The typical loading/unloading sequences are also to be developed so as not to exceed applicable strength limitations. The typical loading sequences are also to be developed paying due attention to the loading rate and deballasting capability
- typical sequences for change of ballast at sea, where applicable.

### 5.2 Load combinations for direct strength analysis

#### 5.2.1 Applicable general load combinations

The following load combinations are to be considered as defined in:

- Ch 5, Sec 3, [4.2] and Ch 7, Sec 3, [4.3] for ships assigned with the service notation **combination carrier /OOC ESP**
- Ch 4, Sec 3, [3.3] and Ch 7, Sec 3, [4.3] for ships assigned with the service notation **combination carrier /OBO ESP**.

### 5.3 Local loads

#### 5.3.1 Bottom impact pressure

For combination carriers of 20000 t deadweight and above, the draught  $T_F$ , to be considered in the calculation of the bottom impact pressure according to Pt B, Ch 5, Sec 5, [4.2.1], is that calculated by using the segregated ballast tanks only.

#### 5.3.2 Oil cargo mass density

In the absence of more precise values, an oil cargo mass density of 0,9 t/m<sup>3</sup> is to be considered for calculating the internal pressures and forces in cargo tanks according to Pt B, Ch 5, Sec 6 or NR600, as applicable.

## 6 Hull scantlings

### 6.1 Strength check with respect to stresses due to the temperature gradient

#### 6.1.1 General

Direct calculations of stresses induced in the hull structures by the temperature gradient are to be performed:

- for ships intended to carry cargoes at temperatures exceeding 90°C
- and when part of the hull structures temperature exceeds 90°C

In these calculations, the water temperature is to be assumed equal to 0°C.

The calculations are to be submitted to the Society for review.

#### 6.1.2 Material

For steels used at a temperature  $\theta$  between 90°C and 300°C, and unless other information is specified, their minimum yield stress  $R_{eH}$  and Young's modulus  $E$  are to be taken as specified in Pt B, Ch 4, Sec 1, [2.1.1].

The material factor is to be adjusted accordingly.

#### 6.1.3 Thermal stress for integral tanks

The stresses induced in the hull structures by the temperature gradient are to comply with the checking criteria in Pt B, Ch 8, App 1, [5.2.3].

#### **6.1.4 Thermal stress for independent tanks**

Where a thermal elongation is made possible due to the design of the tank supports, the thermal stress may be neglected provided the cargo temperature distribution is rather uniform.

In addition, precautions are to be taken, upon loading of any hot cargo, by pre-heating the tanks in order to minimize the temperature gradients within the cargo hold.

### **7 Other structures**

#### **7.1 Machinery space**

##### **7.1.1 Extension of hull structures within the machinery space**

Longitudinal bulkheads or inner side, as applicable, carried through cofferdams are to continue within the machinery space and are to be used preferably as longitudinal bulkheads for liquid cargo tanks. In any case, such extension is to be compatible with the shape of the structures of the double bottom, deck and platforms of the machinery space.

Where topside tanks are fitted, their structures are to extend as far as possible within the machinery space and to be adequately tapered.

#### **7.2 Opening arrangement**

##### **7.2.1 Cargo shore connection**

Entrances, air inlets and openings to accommodation, service and machinery spaces and control stations may not face the cargo shore connection location of bow or stern loading and unloading arrangements. They are to be located on the outboard side of the superstructure or deckhouse at a distance of at least 4% of the ship's length but not less than 3 m from the end of the deckhouse facing the cargo shore connection location of the bow or stern loading and unloading arrangements. This distance, however, need not exceed 5 m. Sidescuttles facing the shore connection location and on the sides of the superstructure or deckhouse within the distance mentioned above are to be of the fixed (non-opening) type. All doors, ports and other openings on the corresponding superstructure or deckhouse side are to be fitted so that they can be kept closed during the use of the bow or stern loading and unloading arrangements. The Society may permit departures from these requirements in the case of small ships when, at its discretion, compliance with them is not possible.

Air pipes and other openings to enclosed compartments not listed above are to be shielded from spray which may come from a leaking hose or connection.

##### **7.2.2 Deck foam system room**

An access to a deck foam system room (including the foam tank and the control station) may be permitted within the limits mentioned in Pt C, Ch 4, Sec 6, [3.3.1], provided that the door is located flush with the bulkhead.

##### **7.2.3 Tanks covers**

Covers fitted on all cargo tank openings are to be of sturdy construction, and to ensure tightness for hydrocarbon and water.

Aluminium is not permitted for the construction of tank covers. The use of reinforced fibreglass covers is to be specially examined by the Society.

### **8 Hull outfitting**

#### **8.1 Equipment**

##### **8.1.1 Emergency towing arrangement**

The specific requirements in Pt B, Ch 12, Sec 4, [3] for ships with either of the service notations **combination carrier /OBO ESP** or **combination carrier /OOC ESP** and of 20000 t deadweight and above are to be complied with.

### **9 Protection of hull metallic structures**

#### **9.1 Protection by aluminium coatings**

**9.1.1** The use of aluminium coatings containing greater than 10% aluminium by weight in the dry film is prohibited in the cargo tanks, cargo tank deck area, pump rooms, cofferdams or any other area where cargo vapour may accumulate.

### **10 Cathodic protection of tanks**

#### **10.1 General**

**10.1.1** Internal structures in spaces intended to carry liquids may be provided with cathodic protection.

Cathodic protection may be fitted in addition to the required corrosion protective coating, if any.

**10.1.2** Details concerning the type of anodes used and their location and attachment to the structure are to be submitted to the Society for approval.

**10.2 Anodes**

**10.2.1** Magnesium or magnesium alloy anodes are not permitted in oil cargo tanks and tanks adjacent to cargo tanks.

**10.2.2** Aluminium anodes are only permitted in cargo tanks and tanks adjacent to cargo tanks in locations where the potential energy does not exceed 28 kg m. The height of the anode is to be measured from the bottom of the tank to the centre of the anode, and its weight is to be taken as the weight of the anode as fitted, including the fitting devices and inserts.

However, where aluminium anodes are located on horizontal surfaces such as bulkhead girders and stringers not less than 1 m wide and fitted with an upstanding flange or face flat projecting not less than 75 mm above the horizontal surface, the height of the anode may be measured from this surface.

Aluminium anodes are not to be located under tank hatches or washing holes, unless protected by the adjacent structure.

**10.2.3** There is no restriction on the positioning of zinc anodes.

**10.2.4** Anodes are to have steel cores and are to be declared by the Manufacturer as being sufficiently rigid to avoid resonance in the anode support and designed so that they retain the anode even when it is wasted.

**10.2.5** The steel inserts are to be attached to the structure by means of a continuous weld. Alternatively, they may be attached to separate supports by bolting, provided a minimum of two bolts with lock nuts are used. However, other mechanical means of clamping may be accepted.

**10.2.6** The supports at each end of an anode may not be attached to separate items which are likely to move independently.

**10.2.7** Where anode inserts or supports are welded to the structure, they are to be arranged by the Shipyard so that the welds are clear of stress peaks.

**10.2.8** As a general rule, the requirements Ch 7, Sec 3, [12.2.3] to Ch 7, Sec 3, [12.2.7] apply also to spaces or compartments adjacent to cargo or slop tanks.

**10.3 Impressed current systems**

**10.3.1** Impressed current cathodic protections are not accepted in cargo or slop tanks, unless specially authorized by the Society.

**11 Construction and testing**

**11.1 Welding and weld connections**

**11.1.1** The weld factors for some hull structural connections are specified in Tab 5. These weld factors are to be used, in lieu of the corresponding factors specified in Pt B, Ch 13, Sec 3, Tab 1, to calculate the leg length of fillet weld T connections according to Pt B, Ch 13, Sec 3, [3.2.6]. For the connections of Tab 5, continuous fillet welding is to be adopted.

**Table 5 : Weld factor  $w_f$**

Hull area	Connection		Weld factor $w_f$
	of	to	
Double bottom in way of cargo holds and tanks	girders	bottom and inner bottom plating	0,48
		floors (interrupted girders)	
	floors	bottom and inner bottom plating	
		girders (interrupted floors)	
Bulkheads in oil cargo tanks	ordinary stiffeners	bulkhead plating	0,48

**11.2 Special structural details**

**11.2.1** The specific requirements in Pt B, Ch 13, Sec 5, [2.7] for ships with either of the service notations **combination carrier / OBO ESP** or **combination carrier / OOC ESP** are to be complied with.

# Section 4 Machinery and Cargo Systems

## 1 General

### 1.1 Application

**1.1.1** Ships having the service notation **combination carrier** are to comply with the requirements of Ch 7, Sec 4 applicable to oil tankers or oil tankers flashpoint > 60°C, as appropriate.

In addition, they are to comply with the provisions of this Section.

### 1.2 Documents

#### 1.2.1 Documents to be submitted

In addition to those listed in Ch 7, Sec 4, Tab 1, the following documents are to be submitted for approval.

**Table 1 : Documents to be submitted**

No.	Description of the document (1)
1	Diagram of the ventilation systems serving cargo spaces and enclosed spaces adjacent to cargo spaces
3	Diagram of the gas measurement system for cargo pump rooms, pipe ducts and cofferdams adjacent to slop tanks
4	Diagram of water filling and draining systems for cofferdams
5	Diagram of discharge pumping and piping systems for slop tanks
(1) Diagrams are also to include, where applicable: <ul style="list-style-type: none"> <li>• the (local and remote) control and monitoring systems and automation systems</li> <li>• the instructions for the operation and maintenance of the piping system concerned (for information).</li> </ul>	

#### 1.2.2 Instruction manual

A manual is to be kept on board giving instructions for the carriage of contaminated sludge in slop tanks when the ship is in the dry cargo mode.

## 2 General requirements

### 2.1 Ventilation and gas detection

#### 2.1.1 Ventilation

Cargo spaces and enclosed spaces adjacent to cargo spaces are to be capable of being mechanically ventilated. The mechanical ventilation may be provided by portable fans. See also Pt C, Ch 4, Sec 2, [2.1.2].

#### 2.1.2 Gas detection

- a) An approved fixed gas warning system capable of monitoring flammable vapours is to be provided in cargo pump rooms and pipe ducts and cofferdams adjacent to slop tanks.
- b) Audible and visual alarms for the gas detection equipment are to be located on the bridge or in other suitable continually manned spaces.

### 2.2 Arrangement of cargo lines

#### 2.2.1

- a) Where cargo wing tanks are provided, cargo oil lines below deck are to be installed inside these tanks. However, the Society may permit cargo oil lines to be placed in special ducts which are to be capable of being adequately cleaned and ventilated and to the satisfaction of the Society.

If connected to a cargo pump room, such ducts are to be considered as cargo pump rooms for the purposes of safety.

- b) Where cargo wing tanks are not provided, cargo oil lines below deck are to be placed in special ducts.

### **2.3 Cargo openings**

**2.3.1** Openings which may be used for cargo operations are not permitted in bulkheads and decks separating oil cargo spaces from other spaces not designed and equipped for the carriage of oil cargoes unless alternative approved means provide equivalent integrity.

### **2.4 Cofferdam filling and draining**

**2.4.1** Means are to be provided for filling the cofferdams surrounding the slop tanks with water and for draining them. See Ch 6, Sec 2, [1.1.5].

## **3 Slop tanks**

### **3.1 Segregation of piping systems**

#### **3.1.1**

- a) Pipes serving the slop tanks are to be segregated from other parts of the cargo pumping and piping system by means of isolation complying with b) or c) below.
- b) Arrangements to isolate slop tanks containing oil or oil residues from other cargo tanks are to consist of blank flanges which are to remain in position at all times when cargoes other than liquid cargoes referred to in Ch 7, Sec 1, [1.1.3] are carried.
- c) Means are to be provided for isolating the piping connecting the pump room with the slop tanks. The means of isolation are to consist of a valve followed by a spectacle flange or a spool piece with appropriate blank flanges. This arrangement is to be located adjacent to the slop tanks, but where this is unreasonable or impracticable, it may be located within the pump room directly after the piping penetrates the bulkhead.

### **3.2 Venting system**

**3.2.1** Slop tanks are to be provided with a separate venting system complying with the provisions of Ch 7, Sec 4, [4.2].

### **3.3 Discharge pumping and piping arrangement**

**3.3.1** A separate pumping and piping arrangement incorporating a manifold is to be provided for discharging the contents of the slop tanks directly to the open deck for disposal to shore reception facilities when the ship is in the dry cargo mode.

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **oil tanker**, as defined in Pt A, Ch 1, Sec 2, [4.4.2].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1
- requirements as defined in [1.1.3] and [1.1.4], as applicable.

**Table 1 : Applicable requirements**

### 1.1.3 Service notation oil tanker

a) The requirements of this Chapter apply to ships having the service notation **oil tanker**, as defined in Pt A, Ch 1, Sec 2, [4.4.2]. They also apply to ships having the additional service feature **flash point > 60°C** and **asphalt carrier**, taking into account the specific provisions given in the different Sections.

Note 1: The specific provisions referred to in a) above do not apply to ships intended for the carriage of bulk cargoes at a temperature above the flash point of the product carried.

b) Departures from these requirements are given for ships that have the service notation **oil tanker-flash point > 60°C** and are intended only for the carriage of bulk cargoes at a temperature below and not within 15°C of their flash point.

c) Ch 7, Sec 4, [8] provides additional requirements for ships having the service notation **oil tanker-asphalt carrier**.

d) The list of substances the carriage in bulk of which is covered by the service notations **oil tanker**, **oil tanker- flash point > 60°C** and **oil tanker-asphalt carrier** is given in Ch 7, App 3, Tab 1.

1.1.4 Service notation FLS tanker

a) The requirements of this Chapter apply to ships having the service notation **FLS tanker**, as defined in Pt A, Ch 1, Sec 2, [4.4.5]. They also apply to ships having the additional service feature **FLS tanker-flash point > 60°C**, taking into account the specific provisions given in Ch 7, Sec 4.

Note 1: The specific provisions referred to in a) above do not apply to ships intended for the carriage of bulk cargoes at a temperature above the flash point of the product carried.

b) Ch 7, Sec 4, [9] provides additional requirements for ships having the service notations **FLS tanker** and **FLS tanker-flash point > 60°C** in the case of carriage of pollution category Z products.

c) The list of substances the carriage in bulk of which is covered by the service notations **FLS tanker** and **FLS tanker-flash point > 60°C** is given in Ch 7, App 4.

Note 2: The service notation **FLS tanker** does not cover cargoes containing 10% of benzene or more. Ships carrying such cargoes are to comply with the relevant requirements of Part D, Chapter 8.

Note 3: Where the provisions of this Chapter applicable to the service notation **oil tanker** and those applicable to the service notation **FLS tanker** are simultaneously complied with, a ship may be granted both service notations **oil tanker-FLS tanker** or **oil tanker-FLS tanker-flash point > 60°C**, as applicable.

1.2 Definitions

1.2.1 Cargo area

The cargo area is that part of the ship that contains cargo tanks as well as slop tanks, cargo pump rooms including pump rooms, cofferdams, ballast or void spaces adjacent to cargo tanks or slop tanks as well as deck areas throughout the entire length and breadth of the part of the ship above these spaces.

When independent tanks are installed in hold spaces, the cofferdams, ballast or void spaces at the after end of the aftermost hold space or at the forward end of the forwardmost hold space are excluded from the cargo area.

1.2.2 Cargo pump room

Cargo pump room is a space containing pumps and their accessories for the handling of products covered by the service notation granted to the ship.

1.2.3 Cargo service spaces

Cargo service spaces are spaces within the cargo area used for workshops, lockers and storerooms of more than 2 m<sup>2</sup> in area, intended for cargo handling equipment.

1.2.4 Cargo tank block

The cargo tank block is the part of the ship extending from the aft bulkhead of the aftmost cargo or slop tank to the forward bulkhead of the forward most cargo or slop tank, extending to the full depth and beam of the ship, but not including the area above the deck of the cargo or slop tank (See Fig 1).

Figure 1 : Cargo tank block definition

1.2.5 Clean ballast

Clean ballast means the ballast in a tank which since oil was last carried therein, has been so cleaned that the effluent therefrom if it were discharged from a ship which is stationary into clean calm water on a clear day would not produce visible traces of oil on the surface of the water or on adjoining shorelines or cause a sludge or emulsion to be deposited beneath the surface of the water or upon adjoining shorelines. If the ballast is discharged through an oil discharge monitoring and control system approved by the Society, evidence based on such a system to the effect that the oil content of the effluent did not exceed 15 parts per million is to be determinative that the ballast was clean, notwithstanding the presence of visible traces.

**1.2.6 Cofferdam**

For the purpose of Ch 7, Sec 2, [2], a cofferdam is an isolating space between two adjacent steel bulkheads or decks. It is to meet the following criteria:

- a) the minimum distance between the two bulkheads or decks is to be sufficient for safe access and inspection.
- b) in order to meet the single failure principle, in the particular case when a corner-to-corner situation occurs, this principle may be met by welding a diagonal plate across the corner.

**1.2.7 Crude oil**

*Crude oil is any oil occurring naturally in the earth whether or not treated to render it suitable for transportation and includes:*

- a) *crude oil from which certain distillate fractions have been removed, and*
- b) *crude oil to which certain distillate fractions may have been added.*

**1.2.8 Crude oil tanker**

*Crude oil tanker means an oil tanker engaged in the trade of carrying crude oil.*

**1.2.9 Hold space**

Hold space is the space enclosed by the ship's structure in which an independent cargo tank is fitted

**1.2.10 Fuel oil**

*Fuel oil means any oil used as fuel in connection with the propulsion and auxiliary machinery of the ship on which such oil is carried.*

**1.2.11 Oil-like substances**

Oil-like substances are those substances listed in Ch 7, App 3, Tab 2.

**1.2.12 Oil mixture**

*Oil mixture means a mixture with any oil content.*

**1.2.13 Product carrier**

*Product carrier means an oil tanker engaged in the trade of carrying oil other than crude oil.*

**1.2.14 Pump room**

Pump room is a space, located in the cargo area, containing pumps and their accessories for the handling of ballast and fuel oil, or cargoes other than those covered by the service notation granted to the ship.

**1.2.15 Segregated ballast**

*Segregated ballast means the ballast water introduced into a tank which is completely separated from the cargo oil and fuel oil system and which is permanently allocated to the carriage of ballast or to the carriage of ballast or cargoes other than oil or noxious substances as variously defined in Part D, Chapter 7 and Part D, Chapter 8.*

**1.2.16 Slop tank**

*Slop tank means a tank specifically designated for the collection of tank draining, tank washings and other oily mixtures.*

**1.2.17 Void space**

Void space is an enclosed space in the cargo area external to a cargo tank, except for a hold space, ballast space, fuel oil tank, cargo pump room, pump room, or any space normally used by personnel.

# Section 2 Ship Arrangement

## Symbols

$L_{LL}$  : Load line length, in m, defined in Pt B, Ch 1, Sec 3, [2.1.2].

## 1 General

### 1.1 Application

1.1.1 Except otherwise specified, the requirements of this Section apply to the ships having one of the following service notations:

- oil tanker
- oil tanker, flash point > 60°C
- oil tanker, asphalt carrier
- FLS tanker
- FLS tanker, flash point > 60°C.

1.1.2 The requirements of this Section apply to ships having a propelling machinery located at the aft part of the ship. Ships with other arrangements are to be specially considered by the Society.

### 1.2 Documents to be submitted

1.2.1 Tab 1 are to be submitted for approval.

**Table 1 : Documents to be submitted**

No.	Description of the document
1	General arrangement drawing with indication of: <ul style="list-style-type: none"> <li>• access and openings</li> <li>• capacity and size of the cargo tanks, slop tanks and ballast tanks</li> </ul>
2	Diagram of the mechanical and natural ventilation with indication of the ventilation inlets and outlets

## 2 General arrangement of the ship with regard to fire prevention and crew safety

### 2.1 Location and separation of spaces

#### 2.1.1 Application

- a) The provisions of [2.1.2] to [2.1.5] apply only to ships having the service notations **oil tanker** or **FLS tanker**.
- b) Ships having one of the following service notations:
- oil tanker, flash point > 60°C
  - oil tanker, asphalt carrier
  - FLS tanker, flash point > 60°C
- are to comply with the provisions of [2.1.6].

#### 2.1.2 Cargo tank area

- a) Fore and aft peaks are not to be used as cargo tanks.
- b) Double bottom tanks adjacent to cargo tanks are not to be used as oil fuel tanks.
- c) On ships having the service notation **oil tanker** or **FLS tanker** without the additional service feature **flash point > 60°C** or **asphalt carrier**, fuel tanks located with a common boundary to cargo or slop tanks are not to be situated within, nor extend partly into, the cargo tank block. Such tanks may, however, be situated aft and/or forward of the cargo tank block. They may be accepted when located as independent tanks on open deck in the cargo area subject to spill and fire safety considerations. The arrangement of independent fuel tanks and associated fuel piping systems, including the pumps, may be as for fuel tanks and associated fuel piping systems located in the machinery spaces. For electrical equipment, requirements applicable to hazardous area classification must however be met.

### **2.1.3 Cargo pump rooms**

- a) The cargo pump rooms are to be separated from the other spaces of the ship by oiltight bulkheads and are not to have, in particular, any direct communications with the machinery spaces.
- b) Where glazed ports are provided on the bulkhead separating the cargo pump room from the machinery compartment, they are to satisfy the following conditions:
  - they are to be efficiently protected from mechanical damage
  - strong covers are to be permanently secured on the machinery compartment side
  - glazed ports are to be so constructed that glass and sealing are not impaired by the working of the ship
  - the glazed ports are to be so constructed as to maintain the structural integrity and the bulkheads resistance to fire and smoke.

**2.1.4** *Cargo pump rooms, cargo tanks, slop tanks and cofferdams are to be positioned forward of machinery spaces. However, oil fuel bunker tanks need not be forward of machinery spaces.*

*Cargo tanks and slop tanks are to be isolated from machinery spaces by cofferdams, cargo pump rooms, oil bunker tanks or ballast tanks.*

*Pump-rooms containing pumps and their accessories for ballasting those spaces situated adjacent to cargo tanks and slop tanks and pumps for oil fuel transfer are to be considered as equivalent to a cargo pump room within the context of this article provided that such pump rooms have the same safety standard as that required for cargo pump rooms. Pump rooms intended solely for ballast or oil fuel transfer, however, need not comply with the requirements of Ch 7, Sec 6, [4.2].*

*The lower portion of the pump room may be recessed into machinery spaces of category A to accommodate pumps, provided that the deck head of the recess is in general not more than one third of the moulded depth above the keel, except that in the case of ships of not more than 25000 tonnes deadweight, where it can be demonstrated that for reasons of access and satisfactory piping arrangements this is impracticable, the Society may permit a recess in excess of such height, but not exceeding one half of the moulded depth above the keel.*

Note 1: Pump rooms intended solely for ballast transfer need not comply with the requirements of Ch 7, Sec 4, [3.5.2]. The requirements of Ch 7, Sec 4, [3.5.2] are only applicable to the pump rooms, regardless of their location, where pumps for cargo, such as cargo pumps, stripping pumps, pumps for slop tanks, pumps for COW or similar pumps are provided.

“Similar pumps” includes pumps intended for transfer of fuel oil having a flashpoint of less than 60°C. Pump-rooms intended for transfer of fuel oil having a flashpoint of not less than 60°C need not comply with the requirements of Ch 7, Sec 4, [3.5.2].

### **2.1.5 Accommodation spaces, service spaces and control stations**

- a) *Accommodation spaces, main cargo control stations, control stations and service spaces (excluding isolated cargo handling gear lockers) are to be positioned aft of cargo tanks, slop tanks, and spaces which isolate cargo or slop tanks from machinery spaces but not necessarily aft of the fuel oil bunker tanks and ballast tanks, but be arranged in such a way that a single failure of a deck or bulkhead not permit the entry of gas or fumes from the cargo tanks into an accommodation space, main cargo control stations, control station, or service spaces. A recess provided in accordance with [2.1.4] need not be taken into account when the position of these spaces is being determined.*
- b) *However, where deemed necessary, the Society may permit accommodation spaces, main cargo control stations, control stations, and service spaces forward of the cargo tanks, slop tanks and spaces which isolate cargo and slop tanks from machinery spaces, but not necessarily forward of fuel oil bunker tanks or ballast tanks. Machinery spaces, other than those of category A, may be permitted forward of the cargo tanks and slop tanks provided they are isolated from the cargo tanks and slop tanks by cofferdams, cargo pump rooms, fuel oil bunker tanks or ballast tanks. All of the above spaces are to be subject to an equivalent standard of safety and appropriate availability of fire-extinguishing arrangements being provided to the satisfaction of the Society. Accommodation spaces, main cargo control spaces, control stations and service spaces are to be arranged in such a way that a single failure of a deck or bulkhead not permit the entry of gas or fumes from the cargo tanks into such spaces. In addition, where deemed necessary for the safety or navigation of the ship, the Society may permit machinery spaces containing internal combustion machinery not being main propulsion machinery having an output greater than 375 kW to be located forward of the cargo area provided the arrangements are in accordance with the provisions of this paragraph.*
- c) *Where the fitting of a navigation position above the cargo area is shown to be necessary, it is to be for navigation purposes only and it is to be separated from the cargo tank deck by means of an open space with a height of at least 2 m. The fire protection of such navigation position is to be in addition as required for control spaces in Ch 7, Sec 6 and other provisions, as applicable, of this Chapter.*
- d) *Means be provided to keep deck spills away from the accommodation and service areas. This may be accomplished by provision of a permanent continuous coaming of a height of at least 300 mm, extending from side to side. Special consideration be given to the arrangements associated with stern loading.*

Note 1: The provisions of paragraph d) above also apply to bow and stern cargo loading stations.

- e) *Exterior boundaries of superstructures and deckhouses enclosing accommodation and including any overhanging decks which support such accommodation, is to be constructed of steel and insulated to A-60 standard for the whole of the portions which face the cargo area and on the outward sides for a distance of 3 m from the end boundary facing the cargo area. The distance of 3 m is to be measured horizontally and parallel to the middle line of the ship from the boundary which faces the*

*cargo area at each deck level. In the case of the sides of those superstructures and deckhouses, such insulation is to be carried up to the underside of the deck of the navigation bridge.*

Note 2: Service spaces and control stations (except the wheelhouse) located in superstructures and deckhouses enclosing accommodation are to comply with the provisions of item e).

- f) The location and arrangement of the room where foods are cooked are to be selected such as to minimize the risk of fire.
- g) Paint lockers, regardless of their use, cannot be located above the tanks and spaces defined in item a).

### **2.1.6 Case of ships having the service notations oil tanker, flash point > 60°C, oil tanker, asphalt carrier or FLS tanker, flash point > 60°C**

On ships having one of the following service notations:

- **oil tanker, flash point > 60°C**
- **oil tanker, asphalt carrier**
- **FLS tanker, flash point > 60°C,**

the location and separation of spaces is not required to comply with requirements [2.1.2] to [2.1.5].

However, the following provisions are to be complied with:

- a) Tanks containing cargo or cargo residues are to be segregated from accommodation, service and machinery spaces, tanks containing drinking water and stores for human consumption by means of a cofferdam or similar space.
- b) Double bottom tanks adjacent to cargo tanks are not to be used as fuel oil tanks.
- c) Means are to be provided to keep deck spills away from accommodation and service areas.

## **2.2 Access and openings**

### **2.2.1 Application**

- a) Ships with the service notation **oil tanker ESP** of less than 500 gross tonnage, and ships with the service notation **oil tanker** or **FLS tanker** are to comply with the provisions of [2.2.2] to [2.2.6].
- b) Ships having one of the following service notations:
  - **oil tanker, flash point > 60°C**
  - **oil tanker, asphalt carrier**
  - **FLS tanker, flash point > 60°C,**are to comply with the provisions of [2.2.7].
- c) Ships with the service notation **oil tanker ESP** of 500 gross tonnage and over, are to comply with the provisions of [2.2.2], [2.2.4], [2.2.5] and [2.2.6] and with the International Convention for the Safety of Life at Sea, 1974, as amended, Chapter II-1, Part A-1, Regulation 3-6, for details and arrangements of openings and attachments to the hull structure.

### **2.2.2 Access and openings to accommodation spaces, service spaces, control stations and machinery spaces**

- a) *Except as permitted in paragraph b), access doors, air inlets and openings to accommodation spaces, service spaces, control stations and machinery spaces are not to face the cargo area. They are to be located on the transverse bulkhead not facing the cargo area or on the outboard side of the superstructure or deckhouse at a distance of at least 4% of the length of the ship but not less than 3 m from the end of the superstructure or deckhouse facing the cargo area. This distance need not exceed 5 m.*
- b) *The Society may permit access doors in boundary bulkheads facing the cargo area or within the 5 m limits specified in paragraph a), to main cargo control stations and to such service spaces used as provision rooms, store-rooms and lockers, provided they do not give access directly or indirectly to any other space containing or providing for accommodation, control stations or service spaces such as galleys, pantries or workshops, or similar spaces containing sources of vapour ignition. The boundary of such a space is to be insulated to "A-60" class standard, with the exception of the boundary facing the cargo area. Bolted plates for the removal of machinery may be fitted within the limits specified in paragraph a). Wheelhouse doors and windows may be located within the limits specified in paragraph a) so long as they are designed to ensure that the wheelhouse can be made rapidly and efficiently gas tight and vapour tight.*

Note 1: An access to a deck foam system room (including the foam tank and the control station) can be permitted within the limits mentioned in paragraph a), provided that the conditions listed in paragraph b) are satisfied and that the door is located flush with the bulkhead.

Note 2: The navigating bridge door and windows are to be tested for gas tightness. If a water hose test is applied, the following test conditions are deemed acceptable by the Society:

- nozzle diameter: minimum 12 mm
  - water pressure just before the nozzle: not less than 2 bar,
  - distance between the nozzle and the doors or windows: maximum 1,5 m.
- c) *Windows and sidescuttles facing the cargo area and on the side of the superstructures and deckhouses within the limits specified in paragraph a) are to be of the fixed (non-opening) type. Such windows and sidescuttles, except wheelhouse windows, are to be constructed to "A-60" class standard.*
  - d) Air intakes and air outlets of machinery spaces are to be located as far aft as practicable and, in any case, outside the limits stated in a) above.

- e) Where the ship is designed for bow or stern loading and unloading, entrance, air inlets and openings to accommodation, service and machinery spaces and control stations are not to face the cargo shore connection location of bow or stern loading or unloading arrangements. They are to be located on the outboard side of the superstructure or deckhouse at a distance of at least 4% of the length of the ship but not less than 3 m from the end of the deckhouse facing the cargo shore connection location of the bow or stern loading and unloading arrangements. This distance, however, need not exceed 5 m. Sidescuttles facing the shore connection location and on the sides of the superstructure or deckhouse within the distance mentioned above are to be of the fixed (non-opening) type. In addition, during the use of the bow or stern loading and unloading arrangements, all doors, ports and other openings on the corresponding superstructure or deckhouse side are to be kept closed.

Note 3: Where, in the case of small ships, compliance with the provisions of paragraph e) is not possible, the Society may permit departures.

### 2.2.3 Access to spaces in the cargo area

- a) Access to cofferdams, ballast tanks, cargo tanks and other compartments in the cargo area is to be direct from the open deck and such as to ensure their complete inspection. Access to double bottom compartments may be through a cargo pump room, pump room, deep cofferdam, pipe tunnel or similar compartments, subject to consideration of ventilation aspects.

*Safe access to cofferdams, ballast tanks, cargo tanks and other compartments in the cargo area is to be direct from the open deck and such as to ensure their complete inspection. Safe access to double bottom compartments or to forward ballast tanks may be from a pump-room, deep cofferdam, pipe tunnel, double hull compartment or similar compartment not intended for the carriage of oil or hazardous cargoes.*

Note 1: Access manholes to forward gas dangerous spaces are permitted from an enclosed gas-safe space provided that:

- their closing means are gastight and
- a warning plate is provided in their vicinity to indicate that the opening of the manholes is only permitted after checking that there is no flammable gas inside the compartment in question.

Note 2: Unless other additional arrangements provided to facilitate their access are considered satisfactory by the Society, the double bottom tanks are to be provided with at least two separate means of access complying with a) above.

- b) For access through horizontal openings, hatches or manholes, the dimensions are to be sufficient to allow a person wearing a self-contained air-breathing apparatus and protective equipment to ascend or descend any ladder without obstruction and also provide a clear opening to facilitate the hoisting of an injured person from the bottom of the compartment. The minimum clear opening is to be not less than 600 mm x 600 mm.

- c) For access through vertical openings, or manholes, in swash bulkheads, floors, girders and web frames providing passage through the length and breadth of the compartment, the minimum opening is to be not less than 600 mm x 800 mm at a height of not more than 600 mm from the bottom shell plating unless gratings or other foot holds are provided.

- d) For oil tankers of less than 5000 t deadweight smaller dimensions may be approved by the Society in special circumstances, if the ability to traverse such openings or to remove an injured person can be proved to the satisfaction of the Society.

*For oil tankers of less than 5,000 tonnes deadweight, the Society may approve, in special circumstances, smaller dimensions for the openings referred to in paragraphs a) and b), if the ability to traverse such openings or to remove an injured person can be proved to the satisfaction of the Society.*

- e) Access ladders of cargo tanks are to be fitted with handrails and to be securely attached to the tank structure. They are not to be fitted vertically, unless justified by the size of the tanks. Rest platforms are to be provided at suitable intervals of not more than 10 m.

### 2.2.4 Access to the pipe tunnels

- a) The pipe tunnels in the double bottom are to comply with the following requirements:

- 1) they are not to communicate with the engine room,
- 2) provision is to be made for at least two exits to the open deck arranged at a maximum distance from each other. One of these exits fitted with a watertight closure may lead to the cargo pump room.

- b) Where there is permanent access from a pipe tunnel to the main pump room, a watertight door is to be fitted complying with the requirements of Pt B, Ch 2, Sec 1, [6] and in addition with the following:

- 1) in addition to the bridge operation, the watertight door is to be capable of being manually closed from outside the main pump room entrance,
- 2) the watertight door is to be kept closed during normal operations of the ship except when access to the pipe tunnel is required.

Note 1: A notice is to be affixed to the door to the effect that it may not be left open.

### 2.2.5 Access to the forecastle spaces

Access to the forecastle spaces containing sources of ignition may be permitted through doors facing cargo area provided the doors are located outside hazardous areas as defined in Ch 7, Sec 5.

### **2.2.6 Access to the bow**

Every tanker is to be provided with the means to enable the crew to gain safe access to the bow even in severe weather conditions. Such means of access are to be approved by the Society.

Note 1: The Society accepts means of access complying with the Guidelines for safe access to tanker bows adopted by the Marine Safety Committee of IMO by Resolution MSC.62(67).

### **2.2.7 Case of ships having the service notations oil tanker, flash point > 60°C, oil tanker, asphalt carrier or FLS tanker, flash point > 60°C**

On ships having one of the following service notations:

- oil tanker, flash point > 60°C
- oil tanker, asphalt carrier
- FLS tanker, flash point > 60°C,

the access and openings are not required to comply with the provisions of [2.2.2]. However, the access doors, air inlets and openings to accommodation spaces, service spaces and control stations are not to face the cargo area.

## **2.3 Ventilation**

### **2.3.1 Application**

- a) The requirements of [2.3.2] to [2.3.5] apply only to ships having the service notations **oil tanker** or **FLS tanker**.
- b) Ships having one of the following service notations:
  - oil tanker, flash point > 60°C
  - oil tanker, asphalt carrier
  - FLS tanker, flash point > 60°C,

are to comply with the provisions of [2.3.6].

### **2.3.2 General**

- a) Enclosed spaces within the cargo area are to be provided with efficient means of ventilation. Unless otherwise specified, portable means are permitted for that purpose. Ventilation fans are to be of non sparking construction according to Pt C, Ch 4, Sec 1, [2.3.2].
- b) *Ventilation inlets and outlets, especially for machinery spaces, are to be situated as far aft as practicable. Due consideration in this regard is to be given when the ship is equipped to load or discharge at the stern. Sources of ignition such as electrical equipment are to be so arranged as to avoid an explosion hazard.*

### **2.3.3 Ventilation of cargo pump rooms**

- a) Ventilation exhaust ducts are to discharge upwards in locations at least 3 m measured horizontally from any ignition source and from any ventilation intake and opening to non-hazardous spaces.
- b) Ventilation intakes are to be so arranged as to minimize the possibility of recycling hazardous vapours from ventilation discharge openings.
- c) The ventilation ducts are not to be led through gas safe spaces, cargo tanks or slop tanks.
- d) See also Ch 7, Sec 4, [3.5.1].

### **2.3.4 Ventilation of other pump rooms**

- a) Ventilation of pump rooms containing:
  - ballast pumps serving spaces adjacent to cargo or slop tanks
  - oil fuel pumps,is to comply with paragraphs a) to c) of [2.3.3] and a) of Ch 7, Sec 4, [3.5.1].
- b) The ventilation intakes of the pump rooms referred to in a) are to be located at a distance of not less than 3 m from the ventilation outlets of cargo pump rooms.

### **2.3.5 Ventilation of double hull and double bottom spaces**

Double hull and double bottom spaces are to be fitted with suitable connections for the supply of air.

**2.3.6 Case of ships having the service notations oil tanker, flash point > 60°C, oil tanker, asphalt carrier or FLS tanker, flash point > 60°C**

On ships having one of the following service notations:

- oil tanker, flash point > 60°C
- oil tanker, asphalt carrier
- FLS tanker, flash point > 60°C,

the ventilation is not required to comply with requirements [2.3.2] to [2.3.5]. However, the following provisions apply:

- spaces located within the cargo area are to be efficiently ventilated. Portable means of ventilation are permitted
- ventilation of the cargo pump room is to comply with [2.3.3].

**3 General arrangement of the ship with regard to pollution prevention**

**3.1 Application**

**3.1.1 Service notations**

The requirements of the present Article apply only to ships having one of the following notations:

- oil tanker
- oil tanker, flash point > 60°C
- oil tanker, asphalt carrier.

**3.1.2 Tonnage**

Unless otherwise specified, the requirements of the present Article apply only to ships of 150 gross tonnage and above.

**3.2 Protection of the cargo tank length in the event of grounding or collision**

**3.2.1 Application**

The requirements of the present sub-article apply to ships of 600 tons deadweight and above.

**3.2.2 General**

- a) The design and construction of oil tankers is to pay due regard to the general safety aspects including the need for maintenance and inspections of wing and double bottom tanks or spaces.
- b) *Oil is not to be carried in any space extending forward of a collision bulkhead located in accordance with Pt B, Ch 2, Sec 1, [3]. An oil tanker that is not required to have a collision bulkhead in accordance with that regulation is not to carry oil in any space extending forward of the transverse plane perpendicular to the centreline that is located as if it were a collision bulkhead located in accordance with that regulation.*

**3.2.3 Case of ships of 5000 tons deadweight and above**

*On oil tankers of 5000 tons deadweight and above, the entire cargo tank length is to be protected by ballast tanks or spaces other than cargo and fuel oil tanks as follows:*

a) *Wing tanks or spaces*

*Wing tanks or spaces are to extend either for the full depth of the ship's side or from the top of the double bottom to the uppermost deck, disregarding a rounded gunwale where fitted. They are to be arranged such that the cargo tanks are located inboard of the moulded line of the side shell plating, nowhere less than the distance w which, as shown in Fig 1 is measured at any cross-section at right angles to the side shell, as specified below:*

$$w = 0,5 + \frac{DW}{20000} \text{ (m)}$$

*or w = 2,0 m, whichever is the lesser.*

*The minimum value of w = 1,0 m.*

b) *Double bottom tanks or spaces*

*At any cross-section, the depth of each double bottom tank or compartment is to be such that the distance h between the bottom of the cargo tanks and the moulded line of the bottom shell plating measured at right angles to the bottom shell plating, as shown in Fig 1 is not less than specified below:*

- *B/15 (m), or*
- *2,0 m, whichever is the lesser.*

*The minimum value of h = 1,0 m.*

Figure 1 : Cargo tank boundary lines

Note 1: Double bottom tanks or spaces as required by the above paragraph may be dispensed with, provided that the design of the tanker is such that the cargo and vapour pressure exerted on the bottom shell plating forming a single boundary between the cargo and the sea does not exceed the external hydrostatic water pressure, as expressed by the following formula:

$$f \times h_c \times \rho_c \times g + 100\Delta_p \leq d_n \times \rho_s \times g$$

where:

- $h_c$  : Height of cargo in contact with the bottom shell plating, in metres
- $\rho_c$  : Maximum cargo density, in  $t/m^3$
- $d_n$  : Minimum operating draught under any expected loading conditions, in metres
- $\rho_s$  : Density of seawater, in  $t/m^3$
- $\Delta_p$  : Maximum set pressure of pressure/vacuum valve provided for the cargo tanks, in bars
- $f$  : Safety factor = 1,1
- $g$  : Standard acceleration of gravity ( $9,81 \text{ m/s}^2$ ).

Any horizontal partition necessary to fulfil the above requirements are to be located at a height of not less than  $B/6$  or 6 m, whichever is the lesser, but not more than  $0,6D$ , above the baseline where  $D$  is the moulded depth amidships.

The location of wing tanks or spaces is to be as defined in paragraph a) above except that, below a level  $1,5h$  above the baseline where  $h$  is as defined above, the cargo tank boundary line may be vertical down to the bottom plating, as shown in Fig 2.

Figure 2 : Cargo tank boundary lines

c) Turn of the bilge area or at locations without a clearly defined turn of the bilge

Where the distance  $h$  and  $w$  are different, the distance  $w$  is to have preference at levels exceeding  $1,5h$  above baseline as shown in Fig 1.

d) Aggregate capacity of the ballast tanks

On crude oil tankers of 20000 t deadweight and above and product carriers of 30000 t deadweight and above, the aggregate capacity of wing tanks, double bottom tanks, forepeak tanks and afterpeak tanks is to be not less than the capacity of segregated ballast tanks necessary to meet the requirements of [3.3.2]. Wing tanks or compartments and double bottom tanks used to meet the requirements of [3.3.2] are to be located as uniformly as practicable along the cargo tank length. Additional segregated ballast capacity provided for reducing longitudinal hull girder bending stress, trim, etc., may be located anywhere within the ship.

In calculating the aggregate capacity, the following is to be taken into account:

- the capacity of engine-room ballast tanks is to be excluded from the aggregate capacity of ballast tanks
- the capacity of ballast tanks located inboard of double hull is to be excluded from the aggregate capacity of ballast tanks
- spaces such as void spaces located in the double hull within the cargo tank length should be included in the aggregate capacity of ballast tanks

Any ballast carried in localised inboard extensions, indentation or recesses of the double hull, such as bulkhead stools, should be considered as excess ballast above the minimum requirement for segregated ballast capacity according to [3.3.2].

- e) Suction wells in cargo tanks may protube into the double bottom below the boundary line defined by the distance  $h$  provided that such wells are as small as practicable and the distance between the well bottom and bottom shell plating is not less than  $0,5 h$ .
- f) Ballast and cargo piping is to comply with the provisions of Ch 7, Sec 4, [2.3.7] and Ch 7, Sec 4, [3.4.1].

Note 2: Other methods of design and construction of oil tankers may also be accepted as alternatives to the requirements prescribed in items a) to f), provided that such methods ensure at least the same level of protection against oil pollution in the event of collision or stranding and are approved in principle by the Society.

The Society will accept the methods of design and construction described in IMO Resolution MEPC.110(49).

### 3.2.4 Case of ships of less than 5000 tons deadweight

Oil tankers of less than 5000 tons deadweight are to:

- a) at least be fitted with double bottom tanks or spaces having such a depth that the distance  $h$  specified in [3.2.3] b) complies with the following:

$$h = B/15 \text{ (m)}$$

with a minimum value of  $h = 0,76 \text{ m}$ ;

in the turn of the bilge area and at locations without a clearly defined turn of bilge, the cargo tank boundary line is to run parallel to the line of the midship flat bottom as shown in Fig 3; and

- b) be provided with cargo tanks so arranged that the capacity of each cargo tank does not exceed  $700 \text{ m}^3$  unless wing tanks or spaces are arranged in accordance with [3.2.3] a) complying with the following:

$$w = 0,4 + \frac{2,4DW}{20000} \text{ (m)}$$

with a minimum value of  $w = 0,76 \text{ m}$ .

**Figure 3 : Cargo tank boundary lines**

## 3.3 Segregation of oil and water ballast

### 3.3.1 General

- a) In oil tankers of 150 gross tonnage and above, no ballast water is to be carried in any oil fuel tank.
- b) Every crude oil tanker of 20000 tons deadweight and above and every product carrier of 30000 tons deadweight and above are to be provided with segregated ballast tanks and are to comply with requirements [3.3.2] and [3.3.3].

### 3.3.2 Capacity of the segregated ballast tanks

The capacity of the segregated ballast tanks is to be so determined that the ship may operate safely on ballast voyages without recourse to the use of cargo tanks for water ballast. In all cases, however, the capacity of segregated ballast tanks is to be at least such that, in any ballast condition at any part of the voyage, including the conditions consisting of lightweight plus segregated ballast only, the ship's draughts and trim can meet each of the following requirements:

- a) the moulded draught amidships,  $d_m$ , in metres (without taking into account any ship's deformation) is to be not less than:  
 $d_m = 2,0 + 0,02 L_{LL}$
- b) the draughts at the forward and after perpendicular are to correspond to those determined by the draught amidships  $d_m$  as specified above, in association with the trim by the stern of not greater than  $0,015L_{LL}$ , and
- c) in any case the draught at the after perpendicular is to be not less than that which is necessary to obtain full immersion of the propeller(s).

Refer also to paragraph d) of [3.2.3].

Note 1: In case of oil tankers less than 150 metres in length, the above formulae may be replaced by those set out in Appendix I to the Unified Interpretations of Annex I of MARPOL 73/78.

### 3.3.3 Carriage of ballast water in cargo tanks

- a) In no case is ballast water to be carried in cargo tanks, except:
- 1) on those rare voyages when weather conditions are so severe that, in the opinion of the Master, it is necessary to carry additional ballast water in cargo tanks for the safety of the ship, and
  - 2) in exceptional cases where the particular character of the operation of an oil tanker renders it necessary to carry ballast water in excess of the quantity required under [3.3.3], provided that such operation of the oil tanker falls under the category of exceptional cases.

Note 1: Exceptional cases are defined in the Unified Interpretations of Annex I of MARPOL 73/78

Such additional ballast water is to be processed and discharged in compliance with regulation 34 of Annex I of MARPOL 73/78 and an entry is to be made in the Oil Record Book Part II referred to in regulation 36 of that Annex.

- b) In the case of crude oil tankers, the additional ballast permitted in paragraph a) above is to be carried in cargo tanks only if such tanks have been crude oil washed in accordance with [3.5] before departure from an oil unloading port or terminal.

## 3.4 Accidental oil outflow performance

3.4.1 Oil tankers are to comply with the requirements of the Regulation 23 of Annex I to Marpol Convention, as amended.

## 3.5 Cleaning of cargo tanks

### 3.5.1 General

- a) Adequate means are to be provided for cleaning the cargo tanks.

Note 1: This provision does not apply to ships of less than 150 gross tonnage provided the conditions stated in [3.6.1] are fulfilled.

- b) Every crude oil tanker of 20000 tons deadweight and above is to be fitted with a cargo tank cleaning system using crude oil washing complying with the following requirements. Unless such oil tanker carries crude oil which is not suitable for crude oil washing, the oil tanker is to operate the system in accordance with those requirements.

The crude oil washing installation and associated equipment and arrangements are to comply with the requirements of Ch 7, App 2.

### 3.5.2 Ballasting of cargo tanks

With respect to the ballasting of cargo tanks, sufficient cargo tanks are to be crude oil washed prior to each ballast voyage in order that, taking into account the tanker's trading pattern and expected weather conditions, ballast water is put only into cargo tanks which have been crude oil washed.

### 3.5.3 Operations and Equipment Manual

Every oil tanker operating with crude oil washing systems is to be provided with an Operations and Equipment Manual detailing the system and equipment and specifying operational procedures. Such a Manual is to be to the satisfaction of the Society and is to contain all the information set out in Ch 7, App 2. If an alteration affecting the crude oil washing system is made, the Operating and Equipment Manual is to be revised accordingly.

## 3.6 Retention of oil on board - Slop tanks

### 3.6.1 Application

- a) The provisions of requirements [3.6.2] to [3.6.4] do not apply to ships of less than 150 gross tonnage for which the control of discharge of oil under Ch 7, Sec 4, [5.2.1] is to be effected by the retention of oil on board with subsequent discharge of all contaminated washings to reception facilities, unless adequate arrangements are made to ensure that any effluent which is allowed to be discharged into the sea is effectively monitored to ensure that the provisions of Ch 7, Sec 4, [5.2.1] are complied with.

Note 1: The provisions of requirements [3.6.2] to [3.6.4] may be waived for any oil tanker which engages exclusively on both voyages of 72 hours or less in duration and within 50 miles from the nearest land, provided that the oil tanker is engaged exclusively in trades between ports or terminals within a State Party to MARPOL 73/78 Convention. Any such waiver is to be subject to the requirements that the oil tanker is to retain on board all oily mixtures for subsequent discharge to reception facilities and to the determination by the Administration that facilities available to receive such oily mixtures are adequate.

- b) The provisions of Ch 7, Sec 4, [5] are also to be complied with.

### **3.6.2 General**

- a) Adequate means are to be provided for transferring the dirty ballast residue and tank washings from the cargo tanks into a slop tank approved by the Society.
- b) Arrangements are to be provided to transfer the oily waste into a slop tank or combination of slop tanks in such a way that any effluent discharged into the sea comply with the provisions of Ch 7, Sec 4, [5.2].

### **3.6.3 Capacity of slop tanks**

The arrangement of the slop tank or combination of slop tanks is to have a capacity necessary to retain the slop generated by tank washings, oil residues and dirty ballast residues. The total capacity of the slop tank or tanks is not to be less than 3% of the oil carrying capacity of the ship, except that the Society may accept:

- a) 2% for oil tankers where the tank washing arrangements are such that once the slop tank or tanks are charged with washing water, this water is sufficient for tank washing and, where applicable, for providing the driving fluid for eductors, without the introduction of additional water into the system
- b) 2% where segregated ballast tanks are provided in accordance with [3.3], or where a cargo tank cleaning system using crude oil washing is fitted in accordance with [3.5]. This capacity may be further reduced to 1,5% for oil tankers where the tank washing arrangements are such that once the slop tank or tanks are charged with washing water, this water is sufficient for tank washing and, where applicable, for providing the driving fluid for eductors, without introduction of additional water into the system.

Oil tankers of 70 000 tons deadweight and above are to be fitted with at least two slop tanks.

### **3.6.4 Design of slop tanks**

Slop tanks are to be so designed particularly in respect of the position of inlets, outlets, baffles or weirs where fitted, so as to avoid excessive turbulence and entrainment of oil or emulsion with the water.

## **3.7 Deck spills**

**3.7.1** Means are to be provided to keep deck spills away from the accommodation and service areas. This may be accomplished by providing a permanent continuous coaming of a suitable height extending from side to side.

Where gutter bars are installed on the weather decks of oil tankers in way of cargo manifolds and are extended aft as far as the aft bulkhead of superstructures for the purpose of containing cargo spills on deck during loading and discharge operations, the free surface effects caused by containment of a cargo spill during liquid transfer operations or of boarding seas while underway are to be considered with respect to the vessel's available margin of positive initial stability (GM<sub>0</sub>).

Where the gutter bars installed are higher than 300 mm, they are to be treated as bulwarks with freeing ports arranged in accordance with Pt B, Ch 11, Sec 12, [6] and provided with effective closures for use during loading and discharge operations. Attached closures are to be arranged in such a way that jamming is prevented while at sea, enabling the freeing ports to remain effective.

An assessment of the initial stability (GM<sub>0</sub>) for compliance with the relevant intact stability requirements taking into account the free surface effect caused by liquids contained by the gutter bars is to be undertaken on:

- tankers having cargo tanks exceeding 60% of the vessel's maximum beam at midships regardless of gutter bar height
- ships without deck camber
- ships where the height of the installed gutter bars exceeds the camber.

## **3.8 Pump-room bottom protection**

**3.8.1** This Article is applicable to oil tankers of 5000 tons deadweight and above.

**3.8.2** The pump-room is to be provided with a double bottom such that at any cross-section the depth of each double bottom tank or space is to be such that the distance  $h$  between the bottom of the pump-room and the ship's base line measured at right angles to the ship's base line is to be not less than the lesser of:

- $h = B/15$  m
- $h = 2$  m

without being taken less than 1 m.

**3.8.3** In case of pump rooms whose bottom plate is located above the base line by at least the minimum height required in [3.8.2] (e.g. gondola stern designs), there is no need for a double bottom construction in way of the pump-room.

**3.8.4** Ballast pumps are to be provided with suitable arrangements to ensure efficient suction from double bottom tanks.

**3.8.5** Notwithstanding the provisions of [3.8.2] and [3.8.3], where the flooding of the pump-room would not render the ballast or cargo pumping system inoperative, a double bottom need not be fitted.

## 4 Structural arrangement of asphalt carrier independent tanks and supports

### 4.1 Supports

#### 4.1.1 General

Supports of independent tanks are to be designed to allow, when expected, free thermal expansion in the three directions (longitudinal, transverse and vertical) to avoid thermal stress in the tank structures and transmission of loads from the tanks to the supports.

Generally, the supports should be also designed so as to limit the transmission of loads relative to hull deflection (global and local) from the ship structure to the tanks.

The supporting of the tanks is usually achieved by means of:

- vertical supports
- antirolling keys
- antipitching keys
- antiftotation keys
- anticollision keys.

The reaction forces in way of tank supports are to be transmitted as directly as possible to the hull primary supporting members, in order to minimize stress concentration.

Where the reaction forces are not in the plane of the primary supporting members, web plates and brackets are to be provided in order to transmit these loads by means of shear stresses.

#### 4.1.2 Information to be submitted

For every support and key, the following information is to be submitted:

- general arrangement on the ship (positioning, total surface)
- detailed fabrication and integration in the ship hull structure
- mechanical characteristics of the support pads, including compressive and shear strengths, frictional coefficients and elasticity.

#### 4.1.3 Type approval

All the support pads (wooden, synthetic) are to be of a type approved material.

#### 4.1.4 Openings

Openings in the structures in way of tank supports are to be reduced as much as possible and local strengthening is to be provided, as necessary.

## 4.2 Inspectability of the cargo area

### 4.2.1 Passage through cargo tanks

a) Where the Surveyor needs to pass between the flat or curved surface to be inspected and structural elements such as deck beams, stiffeners, frames, girders etc., the distance between that surface and the free edge of the structural elements is to be at least 380 mm. The distance between the surface to be inspected and the surface to which the above structural elements are fitted, e.g. deck, bulkhead or shell, is to be at least (see Fig 4):

- 450 mm in the case of a curved tank surface, or
- 600 mm in the case of a flat tank surface.

**Figure 4 : Minimum passage over cargo tanks**

b) Where the Surveyor does not need to pass between the surface to be inspected and any part of the structure, the distance between the free edge of that structural element and the surface to be inspected is, for visibility reasons, to be at least 50 mm, or half the breadth of the structure face plate, whichever is the greater (see Fig 5).

**Figure 5 : Minimum distance of structures from cargo tank to allow visual inspection**

- c) Where, for inspection of a curved surface, the Surveyor needs to pass between that surface and another flat or curved surface, to which no structural elements are fitted, the distance between both surfaces is to be at least 380 mm (see Fig 6). Where the Surveyor does not need to pass between a curved surface and another surface, a distance smaller than 380 mm may be accepted, taking into account the shape of the curved surface.

**Figure 6 : Minimum passage between curved surfaces**

- d) Where, for inspection of an approximately flat surface, the Surveyor needs to pass between two approximately flat and approximately parallel surfaces, to which no structural elements are fitted, the distance between those surfaces is to be at least 600 mm. A clearance of at least 450 mm is to be provided where fixed access ladders are fitted (see Fig 7).

**Figure 7 : Minimum passage between flat surfaces**

- e) The minimum distances between a cargo tank sump and the adjacent double bottom structure in way of a suction well may not be less than that defined in Fig 8. If there is no suction well, the distance between the cargo tank sump and the inner bottom may not be less than 50 mm.

**Figure 8 : Minimum distance of cargo tank sump and inner bottom**

- f) The distance between a cargo tank dome and deck structures may not be less than 150 mm (see Fig 9).  
 g) Where necessary for inspection, fixed or portable staging is to be installed. This staging may not impair the above specified distances.  
 h) Where fixed or portable ventilation ducting is to be fitted, it may not impair the above specified distances.

Figure 9 : Minimum distance between cargo dome and deck structures

**4.2.2 Passage through hatches and manholes**

- a) The minimum clear opening of horizontal hatches may not be less than 600 x 600 mm, with a corner radius not exceeding 100 mm, as specified in Fig 10.
- b) The minimum clear opening of manholes may not be less than 600 x 800 mm, as specified in Fig 11.
- c) Circular access openings in cargo tanks are to have a diameter not less than 600 mm.

**4.2.3 Cofferdams**

Where fitted, cofferdams are to have sufficient size for easy access to all their parts. The width of the cofferdams may not be less than 600 mm.

**4.2.4 Pipe tunnels**

Pipe tunnels are to have enough space to permit inspection of pipes. The pipes in pipe tunnels are to be installed as high as possible from the ship's bottom.

Figure 10 : Minimum size of horizontal hatches

Figure 11 : Minimum size of manholes

## Section 3 Hull and Stability

### Symbols

$L_{LL}$	: Load line length, in m, defined in Pt B, Ch 1, Sec 3, [2.1.2]
$R_y$	: Minimum yield stress, in N/mm <sup>2</sup> , of the material, to be taken equal to 235/k N/mm <sup>2</sup> , unless otherwise specified
$k$	: Material factor for steel, defined in Pt B, Ch 4, Sec 1, [4.4]
$E$	: Young's modulus, in N/mm <sup>2</sup> , to be taken equal to: <ul style="list-style-type: none"> <li>• <math>E = 2,06 \cdot 10^5</math> N/mm<sup>2</sup> for steels in general</li> <li>• <math>E = 1,95 \cdot 10^5</math> N/mm<sup>2</sup> for stainless steels</li> </ul>
$C_{BM-LC}$	: Coefficient taken as the percentage of permissible SWBM
$C_{SF-LC}$	: Coefficient taken as the percentage of permissible SWSF.

### 1 General

#### 1.1 Documents to be submitted

**1.1.1** In addition to the documentation requested in Part B, the following documents are to be submitted for ships assigned with the service notation **oil tanker ESP** or **FLS tanker**:

- Arrangement of pressure/vacuum valves in cargo tanks,
- Cargo temperatures.

### 2 Stability

#### 2.1 Application

**2.1.1** The requirements in [2.2.2] and [2.3] apply only to ships with the service notation **oil tanker ESP**.

#### 2.2 Intact stability

##### 2.2.1 General

The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.6] is to be in compliance with the requirements in Pt B, Ch 3, Sec 2. In addition, the requirements in [2.2.2] are to be complied with.

##### 2.2.2 Liquid transfer operations

Ships with certain internal subdivision may be subjected to lolling during liquid transfer operations such as loading, unloading or ballasting. In order to prevent the effect of lolling, the design of oil tankers of 5000 t deadweight and above is to be such that the following criteria are complied with:

- The intact stability criteria reported in b) is to be complied with for the worst possible condition of loading and ballasting as defined in c), consistent with good operational practice, including the intermediate stages of liquid transfer operations. Under all conditions the ballast tanks are to be assumed slack.*
- The initial metacentric height  $GMO$ , in m, corrected for free surface measured at 0° heel, is to be not less than 0,15. For the purpose of calculating  $GMO$ , liquid surface corrections are to be based on the appropriate upright free surface inertia moment.*
- The vessel is to be loaded with:*
  - *all cargo tanks filled to a level corresponding to the maximum combined total of vertical moment of volume plus free surface inertia moment at 0° heel, for each individual tank*
  - *cargo density corresponding to the available cargo deadweight at the displacement at which transverse  $KM$  reaches a minimum value*
  - *full departure consumable*
  - *1% of the total water ballast capacity. The maximum free surface moment is to be assumed in all ballast tanks.*

**2.3 Damage stability for ships where the additional class notation SDS is required**

**2.3.1 General**

Every oil tanker is to comply with the subdivision and damage stability criteria as specified in [2.3.8], after the assumed side or bottom damage as specified in [2.3.2], for the standard of damage described in [2.3.3], and for any operating draught reflecting actual partial or full load conditions consistent with trim and strength of the ship as well as specific gravities of the cargo.

The actual partial or full load conditions to be considered are those specified in Pt B, Ch 3, App 2, [1.2.6], but ballast conditions where the oil tanker is not carrying oil in cargo tanks, excluding any oil residues, are not to be considered.

**2.3.2 Damage dimensions**

The assumed extent of damage is to be as defined in Tab 1.

The transverse extent of damage is measured inboard the ship side at right angles to the centreline at the level of the summer load line.

For the purpose of determining the extent of assumed damage, suction wells may be neglected, provided such wells are not excessive in areas and extend below the tank for a minimum distance and in no case more than half the height of the double bottom.

The vertical extent of damage is measured from the moulded line of the bottom shell plating at centreline.

If any damage of a lesser extent than the maximum extent of damage specified in Tab 1 would result in a more severe condition, such damage is to be considered.

**Table 1 : Extent of damage**

Damage		Longitudinal extent	Transverse extent	Vertical extent
Side		$l_c = 1/3 L_{LL}^{2/3}$ or 14,5 m (1)	$t_c = B/5$ or 11,5 m (1)	$v_c =$ without limit
Bottom	For 0,3 $L_{LL}$ from the forward perpendicular	$l_s = 1/3 L_{LL}^{2/3}$ or 14,5 m (1)	$t_s = B/6$ or 10 m (1)	$v_s = B/15$ or 6 m (1)
	any other part	$l_s = 1/3 L_{LL}^{2/3}$ or 5 m (1)	$t_s = B/6$ or 5 m (1)	$v_s = B/15$ or 6 m (1)
(1) Whichever is the lesser				

**2.3.3 Standard of damage**

The damage in [2.3.2] is to be applied to all conceivable locations along the length of the ship, according to Tab 2.

**Table 2 : Standard of damage**

Ship's length, in m	Damage anywhere in ship's length	Damage between transverse bulkheads	Machinery space flooded
$L_{LL} \leq 100$	No	Yes (1) (2)	No
$100 < L_{LL} \leq 150$	No	Yes (1)	No
$150 < L_{LL} \leq 225$	Yes	No	Yes, alone
$L_{LL} > 225$	Yes	No	Yes
(1) Machinery space not flooded.			
(2) Exemptions from the requirements of [2.3.8] may be accepted by the Society on a case-by-case basis.			

**2.3.4 Calculation method**

The metacentric heights (GM), the stability levers (GZ) and the centre of gravity positions (KG) for judging the final survival conditions are to be calculated by the constant displacement method (lost buoyancy).

**2.3.5 Flooding assumptions**

The requirements of [2.3.8] are to be confirmed by calculations which take into consideration the design characteristics of the ship, the arrangements, configuration and contents of the damaged compartments and the distribution, specific gravities and free surface effect of liquids.

Where the damage involving transverse bulkheads is envisaged as specified in [2.3.3], transverse watertight bulkheads are to be spaced at least at a distance equal to the longitudinal extent of assumed damage specified in [2.3.2] in order to be considered effective. Where transverse bulkheads are spaced at a lesser distance, one or more of these bulkheads within such extent of damage is to be assumed as non-existent for the purpose of determining flooded compartments.

Where the damage between adjacent transverse watertight bulkheads is envisaged as specified in [2.3.3], no main transverse bulkhead bounding side tanks or double bottom tanks is to be assumed damaged, unless:

- the spacing of the adjacent bulkheads is less than the longitudinal extent of assumed damage specified in [2.3.2] or,
- there is a step or a recess in a transverse bulkhead of more than 3,05 metres in length, located within the extent of penetration of assumed damage. The step formed by the after peak bulkhead and after peak tank top is not to be regarded as a step.

**2.3.6 Progressive flooding**

If pipes, ducts or tunnels are situated within the assumed extent of damage penetration as defined in [2.3.2], arrangements are to be made so that progressive flooding cannot thereby extend to compartments other than those assumed to be floodable in the calculation for each case of damage.

**2.3.7 Permeabilities**

The specific gravity of cargoes carried, as well as any outflow of liquid from damaged compartments, are to be taken into account for any empty or partially filled tank.

The permeability of compartments assumed to be damaged are to be as indicated in Tab 3.

**Table 3 : Permeability**

Compartments	Permeability
Appropriate for stores	0,60
Occupied by accommodation	0,95
Occupied by machinery	0,85
Void compartments	0,95
Intended for consumable liquids	0 to 0,95 <b>(1)</b>
Intended for other liquids	0 to 0,95 <b>(1)</b>
<b>(1)</b> The permeability of partially filled compartments is to be consistent with the amount of liquid carried in the compartment.	

**2.3.8 Survival requirements**

Oil tankers are to be regarded as complying with the damage stability criteria if the requirements of [2.3.9] and [2.3.10] are met.

**2.3.9 Final stage of flooding**

- a) The final waterline, taking into account sinkage, heel and trim, is to be below the lower edge of any opening through which progressive flooding may take place. The progressive flooding is to be considered in accordance with Pt B, Ch 3, Sec 3, [3.3].
- b) The angle of heel due to unsymmetrical flooding may not exceed 25°, except that this angle may be increased up to 30° if no deck edge immersion occurs.
- c) The stability is to be investigated and may be regarded as sufficient if the righting lever curve has at least a range of 20° beyond the position of equilibrium in association with a maximum residual righting lever, in m, of at least 0,1 within the 20° range; the area, in m-rad, under the curve within this range is to be not less than 0,0175.

**2.3.10 Intermediate stage of flooding**

The Society is to be satisfied that the stability is sufficient during the intermediate stages of flooding. To this end the Society applies the same criteria relevant to the final stage of flooding also during the intermediate stages of flooding.

**2.3.11 Bottom raking damage**

This requirement applies to oil tankers of 20000 t deadweight and above.

The damage assumptions relative to the bottom damage prescribed in [2.3.2] are to be supplemented by the assumed bottom raking damage of Tab 4.

The requirements of [2.3.8] are to be complied with for the assumed bottom raking damage.

**Table 4 : Bottom damage extent**

Deadweight	Longitudinal extent	Transverse extent	Vertical extent
< 75000 t	0,4 L <sub>LL</sub> <b>(1)</b>	B/3	<b>(2)</b>
≥ 75000 t	0,6 L <sub>LL</sub> <b>(1)</b>	B/3	<b>(2)</b>
<b>(1)</b> Measured from the forward perpendicular.			
<b>(2)</b> Breach of the outer hull.			

**2.3.12 Equalisation arrangements**

Equalisation arrangements requiring mechanical aids such as valves or cross levelling pipes, if fitted, may not be considered for the purpose of reducing an angle of heel or attaining the minimum range of residual stability to meet the requirements of [2.3.9] and sufficient residual stability is to be maintained during all stages where equalisation is used. Compartments which are linked by ducts of a large cross-sectional area may be considered to be common.

### **2.3.13 Information to the Master**

The Master of every oil tanker is to be supplied in an approved form with:

- information relative to loading and distribution of cargo necessary to ensure compliance with the requirements relative to stability, and
- data on the ability of the ship to comply with damage stability criteria as determined in [2.3.8] including the effect of relaxation that may have been allowed as specified in Tab 2.

## **3 Structure design principles**

### **3.1 Framing arrangement**

**3.1.1** In general, within the cargo tank region of ships of more than 90 m in length, the bottom, the inner bottom and the deck are to be longitudinally framed.

Different framing arrangements are to be considered by the Society on a case-by-case basis, provided that they are supported by direct calculations.

### **3.2 Bulkhead structural arrangement**

#### **3.2.1 General**

Transverse bulkheads may be either plane or corrugated.

#### **3.2.2 Corrugated bulkheads**

For ships of less than 120 m in length, vertically corrugated transverse or longitudinal bulkheads may be connected to the double bottom and deck plating.

For ships equal to or greater than 120 m in length, lower and upper stools are to be fitted.

## **4 Design loads**

### **4.1 Loading conditions for longitudinal strength assessment**

#### **4.1.1 Seagoing conditions**

In addition to the loading conditions specified in Pt B, Ch 5, Sec 8, the following seagoing loading conditions are to be included, as a minimum, in the loading manual:

- a) Heavy ballast condition where the ballast tanks may be full, partially full or empty. Where ballast tanks are partially full, the conditions in item b of Pt B, Ch 5, Sec 8, [3.1.1] are to be complied with. The fore peak water ballast tank is to be full, if fitted. If upper and lower fore peak tanks are fitted, the lower is required to be full and the upper tank may be full, partially full or empty. All the cargo tanks are to be empty including cargo tanks suitable for the carriage of water ballast at sea. The draught at the forward perpendicular is not to be less than that for the normal ballast condition. The propeller is to be fully immersed. The trim is to be by the stern and is not to exceed  $0,015 L_{LL}$
- b) Mid-voyage conditions relating to tank cleaning or other operations where these differ significantly from the ballast conditions
- c) Any specified non-uniform distribution of loading
- d) Conditions with high density cargo including the maximum design cargo density, when applicable
- e) Design ballast condition in which all segregated ballast tanks in the cargo tank region are full and all other tanks are empty including fuel oil and fresh water tanks. This design condition is for assessment of hull strength and is not intended for ship operation.

#### **4.1.2 Additional loading conditions**

In addition to the loading conditions specified in Pt B, Ch 5, Sec 8, the following additional loading conditions are to be included in the loading manual if the ship is specifically approved and intended to be operated in such conditions:

- a) Seagoing ballast conditions including water ballast carried in one or more cargo tanks which are intended for use in emergency situations as allowed by MARPOL Reg. 18
- b) Seagoing loading conditions where the net static upward load on the double bottom exceeds that given with the combination of an empty cargo tank and a mean ship's draught of  $0,9 T_{SC}$
- c) Seagoing loading conditions with cargo tanks less than 25% full with the combination of mean ship's draught greater than  $0,9 T_{SC}$
- d) Seagoing loading conditions where the net static downward load on the double bottom exceeds that given with the combination of a full cargo tank at a cargo density of  $1,025 t/m^3$  or greater and a mean ship's draught of  $0,6 T_{SC}$
- e) For ships arranged with cross ties in the centre cargo tank, seagoing loading conditions showing a non-symmetric loading pattern where the difference in filling level between corresponding port and starboard wing cargo tanks exceeds 25% of the filling height in the wing cargo tank.

## 4.2 Local loads

### 4.2.1 Bottom impact pressure

For oil tankers of 20000 t deadweight and above and product carriers of 30000 t deadweight and above, the draught  $T_{LC}$  corresponding to loading conditions using the segregated ballast tanks only are to be considered in the calculation of the bottom impact pressure according to Pt B, Ch 5, Sec 5, [4.2.1] in addition to other loading conditions.

### 4.2.2 Cargo mass density

In the absence of more precise values, a cargo mass density of  $0,9 \text{ t/m}^3$  is to be considered for calculating the internal pressures and forces in cargo tanks according to Pt B, Ch 5, Sec 6.

### 4.2.3 Partial filling

The carriage of cargoes with a mass density above the one considered for the design of the cargo tanks may be allowed with partly filled tanks under the conditions stated in Pt B, Ch 5, Sec 6, [2]. The classification certificate or a memorandum provided for in Pt A, Ch 1, Sec 2, [4.4] is to mention these conditions of carriage.

### 4.2.4 Overpressure due to cargo filling operations

For ships having the additional service feature **asphalt carrier**, the overpressure which may occur under loading/unloading operations are to be considered, if any. In such a case, the diagram of the pressures in loading/unloading conditions is to be given by the Designer.

## 4.3 Load combinations for direct strength analysis

4.3.1 The loading conditions to be considered for the direct strength analysis are defined in [4.3.1] to [4.3.5].

### 4.3.2 Ships with structure symmetrical about centreline

For ships with structure symmetrical about the centreline, the loading patterns mirrored about centreline of another pattern may be omitted provided the results (yield and buckling) are mirrored.

### 4.3.3 Tankers with two oil-tight longitudinal bulkheads except with a cross tie arrangement in the wing cargo tanks

Any loading patterns with unequal filling levels in transversely paired wing cargo tanks that would result in a more onerous stress response are to be examined. The actual loading pattern, draught, GM and  $k_r$  from the loading manual are to be used in the FE analysis. Where the GM and  $k_r$  are not given in the ship's loading manual, they are to be determined in accordance with Pt B, Ch 5, Sec 3.

If such loading pattern is considered, an operational restriction describing that the difference in filling level between corresponding port and starboard wing cargo tanks is not to exceed 25% of the filling height in the wing cargo tank, is to be added in the loading manual.

### 4.3.4 Tankers with two oil-tight longitudinal bulkheads

- Seagoing loading pattern with all cargo tanks abreast empty are to be analysed with a ship draught of  $0,65 T_{SC}$  and  $0,7 T_{SC}$  respectively. If conditions in the ship loading manual specify greater draughts, then the maximum specified draught in the ship's loading manual for the loading pattern is to be used.
- Seagoing and harbour loading patterns with all cargo tanks abreast fully loaded are to be analysed with a ship draught of  $0,65 T_{SC}$  and  $0,6 T_{SC}$  respectively. If conditions in the ship loading manual specify lesser draughts, then the minimum specified draught in the ship's loading manual for the loading pattern is to be used.

4.3.5 For loading patterns with cargo tank(s) empty, a minimum ship draught of  $0,9 T_{SC}$  is to be used in the analysis. If conditions in the ship loading manual specify greater draughts, then the maximum specified draught for the actual condition is to be used.

### 4.3.6 Ballast conditions

Any ballast condition specified in the ship loading manual with ballast water filled in one or more cargo tanks is to be examined. The actual loading pattern, draught, GM and  $k_r$  from the loading manual are to be used in the direct strength analysis. Where the GM and  $k_r$  are not given in the ship's loading manual, they are to be determined in accordance with Pt B, Ch 5, Sec 3.

## 5 Hull scantlings

### 5.1 Strength check with respect to stresses due to the temperature gradient

#### 5.1.1 General

Direct calculations of stresses induced in the hull structures by the temperature gradient are to be performed:

- for ships intended to carry cargoes at temperatures exceeding  $90^\circ\text{C}$
- and when part of the hull structures temperature exceeds  $90^\circ\text{C}$

In these calculations, the water temperature is to be assumed equal to 0°C.

The calculations are to be submitted to the Society for review.

### **5.1.2 Material**

For steels used at a temperature  $\theta$  between 90°C and 300°C, and unless other information is specified, their minimum yield stress  $R_{eH}$  and Young's modulus  $E$  are to be taken as specified in Pt B, Ch 4, Sec 1, [2.1.1].

The material factor is to be adjusted accordingly.

### **5.1.3 Thermal stress for integral tanks**

The stresses induced in the hull structures by the temperature gradient are to comply with the checking criteria in Pt B, Ch 8, App 1, [5.2.3].

### **5.1.4 Thermal stress for independent tanks**

Where a thermal elongation is made possible due to the design of the tank supports, the thermal stress may be neglected provided the cargo temperature distribution is rather uniform.

In addition, precautions are to be taken, upon loading of any hot cargo, by pre-heating the tanks in order to minimize the temperature gradients within the cargo hold.

## **5.2 Hull girder stress for independent tanks structures**

**5.2.1** In general, the hull girder stresses may be taken equal to zero.

Where the length of the tank under consideration exceeds both 0,15L and 3,5 times its breadth, the stresses in the tank due to the hull girder loads are to be taken into account. These stresses are, in general, to be obtained by means of direct calculations based on a finite element model of the hull and the tank with its supporting and keying system.

## **6 Scantlings of independent tanks structures**

### **6.1 Plating**

**6.1.1** In general, the net plating thickness of independent tanks is to be not less than the values obtained from the applicable formulae given in Pt B, Ch 7, Sec 4, where the lateral pressures are to be calculated according to Part B, Chapter 5.

### **6.2 Ordinary stiffeners**

**6.2.1** In general, the net scantlings of the ordinary stiffeners of independent tanks are to be not less than the values obtained from the applicable formulae given in Pt B, Ch 7, Sec 5, where the lateral pressures are to be calculated according to Part B, Chapter 5.

### **6.3 Primary supporting members**

**6.3.1** The net scantlings of the primary supporting members are to be obtained by means of direct calculations according to [8].

## **7 Supports of independent tanks**

### **7.1 General**

**7.1.1** The reaction forces in way of tank supports are to be obtained from the structural analysis of the tank, taking into account the relative hull bottom stiffness and considering the loads and accelerations specified in Part B, Chapter 5, in addition to the static steel weight of the tank.

If the supports are not able to react in tension, the final distribution of the reaction forces at the supports is not to show any tensile forces.

### **7.2 Vertical supports**

#### **7.2.1 General**

When used together with hot cargoes, the material of a vertical support is to present the following qualities:

- very low thermal conductivity
- good mechanical performances at the highest temperatures:
  - compressive strength, to reduce the supporting area
  - elasticity, to avoid cracks (no brittleness) and to spread the load
  - shear strength, to support horizontal forces due to thermal extension of the tank
  - average frictional coefficient, to reduce loads on keys while avoiding excessive shear stresses in the support.

### **7.2.2 Scantling**

The tank structure and the ship structure are to be reinforced in way of the supports so as to withstand the combined reactions defined in [7.1] (compression induced by the vertical acceleration and shear induced by the longitudinal or transverse acceleration) and corresponding moments.

For the purpose of this assessment, the frictional coefficient of the vertical supports is to be taken equal to 0,3, unless duly justified.

## **7.3 Antirolling keys**

### **7.3.1 General**

Antirolling keys fitted at top of the tank are generally necessary for narrow and high tanks which may capsize at rolling, as well as for filling levels lower than 90%. Otherwise, bottom keys may be sufficient.

A risk of capsizing of the tank is to be considered when:

$$a_y y_G \geq (g - a_z) z_G$$

where:

$g$  : Gravity acceleration, in  $m/s^2$

$a_y, a_z$  : Transverse and vertical accelerations for the BR dynamic load cases, as defined in Pt B, Ch 5, Sec 3, [3.2]

$y_G, z_G$  : Transverse and vertical distances between the vertical support a side and the centre of gravity of the tank.

The frictional load taken by the vertical supports may be deduced from the lateral load, provided the minimum value of the frictional coefficients between tank and vertical supports are duly justified by the Designer. In general, for the purpose of this assessment, the frictional coefficient of the vertical supports is to be taken equal to 0,1.

### **7.3.2 Load cases**

Antirolling keys are to be checked under transverse and vertical accelerations for the inclined ship condition, considering the maximum full tank weight.

## **7.4 Antipitching keys**

**7.4.1** Antipitching keys are fitted to prevent the tank from moving longitudinally.

They may also be used for anticollision purpose (see [7.5]).

### **7.4.2 Load cases**

Antipitching keys are to be checked under longitudinal and vertical accelerations for the upright ship condition, considering the maximum full tank weight.

## **7.5 Anticollision keys**

### **7.5.1 General**

Anticollision keys may be combined with antipitching keys (see [7.4]).

### **7.5.2 Load cases**

Anticollision keys are to withstand a collision force acting on the tank corresponding to half the tank and cargo weight in the forward direction and one quarter of the tank and cargo weight in the aftward direction, considering the maximum full tank weight.

## **7.6 Antiflotation keys**

### **7.6.1 General**

When antiflotation keys are fitted at the top of the tanks, they are positioned on both sides, in order to minimize the bending moment induced on deck transverses.

### **7.6.2 Load cases**

Antiflotation keys are to withstand an upward force caused by an empty tank floating in a hold flooded up to the deepest equilibrium waterline after damage for the loading conditions among which the tank under consideration is empty.

## **7.7 Yielding criteria**

**7.7.1** It is to be checked that the Von Mises stress  $\sigma_{vm}$  in the supports and keys, in  $N/mm^2$ , is in compliance with the requirements in [8.3.3].

## 8 Independent tanks direct strength analysis

### 8.1 General

8.1.1 Yielding and buckling check of primary supporting members is to be performed within the cargo area by means of FE analysis.

Local fine mesh models are to be performed for the analysis of highly stressed areas, supports and keys, as required in [8.3.1].

### 8.2 Three cargo holds model

#### 8.2.1 Model extension

As a rule, the cargo tank to be assessed is to be modelled with its two adjacent holds and tanks (fore and aft). The model is to include the hold, the cargo tank and the supports.

The assessment of a tank may be waived when the tank is similar enough to an already checked cargo tank.

#### 8.2.2 Hold modelling

The following items of the hold are to be modelled:

- outer shell, inner shell, deck, bottom, inner bottom and transverse bulkheads plating
- double bottom longitudinal girders
- double side horizontal girders
- deck longitudinal girders
- transverse web frames
- primary supporting members of transverse bulkheads.

#### 8.2.3 Cargo tank modelling

The following items of the cargo tank are to be modelled:

- shell plating
- bulkheads plating, including wash bulkheads, if any
- bottom plating
- top plating
- transverse web frames
- horizontal stringers
- girders.

In addition, the static steel weight of the tank is to be considered.

#### 8.2.4 Supports and keys modelling

The cargo tanks are linked to the hold by the following supports and keys, acting in one direction:

- vertical supports (Z direction)
- antipitching keys (X direction), used also as anticollision keys
- antirolling keys (Y direction)
- antiflotation keys (Z direction).

They can be modelled by either linear elements (bar, flexible mounts, springs), or non-linear elements (gap elements).

When linear elements are used to model keys and supports not allowing tension loads, they are to be deleted when in tension.

Stiffness of these linear and/or non-linear elements is to be representative of the actual stiffness of the supports and keys.

The stiffness of the pad located between the lower and upper parts of the support may be calculated as follows:  $K = E S / h$  where:

- K : Stiffness of the pad, in N/mm  
E : Young modulus of the pad, in MPa  
S : Sectional area of the pad, in mm<sup>2</sup>  
h : Height of the pad, in mm.

The stiffness of the gap or spring element is to be taken as:  $K_{\text{element}} = K / N_{\text{elements}}$

with:

$N_{\text{elements}}$  : Number of elements used in the pad modelling.

#### 8.2.5 Size of the elements

The mesh size are to be equal to the spacing of the longitudinal ordinary stiffeners. Each of these longitudinal stiffeners is to be modelled. The aspect ratio of the elements is to be as close to 1,0 as possible.

### **8.2.6 Boundary conditions**

The requirements of Pt B, Ch 8, App 1, [2.5] are to be applied.

## **8.3 Local fine mesh models**

### **8.3.1 Areas to be modelled**

The following local fine meshes are, at least, to be carried out for:

- each type of support (vertical support, upper part or lower part)
- high stressed areas which do not meet the screening criterion defined in Pt B, Ch 8, App 2, [1.2.3], where  $\lambda_{sc}$  and  $\lambda_{scperm}$  are to be taken equal to respectively  $\lambda_y$  and  $0,89 \lambda_{yperm}$

Other fine mesh models may be required, at the request of the Society.

### **8.3.2 Size of the elements**

For fine mesh models of the various supports and keys, the size of the elements is not to be taken greater than 50 x 50 mm.

In case of finer mesh, the equivalent stress is to be obtained by averaging over an equivalent area of 50 x 50 mm.

### **8.3.3 Yielding criteria**

It is to be checked that the Von Mises stress  $\sigma_{vm}$  in the supports and keys, in N/mm<sup>2</sup>, is in compliance with the requirements in Pt B, Ch 8, App 2, [4.1.3].

## **9 Other structures**

### **9.1 Machinery space**

#### **9.1.1 Extension of the hull structures within the machinery space**

Longitudinal bulkheads carried through cofferdams are to continue within the machinery space and are to be used preferably as longitudinal bulkheads for liquid cargo tanks. In any case, such extension is to be compatible with the shape of the structures of the double bottom, deck and platforms of the machinery space.

### **9.2 Opening arrangement**

#### **9.2.1 Tanks covers**

Covers fitted on all cargo tank openings are to be of sturdy construction, and to ensure tightness for hydrocarbon and water.

Aluminium is not permitted for the construction of tank covers. The use of reinforced fibreglass covers is to be specially examined by the Society.

*For the protection of cargo tanks carrying crude oil and petroleum products having a flash point not exceeding 60°C, materials readily rendered ineffective by heat are not to be used for tank opening covers so as to prevent the spread of fire to the cargo.*

## **10 Hull outfitting**

### **10.1 Equipment**

#### **10.1.1 Emergency towing arrangements**

The specific requirements in Pt B, Ch 12, Sec 4, [3] for ships with the service notation **oil tanker ESP** or **FLS tanker** and of 20000 t deadweight and above are to be complied with.

## **11 Protection of hull metallic structures**

### **11.1 Protection by aluminium coatings**

**11.1.1** The use of aluminium coatings containing greater than 10% aluminium by weight in the dry film is prohibited in the cargo tanks, cargo tank deck area, pump rooms, cofferdams or any other area where cargo vapour may accumulate.

### **11.2 Material and coatings of tanks**

**11.2.1** The resistance of materials and coatings and their compatibility with intended cargoes are the responsibility of the builder or owner. All supporting documents are, however, to be given to the Society to allow the issue of the list of cargoes annexed to the classification certificate.

Copy of the charts of coating and/or material resistance issued by the manufacturers is to be kept on board. These documents are to indicate the possible restrictions relative to their use.

## 12 Cathodic protection of tanks

### 12.1 General

**12.1.1** Internal structures in spaces intended to carry liquids may be provided with cathodic protection.

Cathodic protection may be fitted in addition to the required corrosion protective coating, if any.

**12.1.2** Details concerning the type of anodes used and their location and attachment to the structure are to be submitted to the Society for approval.

### 12.2 Anodes

**12.2.1** Magnesium or magnesium alloy anodes are not permitted in oil cargo tanks and tanks adjacent to cargo tanks.

**12.2.2** Aluminium anodes are only permitted in cargo tanks and tanks adjacent to cargo tanks in locations where the potential energy does not exceed 28 kg m. The height of the anode is to be measured from the bottom of the tank to the centre of the anode, and its weight is to be taken as the weight of the anode as fitted, including the fitting devices and inserts.

However, where aluminium anodes are located on horizontal surfaces such as bulkhead girders and stringers not less than 1 m wide and fitted with an upstanding flange or face flat projecting not less than 75 mm above the horizontal surface, the height of the anode may be measured from this surface.

Aluminium anodes are not to be located under tank hatches or washing holes, unless protected by the adjacent structure.

**12.2.3** There is no restriction on the positioning of zinc anodes.

**12.2.4** Anodes are to have steel cores and are to be declared by the Manufacturer as being sufficiently rigid to avoid resonance in the anode support and designed so that they retain the anode even when it is wasted.

**12.2.5** The steel inserts are to be attached to the structure by means of a continuous weld. Alternatively, they may be attached to separate supports by bolting, provided a minimum of two bolts with lock nuts are used. However, other mechanical means of clamping may be accepted.

**12.2.6** The supports at each end of an anode may not be attached to separate items which are likely to move independently.

**12.2.7** Where anode inserts or supports are welded to the structure, they are to be arranged by the Shipyard so that the welds are clear of stress peaks.

**12.2.8** As a general rule, the requirements [12.2.1] to [12.2.7] apply also to spaces or compartments adjacent to cargo or slop tanks.

### 12.3 Impressed current systems

**12.3.1** Impressed current cathodic protections are not accepted in cargo or slop tanks, unless specially authorized by the Society.

## 13 Construction and testing

### 13.1 Welding and weld connections

**13.1.1** It is recommended to use continuous fillet welding to connect primary supporting member web to its associated shell plating. The leg length of such a welding is not to be less than the value specified in Pt B, Ch 13, Sec 3, Tab 3.

Discontinuous welds are not allowed for primary members perpendicular to ordinary stiffeners.

For longitudinals, intermittent scallop welding can be accepted as for primary members parallel to longitudinals, especially in small ships.

Intermittent scallop welding can be accepted for some members.

Where scallop fillet is used, the scallops are to be avoided:

- in way of the connecting brackets and at least more than 200 mm beyond the beginning of the bracket
- more than 200 mm about on either side of the connection of the ordinary stiffeners to the primary stiffeners
- on bottom transverses, shell stringers and longitudinal bulkhead stringers
- on the lower half of side shell and longitudinal bulkhead transverses, and on the web frames of transverse bulkheads.

**13.1.2** The weld factors for some hull structural connections are specified in Tab 5. These weld factors are to be used, in lieu of the corresponding factors specified in Pt B, Ch 13, Sec 3, Tab 1, to calculate the leg length of fillet weld T connections according to Pt B, Ch 13, Sec 3, [3.2.6]. For the connections of Tab 5, continuous fillet welding is to be adopted.

Table 5 : Weld factor  $w_F$

Hull area	Connection		Weld factor $w_F$
	of	to	
Double bottom in way of cargo tanks	girders	bottom and inner bottom plating	0,48
		floors (interrupted girders)	
	floors	bottom and inner bottom plating	
		girders (interrupted floors)	
Bulkheads (1)	ordinary stiffeners	bulkhead plating	

(1) Not required to be applied to ships with the additional service feature **flash point > 60°C**.

13.1.3 For ships of more than 250 m in length, leg lengths of fillet welds for transverse web frames and horizontal stringers on transverse bulkheads are to be reinforced as shown in Fig 1 and Fig 2.

The length, in m, of reinforcement is not to be less than the greater of the following values:

- $l = 2s$
- $l = 1,2$

where  $s$  is the spacing, in m, of the ordinary stiffeners.

13.2 Special structural details

13.2.1 The specific requirements in Pt B, Ch 13, Sec 5, [2.3] for ships with the service notation **oil tanker ESP, FLS tanker or asphalt carrier** are to be complied with.

Figure 1 : Reinforcement of throat thickness for ships greater than 250 m

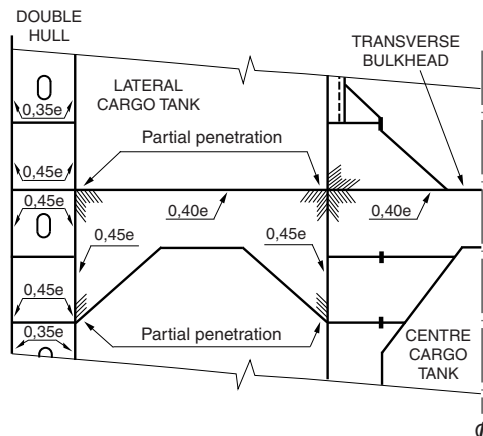

Figure 2 : Reinforcement of throat thickness for ships greater than 250 m

# Section 4 Machinery and Cargo Systems

## 1 General

### 1.1 Application

#### 1.1.1 Relaxations applying to certain service notations

Articles [2] to [7] provide requirements that apply to ships having the service notation **oil tanker** and, where indicated in the relevant notes, the relaxations which may be accepted for ships of less than 500 gross tonnage and for ships having the following service notations:

- **oil tanker, flash point > 60°C**
- **oil tanker, asphalt carrier**
- **FLS tanker**
- **FLS tanker, flash point > 60°C.**

Such relaxations are summarised in Tab 1.

#### 1.1.2 Additional requirements

Additional requirements are provided in:

- [8] for ships having the service notation **oil tanker, asphalt carrier**
- [9] for ships intended to carry substances of pollution category Z.

### 1.2 Documents to be submitted

1.2.1 The documents listed in Tab 2 are to be submitted for approval.

### 1.3 Abbreviations

1.3.1 The following abbreviations are used in this Section.

FP : Flash point, in °C.

**Table 1 : Possible relaxations according to service notation**

Subject	Reference to the Rules	Service notation or other feature of the ship to which relaxations apply	Relaxations
Driven pumps for bilge, ballast, etc.	[2.1.4]	< 500 GT	equivalent arrangements accepted
Drainage of cofferdams	[2.2.5]	< 500 GT	hand pumps permitted
Ballast pumps	[2.3.2]	<ul style="list-style-type: none"> <li>• <b>oil tanker, flash point &gt; 60°C</b></li> <li>• <b>oil tanker, asphalt carrier</b></li> <li>• <b>FLS tanker, flash point &gt; 60°C</b></li> </ul>	Shaft misalignment compensation, gastightness of the shaft gland and temperature sensors are not required
Air and sounding pipes of spaces other than cargo tanks	[2.4]	<ul style="list-style-type: none"> <li>• <b>oil tanker, flash point &gt; 60°C</b></li> <li>• <b>oil tanker, asphalt carrier</b></li> <li>• <b>FLS tanker, flash point &gt; 60°C</b></li> </ul>	NA (1)
Cargo pumps	[3.2.3] [3.2.4] [3.2.5]	<ul style="list-style-type: none"> <li>• <b>oil tanker, flash point &gt; 60°C</b></li> <li>• <b>oil tanker, asphalt carrier</b></li> <li>• <b>FLS tanker, flash point &gt; 60°C</b></li> </ul>	Shaft misalignment compensation, gas-tightness of the shaft gland and temperature sensors are not required
Generation of static electricity	[3.4.4]	<ul style="list-style-type: none"> <li>• <b>oil tanker, flash point &gt; 60°C</b></li> <li>• <b>oil tanker, asphalt carrier</b></li> <li>• <b>FLS tanker, flash point &gt; 60°C</b></li> </ul>	NA (1)
Bow or stern cargo loading and unloading arrangement	[3.4.5]	<ul style="list-style-type: none"> <li>• <b>oil tanker, flash point &gt; 60°C</b></li> <li>• <b>oil tanker, asphalt carrier</b></li> <li>• <b>FLS tanker, flash point &gt; 60°C</b></li> </ul>	NA (1)

(1) NA means that the requirements referred to in the second column of the table are not applicable.

Subject	Reference to the Rules	Service notation or other feature of the ship to which relaxations apply	Relaxations
