Strength assessment	$M = M_{Full}$ <ul style="list-style-type: none"> <li>• if <math>\rho_{C-lm} \leq 1,0</math> <math>\rho_c = \rho_{C-lm}</math></li> <li>• if <math>\rho_{C-lm} &gt; 1,0</math> <math>\rho_c = \max\left(\frac{M_{Full}}{V_{Full}}; 1,0\right)</math></li> </ul>	$M = M_H$ $\rho_c = 3,0$ (2)	$M = M_{HD} + 0,1 M_H$ $\rho_c = \frac{M_{HD} + 0,1 \cdot M_H}{V_{Full}}$	$M = M_{HD} + 0,1 M_H$ $\rho_c = 3,0$ (2)
Fatigue assessment	$M = M_H$ <ul style="list-style-type: none"> <li>• if <math>\rho_{C-lm} \leq 1,0</math> <math>\rho_c = \rho_{C-lm}</math></li> <li>• if <math>\rho_{C-lm} &gt; 1,0</math> <math>\rho_c = \frac{M_{Full}}{V_{Full}}</math></li> </ul>	NA	NA	$M = M_{HD}$ $\rho_c = 3,0$ (2)
Strength assessment in flooded conditions	$M = M_H$ <ul style="list-style-type: none"> <li>• if <math>\rho_{C-lm} \leq 1,0</math> <math>\rho_c = \rho_{C-lm}</math></li> <li>• if <math>\rho_{C-lm} &gt; 1,0</math> <math>\rho_c = \frac{M_{Full}}{V_{Full}}</math></li> </ul>	$M = M_H$ $\rho_c = 3,0$ (2)	$M = M_{HD}$ $\rho_c = \frac{M_{HD}}{V_{Full}}$	$M = M_{HD}$ $\rho_c = 3,0$ (2)

(1) Applicable only if  $\rho_{C-lm}$  is greater than 1,0

(2) To be taken as 3,0 unless an alternative maximum cargo density is specified in the loading manual.

(3)  $\rho_c = 1,78 t/m^3$  is to be considered for the specific alternate loading condition «hold loaded with  $\rho_c \leq 1,78 t/m^3$ »

**Note 1:**

$\rho_{C-lm}$  : Maximum cargo density specified in the loading manual.

### 3.4 Dry bulk cargo pressures

#### 3.4.1 Total pressure

The total pressure due to dry bulk cargo acting on any load point of a cargo hold boundary, in kN/m<sup>2</sup>, is to be taken as:

- For strength assessment in intact condition for static design load scenarios given in Ch 5, Sec 7:

$$P_{in} = P_{bs}$$

- For strength assessment in intact condition and fatigue assessment for static + dynamic design load scenarios given in Ch 5, Sec 7:

$$P_{in} = P_{bs} + P_{bd}$$

but not less than 0.

where:

$P_{bs}$  : Static pressure due to dry bulk cargo, in kN/m<sup>2</sup>, as defined in [3.4.2]

$P_{bd}$  : Dynamic inertial pressure due to dry bulk cargo in cargo holds, in kN/m<sup>2</sup>, as defined in [3.4.3].

Static and dynamic pressures as defined in [3.4.2] and [3.4.3] for FE analysis are to be determined using  $\rho_{eff}$  instead of  $\rho_c$ .

#### 3.4.2 Static pressure

The dry bulk cargo static pressure  $P_{bs}$ , in kN/m<sup>2</sup>, is to be taken as:

$$P_{bs} = \rho_c g K_C (z_{BC} - z)$$

but not less than 0.

#### 3.4.3 Dynamic pressure

The dry bulk cargo dynamic pressure  $P_{bd}$ , in kN/m<sup>2</sup>, for each load case is to be taken as:

- For  $z \leq z_{BC}$ :

$$P_{bd} = \rho_c \left[ \frac{a_x (x_G - x) + a_y (y_G - y)}{4} + f_{dc} K_C a_z (z_{BC} - z) \right]$$

- For  $z > z_{BC}$ :

$$P_{bd} = 0$$

Where:

$f_{dc}$  : Dry cargo factor, taken as 1,0 for strength assessment and 0,5 for fatigue assessment

### 3.5 Shear load

#### 3.5.1 Application

For FE strength assessment and FE fatigue assessment, the following shear load pressures are to be considered in addition to the dry bulk cargo pressures defined in [3.4] when the load point elevation,  $z$ , is lower or equal to  $z_{BC}$

- For static (S) design load scenarios, given in Ch 5, Sec 7: Static shear load,  $P_{bs-s}$ , due to gravitational forces acting on hopper tanks and lower stools plating, as defined in [3.5.2].
- For static plus dynamic (S+D) design load scenarios, given in Ch 5, Sec 7: The following dynamic shear load pressures:
  - $P_{bs-s} + P_{bs-d}$   
for the hopper tank and the lower stool plating, as defined in [3.5.3]
  - $P_{bs-dx}$   
for the inner bottom plating in the longitudinal direction, as defined in [3.5.4]
  - $P_{bs-dy}$   
for the inner bottom plating in the transverse direction, as defined in [3.5.4].

Shear loads as defined in [3.5.2] to [3.5.4] for FE analysis are to be determined using  $\rho_{eff}$  instead of  $\rho_c$ .

#### 3.5.2 Static shear load on the hopper tank and lower stool plating

The static shear load pressure,  $P_{bs-s}$  (positive downward to the plating) due to dry bulk cargo gravitational forces acting on hopper tank and lower stool plating, in kN/m<sup>2</sup>, is to be taken as:

$$P_{bs-s} = \rho_c g \frac{(1 - K_C) (z_{BC} - z)}{\tan \alpha_p}$$

**3.5.3 Dynamic shear load on the hopper tank and lower stool plating**

The dynamic shear load pressure,  $P_{bs-d}$  (positive downward to the plating) due to dry bulk cargo forces on the hopper tank and lower stool plating, in  $kN/m^2$ , for each dynamic load case is to be taken as:

$$P_{bs-d} = \rho_C a_z \frac{(1 - K_C) (z_{BC} - z)}{\tan \alpha_p}$$

**3.5.4 Dynamic shear load along the inner bottom plating for FE analyses**

The dynamic shear load pressures,  $P_{bs-dx}$  in the longitudinal direction (positive to bow) due to dry bulk cargo forces acting along the inner bottom plating, in  $kN/m^2$ , for each dynamic load case is to be taken respectively as:

$$P_{bs-dx} = -0,75 \rho_C a_x h_{BC}$$

The dynamic shear load pressures,  $P_{bs-dy}$  in the transverse direction (positive to port) due to dry bulk cargo forces acting along the inner bottom plating, in  $kN/m^2$ , for each dynamic load case is to be taken respectively as

$$P_{bs-dy} = -0,75 \rho_C a_y h_{BC}$$

The dynamic shear load pressures  $P_{bs-dx}$  and  $P_{bs-dy}$  are only used for FE strength assessment.

**4 Pressures and forces due to dry cargoes in flooded conditions**

**4.1 Local loads on vertically corrugated transverse bulkheads in flooded conditions**

**4.1.1 Application**

The pressure defined in this sub-article applies to vertically corrugated transverse watertight bulkheads of the cargo holds of ships intended for the carriage of dry cargoes in bulk for flooded condition assessment.

Each cargo hold is to be considered individually flooded, see Fig 8, Fig 9 and Fig 10.

**Figure 8 : Flooded level below upper surface of bulk cargo**

**Figure 9 : Flooded level above upper surface of bulk cargo**

Figure 10 : Flooded cargo hold without cargo

#### 4.1.2 General

The loads to be considered as acting on each bulkhead are those given by the combination of those induced by cargo loads with those induced by the flooding of one hold adjacent to the bulkhead under examination. In any case, the pressure due to the flooding water alone is to be considered. This application is to be applied to **self-unloading bulk carrier ESP** where the unloading system maintains the watertightness during seagoing operations. In **self-unloading bulk carrier ESP** with unloading systems that do not maintain watertightness, the combination loads acting on the bulkheads in the flooded conditions are to be considered using the extent to which the flooding may occur.

The most severe combinations of cargo induced loads and flooded loads are to be used for the check of the scantlings of each bulkhead, depending on the loading conditions included in the loading manual considering the individual flooded condition of both loaded and empty holds:

- Homogeneous loading conditions
- Non-homogeneous loading conditions.

For the purpose of this article, the following items are defined as:

- Design load limits:

The specified design load limits for the cargo holds are to be represented by loading conditions defined by the designer in the loading manual.

- Maximum cargo mass to consider:

Unless the ship is intended to carry, in non-homogeneous conditions, only iron ore or cargo having bulk density equal to or greater than  $1,78 \text{ t/m}^3$ , the maximum mass of cargo which may be carried in the hold is also to be considered to fill that hold up to the top of the hatch coaming.

- Homogeneous loading conditions:

Homogeneous loading condition means a loading condition in which the ratio between the highest and the lowest filling level, evaluated for each hold, does not exceed 1,20, to be corrected for different cargo densities.

- Packed cargoes:

Holds carrying packed cargoes (such as steel mill products) are to be considered as empty.

- Unconsidered loading conditions:

Non-homogeneous partially filled loading conditions associated with Multi-port (MP) loading and unloading operations do not need to be considered for the verification of these requirements.

#### 4.1.3 Flooded level

The flooded level  $z_F$  is the distance, in m, measured vertically from the baseline with the ship in the upright position, and obtained from Tab 3.

#### 4.1.4 Flooded patterns

Three different flooded patterns are to be considered:

- the flooded level is below the upper surface of the cargo, (see Fig 8:  $z_{BC} > z_F$ )
- the flooded level is above the upper surface of the cargo, (see Fig 9:  $z_{BC} \leq z_F$ )
- the flooded hold is empty, (see Fig 10:  $z_{BC} = h_{DB}$ ).

**Table 3 : Flooded level  $z_F$ , in m, for vertically corrugated transverse bulkheads**

Ship type	Loading condition	Vertically corrugated transverse bulkhead position	
		Foremost	Others
Ships less than 50,000 t deadweight with Type B freeboard	Non-homogeneous loading conditions with cargo density less than 1,78 t/m <sup>3</sup>	$z_F = 0,9 D_1$	$z_F = 0,8 D_1$
	Other cases	$z_F = 0,95 D_1$	$z_F = 0,85 D_1$
Other ships	Non-homogeneous loading conditions with cargo density less than 1,78 t/m <sup>3</sup>	$z_F = 0,95 D_1$	$z_F = 0,85 D_1$
	Other cases	$z_F = D_1$	$z_F = 0,9 D_1$

**4.1.5 Pressures and forces on vertically corrugated transverse bulkheads of flooded cargo holds**

The static pressure  $P_{bf-sr}$  in kN/m<sup>2</sup>, at any point of the vertically corrugated transverse bulkhead located at a level  $z$  from the baseline is given in Tab 4 for each flooded pattern defined in [4.1.4].

The force  $F_{bf-sr}$  in kN, acting on a corrugation of a transverse bulkhead is given by Tab 5 for each flooded pattern defined in [4.1.4].

where:

$P_{bf-s-LE}$  : Static pressure calculated according to Tab 4 for:  $z = h_{LS} + h_{DB}$ .

**4.1.6 Pressures and forces on vertically corrugated transverse bulkheads of non-flooded cargo holds**

The static pressure  $P_{bsr}$  in kN/m<sup>2</sup>, at a point of the vertically corrugated transverse bulkhead, located at the level  $z$  from the baseline, due to dry bulk cargo of a non-flooded cargo hold acting on the intact side of the transverse bulkhead which is flooded on the other side is to be taken as:

$$P_{bs} = \rho_C g K_{C-f} (z_{BC} - z)$$

but not less than 0.

The resultant force  $F_{bsr}$  in kN, acting on a corrugation is to be taken as:

$$F_{bs} = \rho_C g s_{cg} \frac{(z_{BC} - h_{DB} - h_{LS})^2}{2} K_{C-f}$$

**Table 4 : Static pressure on vertically corrugated transverse bulkhead of a flooded cargo hold  $P_{bf-s}$**

Flooded case	Load point position	Pressure $P_{bf-sr}$ in kN/m <sup>2</sup>
$z_{BC} > z_F$	$z > z_{BC}$	$P_{bf-s} = 0$
	$z_{BC} \geq z \geq z_F$	$P_{bf-s} = \rho_C g (z_{BC} - z) K_{C-f}$
	$z_F > z \geq h_{DB}$	$P_{bf-s} = \rho g (z_F - z) + [\rho_C (z_{BC} - z) - \rho (1 - perm) (z_F - z)] g K_{C-f}$
$h_{DB} \leq z_{BC} \leq z_F$	$z > z_F$	$P_{bf-s} = 0$
	$z_F \geq z \geq z_{BC}$	$P_{bf-s} = \rho g (z_F - z)$
	$z_{BC} > z \geq h_{DB}$	$P_{bf-s} = \rho g (z_F - z) + [\rho_C - \rho (1 - perm)] g (z_{BC} - z) K_{C-f}$

**Table 5 : Force acting on a corrugation in the flooded cargo holds  $F_{bf-s}$**

Flooded case	Force $F_{bf-sr}$ in kN
$z_{BC} > z_F$	$F_{bf-s} = s_{cg} \left\{ \rho_C g \frac{(z_{BC} - z_F)^2}{2} K_{C-f} + \left[ \frac{\rho_C g (z_{BC} - z_F) K_{C-f} + P_{bf-s-LE}}{2} \right] (z_F - h_{DB} - h_{LS}) \right\}$
$z_F \geq z_{BC}$	$F_{bf-s} = s_{cg} \left\{ \rho g \frac{(z_F - z_{BC})^2}{2} + \left[ \frac{\rho g (z_F - z_{BC}) + P_{bf-s-LE}}{2} \right] (z_{BC} - h_{DB} - h_{LS}) \right\}$

**4.1.7 Resultant pressures and forces on vertically corrugated transverse bulkheads of flooded cargo holds**

The resultant pressure  $P_R$ , in  $kN/m^2$ , at each point of the bulkhead, and the resultant force  $F_R$ , in  $kN$ , acting on a corrugation, given in Tab 6, are to be considered for the assessment in flooded conditions of vertically corrugated transverse bulkhead structures, where:

- $P_{bf-s}$  : Pressure in the flooded cargo holds, in  $kN/m^2$ , as defined in [4.1.5]
- $P_{bs}$  : Pressure in the non-flooded cargo holds, in  $kN/m^2$ , as defined in [4.1.6]
- $F_{bf-s}$  : Force acting on a corrugation in the flooded cargo holds, in  $kN$ , as defined in [4.1.5]
- $F_{bs}$  : Force acting on a corrugation in the non-flooded cargo holds, in  $kN$ , as defined in [4.1.6].

**Table 6 : Resultant pressure  $P_R$  and resultant force  $F_R$  on vertically corrugated transverse bulkhead in flooded condition**

Loading condition	Resultant pressure $P_R$ , in $kN/m^2$	Resultant force $F_R$ , in $kN$
<b>Homogeneous</b>	$P_R = P_{bf-s} - 0,8 P_{bs}$	$F_R = F_{bf-s} - 0,8 F_{bs}$
<b>Alternate</b>	$P_R = P_{bf-s}$	$F_R = F_{bf-s}$

**4.2 Local loads on double bottom in flooded conditions**

**4.2.1 Application**

The pressure defined in this sub-article applies to the double bottom in cargo holds of ships intended for the carriage of dry cargoes in bulk for flooded condition assessment.

Each cargo hold is to be considered individually flooded.

**4.2.2 General**

The loads to be considered as acting on the double bottom are those given by the external sea pressures and the combination of the cargo loads with those induced by the flooding of the hold to which the double bottom belongs.

The most severe combinations of cargo induced loads and flooded loads are to be used, depending on the loading conditions included in the loading manual:

- Homogeneous loading conditions;
- Non-homogeneous loading conditions;
- Packed cargo conditions (such as in the case of steel mill products).

For each loading condition, the maximum dry bulk cargo density to be carried is to be considered in calculating the allowable hold loading.

**4.2.3 Flooded level**

The flooded level  $z_f$  is the distance, in m, measured vertically from the baseline with the ship in the upright position, and obtained from Tab 7.

**Table 7 : Flooded level  $z_f$ , for double bottom in cargo hold region**

Ship type	Cargo hold	
	Foremost	Others
Ships less than 50,000 t deadweight with Type-B freeboard	$z_f = 0,95 D_1$	$z_f = 0,85 D_1$
Other ships	$z_f = D_1$	$z_f = 0,9 D_1$

**5 Steel Coil Loads**

**5.1 General**

**5.1.1 Application**

The provision is determined by assuming Fig 11 as the standard means of securing steel coils loaded on wooden dunnage.

It is assumed that all the steel coils have the same characteristics.

In cases where steel coils are lined up in two or more tiers, formulae in [5.1.3] and [5.2] can be applied assuming that only the lowest tier of steel coils is in contact with hopper sloping plate or inner side plate. In other cases, scantling requirements are to be determined on a case-by-case basis.

**5.1.2 Arrangement of steel coils on inner bottom**

The two following arrangements of steel coils on the inner bottom are considered:

- The steel coils are positioned without respect to the location of the inner bottom floors, as shown in Fig 12. In this case,  $n_2$  and  $l_{ip}$  are given by Tab 8 and Tab 9.
- The steel coils are positioned with respect to the location of the inner bottom floors, as shown in Fig 13.

**Figure 11 : Inner bottom loaded by steel coils**

**5.1.3 Arrangement of steel coils independently of the floor locations**

For steel coils loaded without respect to the location of floors in the inner bottom, see Fig 12:

- The number  $n_2$  of load point dunnages per elementary plate panels is to be found in comply with Tab 8.
- The distance  $l_{ip}$ , in m, between outermost load point dunnages per elementary plate panel is to be found in comply with Tab 9.

**Figure 12 : Steel coils loaded independently of inner bottom floors locations**

**Table 8 : Number  $n_2$  of load point dunnages per elementary plate panel**

$n_2$	$n_3$			
	2	3	4	5
1	$0 < \frac{l}{l_{st}} \leq 0,5$	$0 < \frac{l}{l_{st}} \leq 0,33$	$0 < \frac{l}{l_{st}} \leq 0,25$	$0 < \frac{l}{l_{st}} \leq 0,2$
2	$0,5 < \frac{l}{l_{st}} \leq 1,2$	$0,33 < \frac{l}{l_{st}} \leq 0,67$	$0,25 < \frac{l}{l_{st}} \leq 0,5$	$0,2 < \frac{l}{l_{st}} \leq 0,4$
3	$1,2 < \frac{l}{l_{st}} \leq 1,7$	$0,67 < \frac{l}{l_{st}} \leq 1,2$	$0,5 < \frac{l}{l_{st}} \leq 0,75$	$0,4 < \frac{l}{l_{st}} \leq 0,6$
4	$1,7 < \frac{l}{l_{st}} \leq 2,4$	$1,2 < \frac{l}{l_{st}} \leq 1,53$	$0,75 < \frac{l}{l_{st}} \leq 1,2$	$0,6 < \frac{l}{l_{st}} \leq 0,8$
5	$2,4 < \frac{l}{l_{st}} \leq 2,9$	$1,53 < \frac{l}{l_{st}} \leq 1,87$	$1,2 < \frac{l}{l_{st}} \leq 1,45$	$0,8 < \frac{l}{l_{st}} \leq 1,2$

n <sub>2</sub>	n <sub>3</sub>			
	2	3	4	5
6	$2,9 < \frac{l}{l_{st}} \leq 3,6$	$1,87 < \frac{l}{l_{st}} \leq 2,4$	$1,45 < \frac{l}{l_{st}} \leq 1,7$	$1,2 < \frac{l}{l_{st}} \leq 1,4$
7	$3,6 < \frac{l}{l_{st}} \leq 4,1$	$2,4 < \frac{l}{l_{st}} \leq 2,73$	$1,7 < \frac{l}{l_{st}} \leq 1,95$	$1,4 < \frac{l}{l_{st}} \leq 1,6$
8	$4,1 < \frac{l}{l_{st}} \leq 4,8$	$2,73 < \frac{l}{l_{st}} \leq 3,07$	$1,95 < \frac{l}{l_{st}} \leq 2,4$	$1,6 < \frac{l}{l_{st}} \leq 1,8$
9	$4,8 < \frac{l}{l_{st}} \leq 5,3$	$3,07 < \frac{l}{l_{st}} \leq 3,6$	$2,4 < \frac{l}{l_{st}} \leq 2,65$	$1,8 < \frac{l}{l_{st}} \leq 2,0$
10	$5,3 < \frac{l}{l_{st}} \leq 6,0$	$3,6 < \frac{l}{l_{st}} \leq 3,93$	$2,65 < \frac{l}{l_{st}} \leq 2,9$	$2,0 < \frac{l}{l_{st}} \leq 2,4$

**Table 9 : Distance between outermost load point dunnages per elementary plate panel,  $l_{ip}$ , in m**

n <sub>2</sub>	n <sub>3</sub>			
	2	3	4	5
1	Actual breadth of dunnages			
2	$0,5 l_{st}$	$0,33 l_{st}$	$0,25 l_{st}$	$0,2 l_{st}$
3	$1,2 l_{st}$	$0,67 l_{st}$	$0,50 l_{st}$	$0,4 l_{st}$
4	$1,7 l_{st}$	$1,20 l_{st}$	$0,75 l_{st}$	$0,6 l_{st}$
5	$2,4 l_{st}$	$1,53 l_{st}$	$1,20 l_{st}$	$0,8 l_{st}$
6	$2,9 l_{st}$	$1,87 l_{st}$	$1,45 l_{st}$	$1,2 l_{st}$
7	$3,6 l_{st}$	$2,40 l_{st}$	$1,70 l_{st}$	$1,4 l_{st}$
8	$4,1 l_{st}$	$2,73 l_{st}$	$1,95 l_{st}$	$1,6 l_{st}$
9	$4,8 l_{st}$	$3,07 l_{st}$	$2,40 l_{st}$	$1,8 l_{st}$
10	$5,3 l_{st}$	$3,60 l_{st}$	$2,65 l_{st}$	$2,0 l_{st}$

**5.1.4 Arrangement of steel coils between floors**

For steel coils loaded with respect to the locations of floors in the inner bottom, see Fig 13:

- The number n<sub>2</sub> of load point dunnages per elementary plate panels is to be taken as: n<sub>2</sub> = n<sub>3</sub>
- The distance  $l_{ip}$  between outermost load point dunnages per elementary plate panel is to be taken as the distance between the outermost dunnage supporting one row of steel coils.

**Figure 13 : Steel coils loaded between inner bottom floors**

**5.1.5 Centre of gravity of steel coil cargo**

The centre of gravity of the steel coil cargo of the considered cargo hold is to be taken at the following position:

a) Longitudinal position

$x_{Gsc}$  is the X coordinate, in m, of the volumetric centre of gravity of the considered cargo hold with respect to the reference coordinate system defined in Ch 1, Sec 3, [2.6.1].

For better accuracy, in particular in the case of long cargo holds, the length of the holds may be divided into several sub-parts,  $x_{Gsc}$  being taken as the centre of gravity of the considered sub-part.

b) Transverse position

$$y_{Gsc} = \varepsilon \frac{B_H}{4}$$

c) Vertical position

$$z_{Gsc} = h_{DB} + \left[ 1 + (n_l - 1) \frac{\sqrt{3}}{2} \right] \frac{d_{sc}}{2}$$

where:

$\varepsilon$  : Coefficient to be taken as:

- when a port side structural member is assessed:  
 $\varepsilon = 1,0$
- when a starboard side structural member is assessed:  
 $\varepsilon = -1,0$

**5.2 Total loads**

**5.2.1 Total load on the inner bottom**

The total load  $F_{sc-ib}$ , in kN, due to steel coil cargoes on the inner bottom is to be taken as:

$$F_{sc-ib} = \cos(f_\beta C_{XG} \varphi) \cos(C_{YG} \theta) F_{sc-ib-s} + F_{sc-ib-d}$$

but not less than 0

where:

- $F_{sc-ib-s}$  : Static load, in kN, on the inner bottom, given in [5.3.1]
- $F_{sc-ib-d}$  : Dynamic load, in kN, on the inner bottom, given in [5.4.1]
- $C_{XG}, C_{YG}$ : Load combination factors, as defined in Ch 5, Sec 2, [2.2].

**5.2.2 Total load on the hopper side and the inner hull**

The total load  $F_{sc-hs}$ , in kN, due to steel coil cargoes on the hopper side and the inner hull is to be taken as:

$$F_{sc-hs} = \frac{\cos(\theta_h + \varepsilon C_{YG} \theta) \cos(f_\beta C_{XG} \varphi)}{\cos \theta_h} F_{sc-hs-s} + F_{sc-hs-d}$$

but not less than 0.

where:

- $F_{sc-hs-s}$  : Static load, in kN, on the hopper side and the inner hull given in [5.3.2]
- $F_{sc-hs-d}$  : Dynamic load, in kN, on the hopper side and the inner hull given in [5.4.2]
- $C_{XG}, C_{YG}$ : Load combination factors, as defined in Ch 5, Sec 2, [2.2].

**5.3 Static loads**

**5.3.1 Static loads on the inner bottom**

The static load  $F_{sc-ib-s}$ , in kN, on the inner bottom due to steel coils is to be taken as:

$$F_{sc-ib-s} = M_{sc-ib} g$$

where:

$M_{sc-ib}$  : Equivalent mass of steel coils, in t, to be taken as:

$$M_{sc-ib} = K_S W \frac{n_1 n_2}{n_3} \text{ for } n_2 \leq 10 \text{ and } n_3 \leq 5$$

$$M_{sc-ib} = K_S W n_1 \frac{\ell}{\ell_{st}} \text{ for } n_2 > 10 \text{ or } n_3 > 5$$

$K_S$  : Coefficient to be taken as:

- $K_S = 1,4$  when steel coils are lined up in one tier with a key coil.
- $K_S = 1,0$  in other cases.

**5.3.2 Static load on the hopper side and the inner hull**

The static load  $F_{sc-hs-s}$ , in kN, on the hopper side and the inner hull due to steel coils is to be taken as:

$$F_{sc-hs-s} = \cos\theta_h \cdot M_{sc-hs} \cdot g$$

where:

$M_{sc-hs}$  : Equivalent mass of steel coils, in t, to be taken as:

$$M_{sc-hs} = C_k W \frac{n_2}{n_3} \text{ for } n_2 \leq 10 \text{ and } n_3 \leq 5$$

$$M_{sc-hs} = C_k W \frac{\ell}{\ell_{st}} \text{ for } n_2 > 10 \text{ or } n_3 > 5$$

$C_k$  : Coefficient to be taken as:

$C_k = 3,2$  when steel coils are lined up two or more tiers, or when steel coils are lined up one tier and key coil is located second or 3rd from hopper sloping plate or inner hull plate

$C_k = 2,0$  for other cases.

**5.4 Dynamic loads**

**5.4.1 Dynamic load on the inner bottom**

The dynamic load  $F_{sc-ib-d}$ , in kN, on the inner bottom due to steel coils is to be taken as:

$$F_{sc-ib-d} = M_{sc-ib} a_z$$

where:

$a_z$  : Vertical acceleration, in  $m/s^2$ , as defined in Ch 5, Sec 3, [3.2.4], calculated at the centre of gravity of the steel coil cargo of the considered cargo hold, given in [5.1.5].

**5.4.2 Dynamic load on the hopper side and the inner hull**

The dynamic load  $F_{sc-hs-dr}$ , in kN, on the hopper side and the inner hull due to steel coils is to be taken as:

$$F_{sc-hs-d} = \varepsilon \cdot M_{sc-hs} [C_{YR} a_{roll} \Omega - f_{\beta} C_{YS} a_{sway} \sin\theta_h]$$

where:

$\Omega$  : Geometrical coefficient defined as:

$$\Omega = \sqrt{Y_{Gsc}^2 + (R - Z_{Gsc})^2} \cdot \sin \left( \tan^{-1} \left| \frac{Y_{Gsc}}{R - Z_{Gsc}} \right| - \theta_h \right)$$

$C_{YS}, C_{YR}$  : Load combination factors, defined in Ch 5, Sec 2, [2.2]

$a_{roll}$  : Roll acceleration, in  $rad/s^2$ , defined in Ch 5, Sec 3, [2.2.4]

$a_{sway}$  : Sway acceleration, in  $m/s^2$ , as defined in Ch 5, Sec 3, [2.2.2]

$\varepsilon$  : Coefficient defined in [5.1.5]

$Y_{Gsc}$  : Y coordinate, in m, of the centre of gravity of the steel coil cargo of the considered cargo hold, given in [5.1.5]

$Z_{Gsc}$  : Z coordinate, in m, of the centre of gravity of the steel coil cargo of the considered cargo hold, given in [5.1.5].

**6 Loads on decks and platforms**

**6.1 Pressure due to distributed load**

**6.1.1** In accommodation and machinery spaces and when a uniform cargo is carried on deck, a distributed load is to be applied. The static and dynamic pressure due to this distributed load is to be considered.

The total pressure  $P_{dl}$ , in  $kN/m^2$ , due to accommodation or machinery loads or uniform cargo for the static design load scenarios is to be taken as:

$$P_{dl} = P_{dl-s}$$

The total pressure  $P_{dl}$ , in  $kN/m^2$ , due to accommodation or machinery loads or uniform cargo for the static + dynamic design load scenario is to be derived for each dynamic load case and is to be taken as:

$$P_{dl} = P_{dl-s} + P_{dl-d}$$

where:

$P_{dl-s}$  : Static pressure, in  $kN/m^2$ , due to accommodation or machinery loads or uniform cargo, to be defined by the Designer without being less than the values given in Tab 10.

For deck loaded with dry uniform cargo, when the  $P_{dl-s}$  value is not specified by the designer, it may be taken equal to  $6,9 h_{TD}$

$P_{dl-d}$  : Dynamic pressure, in kN/m<sup>2</sup>, due to uniform cargo, to be taken as:

$$P_{dl-d} = P_{dl-s} \frac{a_z}{g}$$

$a_z$  : Vertical acceleration, in m/s<sup>2</sup>, at the load position being considered, for the considered load case, to be obtained according to Ch 5, Sec 3, [3]

$h_{TD}$  : compartment tweendeck height at side, in m.

**6.1.2 Ships with additional service feature heavycargo**

For ships with the additional service feature **heavycargo** [AREA, X1 kN/m<sup>2</sup> - AREA, X2 kN/m<sup>2</sup> - ...] (see Pt A, Ch 1, Sec 2, [4.2.2]), the values of  $p_{dl-sr}$ , in kN/m<sup>2</sup>, are to be specified by the Designer for each AREAi, according to [6.1.1], and introducing as Xi values in the above service feature.

**Table 10 : Minimum static pressure due to distributed loads**

Type of compartment	$P_{dl-s}$ , in kN/m <sup>2</sup>
Large public spaces, such as restaurants, halls, cinemas, lounges	5,0
Muster stations	5,0
Large rooms, such as: <ul style="list-style-type: none"> <li>• rooms with fixed furniture</li> <li>• games and hobbies rooms, hospitals</li> </ul>	3,0
Cabins	3,0
Other accommodation compartments	2,5
Storage rooms	5,0
Machinery spaces	10,0
Technical spaces, such as AC rooms, elevators machinery space, electrical facilities, pump rooms	5,0
Other decks and platforms	10,0
Dry uniform cargo	10,0

**6.2 Concentrated force due to unit cargo**

**6.2.1** When a unit cargo is carried on a deck, a concentrated load is to be applied. The static and dynamic concentrated forces due to this unit cargo are to be considered, when a direct analysis is applied for stiffeners or for primary supporting members, such as in Ch 7, Sec 5, [1.7] or in Ch 7, Sec 6, [2.2], respectively.

The concentrated force  $F_{u-sr}$  in kN, due to this unit cargo for the static design load scenarios is to be taken, in the z direction, as:

$$F_{u-s} = -m_U g$$

The concentrated force  $F_{u-dr}$  in kN, due to this unit cargo for the static + dynamic design load scenarios is to be derived from the dynamic load cases, with components to be taken as defined in Tab 11.

**Table 11 : Force  $F_{u-d}$  due to unit cargo**

Direction	$F_{u-dr}$ in kN, on exposed deck	$F_{u-dr}$ in kN, on non-exposed deck
x	$-m_U a_x$	$-m_U a_{x-env}$
y	$-m_U a_y$	$-m_U a_{y-env}$
z	$-m_U (a_z + g)$	$-m_U (a_{z-env} + g)$

**Note 1:**

$m_U$  : Mass of the unit cargo carried, in t

$a_x, a_y, a_z$  : Accelerations, in m/s<sup>2</sup>, at the centre of gravity of the unit cargo carried for the considered load case, to be obtained according to Ch 5, Sec 3, [3.2].

$a_{x-env}, a_{y-env}, a_{z-env}$  : Envelope of accelerations, in m/s<sup>2</sup>, at the centre of gravity of the unit cargo carried for the considered load case, to be obtained according to Ch 5, Sec 3, [3.3].

## **7 Wheeled cargo**

### **7.1 Application**

#### **7.1.1 General**

Caterpillar trucks and unusual vehicles are considered by the Society on a case by case basis.

The load supported by the crutches of semi-trailers, handling machines and platforms is considered by the Society on a case by case basis.

#### **7.1.2 Tyred vehicles**

The forces transmitted through the tyres are considered as uniformly distributed pressure on the tyre print area, which dimensions are to be given by the Designer together with the arrangement of wheels on axles, the load per axle and the tyre pressure.

For the assessment of stiffeners and primary supporting members, such forces are considered as concentrated in the tyre print centre.

The forces acting on primary supporting members are to be determined taking into account the area of influence of each member and the way ordinary stiffeners transfer the forces transmitted through the tyres.

#### **7.1.3 Non-tyred vehicles**

The requirements of [7.1.2] also apply to tracked vehicles; in this case the print to be considered is that below each wheel or wheelwork.

For vehicles on rails, all the forces transmitted are to be considered as concentrated at the contact area centre.

#### **7.1.4 Fork-lift trucks**

Loaded fork-lift trucks are to be considered only for strength assessment in the harbour design load scenario (H: S).

## **7.2 Forces due to wheeled cargo**

### **7.2.1 Total force induced by a single wheel**

The total wheel force  $P_0$ , in kN, for the static design load scenarios is to be taken as:

$$P_0 = F_{W-S}$$

The total wheel force  $P_0$ , in kN, for the dynamic design load scenarios is to be taken as:

$$P_0 = F_{W-S} + F_{W-D}$$

where:

$F_{W-S}$  : Static wheel force defined in [7.2.2]

$F_{W-D}$  : Dynamic wheel force defined in [7.2.3].

### **7.2.2 Static force**

The static wheel force  $F_{W-S}$ , in kN, for the static design load scenarios is to be taken, in the z direction, as:

$$F_{W-S} = -M g$$

Where:

$M$  : Mass supported by a single wheel, in t, taken equal to:

$$M = \frac{Q_A}{n_W}$$

$Q_A$  : Axle load, in t

$n_W$  : Number of individual wheels for the axle considered.

### **7.2.3 Dynamic force**

The dynamic wheel force  $F_{W-D}$ , in kN, for the static + dynamic design load scenarios is to be derived from the dynamic load cases, with components to be taken as defined in Tab 12.

Table 12 : Dynamic forces due to wheeled cargo

Direction	$F_{W-D}$ , in kN, General (1)	$F_{W-D}$ , in kN, Racking analysis (2)
x	–	–
y	–	$-M a_y$
z	$-\alpha M a_z$	$-\alpha M a_z$

(1) This condition defines the force, applied by one wheel, to be considered for the determination of scantlings of plating, ordinary stiffeners and primary supporting members, as defined in Part B, Chapter 6.

(2) This condition is to be considered for the racking analysis of ships granted with the service notation **PCTC**, **PCC**, **ro-ro cargo ship** or **ro-ro passenger ship**, as defined in Ch 7, App 1, with M taken equal to the mass, in t, of wheel loads located on the structural member under consideration.

**Note 1:**

M : Mass of the unit cargo carried, in t

$a_y, a_z$  : Accelerations, in  $m/s^2$ , at the centre of gravity of the considered vehicle for the considered load case, to be obtained according to Ch 5, Sec 3, [3.2].

$\alpha$  : Coefficient accounting for shock absorbers, taken equal to:

- 0,5 in general
- 1,0 for landing gears of trailers.

## 8 Loads due to containers

### 8.1 Forces applied to containers

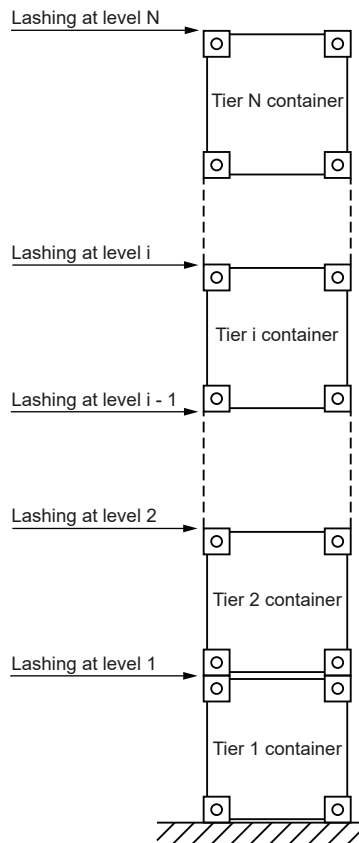

#### 8.1.1 Centre of gravity of a container

The centre of gravity of each container with its cargo is to be taken at 45% of the container height.

#### 8.1.2 Static and dynamic forces

The static and dynamic forces applied to one container located at tier “i”, as defined in Fig 14, are to be obtained, in kN, as specified in Tab 13.

Figure 14 : Container levels in a stack

**Table 13 : Container at tier “i” - Static and dynamic forces, in kN**

Direction	Static force	Dynamic force
x	–	$F_{W,X,i} = -M_i a_{X-env}$
y	–	$F_{W,Y,i} = -M_i a_{Y-env}$
z	$F_{S,i} = -M_i g$	$F_{W,Z,i} = -M_i a_{Z-env}$

**Note 1:**  
 $M_i$  : Mass, in t, of the container at tier “i”  
 $a_{X-env}, a_{Y-env}, a_{Z-env}$  : Envelope of accelerations, in  $m/s^2$ , at the centre of gravity of the container, to be obtained according to Ch 5, Sec 3, [3.3].

**8.2 Stacks of containers**

**8.2.1 Static and dynamic forces**

The static and dynamic forces and the wind force are to be considered as defined in [8.1.2] and Ch 5, Sec 5, [8.1], respectively, and the forces transmitted at the corners of a stack are to be obtained as specified in Tab 14 (see also Fig 15).

**8.2.2 Empty containers**

When empty containers are stowed at the top of a stack, static and dynamic forces are to be derived considering the weight of empty containers equal to:

- 2,5 t for twenty feet containers
- 3,5 t for forty feet containers
- 3,5 t for forty-five feet containers.

For other container sizes, the weight of empty containers is to be taken equal to 0,14 times the maximum gross weight of the container.

**8.2.3 Effect of cell guides**

Where cell guides support the containers stowed in holds, absolute value of  $R_{W,MY}$  calculated according to [8.2.1], may be assumed not to be greater than 160 kN, provided that arrangements of cell guides and horizontal transverse cross-ties effectively block the container corners.

Any other arrangement may be accepted, to the Society’s satisfaction.

**Table 14 : Containers - Static, dynamic and wind forces**

	Static force $F_S$ and dynamic and wind force $F_{W,r}$ , in kN, acting on each container stack	Vertical static force $R_S$ and dynamic and wind force $R_{W,r}$ , in kN, transmitted at the corners of each container stack <b>(1)</b>
Static force	$F_S = \sum_{i=1}^{N_C} F_{S,i}$	$R_S = \frac{F_S}{4}$
Dynamic forces	<ul style="list-style-type: none"> <li>• in x direction:  <math>F_{W,X} = \sum_{i=1}^{N_C} (F_{W,X,i} + F_{X,wind,i})</math></li> <li>• in y direction:  <math>F_{W,Y} = \sum_{i=1}^{N_C} (F_{W,Y,i} + F_{Y,wind,i})</math></li> <li>• in z direction:  <math>F_{W,Z} = \sum_{i=1}^{N_C} F_{W,Z,i}</math></li> </ul>	$R_{W,1} = \frac{F_{W,Z}}{4} + R_{W,MY} + R_{W,MX}$ $R_{W,2} = \frac{F_{W,Z}}{4} - R_{W,MY} - R_{W,MX}$ $R_{W,3} = \frac{F_{W,Z}}{4} - R_{W,MY} + R_{W,MX}$ $R_{W,4} = \frac{F_{W,Z}}{4} + R_{W,MY} - R_{W,MX}$ $R_{W,MY} = \frac{N_C h_C F_{W,X}}{4 \ell_C}$ $R_{W,MX} = \frac{N_C h_C F_{W,Y}}{4 b_C}$
<b>(1)</b> Effect of cell guides may be taken into consideration according to [8.2.3].		
<b>Note 1:</b>		
$F_{X,wind,i}$ : Wind force in the longitudinal direction as defined in Ch 5, Sec 5, [8.1]		
$F_{Y,wind,i}$ : Wind force in the transverse direction as defined in Ch 5, Sec 5, [8.1]		
$N_C$ : Number of containers per stack		
$h_C$ : Height, in m, of a container		
$\ell_C, b_C$ : Dimensions, in m, of the container stack in the ship longitudinal and transverse directions, respectively.		

Figure 15 : Stack of containers and forces

## 9 Loads on hatch covers

### 9.1 Application

9.1.1 The loads on hatch covers and coamings are to be applied for strength assessment only.

### 9.2 Cargo loads

#### 9.2.1 Distributed loads

The distributed load on hatch covers  $p_L$ , in  $kN/m^2$ , due to uniform cargo loads and resulting from heave and pitch (i.e. ship in upright condition), is to be determined according to the following formula:

$$p_L = p_C (1 + \alpha_v)$$

where:

$p_C$  : Uniform cargo load, in  $kN/m^2$

$\alpha_v$  : Vertical acceleration addition, taken equal to:  $\alpha_v = m F$

$m$  : Coefficient taken equal to:

- for  $0 \leq x/L \leq 0,2$ :

$$m = m_0 - 5(m_0 - 1) \frac{x}{L}$$

- for  $0,2 < x/L \leq 0,7$ :

$$m = 1$$

- for  $0,7 < x/L \leq 1,0$ :

$$m = 1 + \left( \frac{m_0 + 1}{0,3} \right) \left( \frac{x}{L} - 0,7 \right)$$

$m_0$  : Coefficient taken equal to:  $m_0 = 1,5 + F$

$F$  : Coefficient taken equal to:

$$F = 0,11 \frac{V_0}{\sqrt{L}}$$

$V_0$  : Maximum speed, in knots, at summer load line draught, to be taken not less than  $L^{1/2}$ .

#### 9.2.2 Concentrated loads

The concentrated load  $P$ , in  $kN$ , due to unit cargo (except container) and resulting from heave and pitch (i.e. ship in upright condition), is to be determined as follows:

$$P = -P_s (1 + \alpha_v)$$

where:

$P_s$  : Concentrated force due to unit cargo, in  $kN$

$\alpha_v$  : Vertical acceleration addition, as defined in [9.2.1].

**9.2.3 Container loads in upright condition**

Where containers are stowed on hatch covers, the load  $P$ , in kN, applied at each corner of a container stack and resulting from heave and pitch (i.e. ship in upright condition), is to be determined as follows:

$$P = -9,81 \frac{M}{4} (1 + \alpha_v)$$

where:

- $M$  : Maximum designed mass of the container stack, in t
- $\alpha_v$  : Vertical acceleration addition, as defined in [9.2.1].

**9.2.4 Container loads in heel condition**

Where containers are stowed on hatch covers, the following loads  $A_z$ ,  $B_z$  and  $B_y$ , in kN, applied at each corner of a container stack and resulting from heave, pitch and rolling motion (i.e. ship in heel condition), are to be determined as follows (see Fig 16):

$A_z, B_z$  : Support forces in z-direction at the forward and aft stack corners, taken respectively equal to:

$$A_z = -9,81 \frac{M}{2} (1 + \alpha_v) \left( 0,45 - 0,42 \frac{h_m}{b} \right)$$

$$B_z = -9,81 \frac{M}{2} (1 + \alpha_v) \left( 0,45 + 0,42 \frac{h_m}{b} \right)$$

$B_y$  : Support force in y-direction at the forward and aft stack corners, taken equal to:

$$B_y = -2,4 M$$

where:

$M$  : Maximum designed mass of the container stack, in t, taken as:

$$M = \sum_i W_i$$

$\alpha_v$  : Vertical acceleration addition, as defined in [9.2.1]

$h_m$  : Designed height of the centre of gravity of the stack above hatch cover top, in m, calculated as weighted mean value of the stack, where the centre of gravity of each tier is assumed to be located at the centre of each container:

$$h_m = \sum_i \frac{z_i W_i}{M}$$

$z_i$  : Distance from hatch cover top to the centre of  $i$ th container, in m

$W_i$  : Weight of  $i$ th container, in t

$b$  : Distance between midpoints of foot points, in m.

When strength of the hatch cover structure is assessed by grillage analysis,  $h_m$  and  $z_i$  need to be taken above the hatch cover supports. Forces  $B_y$  does not need to be considered in this case.

Values of  $A_z$  and  $B_z$  applied for the assessment of hatch cover strength are to be shown in the drawings of the hatch covers.

Note 1: It is recommended that container loads as calculated above are considered as limit for foot point loads of container stacks in the calculations of cargo securing (container lashing).

**Figure 16 : Forces due to container loads**

**9.2.5 Load cases with partial loading**

The loads defined in [9.2.1], [9.2.2] and [9.2.4] are also to be considered for partial non homogeneous loading which may occur in practice, e.g. where specified container stack places are empty. For each hatch cover, the heel directions, as shown in Tab 15, are to be considered.

The load case “partial loading of container hatch covers” can be evaluated using a simplified approach, where the hatch cover is loaded without the outermost stacks that are located completely on the hatch cover. If there are additional stacks that are supported partially by the hatch cover and partially by container stanchions then the loads from these stacks are also to be neglected (see Tab 15).

In addition, the case where only the stack places supported partially by the hatch cover and partially by container stanchions are left empty is to be assessed in order to consider the maximum loads in the vertical hatch cover supports.

It may be necessary to also consider partial load cases where more or different container stack places are left empty. The Society may require that additional partial load cases are to be considered.

**9.2.6 Mixed stowage of 20’ and 40’ container on hatch cover**

In the case of mixed stowage (20’ and 40’ container combined stack), the foot point forces at the fore and aft end of the hatch cover are not to be higher than resulting from the design stack weight for 40’ containers, and the foot point forces at the middle of the cover are not to be higher than resulting from the design stack weight for 20’ containers.

**Table 15 : Partial loading of container hatch covers**

Heel direction	< (Heel towards coaming)	> (Heel opposite to coaming)
Hatch covers supported by the longitudinal hatch coaming with all container stacks located completely on the hatch cover		
Hatch covers supported by the longitudinal hatch coaming with the outermost container stacks supported partially by the hatch cover and partially by container stanchions		
Hatch covers not supported by the longitudinal hatch coaming (center hatch covers)		

**10 Design pressure for tank testing**

**10.1 Definition**

**10.1.1** In order to assess the structure, static design pressures,  $P_{ST}$ , in  $kN/m^2$ , are to be considered, as obtained from the formulae in Tab 16.

Table 16 : Tank testing design pressures

Compartment	Still water pressure $P_{ST}$ , in $kN/m^2$
Double bottom tanks Double side tanks	The greater of the following: $P_{ST} = 10 [(z_{top} - z) + h_{air}]$ $P_{ST} = 10 [(z_{top} - z) + 2,4]$ $P_{ST} = 10 (z_{bd} - z)$
Fuel oil tanks	The greater of the following: $P_{ST} = 10 [(z_{top} - z) + h_{air}]$ $P_{ST} = 10 [(z_{top} - z) + 2,4]$ $P_{ST} = 10 [(z_{top} - z) + 0,1 P_{pv}]$ $P_{ST} = 10 (z_{bd} - z)$
Cargo oil tanks	The greater of the following: $P_{ST} = 10 [(z_{top} - z) + h_{air}]$ $P_{ST} = 10 [(z_{top} - z) + 2,4]$ $P_{ST} = 10 [(z_{top} - z) + 0,1 P_{pv}]$
Ballast holds of ships with service notation <b>bulk carrier, bulk carrier ESP, self-unloading bulk carrier ESP, ore carrier ESP or combination carrier ESP</b>	The greater of the following: $P_{ST} = 10 [(z_{top} - z) + h_{air}]$ $P_{ST} = 10 (z_h - z)$
Ballast ducts	The greater of the following: $P_{ST} = 10 [(z_{top} - z) + 0,1 P_{pv}]$ Ballast pump maximum pressure
Deep tanks Peak tanks	The greater of the following: $P_{ST} = 10 [(z_{top} - z) + h_{air}]$ $P_{ST} = 10 [(z_{top} - z) + 2,4]$
Integral or independent cargo tanks of ships with service notation <b>chemical tanker</b>	The greater of the following: $P_{ST} = 10 [(z_{top} - z) + 2,4]$ $P_{ST} = 10 [(z_{top} - z) + 0,1 P_{pv}]$
Chain locker	$P_{ST} = 10 (z_{cp} - z)$
Fuel chemical tanks	The greater of the following: $P_{ST} = 10 [(z_{top} - z) + 2,4]$ $P_{ST} = 10 [(z_{top} - z) + 0,1 P_{pv}]$
<b>Note 1:</b> $z_{bd}$ : Z coordinate, in m, of the bulkhead deck $z_{cp}$ : Z coordinate, in m, of the top of chain pipe. $z_h$ : Z co-ordinate, in m, of the top of hatch coaming	

# Section 7 Design Load Scenarios

## Symbols

For symbols not defined in this Section, refer to Ch 1, Sec 3.

$F_u$	: Design force due to unit cargo, in kN
$F_{W-D}$	: Dynamic wheel force, in kN, as defined in Ch 5, Sec 6, [7.2.3]
$F_{W-S}$	: Static wheel force, in kN, as defined in Ch 5, Sec 6, [7.2.2]
HBM	: Design horizontal bending moment, in kN·m
HSF	: Design horizontal shear force, in kN
$M_{sw}$	: Permissible maximum and minimum vertical still water bending moment in seagoing operation, in kN·m, at the hull transverse section considered, defined in Ch 5, Sec 4, [2.2.1]
$M_{sw-p}$	: Permissible maximum and minimum vertical still water bending moment for harbour/sheltered water operation, in kN·m, as defined in Ch 5, Sec 4, [2.2.2]
$M_{sw-t-LC}$	: Permissible torsional still water moment for seagoing operation, in kN·m, as defined in Pt D, Ch 2, Sec 2
$M_{sw-t-p}$	: Permissible torsional still water moment for harbour/sheltered water operation, in kN·m, as defined in Pt D, Ch 2, Sec 2
$M_{wh-LC}$	: Horizontal wave bending moment for a considered dynamic load case, in kN·m, as defined in Ch 5, Sec 4, [3.6.3]
$M_{wt-LC}$	: Wave torsional moment for a considered dynamic load case, in kN·m, as defined in Ch 5, Sec 4, [3.6.5]
$M_{ww-LC}$	: Vertical wave bending moment for the considered dynamic load case, in kN·m, as defined in Ch 5, Sec 4, [3.6.1]
$P_0$	: Design force due to wheel loads, in kN, as defined in Ch 5, Sec 6, [7.2.1]
$P_{bs}$	: Dry bulk cargo static pressure, in kN/m <sup>2</sup> , as defined in Ch 5, Sec 6, [3.4.2]
$P_{bd}$	: Dry bulk cargo dynamic pressure for the considered dynamic load case, in kN/m <sup>2</sup> , as defined in Ch 5, Sec 6, [3.4.3]
$P_{bf-s}$	: Static pressure in dry cargo holds under flooded conditions, in kN/m <sup>2</sup> , as defined in Ch 5, Sec 6, [4.1.5]
$P_{dk}$	: Design pressure due to uniform cargo, in kN/m <sup>2</sup>
$P_{dl-s}$	: Static pressure on decks and platforms, in kN/m <sup>2</sup> , as defined in Ch 5, Sec 6, [6.1.1]
$P_{dl-d}$	: Dynamic pressure on decks platforms for a considered dynamic load case, in kN/m <sup>2</sup> , as defined in Ch 5, Sec 6, [6.1.1]
$P_{im}$	: Impact pressure due to liquid motion, in kN/m <sup>2</sup> , as defined in Ch 5, Sec 6, [2.2.2].
$P_{sd}$	: Lateral pressure on sides of superstructures or deckhouses not contributing to the longitudinal strength, in kN/m <sup>2</sup> , as defined in Ch 5, Sec 5, [5.4.1]
$Q_{sw}$	: Permissible hull girder maximum and minimum still water shear force limits for seagoing operation, in kN, as defined in Ch 5, Sec 4, [2.3.1]
$Q_{sw-p}$	: Permissible hull girder maximum and minimum still water shear force limits for harbour/sheltered water operation, in kN, as defined in Ch 5, Sec 4, [2.3.2]
$Q_{wh-LC}$	: Horizontal wave shear force for the considered dynamic load case, in kN, as defined in Ch 5, Sec 4, [3.6.4]
$Q_{ww-LC}$	: Vertical wave shear force for a considered dynamic load case, in kN, as defined in Ch 5, Sec 4, [3.6.2]
TM	: Design torsional moment, in kN·m
VBM	: Design vertical bending moment, in kN·m
VSF	: Design vertical shear force, in kN.

## 1 General

### 1.1 Application

**1.1.1** This Section describes the design load scenarios to be used for:

- strength assessment by prescriptive and direct analysis (Finite Element Analysis or beam models), as given in Article [2]
- fatigue assessment by prescriptive and direct analysis (Finite Element Analysis), as given in [3].

**1.1.2** For the strength assessment, the principal design load scenarios are associated either to the qualifier S or S+D.

In addition, specific design load scenarios are to be considered relating to impact loads and sloshing loads in partly filled tanks.

**1.1.3** For fatigue assessment, the design load scenarios are S+D (Static + Dynamic) loads, with the prefix 'F' for Fatigue.

## 2 Design load scenarios for strength assessment

### 2.1 Principal design load scenarios

2.1.1 The principal design load scenarios for strength assessment are given in Tab 1.

### 2.2 Design load scenarios for impact and sloshing

2.2.1 The additional design load scenarios relating to impact loads and sloshing loads to be considered are:

- bottom or stern slamming impact
- bow flare impact
- sloshing loads in partly filled tanks
- impact loads in partly filled tanks.

#### 2.2.2 Design load scenarios for bottom or stern slamming impact

For the design load scenarios for bottom or stern slamming impact, only the pressure  $P_{SLI}$ , as defined in Ch 5, Sec 5, [4.2], is to be applied to the outer shell.

#### 2.2.3 Design load scenario for bow flare impact

For the design load scenario for bow flare impact, only the pressure  $P_{FI}$ , as defined in Ch 5, Sec 5, [4.3], is to be applied to the outer shell.

**Table 1 : Principal design load scenarios for strength assessment**

<p>(1) Applicability and filling levels for each loading condition are defined in Ch 10, Sec 1, [2.1.1]</p> <p>(2) If needed considering the frequency of loading-unloading operations, the Society may require a specific fatigue assessment of structural elements subjected to wheeled loads in harbour conditions.</p> <p>(3) Still water torsional moment <math>M_{sw-t}</math> is only applicable to ships assigned with the service notation <b>container ship</b>.</p>			

# Section 8 Loading Conditions

## 1 Application

### 1.1 Loading conditions for strength assessment

1.1.1 The typical loading conditions to be considered for strength assessment are given in Article [3].

1.1.2 The loading conditions to be considered for the assessment of longitudinal strength and primary supporting members are to envelop the most critical loading combinations the ship can be subject to when operated in accordance with loading manual.

The loading conditions are to be defined with consideration to:

- all intact loading conditions in loading manual
- operational limitations in loading guidance information
- the ship arrangement and possible combination of local loading and global loading.

1.1.3 Loading conditions from the loading manual which are not covered in this Section are to be considered.

### 1.2 Loading conditions for fatigue assessment

1.2.1 The loading conditions to be considered for fatigue assessment are given in Article [4].

### 1.3 Specific loading conditions

1.3.1 Part D and Part E may specify additional loading conditions which are to be considered depending on the ship type.

## 2 General

### 2.1 Definitions

2.1.1 In general, the design cargo and ballast loading conditions to be considered for the longitudinal strength assessment are to be assessed for both departure and arrival conditions.

Where the amount and disposition of consumables at any intermediate stage of the voyage are considered more severe, calculations for such intermediate conditions are to be submitted in addition to those for departure and arrival conditions.

#### 2.1.2 Departure conditions

The departure conditions are to be based on bunker tanks not taken less than 95% full and other consumables (fresh water and stores) taken at 100% capacity.

In case of liquefied gas fuel tank, the filling level is to be based on the definition as per NR529, 6.8.

#### 2.1.3 Arrival conditions

The arrival conditions are to be based on 10% of the maximum capacity of bunker, fresh water and stores.

## 3 Standard loading conditions for strength assessment

### 3.1 Seagoing conditions

3.1.1 For all ships, the following seagoing loading conditions are to be included, as a minimum, in the loading manual:

- Full load/homogeneous cargo loading conditions including a condition at the scantling draught.
- Ballast conditions where the ballast tanks may be full or empty. All cargo holds are to be empty. The propeller is to be fully immersed.

Ballast loading conditions involving partially filled peak and/or other ballast tanks at departure, arrival or during intermediate conditions are not permitted to be used as design conditions unless:

- the allowable stress limits and buckling criteria defined in Ch 6, Sec 1, [3.5] and Ch 6, Sec 1, [3.7] are satisfied for all filling levels between empty and full and
- for ships with the service notation **bulk carrier**, **bulk carrier ESP** or **self-unloading bulk carrier ESP**, the requirements in Pt D, Ch 4, Sec 3, [3.1], as applicable, are complied with all filling levels between empty and full.

To demonstrate compliance with all filling levels between empty and full, it is acceptable if, in each condition at departure, arrival and any intermediate condition required in Ch 5, Sec 4, [2.1.1], the tanks intended to be partially filled are assumed to be:

- empty
- full
- partially filled at intended level.

Where multiple tanks are intended to be partially filled, all combinations of empty, full or partially filled at intended level for those tanks are to be investigated.

However, for conventional ore carriers with large wing water ballast tanks in cargo area, where empty or full ballast water filling levels of one or maximum two pairs of these tanks lead to the ship's trim exceeding one of the following conditions, it is sufficient to demonstrate compliance with maximum, minimum and intended partial filling levels of these one or maximum two pairs of ballast tanks such that the ship's condition does not exceed any of these trim limits. Filling levels of all other wing ballast tanks are to be considered between empty and full. The trim conditions mentioned above are:

- trim by stern of 3,0% of the ship's length, or
- trim by bow of 1,5% of the ship's length, or
- any trim that cannot maintain propeller immersion (l/D) not less than 25%, where:

l : Distance, in m, from propeller centerline to the waterline

D : Propeller diameter, in m.

The maximum and minimum filling levels of the above mentioned pairs of side ballast tanks are to be indicated in the loading manual.

Note 1: Annex 1 of IACS Unified Requirement UR S11, as amended, contains a guidance for partially filled ballast tanks in ballast loading conditions.

c) Non homogeneous cargo loading conditions.

For cargo loading conditions involving partially filled peak and/or other ballast tanks, the requirements specified in item b apply to the peak tanks only.

d) Special loadings (e.g. light load conditions at less than the maximum draught, deck cargo conditions, etc.), where applicable.

e) When relevant, conditions covering ballast water exchange procedures with the calculations of intermediate conditions just before and just after ballasting and/or deballasting any ballast tank.

For ships with the service notation **general cargo ship** completed by the additional service feature **nonhomload**, the loading conditions to be considered are to include the cases where the selected holds are empty at draught T, according to the indications specified in the ship notation.

## 3.2 Harbour and sheltered water conditions

3.2.1 The following harbour and sheltered water conditions are to be included in the loading manual:

- a) Docking condition afloat.
- b) Loading and unloading transitory conditions, where applicable.

For cargo loading conditions involving partially filled peak and/or other ballast tanks, the requirements specified in item b of requirement [3.1.1] apply to the peak tanks only.

c) Short voyage conditions, where applicable.

## 4 Standard loading conditions for fatigue assessment

### 4.1 General

4.1.1 The standard loading conditions to be applied for fatigue assessment are defined in Ch 10, Sec 1, [2].

Appendix 2	Hull Girder Ultimate Bending Capacity

# Section 1 Hull Girder Yield and Buckling Strength

## Symbols

For symbols not defined in this Section, refer to Ch 1, Sec 3.

- $M_{sw}$  : Permissible maximum and minimum vertical still water bending moment in seagoing operation, in kN·m, at the hull transverse section considered, defined in Ch 5, Sec 4, [2.2.1]
- $M_{sw-p}$  : Permissible maximum and minimum vertical still water bending moment for harbour/sheltered water operation, in kN·m, as defined in Ch 5, Sec 4, [2.2.2]
- $M_{ww}$  : Vertical wave bending moment in seagoing operation, in kN·m, at the hull transverse section considered, defined in Ch 5, Sec 4, [3.1.1]
- $M_{ww-LC}$  : Vertical wave bending moment for a considered dynamic load case, in kN·m, as defined in Ch 5, Sec 4, [3.6.1]
- $M_{wh}$  : Horizontal wave bending moment in seagoing operation, in kN·m, at the hull transverse section considered, defined in Ch 5, Sec 4, [3.3.1]
- $M_{wh-LC}$  : Horizontal wave bending moment for a considered dynamic load case, in kN·m, as defined in Ch 5, Sec 4, [3.6.3]
- $M_{wt}$  : Wave torsional moment in seagoing operation, in kN·m, at any longitudinal position defined in Ch 5, Sec 4, [3.5.1]
- $n$  : Navigation coefficient as defined in Ch 5, Sec 3, [1.1.2] for a reference length calculated with the parameters given in Ch 5, Sec 4, [3.1.1]
- $Q_{sw}$  : Permissible maximum or minimum still water shear force for seagoing operation, in kN, at the hull transverse section considered, as defined in Ch 5, Sec 4, [2.3.1]
- $Q_{sw-p}$  : Permissible maximum or minimum still water shear force for harbour/sheltered operation, in kN, at the hull transverse section considered, as defined in Ch 5, Sec 4, [2.3.2]
- $Q_{ww}$  : Vertical wave shear force in seagoing condition, in kN, at the hull transverse section considered, defined in Ch 5, Sec 4, [3.2.1]
- $Q_{ww-LC}$  : Vertical wave shear force for a considered dynamic load case, in kN, as defined in Ch 5, Sec 4, [3.6.2]
- $Q_{wh-LC}$  : Horizontal wave shear force for a considered dynamic load case, in kN, as defined in Ch 5, Sec 4, [3.6.4]
- $z_n$  : Z coordinate, in m, of horizontal neutral axis of the hull transverse section with net scantling defined in [1.2], with respect to the reference coordinate system defined in Ch 1, Sec 3, [2.6]

## 1 Strength characteristics of hull girder transverse sections

### 1.1 General

**1.1.1** This Article specifies the criteria for calculating the hull girder strength characteristics to be used for the hull girder strength assessment in Article [3], in association with the hull girder loads specified in Ch 5, Sec 4.

### 1.2 Hull girder transverse sections

#### 1.2.1 General

Hull girder transverse sections are to be considered as being constituted by all the members contributing to the hull girder longitudinal strength, taking into account the requirements in [1.2.2] to [1.2.13].

#### 1.2.2 Net scantling

The members contributing to the hull girder longitudinal strength are to be considered using net offered scantlings based on gross offered thickness reduced by  $0,5 t_c$ , as defined in Ch 4, Sec 3, when the hull girder strength characteristics are used for the hull girder yielding and buckling check according to Article [3].

#### 1.2.3 Structural members not contributing to hull girder sectional area

The following members are not to be considered in the calculation as they are considered not contributing to the hull girder sectional area:

- superstructures and deckhouses which do not comply with [1.3.2]
- vertically corrugated bulkheads, according to [1.2.7]
- bulwarks and gutter plates
- bilge keels
- sniped or non-continuous longitudinal stiffeners
- non-continuous hatch coamings.

**1.2.4 Continuous trunks and longitudinal continuous hatch coamings**

Continuous trunks and longitudinal continuous hatch coamings may be included in the hull girder transverse sections, provided that they are effectively supported by longitudinal bulkheads or primary supporting members.

**1.2.5 Longitudinal stiffeners or girders welded above the strength deck**

Longitudinal stiffeners or girders welded above the strength deck, including the deck of any trunk fitted as specified in [1.2.4], are to be included in the hull girder transverse sections.

**1.2.6 Longitudinal girders between hatchways**

Where longitudinal girders are fitted between hatchways, the sectional area  $A_{EFF}$  that can be included in the hull girder transverse sections is obtained, in  $m^2$ , from the following formula:

$$A_{EFF} = A_{LG} a$$

where:

$A_{LG}$  : Sectional area, in  $m^2$ , of longitudinal girders

$a$  : Coefficient:

- for longitudinal girders effectively supported by longitudinal bulkheads or primary supporting members:  $a = 1$
- for longitudinal girders not effectively supported by longitudinal bulkheads or primary supporting members and having dimensions and scantlings such that  $\ell_0 / r \leq 60$ :

$$a = 0,6 \left( \frac{s}{b_1} + 0,15 \right)^{0,5}$$

- for longitudinal girders not effectively supported by longitudinal bulkheads or primary supporting members and having dimensions and scantlings such that  $\ell_0 / r > 60$ :

$$a = 0$$

$\ell_0$  : Span, in m, of longitudinal girders, to be taken as shown in Fig 1

$r$  : Minimum radius of gyration, in m, of the longitudinal girder transverse section

$s, b_1$  : Dimensions, in m, defined in Fig 1.

**Figure 1 : Longitudinal girders between hatchways**

**1.2.7 Longitudinal bulkheads with vertical corrugations**

For longitudinal bulkheads with vertical corrugations, the vertical corrugations are not to be included in the hull girder transverse section. Longitudinal bulkheads with vertical corrugations are not effective for hull girder bending, but they are effective for hull girder shear force.

**1.2.8 Members in materials other than steel**

Where a member contributing to the longitudinal strength is made of material other than steel with a Young's modulus  $E$  equal to  $2,06 \cdot 10^5$  N/mm<sup>2</sup>, the steel equivalent net sectional area  $A_{SE-n50}$  that may be included in the hull girder transverse section is obtained, in  $m^2$ , from the following formula:

$$A_{SE-n50} = \frac{E}{2,06 \cdot 10^5} A_{M-n50}$$

where:

$A_{M-n50}$  : Net sectional area, in  $m^2$ , of the member under consideration.

**1.2.9 Definitions of openings**

Openings include:

- a) Large openings, i.e. openings which are:
  - elliptical openings exceeding 2,5 m in length or 1,2 m in breadth
  - circular openings exceeding 0,9 m in diameter.
- b) Small openings (manholes, lightening holes, single scallops in way of seams, etc.), i.e. openings which are not large openings
- c) Isolated openings, i.e. openings spaced not less than 1 m apart in the ship transverse/vertical direction.

**1.2.10 Large openings and nearby small openings**

Large openings are to be deducted from the sectional area used in the hull girder moment of inertia and section modulus. When small openings are spaced less than 1 m apart, in the ship transverse/vertical direction, from large openings, their total breadth is to be deducted from the sectional area.

Additionally, small openings not complying with the arrangement requirements given in Ch 4, Sec 5, [6.3.2] are to be deducted from the sectional areas included in the hull girder transverse sections.

**1.2.11 Isolated small openings**

Isolated small openings in one transverse section in the strength deck or bottom area need not be deducted from the sectional areas included in the hull girder transverse sections, provided that:

$$\Sigma b_s \leq 0,06 (B - \Sigma b)$$

where:

$\Sigma b_s$  : Total breadth of isolated small openings, in m, in the strength deck or bottom area at the transverse section considered, determined as indicated in Fig 2, not deducted from the section area as per [1.2.10]

$\Sigma b$  : Total breadth of large openings, in m, at the transverse section considered, determined as indicated in Fig 2, deducted from the section area as defined in [1.2.10].

Where the total breadth of isolated small openings  $\Sigma b_s$  does not fulfil the above criteria, only the excess of breadth is to be deducted from the sectional areas included in the hull girder transverse sections.

**Figure 2 : Calculation of  $\Sigma b$  and  $\Sigma b_s$**

**1.2.12 Lightening holes, draining holes and single scallops**

Lightening holes, draining holes and single scallops in longitudinals need not be deducted if their height is less than  $0,25 h_w$ , without being greater than 75 mm for single scallops, where  $h_w$  is the web height, in mm, defined in Ch 4, Sec 2.

Otherwise, the excess is to be deducted from the sectional area or compensated.

**1.2.13 Non-continuous decks and longitudinal bulkheads**

When calculating the effective area in way of non-continuous decks and longitudinal bulkheads, the effective area is to be taken as shown in Fig 3. The shadow area, which indicates the non-effective area, is obtained by drawing two tangent lines with an angle of 15 deg to the longitudinal axis of the ship.

**1.3 Structures contributing to the longitudinal strength**

**1.3.1 Strength deck**

The strength deck is, in general, the uppermost continuous deck. In the case of a superstructure or deckhouses contributing to the longitudinal strength, the strength deck is the deck of the superstructure or the deck of the uppermost deckhouse.

Figure 3 : Effective area in way of non-continuous decks and bulkheads

1.3.2 Other structures

A superstructure extending at least 0,15 L within 0,4 L amidships may generally be considered as contributing to the longitudinal strength. For the other superstructures and for deckhouses, their contribution to the longitudinal strength is to be assessed on a case-by-case basis, through a finite element analysis of the whole ship, which takes into account the general arrangement of the longitudinal structural members (side, decks, bulkheads).

The presence of openings in the side shell and longitudinal bulkheads is to be taken into account in the analysis. This may be done in two ways:

- by including these openings in the finite element model
- by assigning to the plate panel, between the side frames beside each opening, an equivalent thickness,  $t_{EQ}$ , in mm, obtained from the following formula:

$$t_{EQ} = 10^3 \left[ l_p \left( \frac{Gh^2}{12EI_j} + \frac{1}{A_j} \right) \right]^{-1}$$

where (see Fig 4):

- $l_p$  : Longitudinal distance, in m, between the frames beside the opening
- $h$  : Height, in m, of the openings
- $I_j$  : Moment of inertia, in  $m^4$ , of the opening jamb about the transverse axis y-y
- $A_j$  : Shear area, in  $m^2$ , of the frame between two openings in the direction of the longitudinal axis x-x
- $G$  : Coulomb's modulus, in  $N/mm^2$ , of the material used for the frame between two openings, to be taken equal to:
  - for steels:  $G = 8,0 \cdot 10^4 \text{ N/mm}^2$
  - for aluminium alloys:  $G = 2,7 \cdot 10^4 \text{ N/mm}^2$

Figure 4 : Side openings

### 1.4 Section modulus

1.4.1 The net section modulus at any point of a hull transverse section is obtained, in  $m^3$ , from the following formula:

$$Z_A = \frac{I_{y-n50}}{|z - z_n|}$$

1.4.2 The net section moduli at bottom and at the equivalent deck line are obtained, in  $m^3$ , from the following formulae:

- at bottom:

$$Z_{AB} = \frac{I_{y-n50}}{z_n}$$

- at the equivalent deck line:

$$Z_{AD} = \frac{I_{y-n50}}{V_D}$$

where:

$V_D$  : Vertical distance to the equivalent deck line, in m:

- when no effective longitudinal members specified in [1.2.4] and [1.2.5] are positioned above a line extending from strength deck at side to a position  $(z_D - z_N)/0,9$  from the neutral axis at the centreline:

$$V_D = z_D - z_n$$

where:

$z_D$  : Z co-ordinate, in m, of strength deck, defined in [1.3], with respect to the reference co-ordinate system defined in Ch 1, Sec 3, [2.6]

- when effective longitudinal members as specified in [1.2.4] and [1.2.5] are positioned above a line extending from strength deck at side to a position  $(z_D - z_N)/0,9$  from the neutral axis at the centreline:

$$V_D = (z_T - z_n) \left( 0,9 + 0,2 \frac{y_T}{B} \right) \geq z_D - z_n$$

where:

$y_T, z_T$  : Y and Z co-ordinates, in m, of the top of continuous trunk or hatch coaming or longitudinal ordinary stiffeners or girders welded above the strength deck, with respect to the reference co-ordinate system defined in Ch 1, Sec 3, [2.6].

$y_T$  and  $z_T$  are to be measured for the point which maximises the value of  $V_D$ .

### 1.5 Moments of inertia

1.5.1 The net moments of inertia  $I_{y-n50}$  and  $I_{z-n50}$ , in  $m^4$ , are those, calculated about the horizontal and vertical neutral axes respectively, of the hull transverse sections defined in [1.2].

### 1.6 Ships having large openings in the strength deck

#### 1.6.1 Definition

Ships having large openings in the strength decks are ships for which at least one of the three following conditions occur:

- $b / B_0 > 0,7$
- $l_A / l_0 > 0,89$
- $b / B_0 > 0,6$  and  $l_A / l_0 > 0,7$

where  $b, B_0, l_A$  and  $l_0$  are the dimensions defined in Fig 5. In the case of two or more openings in the same hull transverse section,  $b$  is to be taken as the sum of the breadth  $b_1$  of each opening.

Figure 5 : Ships with large openings

## 2 Hull girder stresses

### 2.1 Normal stress

#### 2.1.1 Normal stress induced by bending moments

The normal stress  $\sigma_L$  induced, at any point, by bending moments is to be obtained, in N/mm<sup>2</sup>, from the following formulae:

- for seagoing operation:

$$\sigma_L = \left( \frac{M_{sw} + M_{wv-LC}}{I_{y-n50}} (z - z_n) - \frac{M_{wh-LC}}{I_{z-n50}} y \right) 10^{-3}$$

- for harbour/sheltered operation:

$$\sigma_L = \frac{M_{sw-p}}{I_{y-n50}} (z - z_n) 10^{-3}$$

#### 2.1.2 Normal stress induced by torque and bending moments

The normal stresses induced by torque and bending moments are to be considered for ships having large openings in the strength decks, as defined in [1.6.1].

The normal stress  $\sigma_L$  induced, at any point, by torque and bending moments is to be obtained, in N/mm<sup>2</sup>, from the following formulae:

- for seagoing operation:

$$\sigma_L = \left( \frac{M_{sw} + M_{wv-LC}}{I_{y-n50}} (z - z_n) - \frac{M_{wh-LC}}{I_{z-n50}} y \right) 10^{-3} + \sigma_\Omega$$

- for harbour/sheltered operation:

$$\sigma_L = \frac{M_{sw-p}}{I_{y-n50}} (z - z_n) 10^{-3} + \sigma_\Omega$$

where:

$\sigma_\Omega$  : Warping stress, in N/mm<sup>2</sup>, induced by the wave torsional moment  $M_{wt}$  as defined in Ch 5, Sec 4 and obtained through direct calculation analyses based on a structural model in accordance with Article [4].

#### 2.1.3 Material other than steel

In a member made in material other than steel with a Young's modulus  $E$  equal to  $2,06 \cdot 10^5$  N/mm<sup>2</sup> and included in the hull girder transverse sections as specified in [1.2.8], the normal stress  $\sigma_L$ , in N/mm<sup>2</sup>, is to be obtained from the following formula:

$$\sigma_L = \frac{E}{2,06 \cdot 10^5} \sigma_{Ls}$$

where:

$\sigma_{Ls}$  : Normal stress, in N/mm<sup>2</sup>, in the member under consideration, calculated according to [2.1.1] or [2.1.2] considering this member as having the steel equivalent sectional area  $A_{SE-n50}$  defined in [1.2.8].

## 2.2 Shear stress

#### 2.2.1 Shear stress induced by vertical shear forces

The hull girder shear stress  $\tau_L$ , in N/mm<sup>2</sup>, induced by vertical shear forces is to be determined, at the load calculation point under consideration, from the following formulae:

- for seagoing operation:

$$\tau_L = \frac{Q_{sw} + Q_{wv-LC}}{t_{n50} / q_{vi}} 10^3$$

- for harbour/sheltered operation:

$$\tau_L = \frac{Q_{sw-p}}{t_{n50} / q_{vi}} 10^3$$

where:

$q_{vi}$  : Contribution ratio for hull girder shear force per mm, in mm<sup>-1</sup>, for the plate  $i$  based on net scantlings obtained with half the corrosion addition  $t_c$ , which is equal to the unit shear flow per mm, in N/mm, for a unit vertical shear force, from a numerical calculation based on thin-walled beam theory according to Ch 6, App 1.

#### 2.2.2 Shear stress induced by shear forces and torque

For ships having large openings in the strength deck, the hull girder shear stress  $\tau_L$ , in N/mm<sup>2</sup>, induced by shear forces and torque is to be determined, at the load calculation point under consideration, from the following formulae:

- for seagoing operation:

$$\tau_L = \left( \frac{Q_{sw} + Q_{wv-LC}}{t_{n50}/q_{vi}} + \frac{Q_{wh-LC}}{t_{n50}/q_{hi}} \right) 10^3 + \tau_\Omega$$

- for harbour/sheltered operation:

$$\tau_L = \frac{Q_{sw-p}}{t_{n50}/q_{vi}} 10^3 + \tau_\Omega$$

where:

$q_{vi}$  : Ratio as defined in [2.2.1]

$q_{hi}$  : Contribution ratio for hull girder shear force per mm, in  $\text{mm}^{-1}$ , for the plate  $i$  based on net scantlings obtained with half the corrosion addition  $t_c$ , which is equal to the unit shear flow per mm, in  $\text{N/mm}$ , for a unit horizontal shear force, from a numerical calculation based on thin-walled beam theory according to Ch 6, App 1

$\tau_\Omega$  : Shear stress, in  $\text{N/mm}^2$ , induced by the wave torsional moment  $M_{wtr}$  as defined in Ch 5, Sec 4 and obtained through direct calculation analyses based on a structural model in accordance with Article [4].

### 3 Hull girder strength assessment

#### 3.1 General

**3.1.1** The  $k$  material factors are to be defined with respect to the materials used for the bottom and deck members contributing to the longitudinal strength according to [1]. When material factors for higher strength steels are used, the requirements in [3.6] apply.

#### 3.2 Longitudinal extent

**3.2.1** The yield strength and buckling strength assessments are to be carried out in way of 0,2L to 0,75L with due consideration given to locations where there are significant changes in hull cross-section, e.g. changes of framing system and the fore and aft ends of the forward superstructure in case of twin island designs.

**3.2.2** In addition, yield strength and buckling assessments are to be carried out outside this area. As a minimum, these assessments are to be carried out at forward end of the foremost cargo hold, at aft end of the aftermost cargo hold and at forward end of the engine room.

**3.2.3** In addition, for ships with large openings in the strength deck, sections at, or near to, the aft and forward quarter length positions are to be checked. For such ships with cargo holds aft of the superstructure, deckhouse or engine room, strength checks of sections in way of the aft end of the aft-most holds, and the aft end of the deckhouse or engine room are to be performed.

**3.2.4** Scantlings of members contributing to the longitudinal strength (see [1.3]) are to be maintained within 0,4 L amidships.

#### 3.3 Hull girder stiffness

##### 3.3.1 Minimum net moment of inertia

The net moment of inertia  $I_{y-n50}$ , in  $\text{m}^4$ , of the hull transverse section within 0,4L amidships is to be not less than  $I_{y-min}$ , obtained from the following formula:

$$I_{y-min} = 3,0 \cdot \frac{2n}{n+1} Z'_{R,MIN} L \cdot 10^{-2}$$

where  $Z'_{R,MIN}$  is the required net midship section modulus  $Z_{R,MIN}$ , in  $\text{m}^3$ , calculated as specified in [3.4.1], but assuming  $k = 1$ .

#### 3.4 Hull girder minimum section modulus

**3.4.1** The net section moduli, in  $\text{m}^3$ ,  $Z_{AB}$  and  $Z_{AD}$  at the midship section are to be not less than:

$$Z_{R,MIN} = 0,9 \cdot \frac{1+n}{2} \cdot C \cdot L^2 \cdot B \cdot (C_B + 0,7) \cdot k \cdot 10^{-6}$$

where

$C$  : Coefficient defined in Ch 5, Sec 4

**3.4.2** The scantlings of all continuous longitudinal members are to be maintained within 0,4L amidships based on the modulus requirement as specified in [3.4.1].

However, in special cases, based on consideration of type of ship, hull form and loading conditions, the scantlings may be gradually reduced towards the end of the 0,4L part, bearing in mind the desire not to inhibit the vessel's loading flexibility.

### 3.5 Yield strength assessment

#### 3.5.1 General acceptance criteria

It is to be checked that the equivalent Von Mises stress  $\sigma_{eq}$ , in N/mm<sup>2</sup>, calculated with the load combinations given in [3.5.2] and [3.5.3] for seagoing operations in extreme conditions and for harbour operations, is in compliance with the following formula:

$$\sigma_{eq} < \sigma_{perm}$$

where:

$\sigma_{eq}$  : Equivalent Von Mises stress, in N/mm<sup>2</sup>:

$$\sigma_{eq} = \sqrt{\sigma_L^2 + 3\tau_L^2}$$

$\sigma_{perm}$  : Permissible hull girder normal stress, in N/mm<sup>2</sup>:

$$\sigma_{perm} = \frac{R_{eH}}{\gamma_1 \gamma_2}$$

$\sigma_L$  : Normal stress, in N/mm<sup>2</sup>, calculated according to:

- [2.1.1] for head sea design waves
- [2.1.2] for OHS, OHM and OVA design waves, applicable to ships having large strength deck openings

$\tau_L$  : Shear stress, in N/mm<sup>2</sup>, calculated according to:

- [2.2.1] for head sea design waves
- [2.2.2] for OHS, OHM and OVA design waves, applicable to ships having large strength deck openings

$\gamma_1$  : Partial safety factor for material:

$$\gamma_1 = k \frac{R_{eH}}{235}$$

$\gamma_2$  : Partial safety factor for load combinations and permissible stress:

- $\gamma_2 = 1,24$  for bending strength assessment in seagoing operation
- $\gamma_2 = 1,65$  for bending strength assessment in harbour/sheltered operation
- $\gamma_2 = 1,13$  for shear strength assessment in seagoing operation
- $\gamma_2 = 1,29$  for shear strength assessment in harbour/sheltered operation.

#### 3.5.2 Bending strength assessment

The bending strength is to be assessed at the following locations of the cross-section:

- at bottom
- at equivalent deck line
- at any point where there is a change of steel yield strength
- at top of continuous hatch coaming for ships assigned the service notation **container ship**.

The assessment is to be performed according to [3.5.1], considering a shear stress  $\tau_L$  equal to 0.

#### 3.5.3 Shear strength assessment

The shear strength is to be assessed for all structural elements contributing to the hull girder shear strength capability.

The assessment is to be performed according to [3.5.1], considering a normal stress  $\sigma_L$  equal to 0.

### 3.6 Extent of higher strength steel

**3.6.1** When a material factor for higher strength steel is used in calculating the required section modulus at bottom or at the equivalent deck line according to [1.4] and when the distribution of vertical bending stress across the hull girder transverse section can be assumed to be linear, the vertical extent of higher strength steel,  $z_{hts,i}$  used in the deck zone or bottom zone and measured respectively from the equivalent deck line or baseline is not to be taken less the value obtained from the following formula:

$$z_{hts,i} = z_1 \left( 1 - \frac{\sigma_{perm,i}}{\sigma_L} \right)$$

where:

$\sigma_L$  : Normal stress, in N/mm<sup>2</sup>, at the equivalent deck line or at bottom respectively, calculated according to [2.1]

$z_1$  : Distance from horizontal neutral axis to the equivalent deck line, defined in [1.4.2] or to the baseline respectively, in m.

$\sigma_{perm,i}$  : Allowable normal stress defined in [3.5.1], in N/mm<sup>2</sup>, for the adjacent zone of steel having lower strength (see Fig 6)

Figure 6 : Vertical extent of higher strength steel

**3.6.2** The relevant higher strength steel is to be adopted for all members contributing to the longitudinal strength (see [1]) within the extent defined in [3.6.1].

**3.6.3** The higher strength steel is to extend in length at least throughout 0,4 L amidships where it is required for strength purposes according to the provisions of Part B.

**3.6.4** Longitudinal members not contributing to the hull girder longitudinal strength and welded to the strength deck or bottom plating and bilge strake, such as longitudinal hatch coamings, gutter bars, strengthening of deck openings, bilge keel, are to be made of steel with the same specified minimum yield stress as the strength deck or bottom structure steel.

**3.6.5** The requirement in [3.6.4] is also applicable to non-continuous longitudinal stiffeners welded to the web of a primary structural member contributing to the hull girder longitudinal strength such as hatch coamings, stringers and girders or on the inner bottom when the hull girder stress in those members is higher than the permissible stress as defined in [3.5.1] for normal strength steel.

### 3.7 Buckling strength assessment

**3.7.1** Buckling strength of members contributing to the longitudinal strength and subjected to compressive and shear stresses is to be assessed according to Chapter 8.

## 4 Structural models for the calculation of normal warping stress and shear stress

### 4.1 Calculation methods

**4.1.1** The calculation of normal warping stress and shear stress induced by torque may be achieved by means of thin-walled beam models.

**4.1.2** An alternative methodology such as complete ship FE model (see Ch 8, App 3) for evaluation of warping stress and shear stress induced by torque may be applied, subject to the satisfaction of the Society.

# Section 2 Hull Girder Ultimate Strength

## 1 Application

### 1.1 General

1.1.1 The requirements of this Section apply to ships with length L equal to or greater than 150 m.

1.1.2 The hull girder ultimate strength is to be assessed between 0,2L and 0,75L.

1.1.3 The hull girder ultimate bending capacity is to be checked to ensure that it satisfies the checking criteria given in Article [2]. Such criteria are applicable to intact ship structures for both hogging and sagging conditions, in seagoing and harbour/sheltered water conditions.

## 2 Checking criteria

### 2.1 General

2.1.1 The vertical hull girder ultimate bending capacity at any hull transverse section is to comply with the following criteria:

$$M \leq \frac{M_U}{\gamma_M \gamma_{DB}}$$

where:

M : Vertical bending moment, in kN-m, to be obtained as specified in [2.2.1]

M<sub>U</sub> : Hull girder ultimate bending moment capacity, in kN-m, to be obtained as specified in [2.3]

γ<sub>M</sub> : Partial safety factor covering material, geometric and strength prediction uncertainties, to be taken equal to 1,05

γ<sub>DB</sub> : Partial safety factor covering the effect of double bottom bending under lateral loads, to be taken equal to:

- for hogging conditions:
  - 1,25 for empty holds of ships assigned with the service notation:
    - general cargo ship,**
    - bulk carrier,**
    - bulk carrier ESP or**
    - combination carrier/OBO ESP**
 and which may operate in alternate conditions at scantling draught
  - 1,15 otherwise
- for sagging conditions: 1,0.

For hull transverse sections where the breadth of the inner bottom is less than the one amidships, or where the double bottom structure differs from the one amidships (e.g. engine room sections), the factor γ<sub>DB</sub> for hogging condition may be reduced, based upon agreement with the Society.

### 2.2 Hull girder ultimate bending loads

2.2.1 The vertical hull girder bending moment M, in kN-m, in hogging and sagging conditions, to be considered in the ultimate strength check, is to be taken as:

$$M = \gamma_S M_{sw} + \gamma_W M_{ww}$$

where:

M<sub>sw</sub> : Permissible hogging and sagging vertical still water bending moment, in kN-m, at the hull transverse section considered, defined in Ch 5, Sec 4, [2.2.1] and Ch 5, Sec 4, [2.2.2]

M<sub>ww</sub> : Vertical wave bending moment in seagoing operation, in kN-m, at the hull transverse section considered, defined in Ch 5, Sec 4, [3.1.1]

γ<sub>S</sub> : Partial safety factor for the still water bending moment, to be taken equal to 1,0

γ<sub>W</sub> : Partial safety factor for the vertical wave bending moment, to be taken equal to 1,2.

### 2.3 Hull girder ultimate bending moment capacity

#### 2.3.1 General

The hull girder ultimate bending moment capacity  $M_U$  is defined as the maximum bending moment capacity of the hull girder beyond which the hull structure collapses.

#### 2.3.2 Determination of hull girder ultimate bending moment capacity

The ultimate bending moment capacities of a hull girder transverse section, in hogging and sagging conditions, are defined as the maximum values of the curve of bending moment  $M$  versus the curvature  $\chi$  of the transverse section considered ( $M_{UH}$  for hogging condition and  $M_{US}$  for sagging condition, see Fig 1). The curvature  $\chi$  is positive for hogging condition and negative for sagging condition.

The hull girder ultimate bending moment capacity  $M_U$  is to be calculated according to Ch 6, App 2.

**2.3.3** The effective area to be considered for the hull girder ultimate strength capacity assessment is specified in Ch 6, App 2.

**Figure 1 : Bending moment capacity versus curvature  $\chi$**

# Appendix 1 Direct Calculation of Shear Flow

## Symbols

For symbols not defined in this Appendix, refer to Ch 1, Sec 3.

### 1 Calculation formula

#### 1.1 General

**1.1.1** This Appendix describes the procedures for direct calculation of shear flow around a ship cross-section due to hull girder vertical shear force. The shear flow  $q_v$ , at each location in the cross-section, is calculated considering the cross-section subjected to a unit vertical shear force of 1 N.

The unit shear flow per mm  $q_v$ , in N/mm, is to be taken as:  $q_v = q_D + q_I$

where:

$q_D$  : Determinate shear flow, as defined in [1.2]

$q_I$  : Indeterminate shear flow which circulates around the closed cells, as defined in [1.3].

In the calculation of the unit shear flow  $q_v$ , the longitudinal stiffeners are to be taken into account.

#### 1.2 Determinate shear flow $q_D$

**1.2.1** The determinate shear flow  $q_D$ , in N/mm, at each location in the cross-section is to be obtained from the following line integration:

$$q_D(s) = -\frac{1}{10^6 I_{y-n50}} \int_0^s (z - z_n) t_{n50} ds$$

where:

$s$  : Coordinate value of the running coordinate along the cross-section, in m

$I_{y-n50}$  : Net moment of inertia of the cross-section, in  $m^4$

$t_{n50}$  : Net thickness of plating, in mm.

**1.2.2** It is assumed that the cross-section is composed of line segments as shown in Fig 1, where each line segment has a constant plate net thickness. The determinate shear flow is obtained by the following equation:

$$q_{Dk} = -\frac{t_{n50} \cdot \ell}{2 \cdot 10^6 I_{y-n50}} (z_k + z_i - 2z_n) + q_{Di}$$

where:

$q_{Dk}, q_{Di}$  : Determinate shear flow, at node k and node i respectively, in N/mm

$\ell$  : Length of line segments, in m

$z_i, z_k$  : Z coordinates, in m, of the end points i and k of a line segment, as defined in Fig 1.

**1.2.3** Where the cross-section includes closed cells as shown in Fig 2, the closed cells are to be cut with virtual slits, as shown in Fig 3 in order to obtain the determinate shear flow.

These virtual slits are not to be located in walls which form part of another closed cell.

**Figure 1 : Definition of line segment**

Figure 2 : Closed cells and common wall

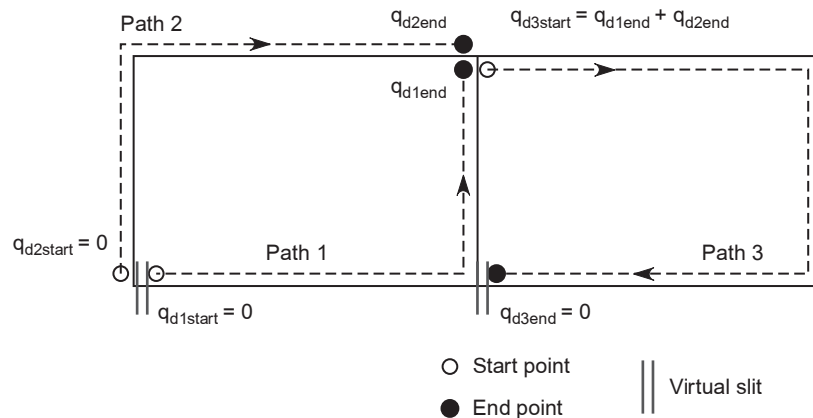

Figure 3 : Placement of virtual slits and calculation of determinate shear flow at bifurcation points

1.2.4 Determinate shear flow at bifurcation points is to be calculated by water flow calculations or similar, as shown in Fig 3.

### 1.3 Indeterminate shear flow $q_i$

1.3.1 The indeterminate shear flow  $q_i$  around the closed cells of a cross-section is considered as a constant value within the same closed cell. The following system of equations for determination of indeterminate shear flows can be developed. In the equations, contour integrations of several parameters around all the closed cells are performed.

$$q_{ic} \oint_c \frac{1}{t_{n50}} ds - \sum_{m=1}^{N_w} \left( q_{im} \oint_{cm} \frac{1}{t_{n50}} ds \right) = - \oint_c \frac{q_D}{t_{n50}} ds$$

where (see Fig 2):

$N_w$  : Number of common walls shared by cell c and all the other cells

$cm$  : Common wall shared by cells c and m

$q_{ic}, q_{im}$  : Indeterminate shear flows around the closed cells c and m respectively, in N/mm.

1.3.2 Under the assumption of the assembly of line segments as shown in Fig 1 and constant plate thickness of each line segment, the equation in [1.3.1] is expressed as follows:

$$q_{ic} \sum_{j=1}^{N_c} \left( \frac{\ell}{t_{n50}} \right)_j - \sum_{m=1}^{N_w} \left\{ q_{im} \left[ \sum_{j=1}^{N_m} \left( \frac{\ell}{t_{n50}} \right)_{j|m} \right] \right\} = - \sum_{j=1}^{N_c} \phi_j$$

$$\phi_j = \left[ - \frac{\ell^2}{6 \cdot 10^3 I_{y-n50}} (z_k + 2z_i - 3z_n) + \frac{\ell}{t_{n50}} q_{Di} \right]_j$$

where (see Fig 2):

$N_c$  : Number of line segments in cell c

$N_m$  : Number of line segments on the common wall shared by cells c and m

$q_{Di}$  : Determinate shear flow, in N/mm, calculated according to [1.2.2].

The difference in the directions of running coordinates specified in [1.2] and the present [1.3] is to be considered.

## 1.4 Computation of sectional properties

**1.4.1** Properties of the cross-section are to be obtained by the following formulae, where the cross-section is assumed to be made of the assembly of line segments:

$$\ell = \sqrt{(y_k - y_i)^2 + (z_k - z_i)^2}$$

$$a_{n50} = 10^{-3} \ell t_{n50}$$

$$A_{n50} = \sum a_{n50}$$

$$s_{y-n50} = \frac{a_{n50}}{2} (z_k + z_i)$$

$$S_{y-n50} = \sum s_{y-n50}$$

$$i_{y0-n50} = \frac{a_{n50}}{3} (z_k^2 + z_k z_i + z_i^2)$$

$$I_{y0-n50} = \sum i_{y0-n50}$$

where:

$y_i, z_i$  : Y and Z coordinates of start point i of a line segment, in m, as defined in Fig 1

$y_k, z_k$  : Y and Z coordinates of end point k of a line segment, in m, as defined in Fig 1

$a_{n50}, A_{n50}$  : Areas of the line segment and the cross-section respectively, in m<sup>2</sup>

$s_{y-n50}, S_{y-n50}$  : First moments of the line segment and the cross-section about the baseline, in m<sup>3</sup>

$i_{y0-n50}, I_{y0-n50}$  : Moments of inertia of the line segment and the cross-section about the baseline, in m<sup>4</sup>.

**1.4.2** The height of the horizontal neutral axis  $z_n$ , in m, is to be obtained as follows:

$$z_n = \frac{S_{y-n50}}{A_{n50}}$$

**1.4.3** The moment of inertia about the horizontal neutral axis, in m<sup>4</sup>, is to be obtained as follows:

$$I_{y-n50} = I_{y0-n50} - z_n^2 A_{n50}$$

# Appendix 2 Hull Girder Ultimate Bending Capacity

## Symbols

For symbols not defined in this Appendix, refer to Ch 1, Sec 3.

$Z_{B-n50}$  : Net section moduli at bottom, in  $m^3$ , to be taken as:

$$Z_{B-n50} = \frac{I_{y-n50}}{Z_n}$$

$Z_{D-n50}$  : Net section moduli at deck, in  $m^3$ , to be taken as:

$$Z_{D-n50} = \frac{I_{y-n50}}{|Z_D - Z_n|}$$

$Z_D$  : Z coordinate, in m, of the strength deck at side, defined in Ch 6, Sec 1, [1.3]

$Z_n$  : Z coordinate, in m, of horizontal neutral axis of the hull transverse section, defined in Ch 6, Sec 1

$R_{eHs}$  : Minimum yield stress, in  $N/mm^2$ , of the material of the considered stiffener

$R_{eHp}$  : Minimum yield stress, in  $N/mm^2$ , of the material of the considered plate

$A_{s-n50}$  : Net sectional area, in  $cm^2$ , of stiffener, without attached plating

$A_{p-n50}$  : Net sectional area, in  $cm^2$ , of attached plating.

## 1 General

### 1.1 Application

**1.1.1** This Appendix provides the criteria to obtain the ultimate longitudinal bending moment capacity  $M_U$  to be used in the hull girder ultimate capacity check according to Ch 6, Sec 2.

**1.1.2**  $M_U$  is defined as the maximum bending moment capacity of the hull girder beyond which the hull structure collapses. Hull girder failure is controlled by buckling, ultimate strength and yielding of longitudinal structural elements.

### 1.2 Methods

#### 1.2.1 Incremental-iterative method

The hull girder ultimate bending moment capacity is to be assessed by the incremental-iterative method defined in Article [2].

#### 1.2.2 Alternative methods

Principles for alternative methods for the calculation of the hull girder ultimate bending moment capacity, e.g. the non-linear finite element analysis, are given in [3].

Application of alternative methods is to be agreed by the Society prior to commencement. Documentation of the analysis methodology and detailed comparison of its results are to be submitted for review and acceptance. The use of such methods may require the partial safety factors to be recalibrated.

### 1.3 General assumptions

**1.3.1** The method for calculating the ultimate hull girder bending capacity is to identify the critical failure modes of all the main longitudinal structural elements.

**1.3.2** Structures compressed beyond their buckling limit have reduced load carrying capacity. All relevant failure modes for individual structural elements, such as plate buckling, torsional stiffener buckling, stiffener web buckling, lateral or global stiffener buckling and their interactions, are to be considered in order to identify the weakest inter-frame failure mode.

**1.3.3** Only vertical bending is considered, except for ships having large openings in the strength decks for which the effects of shear force, torsional loading, horizontal bending moment and lateral pressure are to be considered.

## 2 Incremental-iterative method

### 2.1 Assumptions

**2.1.1** In applying the procedure described in [2.2], the following assumptions are generally to be made:

- the ultimate strength is calculated at hull transverse sections between two adjacent transverse webs
- the hull girder transverse section remains plane during each curvature increment

- the hull material has an elasto-plastic behaviour
- the hull girder transverse section is divided into a set of elements which are considered to act independently.

These elements are:

- transversely framed plating panels and/or stiffeners with attached plating, whose structural behaviour is described in [2.3.1]
- hard corners, constituted by plating crossing, whose structural behaviour is described in [2.3.2].

According to the iterative procedure, the bending moment  $M_i$  acting on the transverse section at each curvature value  $\chi_i$  is obtained by summing the contribution given by the stress  $\sigma$  acting on each element. The stress  $\sigma$  corresponding to the element strain  $\epsilon$  is to be obtained, for each curvature increment, from the non-linear load-end shortening curves  $\sigma$ - $\epsilon$  of the element.

These curves are to be calculated, for the failure mechanisms of the element, from the formulae specified in [2.2]. The stress  $\sigma$  is selected as the lowest value among those obtained from each of the considered load-end shortening curves  $\sigma$ - $\epsilon$ .

The procedure is to be repeated until the value of the imposed curvature reaches the value  $\chi_F$ , in  $m^{-1}$ , in hogging and sagging conditions, obtained from the following formula:

$$\chi_F = \pm 0,003 \frac{M_Y}{E I_{y-n50}}$$

where:

$M_Y$  : The lesser of the following values  $M_{Y1}$  and  $M_{Y2}$ , in  $kN \cdot m$ :

$$M_{Y1} = 10^3 R_{eH} Z_{B-n50}$$

$$M_{Y2} = 10^3 R_{eH} Z_{D-n50}$$

If the value  $\chi_F$  is not sufficient to evaluate the peaks of the curve  $M$ - $\chi$ , the procedure is to be repeated until the value of the imposed curvature permits the calculation of the maximum bending moments of the curve.

## 2.2 Procedure

### 2.2.1 General

The curve  $M$ - $\chi$  is to be obtained by means of an incremental-iterative approach, summarised in the flow chart of Fig 1.

In this procedure, the hull girder ultimate bending moment capacity  $M_U$  is defined as the peak value of the curve with vertical bending moment  $M$  versus the curvature  $\chi$  of the ship cross-section as shown in Fig 1.

Each step of the incremental procedure is represented by the calculation of the bending moment  $M_i$  which acts on the hull transverse section as the effect of an imposed curvature  $\chi_i$ .

For each step, the value  $\chi_i$  is to be obtained by summing an increment of curvature  $\Delta\chi$  to the value relevant to the previous step  $\chi_{i-1}$ . This increment of curvature corresponds to an increment of the rotation angle of the hull girder transverse section around its horizontal neutral axis.

This rotation increment induces axial strains  $\epsilon$  in each hull structural element, whose value depends on the position of the element. In hogging condition, the structural elements above the neutral axis are lengthened, while the elements below the neutral axis are shortened, and vice-versa in sagging condition.

The stress  $\sigma$  induced in each structural element by the strain  $\epsilon$  is to be obtained from the load-end shortening curve  $\sigma$ - $\epsilon$  of the element, which takes into account the behaviour of the element in the non-linear elasto-plastic domain.

The distribution of the stresses induced in all the elements composing the hull transverse section determines, for each step, a variation of the neutral axis position, due to the non-linear  $\sigma$ - $\epsilon$  relationship. The new position of the neutral axis relevant to the step considered is to be obtained by means of an iterative process, imposing the equilibrium among the stresses acting in all the hull elements on the transverse section.

Once the position of the neutral axis is known and the relevant element stress distribution in the section is obtained, the bending moment of the section  $M_i$  around the new position of the neutral axis, which corresponds to the curvature  $\chi_i$  imposed in the step considered, is to be obtained by summing the contribution given by each element stress.

The main steps of the incremental-iterative approach described above are summarised as follows (see also Fig 1):

- Step 1: Divide the transverse section of hull into stiffened plate elements
- Step 2: Define stress-strain relationships for all the elements, as shown in Tab 1
- Step 3: Initialise curvature  $\chi_1$  and neutral axis for the first incremental step with the value of the incremental curvature (i.e. curvature that induces a stress equal to 1% of yield strength in strength deck):

$$\chi_1 = \Delta\chi = 0,01 \frac{R_{eH}}{E} \cdot \frac{1}{z_D - z_n}$$

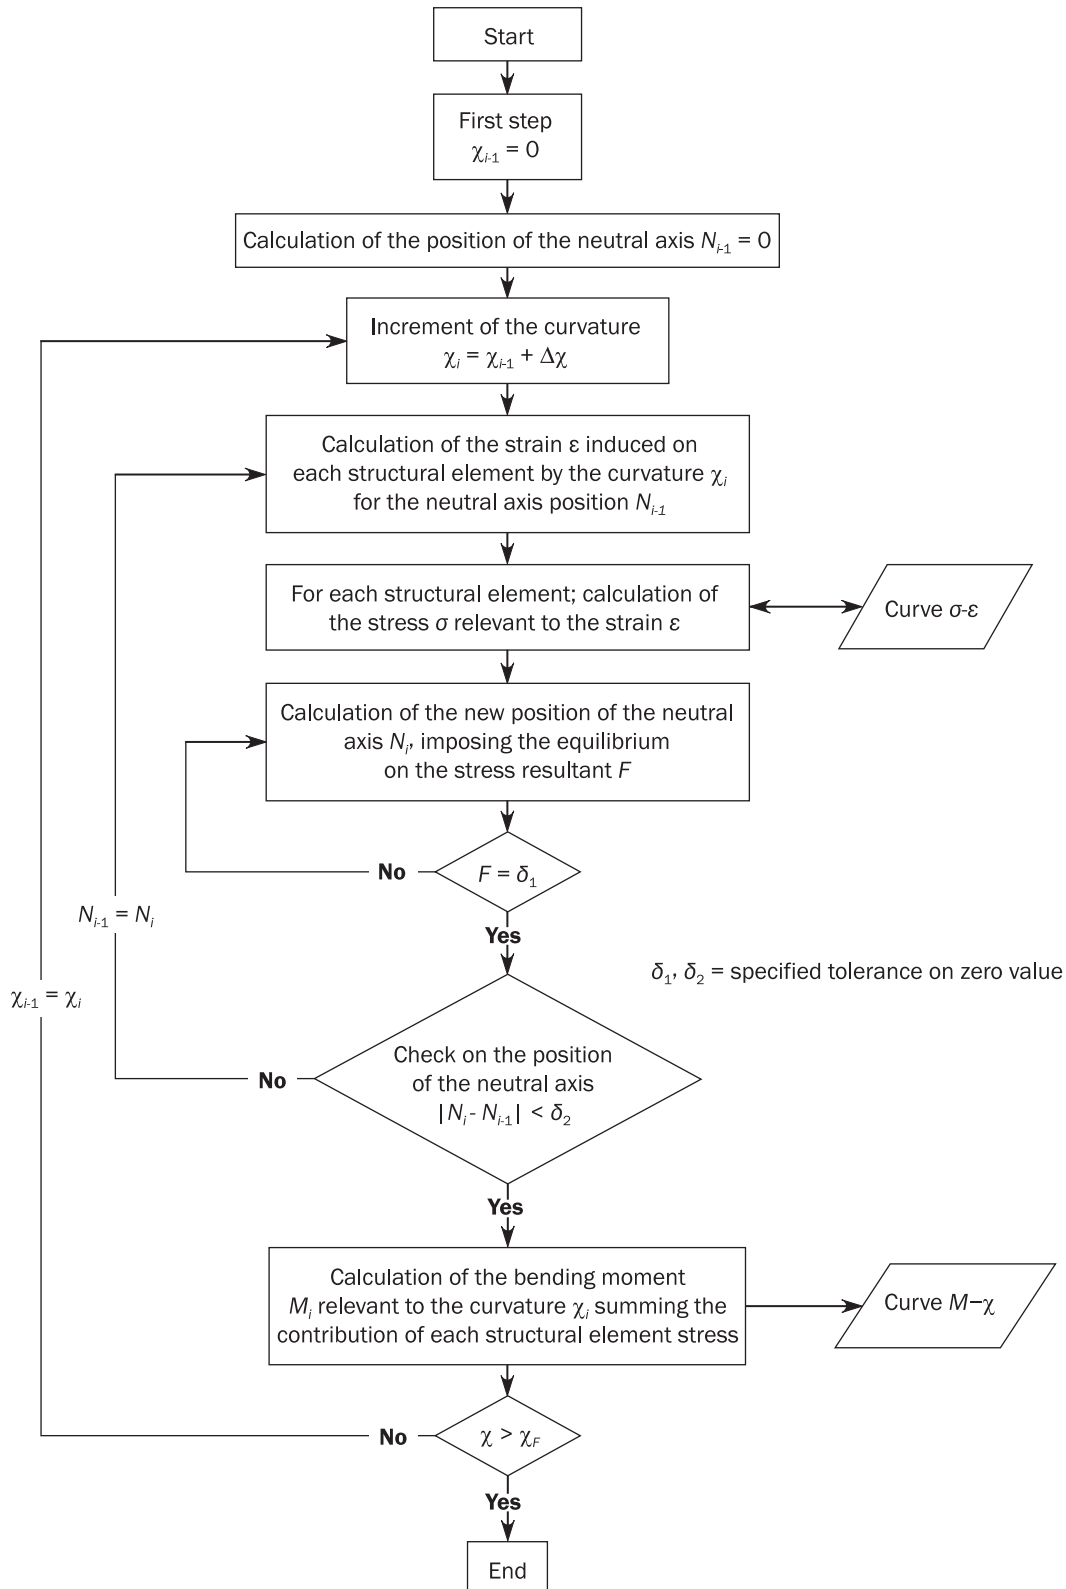

where:

$z_D$  : Z coordinate, in m, of the strength deck at side, with respect to the reference coordinate system defined in Ch 1, Sec 3, [2.6]

$z_n$  : Z coordinate, in m, of the horizontal neutral axis of the hull transverse section, with respect to the reference coordinate system defined in Ch 1, Sec 3, [2.6]

- Step 4: Calculate, for each element, the corresponding strain  $\epsilon_i = \chi (z_i - z_n)$  and the corresponding stress  $\sigma_i$
- Step 5: Determine the neutral axis  $z_{NA\_cur}$  at each incremental step by establishing force equilibrium over the whole transverse section:  
 $\Sigma (A_{i-n50} \sigma_i) = \Sigma (A_{j-n50} \sigma_j)$ ,  
 the i-th element being under compression and the j-th element under tension

**Figure 1 : Flow chart of the procedure for the evaluation of the curve M- $\chi$**

- Step 6: Calculate the corresponding moment by summing the contributions of all the elements:

$$M_U = \sum \sigma_{Ui} A_{i-n50} |z_i - z_{NA,cur}|$$

- Step 7: Compare the moment in the current incremental step with the moment in the previous incremental step. If the slope in  $M-\chi$  relationship is less than a negative fixed value, terminate the process and define the peak value  $M_U$ . Otherwise, increase the curvature by the amount of  $\Delta\chi$  and go to Step 4.

**2.2.2 Modeling of the hull girder cross-section**

Hull girder transverse sections are to be considered as being constituted by the members contributing to the hull girder ultimate strength.

Sniped stiffeners are also to be modeled, taking account of the fact that they do not contribute to the hull girder strength.

The structural members are categorised into a stiffener element, a stiffened plate element or a hard corner element.

The plate panel including web plate of girder or side stringer is idealised into either a stiffened plate element, an attached plate of a stiffener element, or a hard corner element.

The plate panel is categorised into the following two kinds:

- longitudinally stiffened panel, the longer side of which is in the ship longitudinal direction, and
- transversely stiffened panel, the longer side of which is in the direction perpendicular to the ship longitudinal direction.

a) Hard corner element

Hard corner elements are sturdier elements composing the hull girder transverse section, which collapse mainly according to an elasto-plastic mode of failure (material yielding); they are generally constituted by two plates not lying in the same plane.

The extent of a hard corner element from the point of intersection of the plates is taken equal to (see Fig 2):

- $20 t_{n50}$  on a transversely stiffened panel, and
- $0,5 s$  on a longitudinally stiffened panel,

where:

- $t_{n50}$  : Net offered thickness of the plate, in mm
- $s$  : Spacing of the adjacent longitudinal stiffener, in mm.

Sheer strake-deck stringer elements, girder-deck connections and face plate-web connections on large girders are typical hard corners. Enlarged stiffeners, with or without web stiffening, used for Permanent Means of Access (PMA) are not to be considered as a large girder, so the attached plate/web connection is only considered as a hard corner, see Fig 3.

b) Stiffener element

The stiffener constitutes a stiffener element together with the attached plate.

The attached plate width is, in principle, equal to:

- the mean spacing of the stiffener, when the panels on both sides of the stiffener are longitudinally stiffened, or
- the width of the longitudinally stiffened panel, when the panel on one side of the stiffener is longitudinally stiffened and the other panel is transversely stiffened, see Fig 2.

c) Stiffened plate element

The plate between stiffener elements, between a stiffener element and a hard corner element or between hard corner elements is to be treated as a stiffened plate element, see Fig 2.

The typical examples of modeling of hull girder section are illustrated in Fig 3. Notwithstanding the foregoing principle, these figures are to be applied to the modeling in the vicinity of upper deck, sheer strake and hatch coaming.

**Figure 2 : Extension of the breadth of an attached plating and hard corner element**

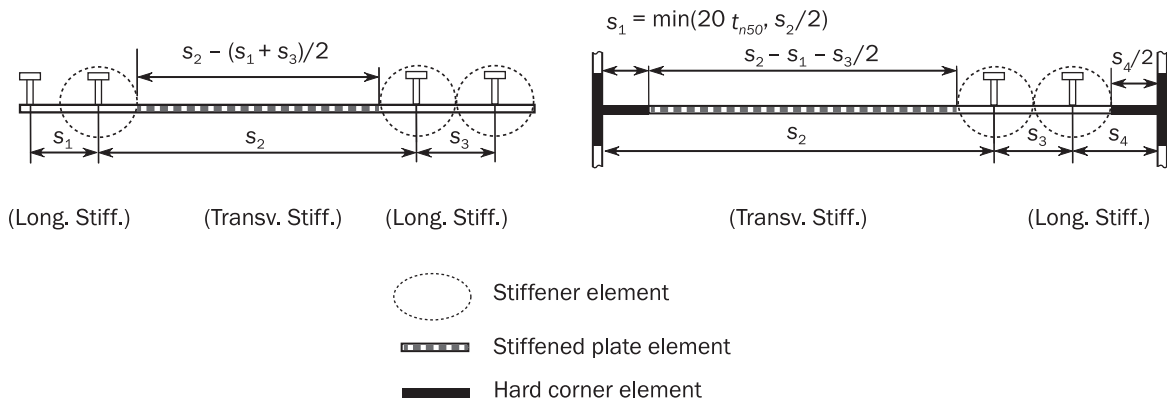

Figure 3 : Examples of the configuration of stiffened plate elements, stiffener elements and hard corner elements on a hull section

- in case of knuckle points as shown in Fig 4, the plating area adjacent to the knuckles in a plating having an angle greater than 30° is defined as a hard corner. The extent, from the knuckle point, of one side of the corner is taken equal to  $20 t_{n50}$  on transversely framed panels and to  $0,5 s$  on longitudinally framed panels
- where plate elements are stiffened by non-continuous longitudinal stiffeners, the non-continuous stiffeners are considered only as dividing a plate into various elementary plate panels
- where openings are provided in stiffened plate elements, the openings are to be considered in accordance with Ch 6, Sec 1, [1.2.9]
- where an attached plating is made of steels having different thicknesses and/or yield stresses, an average thickness and/or average yield stress, obtained from the following formulae, are to be used for the calculation:

$$t_{n50} = \frac{t_{1-n50} S_1 + t_{2-n50} S_2}{s}$$

$$R_{eHp} = \frac{R_{eHp1} t_{1-n50} S_1 + R_{eHp2} t_{2-n50} S_2}{t_{n50} s}$$

where:

$R_{eHp1}$ ,  $R_{eHp2}$ ,  $t_{1-n50}$ ,  $t_{2-n50}$ ,  $S_1$ ,  $S_2$ ,  $s$  : As shown in Fig 5.

Figure 4 : Plating with knuckle point

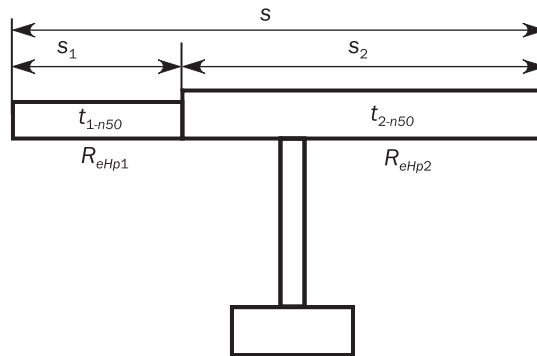

Figure 5 : Element with different thickness and/or different yield strength

### 2.3 Load-end shortening curves

#### 2.3.1 Stiffened plate element and stiffener element

Stiffened plate element and stiffener element composing the hull girder transverse sections may collapse, following one of the modes of failure specified in Tab 1.

- where the plate elements are stiffened by non-continuous longitudinal stiffeners, the stress of the element is to be obtained in accordance with [2.3.3] to [2.3.8], taking account of the non-continuous longitudinal stiffener. In the calculation of the total forces for checking the hull girder ultimate strength, the area of the non-continuous longitudinal stiffener is to be assumed as zero.
- where an opening is provided in the stiffened plate element, the considered area of the stiffened plate element is to be obtained by deducting the opening area from the plating in the calculation of the total forces for checking the hull girder ultimate strength. The consideration of the opening is in accordance with the requirement in Ch 6, Sec 1, [1.2.9] to Ch 6, Sec 1, [1.2.13].
- for the stiffened plate element, the effective width of plate for the load shortening portion of the stress-strain curve is to be taken as the full plate width, i.e. to the intersection of the other plate or longitudinal stiffener – neither from the end of the hard corner element nor from the attached plating of the stiffener element, if any. In the calculation of the total forces for checking the hull girder ultimate strength, the area of the stiffened plate element is to be taken between the hard corner element and the stiffener element or between the hard corner elements, as applicable.

Table 1 : Modes of failure of stiffened plate elements and stiffener elements

Elements	Mode of failure	Curve $\sigma$ - $\epsilon$ defined in
Lengthened stiffened plate elements or lengthened stiffener elements	Elasto-plastic collapse	[2.3.3]
Shortened stiffener elements	Beam column buckling	[2.3.4]
	Torsional buckling	[2.3.5]
	Web local buckling of flanged profiles	[2.3.6]
	Web local buckling of flat bars	[2.3.7]
Shortened stiffened plate elements	Plate buckling	[2.3.8]

**2.3.2 Hard corner element**

The relevant load-end shortening curve  $\sigma$ - $\varepsilon$  is to be obtained for lengthened and shortened hard corners according to [2.3.3].

**2.3.3 Elasto-plastic collapse of structural elements (hard corner element)**

The load-end shortening curve  $\sigma$ - $\varepsilon$  for the elasto-plastic collapse of structural elements composing the hull girder transverse section is to be obtained from the following formula, valid for both positive (shortening) and negative (lengthening) strains (see Fig 6):

$$\sigma = \Phi R_{eHA}$$

where:

$R_{eHA}$  : Equivalent minimum yield stress, in N/mm<sup>2</sup>, of the considered element, obtained by the following formula:

$$R_{eHA} = \frac{R_{eHp} A_{p-50} + R_{eHs} A_{s-50}}{A_{p-50} + A_{s-50}}$$

$\Phi$  : Edge function, equal to:

$$\Phi = -1 \quad \text{for } \varepsilon < -1$$

$$\Phi = \varepsilon \quad \text{for } -1 \leq \varepsilon \leq 1$$

$$\Phi = 1 \quad \text{for } \varepsilon > 1$$

$\varepsilon$  : Relative strain, equal to:

$$\varepsilon = \frac{\varepsilon_E}{\varepsilon_Y}$$

$\varepsilon_E$  : Element strain

$\varepsilon_Y$  : Strain at yield stress in the element, equal to:

$$\varepsilon_Y = \frac{R_{eHA}}{E}$$

**Figure 6 : Load-end curve  $\sigma$ - $\varepsilon$  for elasto-plastic collapse**

**2.3.4 Beam column buckling**

The load-end shortening curve  $\sigma_{CR1}$ - $\varepsilon$  for the beam column buckling of stiffeners composing the hull girder transverse section is to be obtained from the following formula:

$$\sigma_{CR1} = \Phi \sigma_{C1} \frac{A_{s-n50} + A_{pE-n50}}{A_{s-n50} + A_{p-n50}}$$

where:

$\Phi$  : Edge function, as defined in [2.3.3]

$\sigma_{C1}$  : Critical stress, in N/mm<sup>2</sup>, equal to:

- for  $\sigma_{E1} \leq \frac{R_{eHB}}{2} \varepsilon$ :

$$\sigma_{C1} = \frac{\sigma_{E1}}{\varepsilon}$$

- for  $\sigma_{E1} > \frac{R_{eHB}}{2} \varepsilon$ :

$$\sigma_{C1} = R_{eHB} \left( 1 - \frac{R_{eHB} \varepsilon}{4 \sigma_{E1}} \right)$$

$R_{eHB}$  : Equivalent minimum yield stress, in N/mm<sup>2</sup>, of the considered element, obtained by the following formula:

$$R_{eHB} = \frac{R_{eHp} A_{pEI-n50} \ell_{pE} + R_{eHs} A_{s-n50} \ell_{sE}}{A_{pEI-n50} \ell_{pE} + A_{s-n50} \ell_{sE}}$$

$A_{pEI-n50}$  : Effective area, in cm<sup>2</sup>, equal to:  $A_{pEI-n50} = 10 b_{E1} t_{n50}$

$\ell_{pE}$  : Distance, in mm, measured from the neutral axis of the stiffener with attached plate of width  $b_{E1}$  to the bottom of the attached plate

$\ell_{sE}$  : Distance, in mm, measured from the neutral axis of the stiffener with attached plating of width  $b_{E1}$  to the top of the stiffener

$\varepsilon$  : Relative strain, as defined in [2.3.3]

$\sigma_{E1}$  : Euler column buckling stress, in N/mm<sup>2</sup>, equal to:

$$\sigma_{E1} = \pi^2 E \frac{I_{E-n50}}{A_{E-n50} \ell^2} 10^{-4}$$

$I_{E-n50}$  : Net moment of inertia of stiffeners, in cm<sup>4</sup>, with attached plating of width  $b_{E1}$

$A_{E-n50}$  : Net area, in cm<sup>2</sup>, of stiffeners with attached plating of width  $b_E$

$b_{E1}$  : Effective width corrected for relative strain, in m, of the attached plating, equal to:

- for  $\beta_E > 1,0$ :

$$b_{E1} = \frac{s}{\beta_E} 10^{-3}$$

- for  $\beta_E \leq 1,0$ :

$$b_{E1} = 10^{-3} s$$

$$\beta_E = \frac{s}{t_{n50}} \sqrt{\frac{\varepsilon R_{eHp}}{E}}$$

$A_{pE-n50}$  : Net sectional area, in cm<sup>2</sup>, of attached plating of width  $b_E$ , equal to:  $A_{pE-n50} = 10 b_E t_{n50}$

$b_E$  : Effective width, in m, of the attached plating, equal to:

- for  $\beta_E > 1,25$ :

$$b_E = 10^{-3} \left( \frac{2,25}{\beta_E} - \frac{1,25}{\beta_E^2} \right) s$$

- for  $\beta_E \leq 1,25$ :

$$b_E = 10^{-3} s$$

### 2.3.5 Torsional buckling

The load-end shortening curve  $\sigma_{CR2}-\varepsilon$  for the flexural-torsional buckling of stiffeners composing the hull girder transverse section is to be obtained according to the following formula:

$$\sigma_{CR2} = \Phi \frac{A_{s-n50} \sigma_{C2} + A_{p-n50} \sigma_{CP}}{A_{s-n50} + A_{p-n50}}$$

where:

$\Phi$  : Edge function, as defined in [2.3.3]

$\sigma_{C2}$  : Critical stress, in N/mm<sup>2</sup>, equal to:

- for  $\sigma_{E2} \leq \frac{R_{eHs}}{2} \varepsilon$ :

$$\sigma_{C2} = \frac{\sigma_{E2}}{\varepsilon}$$

- for  $\sigma_{E2} > \frac{R_{eHs}}{2} \varepsilon$ :

$$\sigma_{C2} = R_{eHs} \left( 1 - \frac{R_{eHs} \varepsilon}{4 \sigma_{E2}} \right)$$

$\sigma_{E2}$  : Euler column buckling stress, in N/mm<sup>2</sup>, taken equal to  $\sigma_{ET}$ , as defined in Ch 9, Sec 1.

$\varepsilon$  : Relative strain, as defined in [2.3.3]

$\sigma_{CP}$  : Buckling stress of the attached plating, in N/mm<sup>2</sup>, equal to:

- for  $\beta_E > 1,25$ :

$$\sigma_{CP} = \left( \frac{2,25}{\beta_E} - \frac{1,25}{\beta_E^2} \right) R_{eHp}$$

- for  $\beta_E \leq 1,25$ :  $\sigma_{CP} = R_{eHp}$

$\beta_E$  : Coefficient, as defined in [2.3.4].

**2.3.6 Web local buckling of stiffeners made of flanged profiles**

The load-end shortening curve  $\sigma_{CR3-\varepsilon}$  for the web local buckling of flanged stiffeners composing the hull girder transverse section is to be obtained from the following formula:

$$\sigma_{CR3} = \Phi \frac{10^3 b_E t_{n50} R_{eHP} + (h_{we} t_{w-n50} + b_f t_{f-n50}) R_{eHS}}{s t_{n50} + h_w t_{w-n50} + b_f t_{f-n50}}$$

where:

- $\Phi$  : Edge function, as defined in [2.3.3]
- $b_E$  : Effective width, in m, of the attached shell plating, as defined in [2.3.4]
- $h_{we}$  : Effective height of the web, in mm, equal to:

- for  $\beta_w > 1,25$ :

$$h_{we} = \left( \frac{2,25}{\beta_w} - \frac{1,25}{\beta_w^2} \right) h_w$$

- for  $\beta_w \leq 1,25$ :

$$h_{we} = h_w$$

$$\beta_w = \frac{h_w}{t_{w-n50}} \sqrt{\frac{\varepsilon R_{eHS}}{E}}$$

- $\varepsilon$  : Relative strain, as defined in [2.3.3].

**2.3.7 Web local buckling of stiffeners made of flat bars**

The load-end shortening curve  $\sigma_{CR4-\varepsilon}$  for the web local buckling of flat bar stiffeners composing the hull girder transverse section is to be obtained from the following formula:

$$\sigma_{CR4} = \Phi \frac{A_{p-n50} \sigma_{CP} + A_{s-n50} \sigma_{C4}}{A_{p-n50} + A_{s-n50}}$$

where:

- $\Phi$  : Edge function, as defined in [2.3.3]
- $\sigma_{CP}$  : Buckling stress of the attached plating, in N/mm<sup>2</sup>, as defined in [2.3.5]
- $\sigma_{C4}$  : Critical stress, in N/mm<sup>2</sup>, equal to:

- for  $\sigma_{E4} \leq \frac{R_{eHS}}{2} \varepsilon$ :

$$\sigma_{C4} = \frac{\sigma_{E4}}{\varepsilon}$$

- for  $\sigma_{E4} > \frac{R_{eHS}}{2} \varepsilon$ :

$$\sigma_{C4} = R_{eHS} \left( 1 - \frac{R_{eHS} \varepsilon}{4 \sigma_{E4}} \right)$$

- $\sigma_{E4}$  : Local Euler buckling stress, in N/mm<sup>2</sup>, equal to:

$$\sigma_{E4} = 160000 \left( \frac{t_{w-n50}}{h_w} \right)^2$$

- $\varepsilon$  : Relative strain, as defined in [2.3.3].

**2.3.8 Plate buckling**

The load-end shortening curve  $\sigma_{CR5-\varepsilon}$  for the buckling of transversely stiffened panels composing the hull girder transverse section is to be obtained from the following formula:

$$\sigma_{CR5} = \Phi R_{eHP} \left[ \frac{s}{\ell} \left( \frac{2,25}{\beta_E} - \frac{1,25}{\beta_E^2} \right) 10^{-3} + 0,1 \left( 1 - \frac{s}{\ell} 10^{-3} \right) \left( 1 + \frac{1}{\beta_E^2} \right)^2 \right]$$

without being taken greater than  $\Phi R_{eHP}$ ,

where:

- $\Phi$  : Edge function, as defined in [2.3.3]
- $\beta_E$  : Coefficient, as defined in [2.3.4].
- $s$  : Plate breadth, in mm, taken as the spacing between the stiffeners
- $\ell$  : Longer side of the plate, in m.

### 3 Alternative methods

#### 3.1 General

**3.1.1** The bending moment-curvature relationship  $M-\chi$  may be established by alternative methods. Such models are to consider all the relevant effects important to the non-linear response, with due consideration to:

- a) non-linear geometrical behaviour
- b) inelastic material behaviour
- c) geometrical imperfections and residual stresses (geometrical out-of-flatness of plate and stiffeners)
- d) simultaneously acting loads:
  - bi-axial compression
  - bi-axial tension
  - shear and lateral pressure
- e) boundary conditions
- f) interactions between buckling modes
- g) interactions between structural elements such as plates, stiffeners, girders, etc
- h) post-buckling capacity
- i) overstressed elements on the compression side of hull girder cross-section possibly leading to local permanent sets/buckle damages in plating, stiffeners etc (double bottom effects or similar).

#### 3.2 Non-linear finite element analysis

**3.2.1** Advanced non-linear finite element analysis models may be used for the assessment of the hull girder ultimate capacity. Such models are to consider the relevant effects important to the non-linear responses, with due consideration to the items listed in [3.1.1].

**3.2.2** Particular attention is to be given to modeling the shape and size of geometrical imperfections. It is to be ensured that the shape and size of geometrical imperfections trigger the most critical failure modes.

## Hull and Stability

---

### CHAPTER 7

## HULL SCANTLINGS

---

Section 1	General
Section 2	Load Application
Section 3	Minimum Thickness
Section 4	Plating
Section 5	Stiffeners
Section 6	Primary Supporting Members and Pillars
Appendix 1	Analyses of Primary Supporting Members Subject to Wheeled Loads

# Section 1                      General

## 1 Application

### 1.1 Application

**1.1.1** This Chapter applies to hull structure over the full length of the ship including fore end, cargo hold region, machinery space, aft end, side shell, engine casing, exposed and internal decks.

**1.1.2** This Chapter provides requirements for evaluation of plating, stiffeners and primary supporting members (PSM) subject to lateral pressure, local loads and hull girder loads, as applicable. Requirements are specified in:

- Ch 7, Sec 2 for load application
- Ch 7, Sec 3 for minimum thickness of plates, stiffeners and PSM
- Ch 7, Sec 4 for plating
- Ch 7, Sec 5 for stiffeners
- Ch 7, Sec 6 for PSM and pillars.

#### 1.1.3 Required scantlings

The offered net scantling is to be greater than, or equal to, the required scantlings based on requirements provided in this Chapter.

#### 1.1.4 Additional local strength requirements

Additional local strength requirements are provided as listed below:

- fore part, bow flare impact and bottom forward slamming: Ch 11, Sec 1
- machinery space: Ch 11, Sec 2
- aft part and stern impact: Ch 11, Sec 3
- sloshing: Ch 11, Sec 4.
- superstructures, deckhouses and companionways: Ch 11, Sec 5

### 1.2 Acceptance criteria

**1.2.1** Acceptance criteria sets are to be selected as defined in Ch 7, Sec 2, Tab 1 to Ch 7, Sec 2, Tab 4.

# Section 2 Load Application

## Symbols

For symbols not defined in this Section, refer to Ch 1, Sec 3.

$P_{ex}$	: Design external pressure, in $\text{kN/m}^2$ , defined in Ch 5, Sec 5
$P_{in}$	: Design internal pressure, in $\text{kN/m}^2$ , defined in Ch 5, Sec 6
$P_d$	: Green sea pressure for a considered dynamic load case, in $\text{kN/m}^2$ , as defined in Ch 5, Sec 5
$P_{dl}$	: Design pressure due to uniform cargo, in $\text{kN/m}^2$ , defined in Ch 5, Sec 6
$P_{sc}$	: Overpressure due to the inlet grating cleaning system, in $\text{kN/m}^2$ , defined in Ch 5, Sec 5
$F_{sc}$	: Load due to steel coil cargoes, in $\text{kN}$ , taken equal to $F_{sc-ib-s}$ , $F_{sc-ib}$ , $F_{sc-hs-s}$ or $F_{sc-hs}$ , as defined in Ch 5, Sec 6
$F_u$	: Design force due to unit cargo, in $\text{kN}$ , taken equal to $F_{u-s}$ or $F_{u-d}$ , as defined in Ch 5, Sec 6
$R$	: Vertical force at the corners of container stacks, in $\text{kN}$ , taken equal to $R_s$ , $R_w$ , as defined in Ch 5, Sec 6.

## 1 Load combination

### 1.1 Hull girder

#### 1.1.1 Normal stress

The hull girder normal stress  $\sigma_L$ , in  $\text{N/mm}^2$ , is to be calculated according to Ch 6, Sec 1, [2.1] at the considered position for each design load set defined in [2].

### 1.2 Pressure combination

#### 1.2.1 Elements of the outer shell

The static and dynamic lateral pressures to be considered are the differences between the internal pressures and the external sea pressures at the corresponding loading condition. At least the two following cases are to be considered:

- combination of the maximum external pressure with the minimum internal pressure (generally full load with empty ballast)
- combination of the minimum external pressure with the maximum internal pressure (generally ballast loading condition).

If the compartment adjacent to the outer shell is not intended to carry liquids, the internal pressures and external sea pressures are to be considered independently.

#### 1.2.2 Elements other than those of the outer shell

The static and dynamic lateral pressures on an element separating two adjacent compartments are those obtained considering the two compartments individually loaded.

## 2 Design load sets

### 2.1 Application of load components

#### 2.1.1 Application

These requirements apply to:

- plating and stiffeners along the full length of the ship
- the primary supporting members assessed by means of prescriptive analysis or beam model according to Pt B, Ch 7, Sec 6 (see Ch 7, Sec 6, Tab 1).

#### 2.1.2 Load components

The static and dynamic load components are to be determined in accordance with Ch 5, Sec 7, Tab 1.

Radius of gyration  $k_r$  and metacentric height  $GM$  are to be in accordance with Ch 5, Sec 3, Tab 4 for the considered loading conditions specified in the design load sets given in Tab 1.

#### 2.1.3 Design load sets

Design load sets are defined in Tab 1 for:

- plating and stiffeners along the full length of the ship
- primary supporting members located outside the cargo hold region
- primary supporting members along the full length of non-cargo ships.

For primary supporting members located within the cargo hold region of ships carrying containers, dry bulk or liquid cargo, design load sets are defined respectively in Tab 2, Tab 3 and Tab 4.

Only the design load sets corresponding to the loading conditions defined in Ch 5, Sec 8 for the considered ship type are to be applied.

**Table 1 : Design load sets**

Item	Design load set	Load component	Draught	Acceptance criteria (7)	Design load scenario / Loading condition
Outer shell, superstructure walls and exposed deck	SEA-1	$P_{ex}, P_d$	$T_{SC}$	AC-2	Sea-going / Full load condition
	SEA-2 (1)	$P_{ex}$	$T_{SC}$	AC-1	Harbour condition
Water ballast tank	WB-1	$P_{in} - P_{ex}$ (2)	$T_{BAL}$	AC-2	Sea-going / Normal ballast condition
	WB-2	$P_{in} - P_{ex}$ (2)	$T_{BAL}$	AC-2	Water ballast exchange / Normal ballast condition
	WB-3	$P_{in} - P_{ex}$ (2)	$0,25 T_{SC}$ (10)	AC-1	Harbour condition
	WB-4	$P_{in} - P_{ex}$ (2)	$0,25 T_{SC}$ (10)	AC-3	Tank testing condition
Water ballast tank and bulk cargo hold assigned as ballast hold	WB-5	$P_{in} - P_{ex}$ (2)	$T_{BAL-H}$ (6)	AC-2	Sea-going / Heavy ballast condition
	WB-6 (8)	$P_{in} - P_{ex}$ (2) (11)	$T_{BAL-H}$ (6)	AC-2	Water ballast exchange / Heavy ballast condition
	WB-7 (9)	$P_{in}$	–	AC-1	Harbour condition
Liquid cargo hold	WB-8 (9)	$P_{in}$	–	AC-3	Tank testing condition
	LC-1	$P_{in}$	$T_{SC}$	AC-2	Sea-going / Full load condition
	LC-2	$P_{in}$	$0,6 T_{SC}$	AC-2	Sea-going / Partial load condition
	LC-3	$P_{in}$	–	AC-1	Harbour condition
Dry bulk cargo hold	LC-4	$P_{in}$	–	AC-3	Tank testing condition
	FBC-0	$P_{in}$ (12)	–	AC-3 (13)	Flooded / flooded and opposite holds empty
	BC-1	$P_{in}$	$T_{SC}$	AC-2	Sea-going / Homogeneous loading, fully filled
	FBC-1	$P_{in}$ (12)	–	AC-3 (13)	Flooded / Homogeneous, flooded and opposite holds fully filled
	BC-2	$P_{in}$	–	AC-1	Harbour / Homogeneous loading, fully filled
	BC-3	$P_{in}$	$T_{SC}$	AC-2	Sea-going / Homogeneous heavy cargo, partially filled
	FBC-3 (14)	$P_{in}$ (12)	–	AC-3 (13)	Flooded / Homogeneous heavy cargo, flooded and opposite holds partially filled
	BC-4	$P_{in}$	–	AC-1	Harbour / Homogeneous heavy cargo, partially filled
	BC-5	$P_{in}$	$T_{SC}$	AC-2	Sea-going / Alternate light cargo, fully filled
	FBC-5 (15)	$P_{in}$ (12)	–	AC-3 (13)	Flooded / Alternate light, flooded hold fully filled, opposite hold empty
	BC-6	$P_{in}$	–	AC-1	Harbour / Alternate light cargo, fully filled
	BC-7	$P_{in}$	$T_{SC}$	AC-2	Sea-going / Alternate heavy cargo, partially filled
	FBC-7 (15)	$P_{in}$ (12)	–	AC-3 (13)	Flooded / Alternate heavy, flooded hold partially filled, opposite hold empty
	BC-8	$P_{in}$	–	AC-1	Harbour / Alternate heavy cargo, partially filled
BC-9	$F_{sc-ib}$ or $F_{sc-hs}$	$T_{SC}$	AC-2	Sea-going / Steel Coils condition	
BC-10	$F_{sc-ib-s}$ or $F_{sc-hs-s}$	$T_{SC}$	AC-1	Harbour / Steel Coils condition	

Item	Design load set	Load component	Draught	Acceptance criteria (7)	Design load scenario / Loading condition
Other tanks (fuel oil tank, fresh water tank, bilge tank, drain storage tank)	TK-1	$P_{in} - P_{ex}$ (2)	$T_{BAL}$	AC-2	Sea-going / Normal ballast condition
	TK-2	$P_{in} - P_{ex}$ (2)	$0,25 T_{SC}$ (10)	AC-1	Harbour condition
	TK-3 (5)	$P_{in} - P_{ex}$ (2) (11)	$0,25 T_{SC}$ (10)	AC-3	Tank testing condition
Sea chest	SC-1	$P_{sc}$	–	AC-1	Harbour / Inlet grating cleaning overpressure
Structural watertight boundaries intended to stop vertical and horizontal flooding	FD-1 (4)	$P_{in}$	$T_{SC}$	AC-3	Flooded condition
Exposed deck, internal decks or platforms	DL-1 (3)	$P_{dl}, F_U$	$T_{SC}$	AC-2	Sea-going / Full load condition
	DL-2 (3)	$P_{dl}, F_U$	–	AC-1	Harbour condition
<p>(1) For outer shell only                      (2) <math>P_{ex}</math> is to be considered for external shell only                      (3) Distributed or concentrated loads only. Need not be combined with simultaneously occurring green sea pressure                      (4) Not applicable to external shell and to vertically corrugated transverse bulkheads separating dry bulk cargo holds                      (5) Not applicable to gas fuel tanks                      (6) Minimum draught among heavy ballast conditions is to be used                      (7) See acceptance criteria definition in Ch 1, Sec 2, [3.4]                      (8) Not to be applied to bulk cargo hold assigned as ballast hold                      (9) Dry bulk cargo hold only                      (10) <math>0,7 T_{SC}</math> is to be used for ships assigned with service notations <b>ro-ro cargo ship, PCTC, PCC, ro-ro passenger ship or passenger ship</b>                      (11) <math>P_{ex}</math> is not to be considered for tanks tested in dry dock conditions                      (12) Loads for the flooded hold and opposite hold are defined in Ch 5, Sec 6, [4.1.7]                      (13) Applicable only to plane bulkheads. For vertically corrugated bulkheads, specific criteria are given in Ch 7, Sec 4, [2]                      (14) Applicable only to homogeneous heavy cargo loading condition                      (15) Applicable only to non homogeneous loading conditions.</p>					

**Table 2 : Design load sets for primary supporting members within container holds**

Item	Design load set	Load component	Draught	Acceptance criteria	Design load scenario / Loading condition
Double bottom floors and girders	PC-1	$R - P_{ex}$	$0,9 T_{SC}$	AC-2	Sea-going / Containers stacks forces and sea pressure
	SEA-2	$P_{ex}$	$T_{SC}$	AC-1	Harbour condition / Sea pressure only
Side transverses and stringers	SEA-1	$P_{ex}$	$T_{SC}$	AC-2	Sea-going / Full load condition
<b>Note 1:</b> For the other primary supporting members, design load sets listed in Tab 1 are to be considered.					

**Table 3 : Design load sets for primary supporting members within dry bulk cargo holds**

Item	Design load set	Load component	Draught	Acceptance criteria (3)	Design load scenario / Loading condition
Bulk cargo hold assigned as ballast hold	WB-5	$P_{in} - P_{ex}$ (1)	$T_{BAL-H}$	AC-2	Sea-going / Heavy ballast condition
	WB-7	$P_{in}$	–	AC-1	Harbour condition
	WB-8	$P_{in}$	–	AC-3	Tank testing condition
Dry bulk cargo hold	BC-11	$P_{in} - P_{ex}$ (1)	$T_{SC}$	AC-2	Cargo loading condition
	BC-12	$P_{in} - P_{ex}$ (1)	–	AC-1	Harbour condition
	FBC-0	$P_{in}$ (4)	–	AC-3 (5)	Flooded / flooded and opposite holds empty
	FBC-1	$P_{in}$ (4)	–	AC-3 (5)	Flooded / Homogeneous, flooded and opposite holds fully filled
	FBC-3 (6)	$P_{in}$ (4)	–	AC-3 (5)	Flooded / Homogeneous heavy cargo, flooded and opposite holds partially filled
	FBC-5 (7)	$P_{in}$ (4)	–	AC-3 (5)	Flooded / Alternate light, flooded hold fully filled, opposite hold empty
	FBC-7 (7)	$P_{in}$ (4)	–	AC-3 (5)	Flooded / Alternate heavy, flooded hold partially filled, opposite hold empty
Structural watertight boundaries intended to stop vertical and horizontal flooding	FD-1 (2)	$P_{in}$	$T_{SC}$	AC-3	Flooded condition

(1)  $P_{ex}$  is to be considered for external shell only  
(2) Not applicable to external shell and vertically corrugated transverse bulkheads separating dry bulk cargo holds  
(3) See acceptance criteria definition in Ch 1, Sec 2, [3.4]  
(4) Loads for the flooded hold and opposite hold are defined in Ch 5, Sec 6, [4.1.7]  
(5) Applicable only to plane bulkheads. For vertically corrugated bulkheads, specific criteria are given in Ch 7, Sec 6, [4.7]  
(6) Applicable only to homogeneous heavy cargo loading condition  
(7) Applicable only to non-homogeneous loading conditions.

**Table 4 : Design load sets for primary supporting members within liquid cargo holds**

Item	Design load set (4)	Load component	Draught	Acceptance criteria (5)	Design load scenario / Loading condition
Double bottom floors and girders (2)	SEA-1	$P_{ex}$	$0,9 T_{SC}$ (1)	AC-2	Sea-going / Full load condition
	SEA-2	$P_{ex}$	$T_{SC}$	AC-1	Harbour / Full load condition
	LC-2	$P_{in} - P_{ex}$	$0,6 T_{SC}$	AC-2	Sea-going / Partial load condition
	LC-6	$P_{in} - P_{ex}$	(3)	AC-1	Harbour / Partial load condition
Side transverses (2)	SEA-1	$P_{ex}$	$0,9 T_{SC}$	AC-2	Sea-going / Full load condition
	SEA-2	$P_{ex}$	$T_{SC}$	AC-1	Harbour / Full load condition
	LC-1	$P_{in}$	$T_{SC}$	AC-2	Sea-going / Full load condition
	LC-2	$P_{in}$	$0,6 T_{SC}$	AC-2	Sea-going / Partial load condition
	LC-3	$P_{in}$	–	AC-1	Harbour condition
	LC-4	$P_{in}$	–	AC-3	Tank testing condition
Deck transverses	SEA-1	$P_{ex}$ (6)	$T_{SC}$	AC-2	Sea-going / Full load condition
	LC-1	$P_{in}$	$T_{SC}$	AC-2	Sea-going / Full load condition
	LC-2	$P_{in}$	$0,6 T_{SC}$	AC-2	Sea-going / Partial load condition
	LC-3	$P_{in}$	–	AC-1	Harbour condition
	LC-4	$P_{in}$	–	AC-3	Tank testing condition

Item	Design load set (4)	Load component	Draught	Acceptance criteria (5)	Design load scenario / Loading condition
Vertical web frames on longitudinal bulkheads, horizontal stringers on transverse bulkheads and corrugations on corrugated bulkheads	LC-1	$P_{in}$	$T_{SC}$	AC-2	Sea-going / Full load condition
	LC-2	$P_{in}$	$0,6 T_{SC}$	AC-2	Sea-going / Partial load condition
	LC-3	$P_{in}$	–	AC-1	Harbour condition
	LC-4	$P_{in}$	–	AC-3	Tank testing condition
Cross ties in centre tanks (7)	LC-1	$\frac{P_{in-p} + P_{in-s}}{2}$	$T_{SC}$	AC-2	Sea-going / Full load condition
	LC-2	$\frac{P_{in-p} + P_{in-s}}{2}$	$0,6 T_{SC}$	AC-2	Sea-going / Partial load condition
	LC-3	$P_{in}$	–	AC-1	Harbour condition
	LC-4	$P_{in}$	–	AC-3	Tank testing condition
Cross ties in wing tanks (8)	LC-7	$\frac{P_{in} + P_{ex}}{2}$	$T_{SC}$	AC-2	Sea-going / Full load condition
	LC-8	$\frac{P_{in} + P_{ex}}{2}$	$0,6 T_{SC}$	AC-2	Sea-going / Partial load condition
	LC-9	$\frac{P_{in} + P_{ex}}{2}$	$T_{SC}$	AC-1	Harbour condition
	LC-10	$\frac{P_{in} + P_{ex}}{2}$	$T_{SC}$	AC-3	Tank testing condition
Structural watertight boundaries intended to stop vertical and horizontal flooding	FD-1 (9)	$P_{in}$	$T_{SC}$	AC-3	Flooded condition

$P_{in-p}$  : Design pressure from port side wing cargo tank, in kN/m<sup>2</sup>.

$P_{in-s}$  : Design pressure from starboard side wing cargo tank, in kN/m<sup>2</sup>.

- (1) If the loading condition where the combination of an empty cargo tank and a mean ship's draught greater than  $0,9 T_{SC}$  is included in ship's loading manual, the maximum corresponding draught is to be considered
- (2) Draughts specified for bottom floors, girders and side transverses are based on operational limits specified in Chapter 4. Where the optional loading conditions exceed the minimum Rule required loading conditions, the draughts will be subject to special consideration.
- (3) For ships with two watertight or oil-tight longitudinal bulkheads, the draught is to be taken as  $0,25 T_{SC}$ . For ships with a centreline bulkhead, the draught is to be taken as  $0,33 T_{SC}$ .
- (4) When the ship's configuration cannot be described by the structural members or structural configurations identified above, the applicable Design Load Sets to determine the scantling requirements of primary supporting member are to be selected so as to cover the following cases, as applicable:
  - A full tank on one side of the member with the tank or space on the other side empty.
  - A full tank on one side of the member with the external pressure minimised.
  - External pressure maximised with the adjacent tank or space empty.

The boundary is to be evaluated for loading from both sides. Design Load Sets are to be selected based on the tank or space contents and are to maximise the net pressure on the structural boundary, the draught to use is to be taken in accordance with the Design Load Set and this table. Design Load Sets covering the AC-1 and AC-2 acceptance criteria are to be selected.
- (5) See acceptance criteria definition in Ch 1, Sec 2, [3.4]
- (6) Green sea pressure only or other loads on deck
- (7) Full wing cargo tanks, centre tank empty
- (8) Full centre tank, wing cargo tanks empty
- (9) Not applicable to external shell and vertically corrugated transverse bulkheads separating dry bulk cargo holds.

## Section 3 Minimum Thickness

### 1 General

#### 1.1 Minimum thickness requirements

**1.1.1** The gross thickness, in mm, of all structural elements including plating, web and face plate, if any, of stiffeners and tripping brackets, web plating and flange of primary supporting members, is to be not less than 5,0 mm.

#### 1.1.2 Stiffener minimum thickness

Where minimum thickness requirements are specified for stiffeners in addition to the requirement of [1.1.1], the net thickness of the web and face plate, if any, of stiffeners and tripping brackets, in mm, is to comply with those minimum net thickness requirements.

In addition, the net thickness of the web of stiffeners and tripping brackets, in mm, is to be:

- not less than 40% of the net required thickness of the attached plating, to be determined according to Ch 7, Sec 4.
- less than twice the net offered thickness of the attached plating.

# Section 4 Plating

## Symbols

For symbols not defined in this Section, refer to Ch 1, Sec 3.

$\alpha_p$  : Correction factor for the panel aspect ratio, to be taken as follows:

$$\alpha_p = 1,2 - \frac{b}{2,1 a}$$

without being taken greater than 1,0

$K_{corr}$  : Coefficient to take into account the corrosion:

- In general:  $K_{corr} = 1,0$
- For tank testing:  $K_{corr} = 1,2$

$P$  : Pressure for the considered design load set (see Ch 7, Sec 2, [2]), in  $kN/m^2$ , calculated at the load calculation point defined in Ch 4, Sec 6, [2.2]

$\sigma_l$  : Hull girder normal stress, in  $N/mm^2$ , as defined in Ch 7, Sec 2, [1.1], calculated at the load calculation point as defined in Ch 4, Sec 6, [2.2]

$\chi$  : Coefficient taken equal to:

- in intact condition:  $\chi = 1,00$
- in flooded condition:
  - $\chi = 1,00$  for collision bulkheads
  - $\chi = 1,15$  for other watertight boundaries of compartments.

## 1 Plating subject to lateral pressure

### 1.1 Yielding check

#### 1.1.1 Plating

The net thickness  $t$ , in mm, of plate panels subject to lateral pressure is to be not less than the greatest of the values obtained, for all the applicable design load sets defined in Ch 7, Sec 2, [2.1.3], from the following formula:

$$t = 0,0158 \alpha_p b \sqrt{\frac{|P|}{\chi C_a R_{eH}}}$$

where:

$C_a$  : Permissible bending stress coefficient for plate, taken equal to:

$$C_a = K_{corr} \beta - \alpha \frac{|\sigma_l|}{R_{eH}}$$

without being taken greater than  $K_{corr} C_{a-max}$

$\beta, \alpha$  : Coefficients as defined in Tab 1

$C_{a-max}$  : Maximum permissible bending stress coefficient, as defined in Tab 1.

**Table 1 : Coefficients  $\beta$ ,  $\alpha$  and  $C_{a-max}$**

Acceptance criteria set	Structural member		$\beta$	$\alpha$	$C_{a-max}$
AC-1	Longitudinal strength members	Longitudinally stiffened plating	0,9	0,5	0,8
		Transversely stiffened plating		1,0	
	Other members		0,8	0	
AC-2	Longitudinal strength members	Longitudinally stiffened plating	1,05	0,5	0,95
		Transversely stiffened plating		1,0	
	Other members		1,0	0	
AC-3	Longitudinal strength members	Longitudinally stiffened plating	1,1	0,5	1,0
		Transversely stiffened plating		1,0	
	Other members		1,0	0	

## 1.2 Plating of corrugated bulkheads

### 1.2.1 Cold and hot formed corrugations

The net plate thickness  $t$ , in mm, of corrugated bulkheads is not to be taken less than the greatest value calculated for all applicable design load sets, as defined in Ch 7, Sec 2, [2.1.3], given by:

$$t = 0,0158b_p \sqrt{\frac{|P|}{C_{CB} R_{eH}}}$$

where:

$b_p$  : Plate width, in mm, taken as the width of the corrugation flange  $b_{f-cg}$  or the web  $b_{w-cg}$ , see Ch 4, Sec 5, Fig 27

$C_{CB}$  : Permissible bending stress coefficient for corrugated bulkhead plating taken equal to:

- For acceptance criteria set AC-1 for transverse corrugated bulkheads and vertically corrugated longitudinal bulkheads:

$$C_{CB} = 0,75$$

- For acceptance criteria set AC-2 for transverse corrugated bulkheads and vertically corrugated longitudinal bulkheads:

$$C_{CB} = 0,90$$

- For acceptance criteria set AC-3 for transverse corrugated bulkheads and vertically corrugated longitudinal bulkheads:

$$C_{CB} = K_{corr} 0,95$$

- For horizontally corrugated longitudinal bulkheads, without being greater than  $C_{CB-max}$ :

$$C_{CB} = K_{corr} \beta_{CB} - \alpha_{CB} \frac{|\sigma|}{R_{eH}}$$

$\beta_{CB}$  : Coefficient as defined in Tab 2

$\alpha_{CB}$  : Coefficient as defined in Tab 2

$C_{CB-max}$  : Maximum permissible bending stress coefficient as defined in Tab 2.

**Table 2 : Coefficients  $\beta_{CB}$ ,  $\alpha_{CB}$  and  $C_{CB-max}$**

Acceptance criteria set	Structural member	$\beta_{CB}$	$\alpha_{CB}$	$C_{CB-max}$
AC-1	Horizontally corrugated longitudinal bulkheads	0,9	0,5	0,75
AC-2		1,05	0,5	0,9
AC-3		1,1	0,5	0,95

### 1.2.2 Built-up corrugations

In addition to [1.2.1], the net required thickness of the wider plating of built-up corrugations,  $t_w$  in mm, is to be taken as the greatest value calculated for all applicable design load sets, as defined in Ch 7, Sec 2, [2.1.3], given by:

$$t_w = \sqrt{\frac{5b_w^2 |P| 10^{-4}}{C_{CB} R_{eH}} - t_N^2}$$

$t_N$  : Net required thickness of the narrower plating, either flange or web, in mm, as obtained in [1.2.1]

$b_w$  : Plate width, in mm, of the wider plating, taken as the width of the corrugation flange  $b_{f-cg}$  or the web  $b_{w-cg}$ , whichever is greater, see Ch 4, Sec 5, Fig 27

## 1.3 Buckling check

1.3.1 The buckling check of plate panels is to be performed according to Ch 9, Sec 1.

## 2 Transverse vertically corrugated bulkheads separating dry bulk cargo holds in flooded condition

### 2.1 Application

2.1.1 These requirements apply to vertically corrugated transverse watertight bulkheads of the cargo holds of ships intended for the carriage of dry cargoes in bulk.

## 2.2 Net thickness of corrugation

### 2.2.1 Cold and hot formed corrugations

The net plate thickness  $t$ , in mm, of transverse vertically corrugated watertight bulkheads separating cargo holds is not to be taken less than:

$$t = 0,0149b_p \sqrt{\frac{1,05 P_R}{R_{eH}}}$$

where:

$b_p$  : Plate width, in mm, taken as the width of the corrugation flange  $b_{f-cg}$  or the web  $b_{w-cg}$ , see Ch 4, Sec 5, Fig 27

$P_R$  : Resultant pressure, in kN/m<sup>2</sup>, as defined in Ch 5, Sec 6, [4.1.7].

The net thickness is also to comply with the requirements given in [1.2.1].

### 2.2.2 Built-up corrugations

Where the thicknesses of the flange and web of built-up corrugations of transverse vertically corrugated watertight bulkheads separating cargo holds are different, the net plate thicknesses are not to be taken less than that obtained from the following formula.

The net thickness  $t_N$ , in mm, of the narrower plating is not to be taken less than that calculated according to [2.2.1] with  $b_p$  taken as the width of the corrugation flange  $b_{f-cg}$  or the web  $b_{w-cg}$ , whichever is smaller.

The net thickness  $t_W$ , in mm, of the wider plating is not to be taken less than the greater of:

a) The thickness calculated according to [2.2.1] with  $b_p$  taken as the width of the corrugation flange  $b_{f-cg}$  or the web  $b_{w-cg}$ , whichever is greater.

$$b) t_W = \sqrt{\frac{4,62b_W^2 P_R 10^{-4}}{R_{eH}} - t_{NO}^2}$$

where:

$t_{NO}$  : Net offered thickness of the narrower plating, in mm, not to be taken greater than that obtained in a)

$b_W$  : Plate width, in mm, of the wider plating, taken as the width of the corrugation flange  $b_{f-cg}$  or the web  $b_{w-cg}$ , whichever is greater, see Ch 4, Sec 5, Fig 27.

The net thickness is also to comply with the requirements given in [1.2.2].

### 2.2.3 Lower part of corrugation

The net thickness of the lower part of corrugations is to be maintained for a distance of not less than  $0,15 \ell_C$  measured from the top of the lower stool, or from the inner bottom where no lower stool is fitted. The span of the corrugations  $\ell_C$ , in m, is to be taken as given in Ch 4, Sec 5, [10.3.5].

### 2.2.4 Middle part of corrugation

The net thickness of the middle part of corrugations is to be maintained for a distance not greater than  $0,3 \ell_C$  from the bottom of the upper stool, or from the deck if no upper stool is fitted. The net thickness is also to comply with the requirements in Ch 7, Sec 6, [4.7.2] and [1.2].

## 3 Strength check of plating supporting wheeled cargo

### 3.1 General

3.1.1 The requirements of this Article apply for the strength check of plating supporting wheeled cargo.

3.1.2 If deemed necessary, the Society may require a fatigue assessment of plating supporting wheeled cargo.

### 3.2 Load model

#### 3.2.1 General

Static and dynamic forces induced by relevant types of wheeled cargo are to be considered.

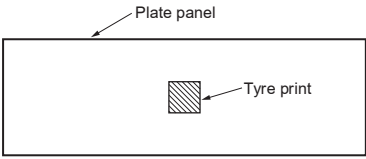

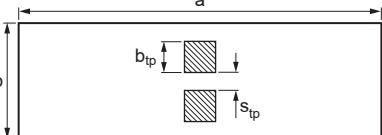

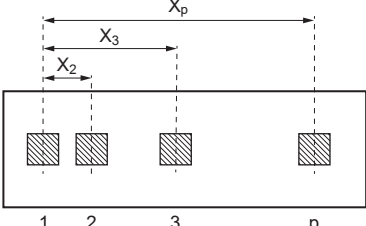

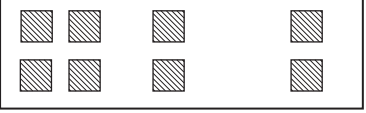

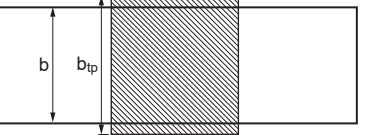

#### 3.2.2 Tyre print

For the purpose of applying the requirements in [3.3], a single tyre print is to be considered for wheels that belong to the same axle and are separated from each other by not more than half of their individual width.

#### 3.2.3 Forces due to wheeled cargo

The wheel force  $P_0$  induced by a single wheel, in kN, is to be taken as defined in Ch 5, Sec 6, [7.2] considering dynamic forces in the vertical direction only.

Table 3 : Tyre print arrangements on plate panel

Tyre print arrangement	Total load on plate panel	m	$\alpha$	$\delta$	$C_1$
	$n P_0$	1	$\frac{A_T}{ab} 10^6$	1	1
	$2 n P_0$	2	$\frac{A_T}{ab} 10^6$	$\frac{\delta_1 + \delta_2}{2}$	1
	$p n P_0$ $p \geq 2$	1	$\frac{A_T}{ab} 10^6$	1	$\max \left( 1 + \sum_{\substack{i=1 \\ i \neq j}}^p \beta_i, j \in [1;p] \right)$
	$2 p n P_0$ $p \geq 2$	2	$\frac{A_T}{ab} 10^6$	$\frac{\delta_1 + \delta_2}{2}$	$\max \left( 1 + \sum_{\substack{i=1 \\ i \neq j}}^p \beta_i, j \in [1;p] \right)$
	$\delta n P_0$	1	$\frac{A_T}{ab_{tp}} 10^6$	$\frac{b}{b_{tp}}$	1

**Note 1:**

$A_T$  : Tyre print area, in  $m^2$ , as defined in [3.3.2]

$$\delta_1 = 1 - \frac{s_{tp}}{b - b_{tp}}$$

$$\delta_2 = 1 - \frac{3s_{tp}^2 + 6s_{tp}b_{tp}}{3b^2 - 4b_{tp}^2}$$

$s_{tp}$  : Distance, in mm, between the two tyre prints

$b_{tp}$  : Tyre print breadth, in mm

$\beta_i$  : Coefficient for the considered tyre print:

- for  $\alpha_i < 2$ :  $\beta_i = 0,8 (1,2 - 2,02 \alpha_i + 1,17 \alpha_i^2 - 0,23 \alpha_i^3)$
- for  $\alpha_i \geq 2$ :  $\beta_i = 0$

with:

$$\alpha_i = \frac{x_i}{b}$$

$x_i$  : Distance, in mm, from the considered tyre print (i) to the reference tyre print (j)

$p$  : Number of tyre prints along the panel length.

**Note 2:** For multiple tyre prints arrangements, all tyre prints are to be identical. Tyre prints with various characteristics acting simultaneously on a plate panel are considered by the Society on a case by case basis.

### 3.3 Plating

#### 3.3.1 Net thickness

The net thickness  $t$ , in mm, of plate panels supporting wheeled cargo is to be not less than the value obtained from the following formula:

$$t = 0,9 C_{WL} \sqrt{\frac{mn|P_0|k}{C_a} \delta C_1}$$

where:

$C_{WL}$  : Coefficient to be taken equal to:

$$C_{WL} = 2,15 - 0,05 \frac{a}{b} + 0,02 \left(4 - \frac{a}{b}\right) \alpha^{0,5} - 1,75 \alpha^{0,25}$$

where  $a/b$  is to be taken not greater than 3

- $\alpha$  : Coefficient to be taken as given in Tab 3
- $m$  : Number of tyre prints over the panel breadth, to be taken as given in Tab 3
- $n$  : Number of wheels per tyre print
- $P_0$  : Wheel force, in kN, as defined in [3.2.3].
- $C_a$  : Permissible bending stress coefficient for plate, as defined in [1.1.1].
- $\delta$  : Coefficient to be taken as given in Tab 3
- $C_1$  : Coefficient to be taken as given in Tab 3

#### 3.3.2 Tyre print area

The tyre print area,  $A_T$ , in  $m^2$ , is to be taken as indicated by the Designer but not greater than:

$$A_T = 9,81 \frac{nQ_A}{n_W p_T}$$

where:

- $n$  : number of wheels per tyre print
- $Q_A$  : Axle load, in t
- $n_W$  : Number of individual wheels for the axle considered
- $p_T$  : Tyre pressure, in  $kN/m^2$ . When the tyre pressure is not indicated by the designer, it may be taken as defined in Tab 4. When the tyre print consists of several wheels (see [3.2.2]),  $A_T$  is the total print area, including the area in between single wheels.

**Table 4 : Tyre pressures  $p_T$  for vehicles**

Vehicle type	Tyre pressure $p_T$ , in $kN/m^2$	
	Pneumatic tyres	Solid rubber tyres
Private cars	250	Not applicable
Vans	600	Not applicable
Trucks and trailers	800	Not applicable
Handling machines	1100	1600

## 4 Plating subject to impact loads

### 4.1 General

**4.1.1** Unless otherwise specified, the net thickness of plate panels subject to impact is to be not less than the value obtained, in mm, from the following formula:

$$t = \frac{0,0158 \alpha_p b}{C_d} \sqrt{\frac{P_i}{C_a R_{eH}}}$$

where:

- $C_d$  : Plate capacity correction coefficient:
  - for impact on flat bottom forward, on flat area of the bottom aft and for berthing impact on the side shell:  
 $C_d = 1,3$
  - for sloshing:  
 $C_d = 1,0$
  - for impact on bow flare:  
 $C_d = 1,2$

$C_a$  : Permissible bending stress coefficient taken as: for acceptance criteria AC-4:

$$C_a = 1,0$$

$P_1$  : Any impact pressure defined in the Rules, including:

- bottom impact pressure, as defined in Ch 5, Sec 5, [4.2.1]
- bow impact pressure, as defined in Ch 5, Sec 5, [4.3.1]
- sloshing impact pressure, as defined in Ch 5, Sec 6, [2.2.2]
- stern impact pressure, as defined in Ch 5, Sec 5, [4.2.2]
- berthing impact pressure, as defined in Ch 5, Sec 5, [4.4]

If deemed necessary by the Society and depending on specific natures of loadings, different calculation methods may be applied, on a case-by-case basis.

## 5 Strength check of plating supporting steel coils on wooden dunnage

### 5.1 General

**5.1.1** The net thickness of inner bottom plating, hopper side plating and inner hull plating for ships intended to carry steel coils is to comply with [5.2.1] up to a height not less than the one corresponding to the top of upper tier in touch with hopper or inner hull plating.

### 5.2 Yielding check

**5.2.1** The net thickness  $t$ , in mm, of plating of longitudinally framed inner bottom, bilge hopper sloping plate and inner hull is not to be taken less than:

$$t = K_1 \sqrt{\frac{F_{sc} \times 10^3}{C_a R_{eH}}}$$

where:

$K_1$  : Coefficient taken as:

$$K_1 = \sqrt{\frac{1,7 \frac{s}{1000} \ell K_2 - 0,73 \left(\frac{s}{1000}\right)^2 K_2^2 - (\ell - \ell_{ip})^2}{2 \ell_{ip} \left(2 \frac{s}{1000} + 2 \ell K_2\right)}}$$

$K_2$  : Coefficient taken as:

$$K_2 = -\frac{s}{1000 \ell} + \sqrt{\left(\frac{s}{1000 \ell}\right)^2 + 1,37 \left(\frac{1000 \ell}{s}\right)^2 \left(1 - \frac{\ell_{ip}}{\ell}\right)^2 + 2,33}$$

$F_{sc}$  : Load due to steel coil cargoes, taken equal to  $F_{sc-ib-sr}$ ,  $F_{sc-ibr}$ ,  $F_{sc-hs-s}$  or  $F_{sc-hs}$  as defined in Ch 5, Sec 6, [5], depending on the considered design load set (see Ch 7, Sec 2, [2])

$C_a$  : Permissible bending stress coefficient, as defined in [1.1.1].

## 6 Special requirements

### 6.1 Minimum thickness of keel plating

**6.1.1** The net thickness of the keel plating is not to be taken less than the offered net thickness of the adjacent 2 m width bottom plating, measured from the edge of the keel strake.

The width of the keel is defined in Ch 4, Sec 5, [7.2.1].

### 6.2 Bilge plating

#### 6.2.1 Bilge plate thickness

a) The net thickness of bilge plating is not to be taken less than the offered net thickness for the adjacent bottom shell or adjacent side shell plating, whichever is greater.

b) The net thickness of rounded bilge plating  $t$ , in mm, is not to be taken less than:

$$t = 6,45 \cdot 10^{-4} (P_{ex} s_b)^{0,4} R^{0,6}$$

where:

$P_{ex}$  : Sea pressure for the design load set SEA-1 as defined in Ch 7, Sec 2, [2.1.3], calculated at the lower turn of the bilge, in kN/m<sup>2</sup>

$R$  : Effective bilge radius in mm:  $R = R_0 + 0,5 (\Delta s_1 + \Delta s_2)$

$R_0$  : Radius of curvature, in mm (see Fig 1)

- $\Delta s_1$  : Distance between the lower turn of bilge and the outermost bottom longitudinal, in mm, see Fig 1. Where the outermost bottom longitudinal is within the curvature, this distance is to be taken as zero
  - $\Delta s_2$  : Distance between the upper turn of bilge and the lowest side longitudinal, in mm, see Fig 1. Where the lowest side longitudinal is within the curvature, this distance is to be taken as zero
  - $s_b$  : Distance between transverse stiffeners, webs or bilge brackets, in mm.
- c) Longitudinally stiffened bilge plating is to be assessed as regular stiffened plating. The bilge thickness is not to be less than the lesser of the values obtained by [1.1.1] and item b). A bilge keel is not considered as an effective 'longitudinal stiffening' member.

**Figure 1 : Transverse stiffened bilge plating**

**6.2.2 Transverse extension of bilge minimum plate thickness**

Where a plate seam is located in the straight plate just below the lowest stiffener on the side shell, any increased thickness required for the bilge plating does not have to be extended to the adjacent plate above the bilge, provided the plate seam is not more than  $s_2/4$  below the lowest side longitudinal. Similarly, for the flat part of adjacent bottom plating, any increased thickness for the bilge plating does not have to be extended to the adjacent plate, provided the plate seam is not more than  $s_1/4$  beyond the outboard bottom longitudinal. For definition of  $s_1$  and  $s_2$ , see Fig 1.

**6.2.3 Hull envelope framing in bilge area**

For transversely stiffened bilge plating, a longitudinal is to be fitted at the bottom and at the side close to the position where the curvature of the bilge plate starts. The scantling of those longitudinals is to be not less than the one of the closer adjacent stiffener. The distance  $\Delta s_1$  between the lower turn of bilge and the outermost bottom longitudinal is generally not to be greater than one-third of the spacing between the two outermost bottom longitudinals  $s_1$ . Similarly, the distance  $\Delta s_2$  between the upper turn of the bilge and the lowest side longitudinal is generally not to be greater than one-third of the spacing between the two lowest side longitudinals  $s_2$ . See Fig 1.

**6.3 Inner bottom of cargo holds intended to carry dry cargo**

**6.3.1** For ships with one of the following service notations:

- **general cargo ship**, intended to carry dry bulk cargo in holds
- **bulk carrier**
- **bulk carrier ESP**
- **self-unloading bulk carrier ESP**
- **ore carrier ESP**
- **combination carrier/OBO ESP**
- **combination carrier/OOC ESP**

the inner bottom net thickness is to be increased by 2 mm unless it is protected by a continuous wooden ceiling.

**6.4 Sheer strake**

**6.4.1 General**

The minimum width of the sheer strake is defined in Ch 4, Sec 5, [8.1.4].

#### **6.4.2 Welded sheer strake**

The net thickness of a welded sheer strake is not to be less than the offered net thickness of the adjacent side plating, provided this adjacent side plating is located entirely within the top wing tank or the double side tank, as the case may be.

#### **6.4.3 Rounded sheer strake**

The net thickness of a rounded sheer strake is not to be less than:

- the offered net thickness of the adjacent 2 m width deck plating, or
- the offered net thickness of the adjacent 2 m width side plating,

whichever is greater.

### **6.5 Deck stringer plating**

**6.5.1** The minimum width of deck stringer plating is defined in Ch 4, Sec 5, [9.1.2].

**6.5.2** Within 0,6 L amidships, the net thickness of the deck stringer plate is not to be less than the offered net thickness of the adjacent deck plating.

### **6.6 Deck plating protected by wood sheathing or deck composition**

**6.6.1** The net thickness of deck plating protected by wood sheathing, deck composition or other arrangements deemed suitable by the Society may be reduced on a case by case basis. In no case this net thickness is to be less than the minimum value as given in Ch 7, Sec 3.

**6.6.2** The sheathing is to be secured to the deck to the satisfaction of the Society.

### **6.7 Supporting structure in way of corrugated bulkheads**

#### **6.7.1 General**

Requirements for the arrangement of bulkhead as given in Ch 4, Sec 5, [10.3] are to be considered together with [6.7.2] to [6.7.4].

#### **6.7.2 Lower stool**

- a) The net thickness of the stool top plate is not to be less than that required for the attached corrugated bulkhead and is to be of at least the same material yield strength as the attached corrugation. The extension of the top plate beyond the corrugation is not to be less than the as-built flange thickness of the corrugation.
- b) The net thickness of the stool side plate, within the region of the corrugation depth from the stool top plate, is not to be less than the greater of the following:
  - the net thickness obtain from [1.1]
  - the corrugated bulkhead flange net actual thickness at the lower end.

If material of different yield strength are used, the required thickness is to be adjusted by the ratio of the two material factors as defined in Ch 4, Sec 1, [2.2].

- c) Continuity between corrugation web and lower stool supporting brackets is to be maintained inside the stool.
- d) The net thickness of supporting bracket is not to be less than 80% of the required net thickness of the corrugation webs and is to be of at least the same material yield strength.
- e) The net thickness of supporting floors or girders is not to be less than the net required thickness of the stool side plating connected to the inner bottom and is to be of at least the same material yield strength. If material of different yield strength is used, the required thickness is to be adjusted by the ratio of the two material factors  $k$ , as defined in Ch 4, Sec 1, [2.2].
- f) Where a lower stool is fitted, particular attention is to be given to the through-thickness properties, and arrangements for continuity of strength, at the connection of the bulkhead stool to the inner bottom. For requirements for plates with specified through-thickness properties, see Ch 4, Sec 1, [2.6].

#### **6.7.3 Upper stool**

- a) The net thickness of the stool bottom plate is not to be less than that required for the attached corrugated bulkhead and is to be of at least the same material yield strength as the attached corrugation. The extension of the top plate beyond the corrugation is not to be less than the as-built flange thickness of the corrugation.
- b) The net thickness of the lower portion of stool side plating is not to be less than the greater of the following
  - the net thickness obtain from [1.1]
  - 80% of the upper part of the bulkhead plating as required by [1.2]
  - the corrugated bulkhead flange net actual thickness at the upper end.

If material of different yield strength are used, the required thickness is to be adjusted by the ratio of the two material factors as defined in Ch 4, Sec 1, [2.2].

**6.7.4 Local supporting structure in way of corrugated bulkheads without a lower stool**

- a) The net thickness of the supporting floors or girders and pipe tunnel beams in way of a corrugated bulkhead are not to be less than the required net thickness of the corrugation flanges and are to be of at least the same material yield strength. The inner bottom and hopper tank in way of the corrugation is to be of at least the same material yield strength as the attached corrugation, and Z grade steel as defined in Ch 4, Sec 1, [2.6.1] is to be used unless through thickness properties are documented for approval.
- b) Brackets/carlings arranged in line with the corrugation web are to have a depth of not less than 0.5 times the corrugation depth and a net thickness not less than 80% of the net thickness of the corrugation webs and are to be of at least the same material yield strength. Where support is provided by gussets with shedder plates instead of brackets/carlings, the height of the gusset plate is to be at least equal to the corrugation depth. The gusset plates are to be fitted in line with and between the corrugation flanges. The net thickness of the gusset and shedder plates is not to be less than 100% and 80%, respectively, of the net thickness of the corrugation flange and is to be of at least the same material yield strength.

**6.8 Aft peak bulkhead**

**6.8.1** The net thickness of the aft peak bulkhead plating in way of the stern tube penetration is to be at least 1,6 times the required thickness for the bulkhead plating.

# Section 5 Stiffeners

## Symbols

For symbols not defined in this Section, refer to Ch 1, Sec 3.

- $d_{shr}$  : Effective shear depth, in mm, as defined in Ch 4, Sec 6, [1.4.4]
- $f_{bdg}$  : Bending moment factor taken as:
- for continuous stiffeners with fixed ends,  $f_{bdg}$  is to be taken equal to:
    - $f_{bdg} = 12$  for horizontal stiffeners and upper end of vertical stiffeners
    - $f_{bdg} = 10$  for lower end of vertical stiffeners
  - for stiffeners with reduced end fixity, variable load or being part of grillage, the requirements in [1.7] applies
- $K_{corr}$  : Coefficient to take into account the corrosion:
- in general:
    - $K_{corr} = 1,0$
  - for tank testing:
    - $K_{corr} = 1,1$
- $l_{bdg}$  : Effective bending span, in m, as defined in Ch 4, Sec 6, [1.1.2]
- $l_{shr}$  : Effective shear span, in m, as defined in Ch 4, Sec 6, [1.1.3]
- $l_{lp}$  : Distance, in m, between outermost dunnage per EPP in the ship X direction, as defined in Ch 5, Sec 6
- $P$  : Design pressure for the design load set being defined in Ch 7, Sec 2 and calculated at the load calculation point defined in Ch 4, Sec 6, [3.2], in  $kN/m^2$
- $\chi$  : Coefficient as defined in Ch 7, Sec 4.

## 1 General

### 1.1 Yielding check of stiffeners subject to lateral pressure

#### 1.1.1 Web plating

The net web thickness  $t_w$ , in mm, of stiffeners subject to lateral pressure is not to be taken less than the greatest of the values calculated for all applicable design load sets as defined in Ch 7, Sec 2, [2], as obtained from the following formulae:

$$t_w = \frac{f_{shr}|P|s l_{shr}}{d_{shr} K_{corr} \chi C_t \tau_{eH}}$$

with  $\chi C_t$  not to be taken greater than 1,0

where:

- $f_{shr}$  : Shear force distribution factor taken as:
- for continuous stiffeners with fixed ends,  $f_{shr}$  is to be taken equal to:
    - $f_{shr} = 0,5$  for horizontal stiffeners and upper end of vertical stiffeners
    - $f_{shr} = 0,7$  for lower end of vertical stiffeners
  - for stiffeners with reduced end fixity or being part of grillage, the requirements in [1.7] applies
- $C_t$  : Permissible shear stress coefficient for the design load set being considered, as defined in Tab 2.

#### 1.1.2 Section modulus

The net section modulus,  $Z$  in  $cm^3$ , of stiffeners subject to lateral pressure is not to be taken less than the greatest of the values calculated for all applicable design load sets as defined in Ch 7, Sec 2, [2.1.3], as obtained from the following formulae:

$$Z = \frac{|P|s l_{bdg}^2}{f_{bdg} \chi C_s R_{eH}}$$

with  $\chi C_s$  not to be taken greater than  $K_{corr}$

where:

- $C_s$  : Permissible bending stress coefficient as defined in Tab 1 for the design load set being considered
- $\sigma_L$  : Hull girder normal stress, in  $N/mm^2$ , as defined in Ch 7, Sec 2, [1.1], calculated at the load calculation point as defined in Ch 4, Sec 6, [2.2]
- $\beta_s, \alpha_s, C_{s-max}$ : Coefficients as defined in Tab 2.

**Table 1 : Definition of  $C_s$**

Sign of hull girder bending stress $\sigma_L$	Lateral pressure acting on	Coefficient $C_s$
Tension (positive)	stiffener side	$C_s = K_{corr} \beta_s - \alpha_s \frac{ \sigma_L }{R_{eH}}$ but not to be taken greater than $K_{corr} C_{s-max}$
Compression (negative)	plate side	
Tension (positive)	plate side	$C_s = K_{corr} C_{s-max}$
Compression (negative)	stiffener side	

**Table 2 : Coefficients  $\beta_s$ ,  $\alpha_s$ ,  $C_{s-max}$ ,  $C_t$  and  $C_{comb}$**

Acceptance criteria set	Structural member	$\beta_s$	$\alpha_s$	$C_{s-max}$	$C_t$	$C_{comb}$
AC-1	Longitudinal strength member	0,85	1,0	0,75	0,75	0,75
	Transverse or vertical member	0,75	0			
AC-2	Longitudinal strength member	1,00	1,0	0,9	0,9	0,9
	Transverse or vertical member	0,90	0			
AC-3	Longitudinal strength member	1,10	1,0	1,0	1,0	1,0
	Transverse or vertical member	1,00	0			

**1.1.3 Group of stiffeners**

Where stiffeners of equal scantlings are sequentially placed on a single stiffened panel, between primary supporting members, the scantling of every stiffener of the designated group may alternatively be taken as the greatest of the following:

- the average of the scantlings individually required for every stiffener within the group according to [1.1.1] and [1.1.2]
- 90% of the maximum scantling individually required for any of the stiffeners within the group according to [1.1.1] and [1.1.2].

**1.2 Yielding check of stiffeners supporting wheeled cargo**

**1.2.1 General**

Static and dynamic forces induced by relevant types of wheeled cargo are to be considered.

**1.2.2 Forces due to wheeled cargo**

The wheel force  $P_0$  induced by a single wheel, in kN, is to be taken as defined in Ch 5, Sec 6, [7.2] considering dynamic forces only in the vertical direction.

**1.2.3 Web plating**

The net web thickness  $t_w$ , in mm, of stiffeners supporting wheeled cargo is not to be taken less than the greatest of the values calculated for all applicable design load sets, as obtained from the following formulae:

$$t_w = \frac{\alpha_w K_T |P_0|}{d_{shr} C_t \tau_{eH}} 10^3$$

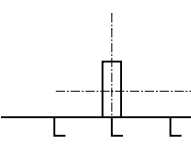

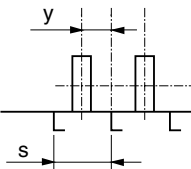

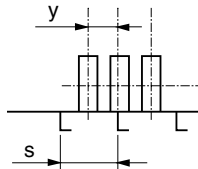

where:

$\alpha_w$  : Coefficient taking into account the number of individual wheels per axle considered as acting on the stiffener, defined in Tab 3, without being taken less than 1,0

$K_S, K_T$  : Coefficients taking account of the number of axles considered as acting on the stiffener, defined in Tab 4

$C_t$  : Permissible shear stress coefficient defined in [1.1.1].

**Table 3 : Wheeled cargo - Coefficient  $\alpha_w$**

Single wheel configuration	Double wheels configuration	Triple wheels configuration
 <p><math>\alpha_w = 1</math></p>	 <p><math>\alpha_w = 2 \left( 1 - \frac{y}{s} \right)</math></p>	 <p><math>\alpha_w = 3 - 2 \frac{y}{s}</math></p>

**Note 1:**

$y$  : Distance, in mm, from the external wheel to the stiffener under consideration, to be taken equal to half the distance between the middle of the external wheels.

Table 4 : Wheeled cargo - Coefficients  $K_S$  and  $K_T$

Coefficient	Configuration	
	Single axle	Double axles
$K_S$	1	<ul style="list-style-type: none"> <li>if <math>d \leq \ell/\sqrt{3}</math></li> </ul> $\frac{172}{81} - \frac{4d}{3\ell} - \frac{d^2}{\ell^2} + \frac{d^4}{\ell^4}$ <ul style="list-style-type: none"> <li>if <math>d &gt; \ell/\sqrt{3}</math></li> </ul> $\frac{4}{3} - \frac{4d}{3\ell} + \frac{3d^2}{\ell^2} - \frac{8d^3}{3\ell^3}$
$K_T$	1	$2 - \frac{d}{2\ell} - \frac{3d^2}{2\ell^2} + \frac{d^3}{\ell^3}$

**Note 1:**  
 $d$  : Distance, in m, between two axles (see Fig 1).

Figure 1 : Wheeled cargo on stiffeners - Double axles

**1.2.4 Section modulus**

The minimum net section modulus,  $Z$  in  $\text{cm}^3$ , of stiffeners supporting wheeled cargo is not to be taken less than the greatest of the values calculated for all applicable design load sets, as obtained from the following formulae:

$$Z = \frac{\alpha_w K_S |P_0| \ell_{bdg}}{6 C_S R_{eH}} 10^3$$

where:

$C_S$  : Permissible bending stress coefficient defined in [1.1.2]

$\alpha_w, K_S, K_T$ : Coefficients defined in [1.2.3]

**1.2.5 Multispan stiffeners**

For multispan stiffeners supporting wheeled cargo and for stiffeners supporting more than 2 axles, it is to be checked that the normal stress  $\sigma$  and the shear stress  $\tau$ , determined by a direct calculation, are in compliance with the requirements in [1.7].

**1.3 Net section modulus and net shear sectional area of ordinary stiffeners subject to impact loads**

**1.3.1 Single span longitudinal, transverse and vertical ordinary stiffeners**

Unless otherwise specified, the net plastic section modulus  $Z_{pl}$ , in  $\text{cm}^3$ , as defined in Ch 4, Sec 6, [1.4.8] and the net web thickness  $t_w$ , in mm, of stiffeners subject to impact loads are to be not less than the values obtained from the following formulae:

$$Z_{pl} = \frac{P_I S \ell_{bdg}^2}{8(1 + n_s/2) C_S R_{eH}}$$

$$t_w = \frac{P_I S \ell_{shr}}{2 d_{shr} C_t \tau_{eH}}$$

where:

$C_S$  : Permissible bending stress coefficient taken equal to 0,9 for acceptance criteria set AC-4

$C_t$  : Permissible shear stress coefficient taken equal to 1,0 for acceptance criteria set AC-4

- $P_1$  : Any impact pressure defined in the Rules, including:
- bottom impact pressure, as defined in Ch 5, Sec 5, [4.2.1]
  - bow impact pressure, as defined in Ch 5, Sec 5, [4.3.1]
  - sloshing impact pressure, as defined in Ch 5, Sec 6, [2.2.2]
  - stern impact pressure, as defined in Ch 5, Sec 5, [4.2.2]
  - berthing impact pressure, as defined in Ch 5, Sec 5, [4.4.1]

- $n_s$  : End fixation factor taken as:
- $n_s = 0$  for both ends with low end fixity (simply supported)
  - $n_s = 1$  for one end fixed and one end simply supported
  - $n_s = 2$  for continuous members or members with bracketed fitted at both ends

If deemed necessary by the Society and depending on specific natures of loadings, different calculation methods may be applied, on a case-by-case basis.

**1.4 Yielding check of stiffeners supporting steel coils on wooden dunnage**

**1.4.1 General**

The net section modulus and the net shear sectional area of longitudinal stiffeners on inner bottom, bilge hopper sloping plate and inner hull for ships intended to carry steel coils are to comply with [1.4.2] up to a height not less than the one corresponding to the top of upper tier in touch with hopper or inner hull plating.

**1.4.2 Yielding check**

The net section modulus  $Z$ , in  $\text{cm}^3$ , and the net web thickness,  $t_w$ , in mm, of single span stiffeners located on inner bottom, bilge hopper sloping plate and inner hull are not to be taken less than:

$$Z = K_3 \frac{F_{sc}}{8 C_s R_{eH}} 10^3$$

$$t_w = \frac{0,5 F_{sc}}{d_{shr} C_t \tau_{eH}} 10^3$$

where:

- $K_3$  : Span parameter, in m, as defined in Tab 5
- $n_2$  : Number of load points per EPP of the inner bottom, see Ch 5, Sec 6, [5.1.3]
- $F_{sc}$  : Load due to steel coil cargoes, taken equal to  $F_{sc-ib-sr}$ ,  $F_{sc-ibr}$ ,  $F_{sc-hs-s}$  or  $F_{sc-hs}$  as defined in Ch 5, Sec 6, [5], depending on the considered design load set (see Ch 7, Sec 2, [2])
- $C_s$  : Permissible bending stress coefficient defined in [1.1.2]
- $C_t$  : Permissible shear stress coefficient for the design load set being considered, to be taken as:
  - 0,85 for acceptance criteria set AC-1
  - 1,00 for acceptance criteria set AC-2

**Table 5 : Coefficient  $K_3$**

$n_2 = 1$	$n_2 = 2$	$n_2 = 3$	$n_2 = 4$	$n_2 = 5$	$n_2 = 6$
$K_3 = \ell_{bdg}$	$K_3 = \ell_{bdg} - \frac{\ell_{fp}^2}{\ell_{bdg}}$	$K_3 = \ell_{bdg} - \frac{2 \ell_{fp}^2}{3 \ell_{bdg}}$	$K_3 = \ell_{bdg} - \frac{5 \ell_{fp}^2}{9 \ell_{bdg}}$	$K_3 = \ell_{bdg} - \frac{\ell_{fp}^2}{2 \ell_{bdg}}$	$K_3 = \ell_{bdg} - \frac{7 \ell_{fp}^2}{15 \ell_{bdg}}$

$n_2 = 7$	$n_2 = 8$	$n_2 = 9$	$n_2 = 10$	$n_2 > 10$	
$K_3 = \ell_{bdg} - \frac{4 \ell_{fp}^2}{9 \ell_{bdg}}$	$K_3 = \ell_{bdg} - \frac{3 \ell_{fp}^2}{7 \ell_{bdg}}$	$K_3 = \ell_{bdg} - \frac{5 \ell_{fp}^2}{12 \ell_{bdg}}$	$K_3 = \ell_{bdg} - \frac{11 \ell_{fp}^2}{27 \ell_{bdg}}$	$K_3 = 2 \ell_{bdg} / 3$	

**1.5 Deck stiffeners in way of launching appliances used for survival craft or rescue boat**

**1.5.1** The scantlings of deck stiffeners are to be determined by direct calculations.

**1.5.2** The loads exerted by launching appliance are to correspond to the SWL of the launching appliance.

**1.5.3** The combined stress, in  $\text{N/mm}^2$ , is not to exceed the smaller of  $R_{eH}/2,2$  and  $R_m/4,5$  where  $R_m$  is the ultimate minimum tensile strength of the stiffener material, in  $\text{N/mm}^2$ .

## 1.6 Plate and stiffener of different materials

**1.6.1** When the minimum specified yield stress of a stiffener exceeds the minimum specified yield stress of the attached plate by more than 35%, the following criterion is to be satisfied:

$$R_{eH+S} \leq \left( R_{eH+P} - \frac{\alpha_s |\sigma_L|}{\beta_s} \right) \frac{Z_P}{Z} + \frac{\alpha_s |\sigma_L|}{\beta_s}$$

where:

$R_{eH+S}$  : Minimum specified yield stress of the material of the stiffener, in N/mm<sup>2</sup>

$R_{eH+P}$  : Minimum specified yield stress of the material of the attached plate, in N/mm<sup>2</sup>

$\sigma_L$  : Hull girder normal stress, in N/mm<sup>2</sup>, as defined in Ch 7, Sec 2, [1.1] with  $|\sigma_L|$  not to be taken less than  $0,4 R_{eH+P}$

$Z$  : Net section modulus, in cm<sup>3</sup>, in way of face plate/free edge of the stiffener

$Z_P$  : Net section modulus, in cm<sup>3</sup>, in way of the attached plate of stiffener

$\alpha_s, \beta_s$  : Coefficients defined in Tab 2.

## 1.7 Beam analysis

### 1.7.1 Model definition

The maximum normal bending stress  $\sigma$  and shear stress  $\tau$  in a stiffener using net properties with reduced end fixity, variable load or being part of grillage are to be determined by direct calculations taking into account:

- the distribution of static and dynamic pressures and forces, if any
- the distribution of static and dynamic hull girder stresses, if any
- the number and position of intermediate supports (e.g. decks, girders, etc)
- the condition of fixity at the ends of the stiffener and at intermediate supports
- the geometrical characteristics of the stiffener on the intermediate spans.

### 1.7.2 Stress criteria

The stress is to comply with the following criteria:

a) for isolated beam analysis:

$$\tau \leq \chi K_{corr} C_t \tau_{eH}$$

$$\sigma \leq \chi C_s P_{eH}$$

b) for grillage analysis:  $\sigma_{eq} \leq \chi K_{corr} C_{comb} R_{eH}$

where:

$C_t, C_s$  : Permissible shear and bending stress coefficients defined in [1.1]

$C_{comb}$  : Permissible combined stress coefficient for the design load set being considered, as defined in Tab 2

$\sigma_{eq}$  : Equivalent Von Mises stress, in N/mm<sup>2</sup>:

$$\sigma_{eq} = \sqrt{\sigma^2 + 3\tau^2}$$

## 1.8 Buckling check

**1.8.1** The buckling check of stiffeners is to be performed according to Ch 9, Sec 1.

# Section 6 Primary Supporting Members and Pillars

## Symbols

For symbols not defined in this Section, refer to Ch 1, Sec 3.

$K_{corr}$	: Coefficient to take into account the corrosion as defined in Ch 7, Sec 4
$P$	: Design pressure, in kN/m <sup>2</sup> , for the design load set being considered as defined in Ch 7, Sec 2 and calculated at the load calculation point as defined in Ch 4, Sec 6, [4.1.1]
$l_{bdg}$	: Effective bending span, in m, as defined in Ch 4, Sec 6, [1.1.6]
$l_{shr}$	: Effective shear span, in m, as defined in Ch 4, Sec 6, [1.1.7]
$\chi$	: Coefficient as defined in Ch 7, Sec 4
$C_t$	: Permissible shear stress coefficient for the acceptance criteria set being considered, as given in Tab 2
$C_s$	: Permissible bending stress coefficient for the acceptance criteria set, as given in Tab 2
$\phi_H$	: Depth of the opening measured in the direction parallel to the web height, in m
$\alpha$	: The greater of a or S1, in m, where a and S1 are defined in [4.4.1].

## 1 Application

### 1.1 Application

#### 1.1.1 General requirements

The requirements in Article [2] apply to primary supporting members other than those covered by Article [3] and Article [4] subject to lateral pressure and/or concentrated loads, and to pillars subject to compressive and tensile axial loads.

The yielding and buckling checks are also to be carried out for members subject to any other specific loads.

#### 1.1.2 Type of structural models

Depending on the service notation, ship type, structural arrangement and length, the supporting members are to be verified according to the requirements specified in Tab 1.

#### 1.1.3 Requirements for holds intended to carry liquid cargo

The requirements in Article [3] apply to primary supporting members and vertical corrugations of bulkheads in holds intended to carry liquid cargo.

**Table 1 : Primary supporting members applicable requirements**

Ship type / length / structural arrangement	Structural models	Applicable requirements
<b>general cargo ship</b> <b>ro-ro cargo ship</b> <b>PCTC</b> <b>PCC</b> <b>ro-ro passenger ship</b> <b>passenger ship</b>	$L < 150$ m	Over whole ship length: Prescriptive or beam models (isolated beam model or grillage as applicable)
	$L \geq 150$ m	Over whole ship length: Complete ship model
All other cargo ships	$L < 150$ m	Over whole ship length: Prescriptive or beam models (isolated beam model or grillage as applicable)
	$L \geq 150$ m	<ul style="list-style-type: none"> <li>• Within cargo area: cargo hold models</li> <li>• Outside cargo area: Prescriptive or beam model</li> </ul>
	$L \geq 250$ m with large deck openings	<ul style="list-style-type: none"> <li>• Within cargo area: cargo hold models</li> <li>• Over whole ship length: Complete ship model</li> </ul>
(1) Specific prescriptive requirements in [4.7] and [4.8] applicable to dry bulk cargo holds are to be verified in addition to any direct strength analysis.		

**Table 2 : Permissible bending and shear stress coefficients for primary supporting members**

Acceptance criteria set	Structure attached to PSM	$C_s$	$C_t$	$C_{comb}$
AC-1	All boundaries, including decks and flats	0,70	0,70	0,70
AC-2		0,85	0,85	0,85
AC-3		0,90	0,90	0,90

**1.1.4 Requirements for holds intended to carry dry bulk cargo**

The requirements in Article [4] apply to primary supporting members and vertical corrugations of bulkheads in holds intended to carry dry bulk cargo.

**1.1.5 Alternative to prescriptive requirements**

Primary supporting members verified by direct strength analysis need not to comply with the requirements of this Section for all the design load scenarios already covered by such direct analysis (see typical design load scenarios for strength assessment in Ch 5, Sec 7, [2.1]).

However, the specific requirements in [4.7] and [4.8] related to the strength of corrugated bulkheads and double bottom in flooded conditions are to be applied for any hold intended to carry dry bulk cargo, irrespective of the achievement of direct strength analysis.

**2 General**

**2.1 Scantling requirements**

**2.1.1 Net section modulus**

The net section modulus  $Z_{n50}$ , in  $cm^3$ , of primary supporting members subject to lateral pressure is not to be taken less than the greatest value given by the following formula for all applicable design load sets defined in Ch 7, Sec 2, [2]:

$$Z_{n50} = 1000 \frac{|P| S \ell_{bdg}^2}{\chi f_{bdg} C_s R_{eH}}$$

where:

$f_{bdg}$  : Bending moment distribution factor, as given in Tab 3

**2.1.2 Net shear area**

The net shear area,  $A_{shr-n50}$  in  $cm^2$ , of primary supporting members subject to lateral pressure is not to be taken less than the greatest value given by the following formula for all applicable design load sets defined in Ch 7, Sec 2, [2]:

$$A_{shr-n50} = 10 \frac{f_{shr} |P| S \ell_{shr}}{\chi C_t \tau_{eH}}$$

where:

$f_{shr}$  : Shear force distribution factor, as given in Tab 3.

**2.2 Wheeled loads**

**2.2.1** For primary supporting members subject to wheeled loads, the yielding check may be carried out according to [2.1] considering uniform pressures equivalent to the distribution of vertical concentrated forces, when such forces are closely located. For the determination of the equivalent uniform pressures, the most unfavourable case, i.e. where the maximum number of axles is located on the same primary supporting member according to Fig 1 to Fig 3, is to be considered.

The equivalent static pressure  $P_{w-s}$  in  $kN/m^2$ , is to be obtained from the following formula:

$$P_{w-s} = 10 \frac{n_V Q_A}{\ell S} \left( 3 - \frac{X_1 + X_2}{S} \right)$$

where:

- $n_V$  : Maximum number of vehicles possible located on the primary supporting member
- $Q_A$  : Maximum axle load, in t, defined in Ch 5, Sec 6, [7.2.2]
- $X_1$  : Minimum distance, in m, between two consecutive axles (see Fig 2 and Fig 3)
- $X_2$  : Minimum distance, in m, between axles of two consecutive vehicles (see Fig 3)
- $\ell$  : Length of the primary supporting members (see Fig 1)
- $S$  : Primary supporting member spacing (see Fig 2)

The corresponding dynamic pressure  $P_{w-dr}$  in kN/m<sup>2</sup>, is to be calculated for the HVM and FVM load cases by using the following formula:

$$P_{w-d} = \alpha P_{w-s} \frac{az}{g}$$

where:

$\alpha$  : Coefficient taken equal to:

- 0,5 in general
- 1,0 for landing gears of trailers.

For arrangements different from those shown in Fig 1 to Fig 3, the yielding check of primary supporting members is to be carried out by a direct calculation analysis according to the requirements of Ch 7, App 1.

**Table 3 : Bending moment and shear force distribution factors  $f_{bdg}$  and  $f_{shr}$**

Load and boundary condition				Bending moment and shear force distribution factors (based on load at mid-span, where load varies)		
Load model	Position 1 Support	Position 2 Field	Position 3 Support	Position 1	Position 2	Position 3
A				$f_{bdg1} = 12,0$ $f_{shr1} = 0,50$	$f_{bdg2} = 24,0$ -	$f_{bdg3} = 12,0$ $f_{shr3} = 0,50$
B				- $f_{shr1} = 0,38$	$f_{bdg2} = 14,2$ -	$f_{bdg3} = 8,0$ $f_{shr3} = 0,63$
C				- $f_{shr1} = 0,50$	$f_{bdg2} = 8,0$ -	- $f_{shr3} = 0,50$
D				$f_{bdg1} = 15,0$ $f_{shr1} = 0,30$	$f_{bdg2} = 23,3$ -	$f_{bdg3} = 10,0$ $f_{shr3} = 0,70$
E				- $f_{shr1} = 0,20$	$f_{bdg2} = 16,8$ -	$f_{bdg3} = 7,50$ $f_{shr3} = 0,80$
F				- -	- -	$f_{bdg3} = 2,0$ $f_{shr3} = 1,0$

**Note 1:** The bending moment distribution factor  $f_{bdg}$  for the support positions is applicable for a distance of  $0,2 \ell_{bdg}$  from the end of the effective bending span of the primary supporting member.

**Note 2:** The shear force distribution factor  $f_{shr}$  for the support positions is applicable for a distance of  $0,2 \ell_{shr}$  from the end of the effective shear span of the primary supporting member.

**Note 3:** Application of  $f_{bdg}$  and  $f_{shr}$  :

The section modulus requirement within  $0,2 \ell_{bdg}$  from the end of the effective span is to be determined using the applicable  $f_{bdg1}$  and  $f_{bdg3}$ , however  $f_{bdg}$  is not to be taken greater than 12.

The section modulus of mid-span area is to be determined using  $f_{bdg} = 24$ , or  $f_{bdg2}$  from the Table if lesser.

The shear area requirement of end connections within  $0,2 \ell_{shr}$  from the end of the effective span is to be determined using  $f_{shr} = 0,5$  or the applicable  $f_{shr1}$  or  $f_{shr3}$ , whichever is greater.

For models A through F, the value of  $f_{shr}$  may be gradually reduced outside of  $0,2 \ell_{shr}$  towards  $0,5 f_{shr}$  at mid-span, where  $f_{shr}$  is the greater value of  $f_{shr1}$  and  $f_{shr3}$ .

Figure 1 : Wheeled loads - Distribution of vehicles on a primary supporting member

Figure 2 : Wheeled loads Distance between two consecutive axles

Figure 3 : Wheeled loads Distance between axles of two consecutive vehicles

### 2.3 Primary members subject to impact loads

2.3.1 The net section modulus  $Z_{n50}$ , in  $\text{cm}^3$ , of primary supporting members and their net shear area  $A_{shr-n50}$ , in  $\text{cm}^2$ , at any position along their span are not to be less than the values obtained from the following formulae:

$$Z_{n50} = \frac{f_{cb} P_1 f_{pb} \ell_{bdg}^2 b_1}{f_{bdg} C_s R_{eH}} 10^3$$

$$A_{shr-n50} = 10 \frac{\sqrt{3} Q_1}{0,9 R_{eH}}$$

where:

$f_{cb}$  : Correction factor for the bending moment at the ends and considering the patch load, taken as:

$$f_{cb} = 3f_{pb}^3 - 8f_{pb}^2 + 6f_{pb}$$

$C_s$  : 0,8 for acceptance criteria AC-4

$P_1$  : Any impact pressure defined in the Rules, including:

- bottom impact pressure, as defined in Ch 5, Sec 5, [4.2.1]
- bow impact pressure, as defined in Ch 5, Sec 5, [4.3.1]
- sloshing impact pressure, as defined in Ch 5, Sec 6, [2.2.2]
- stern impact pressure, as defined in Ch 5, Sec 5, [4.2.2]

$f_{pb}$  : Patch load modification factor for bending, taken as:

$$f_{pb} = \frac{\ell_1}{\ell_{bdg}}$$

$Q_1$  : Shear force, in kN, taken as:  $Q_1 = f_{cs} f_{dist} P_1 \ell_1 b_1$

$\ell_1$  : Extent of impact load area, in m, along the span:

$$\ell_1 = \sqrt{A_1}$$

not to be taken greater than:

- $0,5 \ell_{shr}$  for the calculation of  $Q_1$
- $\ell_{bdg}$  for the calculation of  $f_{pb}$

$f_{cs}$  : Correction factor for the proportion of patch load acting on a single primary supporting member, taken as:

$$f_{cs} = 0,5(f_{ps}^3 - 2f_{ps}^2 + 2)$$

$f_{dist}$  : Coefficient for shear force distribution along the span, as defined in Fig 4

$f_{ps}$  : Patch load modification factor for shear, taken as:

$$f_{ps} = 0,5 \frac{b_1}{S}$$

$f_{bdg}$  : 12 for primary supporting members with end fixed continuous flange or where brackets at both ends are fitted in accordance with Ch 4, Sec 5, [4.4]

$b_1$  : Breadth of impact area supported by primary supporting member, in m, taken as:

$$b_1 = \sqrt{A_1}$$

not to be taken greater than S

$$A_1 = 1,1 L B C_B 10^{-3}$$

For complex arrangements of primary supporting members, especially where grillage effect may not be ignored, for primary supporting members having variable cross sections, or for primary supporting members subject to berthing impact pressure as defined in Ch 5, Sec 5, [4.4], direct calculation is to be performed.

It is to be checked that the maximum obtained equivalent stress is not greater than  $0,85 R_{eH}$  when applying:

- in general: the load  $Q_1$  on a square area  $A_1$  to various locations on the model
- in case of berthing impact pressure: the pressure  $P_{BI}$  on an area corresponding to the fender contact zone, as specified in Tab 4.

**Figure 4 : Distribution of  $f_{dist}$  along the span of simple primary supporting members**

**Table 4 : Berthing impact area**

Ship moulded displacement $\Delta$ at $T_{sc}$ in t	Patch dimensions (m)	
	Length	Height
$8000 < \Delta \leq 50000$	3,5	2,4
$50000 < \Delta \leq 150000$	4	3
$150000 < \Delta \leq 250000$	5,5	3
$250000 < \Delta \leq 400000$	6,5	4
$\Delta > 400000$	10,6	4

## 2.4 Deck primary members in way of launching appliances used for survival craft or rescue boat

2.4.1 The scantlings of deck primary supporting members are to be determined by direct calculations.

2.4.2 The loads exerted by launching appliance are to correspond to the SWL of the launching appliance.

2.4.3 The combined stress, in N/mm<sup>2</sup>, is not to exceed the smaller of  $R_{eH}/2,2$  and  $R_m/4,5$  where  $R_m$  is the ultimate minimum tensile strength of the primary supporting member material, in N/mm<sup>2</sup>.

## 2.5 Buckling check

2.5.1 The buckling check of primary supporting members is to be performed according to Ch 9, Sec 1.

## 2.6 Pillars subject to compressive axial load

### 2.6.1 Criteria

The maximum applied compressive axial load on a pillar  $F_{pill}$ , in kN, is to be taken as the greatest value calculated for all the applicable design load sets defined in Ch 7, Sec 2, [2], and is given by the following formula:

$$F_{pill} = P b_{a-sup} \ell_{a-sup} + \sum r_i F_{pill-i}$$

where:

$b_{a-sup}$  : Mean breadth of area supported, in m

$\ell_{a-sup}$  : Mean length of area supported, in m

$F_{pill-i}$  : Axial load from the  $i^{th}$  pillar above the pillar considered, in kN, if any

$r_i$  : Coefficient which depends on the relative position of each pillar above the one considered, to be taken equal to 0,9<sup>i</sup> for the  $i^{th}$  pillar of the line above the pillar considered, to be taken not less than 0,478

$A_{pill-n50}$  : Net cross-section area of the pillar, in cm<sup>2</sup>.

### 2.6.2 Buckling check

The buckling check of pillars is to be performed according to Ch 9, Sec 1, with  $\sigma_{av}$ , in N/mm<sup>2</sup>, taken equal to:

$$\sigma_{av} = 10 \frac{F_{pill}}{A_{pill-n50}}$$

## 2.7 Pillars subject to tensile axial load

### 2.7.1 Criteria

Pillars and PSM members subject to tensile axial load are to satisfy the criteria given in [5.1.4].

## 3 Primary supporting members in holds intended to carry liquid cargo

### 3.1 Floors in double bottom

#### 3.1.1 Structural arrangement

Plate floors are to be arranged in way of transverse bulkheads and bulkhead stools.

#### 3.1.2 Net shear area

The net shear area,

$A_{shr-n50}$  in cm<sup>2</sup>, of the floors at any position in the floor is not to be less than:

$$A_{shr-n50} = \frac{8,5Q}{C_t \tau_{eH}}$$

where:

$Q$  : Design shear force, in kN.

$$Q = f_{shr} P S \ell_{shr}$$

$f_{shr}$  : Shear force distribution factor, taken as:

$$f_{shr} = f_{shr-i} \left( 1 - \frac{2y_i}{\ell_{shr}} \right)$$

without being taken less than 0,2

$f_{shr-i}$  : Shear force distribution factor at the end of the span,  $\ell_{shr}$ , as given in Tab 5

**Table 5 : Shear force distribution factors of floors**

Structural configuration	Centre tank ( $f_{shr3}$ in Fig 6)	Wing tank	
		At inboard end ( $f_{shr2}$ in Fig 6)	At hopper knuckle end ( $f_{shr1}$ in Fig 6)
Ships with centreline longitudinal bulkhead	–	0,40	0,60
Ships with two longitudinal bulkheads	0,50	0,50	0,65

- $l_{shr}$  : Effective shear span, of the double bottom floor, in m, as shown in Fig 5. In way of bracket ends, the effective shear span is measured to the toes of the effective end bracket, as defined in Ch 4, Sec 6, [1.1.7]. Where the floor ends on a girder at a hopper or stool structure, the effective shear span is measured to a point that is one-half of the distance from the girder to the adjacent bottom and inner-bottom longitudinal, as shown in Fig 5
- $y_i$  : Distance from the considered cross section of the floor to the nearest end of the effective shear span,  $l_{shr}$  in m.
- P : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid point of effective shear span,  $l_{shr}$  of a floor located midway between transverse bulkheads or transverse bulkhead and wash bulkhead, where fitted, in  $kN/m^2$ .

**Figure 5 : Effective shear span of floors**

Typical arrangement with hopper and end bracket

Typical arrangement with hopper and stool

**Figure 6 : Shear force distribution factors of floors**

### 3.2 Girders in double bottom

#### 3.2.1 Structural arrangement

Continuous double bottom girders are to be arranged at the centreline or duct keel, at the hopper side, in way of longitudinal bulkheads and bulkhead stools and in way of flanges of vertically corrugated bulkheads without stools.

#### 3.2.2 Net shear area of centre girders

For double bottom centre girders where no longitudinal bulkhead is fitted above, the net shear area,  $A_{shr-n50}$  in  $cm^2$ , of the double bottom centre girder in way of the first bay from each transverse bulkhead and wash bulkhead, where fitted, is not to be less than:

$$A_{shr-n50} = \frac{8,5Q}{C_t \tau_{eH}}$$

where:

Q : Design shear force, in kN, taken as:

$$Q = 0,21 n_1 n_2 P \ell_{shr}^2$$

$\ell_{shr}$  : Effective shear span as defined in [3.1.2]

P : Design pressure, in  $kN/m^2$ , as defined in [3.1.2]

$n_1$  : Coefficient taken as:

$$n_1 = 0,00935 \left( \frac{\ell_{shr}}{S} \right)^2 - 0,163 \left( \frac{\ell_{shr}}{S} \right) + 1,289$$

$n_2$  : Coefficient taken as:

$$n_2 = 1,3 - \left( \frac{S}{12} \right)$$

S : Double bottom floor spacing, in m, as defined in Ch 4, Sec 6, [1.2.2].

#### 3.2.3 Net shear area of side girders

For double bottom side girders where no longitudinal bulkhead is fitted above, the net shear area,  $A_{shr-n50}$  in  $cm^2$ , of the double bottom side girder in way of the first bay from each transverse bulkhead and wash bulkhead, where fitted, is not to be less than:

$$A_{shr-n50} = \frac{8,5Q}{C_t \tau_{eH}}$$

where:

Q : Design shear force, in kN.

$$Q = 0,14 n_3 n_4 P \ell_{shr}^2$$

$n_3$  : Coefficient taken as:

$$n_3 = 1,072 - 0,0357 \left( \frac{\ell_{shr}}{S} \right)$$

$n_4$  : Coefficient taken as:

$$n_4 = 1,2 - \left( \frac{S}{18} \right)$$

S : Double bottom floor spacing, in m, as defined in Ch 4, Sec 6, [1.2.2]

$\ell_{shr}$  : Effective shear span as defined in [3.1.2]

P : Design pressure, in  $kN/m^2$ , as defined in [3.1.2].

### 3.3 Deck transverses

#### 3.3.1 Web depth

The web depth of deck transverses fitted under the deck is not to be less than:

- 0,20  $\ell_{bdg-dt}$  for deck transverses in the wing cargo tanks of ships with two longitudinal bulkheads
- 0,13  $\ell_{bdg-dt}$  for deck transverses in the centre cargo tanks of ships with two longitudinal bulkheads. The web depth of deck transverses in the centre cargo tank is not to be less than 90% of that of the deck transverses in the wing cargo tank
- 0,10  $\ell_{bdg-dt}$  for the deck transverses of ships with a centreline longitudinal bulkhead
- 2,5 times the depth of the slots for stiffeners if slots are not closed.

The web depth of deck transverses fitted above the deck is not to be less than:

- 0,10  $\ell_{bdg-dt}$
- 2,5 times the depth of the slots for stiffeners if slots are not closed.

where:

$\ell_{bdg-dt}$  : Effective bending span, in m, as defined in [3.3.2].

**3.3.2 Net section modulus of deck transverses fitted below the upper deck**

The net section modulus of deck transverses fitted below the upper deck, in  $cm^3$ , is not to be less than  $Z_{in-n50}$  and  $Z_{ex-n50}$  as given by the following formulae.

The net section modulus of the deck transverses fitted below the upper deck in the wing cargo tanks is also not to be less than required for the deck transverses fitted below the upper deck in the centre tanks.

$$Z_{in-n50} = \frac{850 M_{in}}{C_s R_{eH}}$$

$$Z_{ex-n50} = \frac{850 M_{ex}}{C_s R_{eH}}$$

where:

$M_{in}$  : Design bending moment due to cargo pressure, in kNm, taken as:

- For deck transverses in wing cargo tanks of ships with two longitudinal bulkheads, and for deck transverses in cargo tanks of ships with a centreline longitudinal bulkhead:

$$M_{in} = 0,042 \varphi_t P_{in-dt} S \ell_{bdg-dt}^2 + M_{st}$$

without being taken less than  $M_0$

- For deck transverses in centre cargo tank of ships with two longitudinal bulkheads:

$$M_{in} = 0,042 \varphi_t P_{in-dt} S \ell_{bdg-dt}^2 + M_{vw}$$

without being taken less than  $M_0$

$M_{st}$  : Bending moment transferred from the side transverse, in kNm:

$$M_{st} = c_{st} \beta_{st} P_{in-st} S \ell_{bdg-st}^2$$

where a cross tie is fitted in a wing cargo tank and  $\ell_{bdg-st-ct}$  is greater than  $0,7 \ell_{bdg-st}$ , then  $\ell_{bdg-st}$  in the above formula may be taken as  $\ell_{bdg-st-ct}$

$M_{vw}$  : Bending moment transferred from the vertical web frame on the longitudinal bulkhead, in kNm:

$$M_{vw} = c_{vw} \beta_{vw} P_{in-vw} S \ell_{bdg-vw}^2$$

where  $\ell_{bdg-vw-ct}$  is greater than  $0,7 \ell_{bdg-vw}$ , then  $\ell_{bdg-vw}$  in the above formula may be taken as  $\ell_{bdg-vw-ct}$ . For vertically corrugated bulkheads,  $M_{vw}$  is to be taken equal to bending moment in upper end of corrugation over the spacing between deck transverses

$M_0$  : Minimum bending moment, in kNm

$$M_0 = 0,083 P_{in-dt} S \ell_{bdg-dt}^2$$

$M_{ex}$  : Design bending moment due to green sea pressure, in kNm

$$M_{ex} = 0,067 P_{ex-dt} S \ell_{bdg-dt}^2$$

$P_{in-dt}$  : Design cargo pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid-point of effective bending span,  $\ell_{bdg-dt}$  of the deck transverse located at mid tank, in  $kN/m^2$

$P_{in-st}$  : Corresponding design cargo pressure in wing cargo tank for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at the mid-point of effective bending span,  $\ell_{bdg-st}$  of the side transverse located at mid-tank, in  $kN/m^2$

$P_{in-vw}$  : Corresponding design cargo pressure in the centre cargo tank of ships with two longitudinal bulkheads for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid-point of effective bending span,  $\ell_{bdg-vw}$  of the vertical web frame on the longitudinal bulkhead located at mid-tank, in  $kN/m^2$

$P_{ex-dt}$  : Design green sea pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid-point of effective bending span,  $\ell_{bdg-dt}$  of the deck transverse located at mid tank, in  $kN/m^2$

$\varphi_t$  : Coefficient taken as:

$$\varphi_t = 1 - 5 \left( \frac{y_{toe}}{\ell_{bdg-dt}} \right)$$

without being taken less than 0,6

$y_{toe}$  : Distance from the end of effective bending span,  $\ell_{bdg-dt}$  to the toe of the end bracket of the deck transverse, in m

$\beta_{st}$  : Coefficient taken as:

$$\beta_{st} = \left( 0,9 \left( \frac{\ell_{bdg-st}}{\ell_{bdg-dt}} \right) \left( \frac{\ell_{dt-n50}}{\ell_{st-n50}} \right) \right)$$

without being taken less than 0,10 or greater than 0,65

$\beta_{vw}$  : Coefficient taken as:

$$\beta_{vw} = 0,9 \left( \frac{\ell_{bdg-vw}}{\ell_{bdg-dt}} \right) \left( \frac{I_{dt-n50}}{I_{vw-n50}} \right)$$

without being taken less than 0,10 or greater than 0,50

- $\ell_{bdg-dt}$  : Effective bending span of the deck transverse, in m, see Ch 4, Sec 6, [1.1.6] and Fig 7, but is not to be taken as less than 60% of the breadth of the tank at the location being considered
- $\ell_{bdg-st}$  : Effective bending span of the side transverse, in m, between the deck transverse and the bilge hopper, see Ch 4, Sec 6, [1.1.6] and Fig 7
- $\ell_{bdg-st-ct}$  : Effective bending span of the side transverse, in m, between the deck transverse and the mid depth of the cross tie, where fitted in wing cargo tank, see Ch 4, Sec 6, [1.1.6]
- $\ell_{bdg-vw}$  : Effective bending span of the vertical web frame on the longitudinal bulkhead, in m, between the deck transverse and the bottom structure, see Ch 4, Sec 6, [1.1.6] and Fig 7
- $\ell_{bdg-vw-ct}$  : Effective bending span of the vertical web frame on longitudinal bulkhead, in m, between the deck transverse and the mid depth of the cross tie, see Ch 4, Sec 6, [1.1.6]
- $I_{dt-n50}$  : Net moment of inertia of the deck transverse at mid-span with an effective breadth of attached plating specified in Ch 4, Sec 6, [1.3.2], in  $cm^4$
- $I_{st-n50}$  : Net moment of inertia of the side transverse at mid-span with an effective breadth of attached plating specified in Ch 4, Sec 6, [1.3.2], in  $cm^4$
- $I_{vw-n50}$  : Net moment of inertia of the longitudinal bulkhead vertical web frame at mid-span with an effective breadth of attached plating specified in Ch 4, Sec 6, [1.3.2], in  $cm^4$
- $C_{st}$  : Coefficient given in Tab 6
- $C_{vw}$  : Coefficient given in Tab 6.

**Figure 7 : Definition of spans of deck, side transverses, vertical web frames on longitudinal bulkheads and horizontal stringers on transverse bulkheads**

**Table 6 : Values of  $c_{st}$  and  $c_{vw}$  for deck transverses**

Structural configuration		$C_{st}$	$C_{vw}$
Ships with centreline longitudinal bulkhead		0,056	-
Ships with two longitudinal bulkheads	Cross tie in centre cargo tank	$M_{vw}$ based on $\ell_{bdg-vw-ct}$	0,044
		$M_{st}$ based on $\ell_{bdg-st}$ or $M_{vw}$ based on $\ell_{bdg-vw}$	0,044
	Cross ties in wing cargo tanks	$M_{st}$ based on $\ell_{bdg-st-ct}$ or $M_{vw}$ based on $\ell_{bdg-vw-ct}$	0,044
		$M_{st}$ based on $\ell_{bdg-st}$ or $M_{vw}$ based on $\ell_{bdg-vw}$	0,041

**3.3.3 Net shear area of deck transverses fitted below the upper deck**

The net shear area of deck transverses fitted below the upper deck, in cm<sup>2</sup>, is not to be less than  $A_{shr-in-n50}$  and  $A_{shr-ex-n50}$  as given by:

$$A_{shr-in-n50} = \frac{8,5 Q_{in}}{C_1 \tau_{eH}}$$

$$A_{shr-ex-n50} = \frac{8,5 Q_{ex}}{C_1 \tau_{eH}}$$

where:

- $Q_{in}$  : Design shear force due to cargo pressure, in kN  
 $Q_{in} = 0,65 P_{in-dt} S_{\ell_{shr}} + c_I D b_{ctr} S_{\rho_L} g$
- $Q_{ex}$  : Design shear force due to green sea pressure, in kN  
 $Q_{ex} = 0,65 P_{ex-dt} S_{\ell_{shr}}$
- $P_{in-dt}$  : Design pressure in kN/m<sup>2</sup>, defined in [3.3.2]
- $P_{ex-dt}$  : Design pressure in kN/m<sup>2</sup>, defined in [3.3.2]
- $\ell_{bdg-dt}$  : Effective span, in m, defined in [3.3.2]
- $\ell_{shr}$  : Effective shear span, of the deck transverse, in m, see Ch 4, Sec 6, [1.1.7]
- $C_1$  : Coefficient taken as:
  - $c_1 = 0,04$  in way of wing cargo tanks of ships with two longitudinal bulkheads
  - $c_1 = 0,00$  in way of centre tank of ships with two longitudinal bulkheads
  - $c_1 = 0,00$  for ships with a centreline longitudinal bulkhead
- $b_{ctr}$  : Breadth of the centre tank, in m.

**3.3.4 Deck transverses fitted above the upper deck**

When deck transverses are fitted above the upper deck, the net section modulus and shear area of deck transverses are not to be less than  $Z_{n50}$  and  $A_{shr-n50}$ , in cm<sup>3</sup> and cm<sup>2</sup> respectively, as given by the following formulae. The required section modulus and shear area are to be maintained over the full length of span.

$$Z_{n50} = \frac{850 |P| S_{\ell_{bdg}}^2}{f_{bdg} C_s R_{eH}}$$

$$A_{shr-n50} = \frac{8,5 f_{shr} |P| S_{\ell_{shr}}}{C_1 \tau_{eH}}$$

where:

- $P$  : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at midpoint of effective bending span,  $\ell_{bdg}$  of the deck transverse located at mid tank, in kN/m<sup>2</sup>
- $f_{bdg}$  : Coefficient taken as:
  - $f_{bdg} = 12$  for design load set LC-1, LC-2, LC-3 and LC-4 as defined in Ch 7, Sec 2, Tab 4
  - $f_{bdg} = 15$  for design load set SEA-1 as defined in Ch 7, Sec 2, Tab 4
- $f_{shr}$  : Coefficient taken as:  $f_{shr} = 0,5$
- $\ell_{bdg}$  : Effective bending span of the deck transverse fitted above upper deck, in m, measured from inner hull welded to deck to longitudinal bulkhead, or upper stool plating where upper stool is fitted
- $\ell_{shr}$  : Effective shear span of the deck transverse fitted above upper deck, in m, measured from inner hull welded to deck to longitudinal bulkhead, or upper stool plating where upper stool is fitted

As an alternative, the required section modulus and shear area may be obtained by finite element method in accordance with Part B, Chapter 8 considering the following loading patterns with draught equal to  $T_{sc}$  and cargo density of 1,025 t/m<sup>3</sup>:

- For ships with two longitudinal oil-tight bulkheads:
  - aft-holds and fore-holds full, mid-holds empty on both sides and full on center
  - aft-holds and fore-holds full, mid-holds full on sides and empty on center
- For ships with one centerline oil-tight bulkhead:
  - aft-holds and fore-holds full, mid-holds empty on portside and full on starboard
  - aft-holds and fore-holds full, mid-holds full on portside and empty on starboard.

**3.3.5 Deck transverse adjacent to transverse bulkhead**

The scantling of deck transverse adjacent to the transverse bulkhead is to comply with the requirements of [3.3.2] to [3.3.4] for design green sea pressure only.

**3.4 Side transverses**

**3.4.1 Net shear area**

The net shear area,  $A_{shr-n50}$ , in  $cm^2$ , of side transverses is not to be less than:

$$A_{shr-n50} = \frac{8,5Q}{C_t \tau_{eH}}$$

where:

$Q$  : Design shear force as follows, in kN:

$Q = Q_u$  for upper part of the side transverse

$Q = Q_l$  for lower part of the side transverse

$Q_u$  : Shear force, in kN, taken as:

$$Q_u = S [c_u \ell_{st} (P_u + P_l) - h_u P_u]$$

where a cross tie is fitted in a wing cargo tank and  $\ell_{st-ct}$  is greater than  $0,7 \ell_{str}$ , then  $\ell_{st}$  in the above formula is taken as  $\ell_{st-ct}$

$Q_l$  : Shear force, in kN, taken as the greater of the following:

- $S [c_l \ell_{st} (P_u + P_l) - h_l P_l]$

- $0,35 c_l S \ell_{st} (P_u + P_l)$

- $1,2 Q_u$

where a cross tie is fitted in a wing cargo tank and  $\ell_{st-ct}$  is greater than  $0,7 \ell_{str}$ , then  $\ell_{st}$  in the above formula is taken as  $\ell_{st-ct}$

$P_u$  : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, in  $kN/m^2$ , calculated at mid length of tank and at mid height of  $h_u$

$P_l$  : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid height  $h_l$  located at mid length of tank, in  $kN/m^2$

$\ell_{st}$  : Length of the side transverse, in m, taken as follows:

- where deck transverses are fitted below deck,  $\ell_{st}$  is the length between the flange of the deck transverse and the inner bottom, see Fig 7

- where deck transverses are fitted above deck,  $\ell_{st}$  is the length between the elevation of the deck at side and the inner bottom

$\ell_{st-ct}$  : Length of the side transverse, in m, taken as follows:

- where deck transverses are fitted below deck,  $\ell_{st-ct}$  is the length between the flange of the deck transverse and mid depth of cross tie, where fitted in wing cargo tank

- where deck transverses are fitted above deck,  $\ell_{st-ct}$  is the length between the elevation of the deck at side and mid depth of the cross tie, where fitted in wing cargo tank

$h_u$  : Effective length of upper bracket of the side transverse, in m, taken as follows:

- where deck transverses are fitted below deck,  $h_u$  is as shown in Fig 7

- where deck transverses are fitted above deck:

- when an inner hull longitudinal bulkhead is arranged with a top wing structure as follows,  $h_u$  is taken as the distance between the deck at side and the lower end of slope plate of the top wing structure:

- the breadth at top of the wing structure is greater than 1,5 times the breadth of the double side and

- the angle along a line between the point at base of the slope plate at its intersection with the inner hull longitudinal bulkhead and the point at the intersection of top wing structure and deck is 30 deg or more to vertical

- in the other cases:  $h_u$  is taken as 0

$h_l$  : Height of bilge hopper, in m, as shown in Fig 7

$c_u$  : Coefficient defined in Tab 7

$c_l$  : Coefficient defined in Tab 7.

**Table 7 : Values of  $c_u$  and  $c_l$  for side transverses**

Structural configuration			$c_u$		$c_l$	
			< three	$\geq$ three	< three	$\geq$ three
Number of side stringers			< three	$\geq$ three	< three	$\geq$ three
Ships with a centreline longitudinal bulkhead						
Ships with two longitudinal bulkheads	Cross tie in centre cargo tank		0,12	0,09	0,29	0,21
	Cross ties in wing cargo tanks	$Q_u$ or $Q_l$ based on $\ell_{st-ct}$				
		$Q_u$ or $Q_l$ based on $\ell_{st}$	0,08		0,20	

**3.4.2 Shear area over the length of the side transverse**

The shear area over the length of the side transverse is to comply with the following. When materials of different yield stress are employed, appropriate adjustments are to be made to account for differences in material yield stress.

- a) The required shear area for the upper part is to be maintained over the upper 0,2  $\ell_{shr}$ .
- b) The required shear area for the lower part is to be maintained over the lower 0,2  $\ell_{shr}$ .
- c) Where  $Q_u$  and  $Q_l$  are determined based on  $\ell_{st-ctr}$  the required shear area for the lower part is also to be maintained below the cross tie.
- d) For ships without cross ties in the wing cargo tanks, the required shear area between the upper and lower parts is to be reduced linearly towards 50% of the required shear area for the lower part at mid-span.
- e) For ships with cross ties in the wing cargo tanks, the required shear area along the span is to be tapered linearly between the upper and lower parts.

where:

$\ell_{shr}$  : Effective shear span of the side transverse, in m

$$\ell_{shr} = \ell_{st} - h_u - h_l$$

where  $Q_u$  and  $Q_l$  are determined based on  $\ell_{st}$

$$\ell_{shr} = \ell_{st-ct} - h_u$$

where  $Q_u$  and  $Q_l$  are determined based on  $\ell_{st-ct}$

$\ell_{str}$ ,  $\ell_{st-ctr}$ ,  $h_u$ ,  $h_l$ ,  $Q_u$ ,  $Q_l$  : Parameters defined in [3.4.1].

**3.5 Vertical web frames on longitudinal bulkhead**

**3.5.1 Web depth**

The web depth of the vertical web frame on the longitudinal bulkhead is not to be less than:

- 0,14  $\ell_{bdg-vw}$  for ships with a centreline longitudinal bulkhead
- 0,09  $\ell_{bdg-vw}$  for ships with two longitudinal bulkheads
- 2,5 times the depth of the slots for stiffeners if slots are not closed.

where:

$\ell_{bdg-vw}$  : Effective bending span, in m, defined in [3.5.2].

**3.5.2 Net section modulus**

The net section modulus,  $Z_{n50}$  in  $cm^3$ , of the vertical web frame is not to be less than:

$$Z_{n50} = \frac{850M}{C_s R_{eH}}$$

where:

M : Design bending moment, in kNm, as follows:

$$M = c_u P S \ell_{bdg-vw}^2$$

- for upper part of the web frame:

$$M = c_l P S \ell_{bdg-vw}^2$$

- for lower part of the web frame:

where a cross tie is fitted and  $\ell_{bdg-vw-ct}$  is greater than 0,7  $\ell_{bdg-vw}$  then  $\ell_{bdg-vw}$  in the above formula is to be taken as  $\ell_{bdg-vw-ct}$ .

P : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid-point of the effective bending span,  $\ell_{bdg-vw}$  of the vertical web frame located at mid tank, in  $kN/m^2$

$\ell_{bdg-vw}$  : Effective bending span of the vertical web frame on the longitudinal bulkhead, between the deck transverse and the bottom structure, in m, see Fig 7

$\ell_{bdg-vw-ct}$  : Effective bending span of the vertical web frame on longitudinal bulkhead, between the deck transverse and mid-depth of the cross tie on ships with two longitudinal bulkheads, in m

$c_u$  : Coefficient defined in Tab 8

$c_l$  : Coefficient defined in Tab 8.

Table 8 : Values of  $c_u$  and  $c_l$  for vertical web frame on longitudinal bulkheads

Structural configuration		$c_u$	$c_l$
Ships with a centreline longitudinal bulkhead		0,057	0,071
Ships with two longitudinal bulkheads	Cross tie in centre cargo tank	M based on $l_{bdg-vw-ct}$	0,057
		M based on $l_{bdg-vw}$	0,012
	Cross ties in wing cargo tanks	M based on $l_{bdg-vw-ct}$	0,057
		M based on $l_{bdg-vw}$	0,016

**3.5.3 Section modulus over the length of the vertical web frame**

The section modulus over the length of the vertical web frame on the longitudinal bulkhead is to comply with the following. When materials of different yield stress are employed, appropriate adjustments are to be made to account for differences in material yield stress.

- a) The required section modulus for the upper part is to be maintained over the upper  $0,2 l_{bdg-vw}$  or  $0,2 l_{bdg-vw-ct}$  as applicable.
- b) The required section modulus for the lower part is to be maintained over the lower  $0,2 l_{bdg-vw}$  or  $0,2 l_{bdg-vw-ct}$  as applicable.
- c) Where the required section modulus is determined based on  $l_{bdg-vw-ct}$  the required section modulus for the lower part is also to be maintained below the cross tie.
- d) The required section modulus between the upper and lower parts is to be reduced linearly to 70% of the required section modulus for the lower part at mid-span.

where:

$l_{bdg-vw}$ ,  $l_{bdg-vw-ct}$  : Effective bending span, in m, defined in [3.5.2].

**3.5.4 Net shear area**

The net shear area,  $A_{shr-n50}$  in  $cm^2$ , of the vertical web frame is not to be less than:

$$A_{shr-n50} = \frac{8,5Q}{C_t \tau_{eH}}$$

where:

Q : Design shear force as follows, in kN:

Q =  $Q_u$  for upper part of the web frame

Q =  $Q_l$  for lower part of the web frame

$Q_u$  : Shear force, in kN, taken as:

$$Q_u = S [c_u l_{vw} (P_u + P_l) - h_u P_u]$$

where a cross tie is fitted in a centre or wing cargo tank and  $l_{vw-ct}$  is greater than  $0,7 l_{vw}$  then  $l_{vw}$  in the above formula is to be taken as  $l_{vw-ct}$

$Q_l$  : Shear force, in kN, taken as the greater of the following:

- $S [c_l l_{vw} (P_u + P_l) - h_l P_l]$
- $c_w S c_l l_{vw} (P_u + P_l)$
- $1,2 Q_u$

where a cross tie is fitted in a centre or wing cargo tank and  $l_{vw-ct}$  is greater than  $0,7 l_{vw}$  then  $l_{vw}$  in the above formula is to be taken as  $l_{vw-ct}$

$P_u$  : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid-height of upper bracket of the vertical web frame,  $h_u$  located at mid tank, in  $kN/m^2$

$P_l$  : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid-height of lower bracket of the vertical web frame,  $h_l$  located at mid tank, in  $kN/m^2$

$l_{vw}$  : Length of the vertical web frame, in m, between the flange of the deck transverse and the inner bottom, see Fig 7

$l_{vw-ct}$  : Length of the vertical web frame, in m, between the flange of the deck transverse and mid-depth of the cross tie, where fitted

$h_u$  : Effective length of upper bracket of the vertical web frame, in m, as shown in Fig 7

$h_l$  : Effective length of lower bracket of the vertical web frame, in m, as shown in Fig 7

$c_u$  : Coefficient defined in Tab 9

$c_l$  : Coefficient defined in Tab 9

$c_w$  : Coefficient taken as:

- $c_w = 0,57$  for ships with a centreline longitudinal bulkhead,
- $c_w = 0,50$  for ships with two longitudinal bulkheads.

**Table 9 : Values of  $c_u$  and  $c_l$  for vertical web frame on longitudinal bulkhead**

Structural configuration		$c_u$	$c_l$
Ships with a centreline longitudinal bulkhead		0,17	0,28
Ships with two longitudinal bulkheads			
	$Q_u$ or $Q_l$ based on $l_{vw-ctr}$		
	$Q_u$ or $Q_l$ based on $l_{vw}$	0,075	0,18

**3.5.5 Shear area over the length of the vertical web frame**

The shear area over the length of the vertical web frame on the longitudinal bulkhead is to comply with the following. When materials of different yield stress are employed, appropriate adjustments are to be made to account for differences in material yield stress.

- a) The required shear area for the upper part is to be maintained over the upper  $0,2 l_{shr}$ .
- b) The required shear area for the lower part is to be maintained over the lower  $0,2 l_{shr}$ .
- c) Where  $Q_u$  and  $Q_l$  are determined based on  $l_{vw-ctr}$  the required shear area for the lower part is also to be maintained below the cross tie.
- d) For ships without cross ties in the wing or centre cargo tanks, the required shear area between the upper and lower parts is to be reduced linearly towards 50% of the required shear area for the lower part at mid-span.
- e) For ships with cross ties in the wing or centre cargo tanks, the required shear area along the span is to be tapered linearly between the upper and lower parts.

where:

$l_{shr}$  : Effective shear span of the vertical web frame, in m.

$$l_{shr} = l_{vw} - h_u - h_l$$

where  $Q_u$  and  $Q_l$  are determined based on  $l_{vw}$

$$l_{shr} = l_{vw-ctr} - h_u$$

where  $Q_u$  and  $Q_l$  are determined based on  $l_{vw-ctr}$

$l_{vw}$ ,  $l_{vw-ctr}$ ,  $h_u$ ,  $h_l$ ,  $Q_u$ ,  $Q_l$  : Parameters defined in [3.5.4].

**3.6 Horizontal stringers on transverse bulkheads**

**3.6.1 Web depth**

The web depth of horizontal stringers on transverse bulkhead is not to be less than:

- $0,28 l_{bdg-hs}$  for horizontal stringers in wing cargo tanks of ships with two longitudinal bulkheads
- $0,20 l_{bdg-hs}$  for horizontal stringers in centre tanks of ships with two longitudinal bulkheads, but the web depth of horizontal stringers in centre tank is not to be less than required depth for a horizontal stringer in wing cargo tanks
- $0,20 l_{bdg-hs}$  for horizontal stringers of ships with a centreline longitudinal bulkhead
- 2,5 times the depth of the slots for stiffeners if slots are not closed.

where:

$l_{bdg-hs}$  : Effective bending span, in m, defined in [3.6.2].

**3.6.2 Net section modulus**

The net section modulus,  $Z_{n50}$  in  $cm^3$ , of the horizontal stringer over the end  $0,2 l_{bdg-hs}$  is not to be less than:

$$Z_{n50} = \frac{850M}{C_s R_{eH}}$$

where:

M : Design bending moment, in kNm

$$M = c P S l_{bdg-hs}^2$$

P : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid-point of effective bending span,  $l_{bdg-hs}$  and at mid-point of the spacing, S of the horizontal stringer, in  $kN/m^2$

$l_{bdg-hs}$  : Effective bending span of the horizontal stringer, in m, but is not to be taken as less than 50% of the breadth of the tank at the location being considered, see Fig 7

c : Coefficient taken as:

- $c = 0,073$  for horizontal stringers in cargo tanks of ships with a centreline bulkhead
- $c = 0,083$  for horizontal stringers in wing cargo tanks of ships with two longitudinal bulkheads
- $c = 0,063$  for horizontal stringers in the centre tank of ships with two longitudinal bulkheads.

### 3.6.3 Section modulus over the length of horizontal stringers

The required section modulus at mid effective bending span is to be taken as 70% of that required at the ends, intermediate values are to be obtained by linear interpolation. When materials of different yield stress are employed, appropriate adjustments are to be made to account for differences in material yield stress.

### 3.6.4 Net shear area

The net shear area,  $A_{shr-n50}$  in  $cm^2$ , of the horizontal stringer over the end  $0,2 \ell_{shr}$  is not to be less than:

$$A_{shr-n50} = \frac{8,5Q}{C_t \tau_{eH}}$$

where:

$Q$  : Design shear force, in kN

$$Q = 0,5P S_{hs} \ell_{shr}$$

$P$  : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 4, calculated at mid-point of effective bending span,  $\ell_{bdg-hs}$  and at mid-point of the spacing,  $S$  of the horizontal stringer, in  $kN/m^2$

$S_{hs}$  : Spacing, in m, defined in [3.6.2]

$\ell_{shr}$  : Effective shear span of the horizontal stringer, in m.

### 3.6.5 Shear area at mid effective shear span

The required shear area at mid effective shear span is to be taken as 50% of that required in the ends, intermediate values are to be obtained by linear interpolation. When materials of different yield stress are employed, appropriate adjustments are to be made to account for differences in material yield stress.

## 3.7 Cross ties

### 3.7.1 Maximum applied design axial load

The maximum applied design axial load on cross ties,  $W_{ct}$  is to be less than or equal to the permissible load,  $W_{ct-perm}$  as given by:

$$W_{ct} \leq W_{ct-perm}$$

where:

$W_{ct}$  : Applied axial load, in kN.

$$W_{ct} = P b_{ct} S$$

$W_{ct-perm}$  : Permissible load, in kN.

$$W_{ct-perm} = 0,12 A_{ct-n50} \eta_{all} \sigma_{cr}$$

$P$  : Maximum design pressure for all the applicable design load sets being considered as defined in Ch 7, Sec 2, Tab 4, calculated at centre of the area supported by the cross tie located at mid tank, in  $kN/m^2$

$b_{ct}$  : Span, in m, taken as:

- Cross tie fitted in centre cargo tank:  
 $b_{ct} = 0,5 \ell_{bdg-vw}$
- Cross ties fitted in wing cargo tanks:
  - $b_{ct} = 0,5 \ell_{bdg-vw}$  for design cargo pressure from the centre cargo tank
  - $b_{ct} = 0,5 \ell_{bdg-st}$  for design sea pressure

$\ell_{bdg-vw}$  : Effective bending span, in m, defined in [3.3.2]

$\ell_{bdg-st}$  : Effective bending span, in m, defined in [3.3.2]

$\eta_{all}$  : Allowable buckling utilisation factor as defined in Ch 9, Sec 1, [1.2]

$\sigma_{cr}$  : Critical buckling stress in compression of the cross tie, in  $N/mm^2$ , as calculated using the net sectional properties in accordance with NR615, Sec 5, [3.1.1]

$A_{ct-n50}$  : Net cross sectional area of the cross tie, in  $cm^2$ .

### 3.7.2 Welded connections

Special attention is to be paid to the adequacy of the welded connections for the transmission of the forces, and also to the stiffening arrangements, in order to provide effective means for transmission of the compressive forces into the webs.

Particular attention is to be paid to the welding at the toes of all end brackets of the cross ties.

### 3.7.3 Horizontal stiffeners

Horizontal stiffeners are to be located in line with, and attached to, the longitudinals at the ends of the cross ties.

### 3.8 Vertically corrugated bulkheads separating liquid cargo holds

#### 3.8.1 Application

In addition to the requirements of Ch 7, Sec 4, [1.2], vertically corrugated bulkheads separating liquid cargo holds are also to comply with the requirements of [3.8.2] to [3.8.5].

#### 3.8.2 Net plate thickness over the height

The net plate thicknesses as required by [3.8.4] is to be maintained for two thirds of the corrugation length,  $\ell_{cg}$  from the lower end. Above that, the net plate thickness may be reduced by 20% from the net thickness required in [3.8.4] for the mid part of the corrugation provided that the net section modulus of the upper end of the corrugation complies with [3.8.5].

#### 3.8.3 Net web plating thickness over the height

The net web plating thickness of the lower 15% of the corrugation,  $t_w$  in mm, is to be taken as the greatest value calculated for all applicable design load sets, as given in Ch 7, Sec 2, [2], and given by the following. This requirement is not applicable to corrugated bulkheads without a lower stool.

$$t_w = \frac{1000|Q_{cg}|}{d_{cg}K_{corr}\chi C_{t-cg}\tau_{eH}}$$

where:

$Q_{cg}$  : Design shear force imposed on the web plating at the lower end of the corrugation, in kN

$$Q_{cg} = \frac{s_{cg} \ell_{cg} |3P_l + P_u|}{8000}$$

$P_l$  : Design pressure given in Ch 7, Sec 2, Tab 1 for the design load set being considered, calculated at the lower end of the corrugation, in kN/m<sup>2</sup>

$P_u$  : Design pressures given in Ch 7, Sec 2, Tab 1 for the design load set being considered, calculated at the upper end of the corrugation, in kN/m<sup>2</sup>

$d_{cg}$  : Depth of corrugation, in mm, see Fig 8

$C_{t-cg}$  : Permissible shear stress coefficient:

- $C_{t-cg} = 0,75$  for acceptance criteria set AC-1
- $C_{t-cg} = 0,90$  for acceptance criteria set AC-2
- $C_{t-cg} = 0,95$  for acceptance criteria set AC-3.

#### 3.8.4 Net thicknesses of the flanges over the height

The net thicknesses of the flanges of corrugated bulkheads,  $t_f$  in mm, for two thirds of the corrugation length from the lower end are to be taken as the greatest value calculated for all applicable design load sets, as given in Ch 7, Sec 2, [2], and given by the following. This requirement is not applicable to corrugated bulkheads without a lower stool.

$$t_f = \frac{6,57 b_{f-cg} \sqrt{\sigma_{bdg-max}}}{C_f} 10^{-3}$$

where:

$\sigma_{bdg-max}$  : Maximum value of the vertical bending stresses in N/mm<sup>2</sup> in the flange. The bending stress is to be calculated at the lower end and at the mid span of the corrugation length:

$$\sigma_{bdg-max} = \frac{M_{cg}}{Z_{cg-act}} 10^3$$

$M_{cg}$  : Vertical bending moment, in kNm, as defined in [3.8.5]

$Z_{cg-act}$  : Actual net section modulus at the lower end and at the mid length of a unit corrugation, in cm<sup>3</sup>

$b_{f-cg}$  : Breadth of flange plating, in mm. See Fig 8

$b_{w-cg}$  : Breadth of web plating, in mm. See Fig 8

$C_f$  : Coefficient taken as:

$$C_f = 7,65 - \left(0,26 \left(\frac{b_{w-cg}}{b_{f-cg}}\right)^2\right)$$

#### 3.8.5 Net section modulus over the height

The net section modulus at the lower and upper ends and at the mid length of the corrugation ( $\ell_{cg} / 2$ ) of a unit corrugation of vertically corrugated bulkheads separating liquid cargo holds,  $Z_{cg}$  are to be taken as the greatest value calculated for all applicable design load sets, as given in Ch 7, Sec 2, [2] and given by the following.

$$Z_{cg} = \frac{1000M_{cg}}{K_{corr}C_{s-cg}R_{eH}}$$

where:

$M_{cg}$  : Vertical bending moment in kNm

$$M_{cg} = \frac{C_i |P| s_{cg} \ell_o^2}{12000}$$

$P$  : Averaged pressure in kN/m<sup>2</sup>

$$P = \frac{P_u + P_l}{2}$$

$P_l, P_u$  : Design pressure given in Ch 7, Sec 2, Tab 1 for the design load set being considered, calculated at the lower and upper ends of the corrugation, respectively, in kN/m<sup>2</sup>:

- for transverse corrugated bulkheads, the pressures are to be calculated at a section located at  $b_{tk} / 2$  from the longitudinal bulkheads of each tank
- for longitudinal corrugated bulkheads, the pressures are to be calculated at the ends of the tank, i.e. the intersection of the forward and aft transverse bulkheads and the longitudinal bulkhead.

$b_{tk}$  : Maximum breadth of tank under consideration measured at the bulkhead, in m

$\ell_o$  : Effective bending span of the corrugation, in m, measured from the mid depth of the lower stool to the mid depth of the upper stool. Where no lower or upper stool is fitted,  $\ell_o$  is to be measured to lower or upper end. See Fig 8

$C_i$  : Bending moment coefficient given in Tab 10

**Table 10 : Values of  $C_i$**

Bulkhead	At lower end of $\ell_{cg}$	At mid-length of $\ell_{cg}$	At upper end of $\ell_{cg}$
Transverse bulkhead	$C_1$	$C_{m1}$	$0,65 C_{m1}$
Longitudinal bulkhead	$C_3$	$C_{m3}$	$0,65 C_{m3}$

$C_{s-cg}$  : Permissible bending stress coefficient at the mid-length of the corrugation length,  $\ell_{cg}$ :

- $C_{s-cg} = c_e$  but not to be taken as greater than 0,75 for acceptance criteria set AC-1
- $C_{s-cg} = c_e$  but not to be taken as greater than 0,90 for acceptance criteria set AC-2
- $C_{s-cg} = c_e$  but not to be taken as greater than 0,95 for acceptance criteria set AC-3

At the lower and upper ends of the corrugation length,  $\ell_{cg}$ :

- $C_{s-cg} = 0,75$  for acceptance criteria set AC-1
- $C_{s-cg} = 0,90$  for acceptance criteria set AC-2
- $C_{s-cg} = 0,95$  for acceptance criteria set AC-3

$c_e$  : Coefficient taken as:

- for  $\beta \geq 1,25$ :

$$c_e = \frac{2,25}{\beta} - \frac{1,25}{\beta^2}$$

- for  $\beta < 1,25$ :

$$c_e = 1,0$$

$\beta$  : Coefficient taken as:

$$\beta = \frac{b_{f-cg}}{t_f} \sqrt{\frac{R_{eH}}{E}}$$

$b_{f-cg}$  : Breadth of flange plating, in mm, see Fig 8

$t_f$  : Net thickness of the corrugation flange, in mm

where:

$C_1$  : Coefficient taken as:

- In general:

$$C_1 = a_1 + b_1 \sqrt{\frac{A_{dt}}{b_{dk}}}$$

without being taken less than 0,60

- for transverse bulkhead with no lower stool:

$$C_1 = a_1 - b_1 \sqrt{\frac{A_{dt}}{b_{dk}}}$$

without being taken less than 0,55

Figure 8 : Definition of parameters for corrugated bulkhead (Tankers with longitudinal bulkhead at centreline)

$a_1$  : Coefficient taken as:

- In general:

$$a_1 = 0,95 - \frac{0,41}{R_{bt}}$$

- for transverse bulkhead with no lower stool:

$$a_1 = 1,0$$

$b_1$  : Coefficient taken as:

- In general:

$$b_1 = -0,20 + \frac{0,078}{R_{bt}}$$

- for transverse bulkhead with no lower stool:

$$b_1 = 0,13$$

$C_{m1}$  : Coefficient taken as:

- In general:

$$C_{m1} = a_{m1} + b_{m1} \sqrt{\frac{A_{dt}}{b_{dk}}}$$

without being taken less than 0,55

- for transverse bulkhead with no lower stool:

$$C_{m1} = a_{m1} - b_{m1} \sqrt{\frac{A_{dt}}{b_{dk}}}$$

without being taken less than 0,60

$a_{m1}$  : Coefficient taken as:

- In general:

$$a_{m1} = 0,63 + \frac{0,25}{R_{bt}}$$

- for transverse bulkhead with no lower stool:

$$a_{m1} = 0,85$$

$b_{m1}$  : Coefficient taken as:

- In general:

$$b_{m1} = -0,25 - \frac{0,11}{R_{bt}}$$

- for transverse bulkhead with no lower stool:

$$b_{m1} = 0,34$$

$C_3$  : Coefficient taken as:

- In general:

$$C_3 = a_3 + b_3 \sqrt{\frac{A_{dl}}{\ell_{dk}}}$$

without being taken less than 0,60

- for longitudinal bulkhead with no lower stool:

$$C_3 = a_3 - b_3 \sqrt{\frac{A_{dl}}{\ell_{dk}}}$$

without being taken less than 0,55

$a_3$  : Coefficient taken as:

- In general:

$$a_3 = 0,86 - \frac{0,35}{R_{bt}}$$

- for longitudinal bulkhead with no lower stool:

$$a_3 = 1,0$$

$b_3$  : Coefficient taken as:

- In general:

$$b_3 = -0,17 + \frac{0,10}{R_{bl}}$$

- for longitudinal bulkhead with no lower stool:

$$b_3 = 0,13$$

$C_{m3}$  : Coefficient taken as:

- In general:

$$C_{m3} = a_{m3} + b_{m3} \sqrt{\frac{A_{dl}}{\ell_{dk}}}$$

without being taken less than 0,55

- for longitudinal bulkhead with no lower stool:

$$C_{m3} = a_{m3} - b_{m3} \sqrt{\frac{A_{dl}}{\ell_{dk}}}$$

without being taken less than 0,60

$a_{m3}$  : Coefficient taken as:

- In general:

$$a_{m3} = 0,32 + \frac{0,24}{R_{bl}}$$

- for longitudinal bulkhead with no lower stool:

$$a_{m3} = 0,85$$

$b_{m3}$  : Coefficient taken as:

- In general:

$$b_{m3} = -0,12 - \frac{0,10}{R_{bl}}$$

- for longitudinal bulkhead with no lower stool:

$$b_{m3} = 0,19$$

$R_{bt}$  : Coefficient for transverse bulkheads, taken as:

$$R_{bt} = \frac{A_{bt}}{b_{ib}} \left( 1 + \frac{\ell_{ib}}{b_{ib}} \right) \left( 1 + \frac{b_{av-t}}{h_{st}} \right)$$

$R_{bl}$  : Coefficient for longitudinal bulkheads, taken as:

$$R_{bl} = \frac{A_{bl}}{l_{ib}} \left( 1 + \frac{\ell_{ib}}{b_{ib}} \right) \left( 1 + \frac{b_{av-l}}{h_{sl}} \right)$$

$A_{dt}$  : Cross sectional area enclosed by the moulded lines of the transverse bulkhead upper stool, in m<sup>2</sup>. See Fig 8

$A_{dt} = 0$  if no upper stool is fitted

$A_{dl}$  : Cross sectional area enclosed by the moulded lines of the longitudinal bulkhead upper stool, in m<sup>2</sup>. See Fig 8

$A_{dl} = 0$  if no upper stool is fitted

$A_{bt}$  : Cross sectional area enclosed by the moulded lines of the transverse bulkhead lower stool, in m<sup>2</sup>. See Fig 8

$A_{bl}$  : Cross sectional area enclosed by the moulded lines of the longitudinal bulkhead lower stool, in m<sup>2</sup>. See Fig 8

$b_{av-t}$  : Average width of transverse bulkhead lower stool, in m. See Fig 8

$b_{av-l}$  : Average width of longitudinal bulkhead lower stool, in m. See Fig 8

$h_{st}$  : Height of transverse bulkhead lower stool, in m. See Fig 8

$h_{sl}$  : Height of longitudinal bulkhead lower stool, in m. See Fig 8

$b_{ib}$  : Breadth of cargo tank at the inner bottom level between hopper tanks, or between the hopper tank and centreline lower stool, in m. See Fig 8

$b_{dk}$  : Breadth of cargo tank at the deck level between upper wing tanks, or between the upper wing tank and centreline deck box or between the corrugation flanges if no upper stool is fitted, in m. See Fig 8

$\ell_{ib}$  : Length of cargo tank at the inner bottom level between transverse lower stools, in m. See Fig 8

$\ell_{dk}$  : Length of cargo tank at the deck level between transverse upper stools or between the corrugation flanges if no upper stool is fitted, in m. See Fig 8.

## 4 Primary supporting members in holds intended to carry dry bulk cargo

### 4.1 Centre girders and side girders

#### 4.1.1 Net web thickness

The net thickness of girders in double bottom structure, in mm, is not to be less than the greater of the value  $t_1$  and  $t_2$  specified in the followings according to each location:

$$t_1 = C_1 \frac{|P| S |x - x_c|}{(d_0 - d_1) C_t \tau_{eH}} \left\{ 1 - 4 \left( \frac{y}{B_{DB}} \right)^2 \right\}$$

where  $|x - x_c|$  is less than  $0,25 \ell_{DB}$ ,  $|x - x_c|$  is to be taken as  $0,25 \ell_{DB}$ .

$$t_2 = 1,753 \sqrt{\frac{H^2 a^2 C_t \tau_{eH}}{C'_1}} t_1$$

where:

- P : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 3, calculated at mid-point of a floor located midway between transverse bulkheads or transverse bulkhead and toe of stool, where fitted
- S : Distance between the centres of the two spaces adjacent to the centre or side girder under consideration, in m
- $d_0$  : Depth of the centre or side girder under consideration, in m
- $d_1$  : Depth of the opening, if any, at the point under consideration, in m
- $C_1$  : Coefficient given in Tab 11 depending on  $B_{DB}/\ell_{DB}$ . For intermediate values of  $B_{DB}/\ell_{DB}$ ,  $C_1$  is to be obtained by linear interpolation.
- a : Depth of girders at the point under consideration, in m. However, where longitudinal stiffeners are fitted on the girder, a is the breadth of the EPP under consideration
- $S_1$  : Spacing, in m, of vertical stiffeners or floors
- $C'_1$  : Coefficient given in Tab 12 depending on  $S_1/a$   
For intermediate values of  $S_1/a$ ,  $C'_1$  is to be determined by linear interpolation
- H : Value obtained from the following formulae:
  - where the girder is provided with an unreinforced opening:
 
$$H = 1 + 0,5 \frac{\phi_H}{\alpha}$$
  - in other cases:
 
$$H = 1,0.$$

**Table 11 : Coefficient  $C_1$**

$B_{DB}/\ell_{DB}$	0,4 and under	0,6	0,8	1,0	1,2	1,4	1,6 and over
$C_1$	0,5	0,71	0,83	0,88	0,95	0,98	1,00

**Table 12 : Coefficient  $C'_1$**

$S_1/a$	0,3 and under	0,4	0,5	0,6	0,7	0,8	0,9	1,0	1,2	1,4 and over
$C'_1$	64	38	25	19	15	12	10	9	8	7

### 4.2 Floors

#### 4.2.1 Net web thickness

The net thickness of floors in the double bottom structure, in mm, is not to be less than the greatest of values  $t_1$  and  $t_2$  specified in the following according to each location:

$$t_1 = C_2 \frac{|P| S B_{DB}}{(d_0 - d_1) C_t \tau_{eH}} \left( \frac{2|y|}{B'_{DB}} \right) \left\{ 1 - 2 \left( \frac{x - x_c}{\ell_{DB}} \right)^2 \right\}$$

where  $|x - x_c|$  is less than  $0,5 \ell_{DB}$ ,  $|x - x_c|$  is to be taken as  $0,25 \ell_{DB}$  and where  $|y|$  is less than  $B'_{DB}/4$ ,  $|y|$  is to be taken as  $B'_{DB}/4$ .

$$t_2 = 1,753 \sqrt{\frac{H^2 a^2 C_t \tau_{eH}}{C'_2}} t_1$$

where:

- P : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 3, calculated at mid-point of a floor located midway between transverse bulkheads or transverse bulkhead and toe of stool, where fitted

- S : Spacing of solid floors, in m
- $d_0$  : Depth of the solid floor at the point under consideration in m
- $d_1$  : Depth of the opening, if any, at the point under consideration in m
- $B'_{DB}$  : Distance between toes of hopper tanks at the position of the solid floor under consideration, in m
- $C_2$  : Coefficient given in Tab 13 depending on  $B_{DB}/\ell_{DB}$ . For intermediate values of  $B_{DB}/\ell_{DB}$ ,  $C_2$  is to be obtained by linear interpolation
- a : Depth of the solid floor at the point under consideration, in m. However, where horizontal stiffeners are fitted on the floor, a is the breadth of the EPP under consideration
- $S_1$  : Spacing, in m, of vertical stiffeners or girders
- $C'_2$  : Coefficient given in Tab 14 depending on  $S_1/d_0$ . For intermediate values of  $S_1/d_0$ ,  $C'_2$  is to be determined by linear interpolation.
- H : Value obtained from the following formulae:
- where openings with reinforcement or no opening are provided on solid floors:
    - where slots without reinforcement are provided:
 
$$H = \sqrt{4,0 \frac{d_2}{S_1} - 1,0}$$
 without being taken less than 1,0.
    - where slots with reinforcement are provided:  $H = 1,0$ .
  - where openings without reinforcement are provided on solid floors:
    - where slots without reinforcement are provided:
 
$$H = \left(1 + 0,5 \frac{\Phi_H}{d_0}\right) \sqrt{4,0 \frac{d_2}{S_1} - 1,0}$$
 without being taken less than:
 
$$1 + 0,5 \frac{\Phi_H}{d_0}$$
    - where slots with reinforcement are provided:
 
$$H = 1 + 0,5 \frac{\Phi_H}{d_0}$$
- $d_2$  : Depth of slots without reinforcement provided at the upper and lower parts of solid floors, in m, whichever is greater.

**Table 13 : Coefficient  $C_2$**

$B_{DB}/\ell_{DB}$	0,4 and under	0,6	0,8	1,0	1,2	1,4	1,6 and over
$C_2$	0,48	0,47	0,45	0,43	0,40	0,37	0,34

**Table 14 : Coefficient  $C'_2$**

$S_1/d_0$	0,3 and under	0,4	0,5	0,6	0,7	0,8	0,9	1,0	1,2	1,4 and over
$C'_2$	64	38	25	19	15	12	10	9	8	7

### 4.3 Stringer of double side structure

#### 4.3.1 Net web thickness

The net thickness of stringers in double side structure, in mm, is not to be less than the greater of the value  $t_1$  and  $t_2$  specified in the followings according to each location:

$$t_1 = C_3 \frac{|P| S |x - x_c|}{(d_0 - d_1) C_t \tau_{eH}}$$

where  $|x - x_c|$  is under  $0,25 \ell_{DS}$ ,  $|x - x_c|$  is to be taken as  $0,25 \ell_{DS}$

$$t_2 = 1,75 \sqrt[3]{\frac{H^2 a^2 C_t \tau_{eH} t_1}{C'_2}}$$

where:

- P : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 3, as measured vertically at the upper end of hopper tank, longitudinally at the centre of  $\ell_{DS}$
- S : Breadth of part supported by stringer, in m
- $d_0$  : Depth of stringers, in m

- $d_1$  : Depth of opening, if any, at the point under consideration, in m
- $\ell_{DS}$  : Length of the double side structure between the transverse bulkheads under consideration, in m
- $h_{DS}$  : Height of the double side structure between the upper end of hopper tank and the lower end of topside tank located midway between transverse bulkheads of hold under consideration, in m
- $C_3$  : Coefficient given in Tab 15 depending on  $h_{DS}/\ell_{DS}$ . For intermediate values of  $h_{DS}/\ell_{DS}$ ,  $C_3$  is to be obtained by linear interpolation
- $a$  : Depth of stringers at the point under consideration, in m. However, where longitudinal stiffeners are fitted on the stringer,  $a$  is the breadth of the EPP under consideration
- $S_1$  : Spacing, in m, of transverse stiffeners or web frames
- $C'_3$  : Coefficient given in Tab 16 depending on  $S_1/a$ . For intermediate values of  $S_1/a$ ,  $C'_3$  is to be obtained by linear interpolation
- $H$  : Value obtained from the following formulae:
- where the stringer is provided with an unreinforced opening:
 
$$H = 1 + 0,5 \frac{\Phi_H}{\alpha}$$
  - in other cases:
 
$$H = 1,0$$

**Table 15 : Coefficient  $C_3$**

$h_{DS}/\ell_{DS}$	0,5 and under	0,6	0,7	0,8	0,9	1,0	1,1	1,2	1,3 and over
$C_3$	0,16	0,23	0,30	0,36	0,41	0,44	0,47	0,50	0,54

**Table 16 : Coefficient  $C'_3$**

$S_1/a$	0,3 and under	0,4	0,5	0,6	0,7	0,8	0,9	1,0	1,2	1,4 and over
$C'_3$	64	38	25	19	15	12	10	9	8	7

#### 4.4 Transverse web in double side structure

##### 4.4.1 Net web thickness

The net thickness of transverse webs in double side structure, in mm, is not to be less than the greater of the value  $t_1$  and  $t_2$  specified in the followings according to each location:

$$t_1 = C_4 \frac{|P| S h_{DS}}{(d_o - d_1) C_t \tau_{eH}} \left( 1 - 1,75 \frac{z - z_{BH}}{h'_{DS}} \right)$$

where

$z - z_{BH}$  is greater than  $0,4 h'_{DS}$ ,  $z - z_{BH}$  is to be taken as  $0,4 h'_{DS}$ .

$$t_2 = 1,75 \sqrt[3]{\frac{H^2 a^2 C_t \tau_{eH}}{C_4}} t_1$$

where:

- $P$  : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 3, as measured vertically at the upper end of hopper tank, longitudinally at the centre of  $\ell_{DS}$
- $S$  : Breadth of part supported by transverses, in m
- $d_o$  : Depth of transverses, in m
- $d_1$  : Depth of opening at the point under consideration, in m
- $C_4$  : Coefficient given in Tab 17 depending on  $h_{DS}/\ell_{DS}$ . For intermediate values of  $h_{DS}/\ell_{DS}$ ,  $C_4$  is to be obtained by linear interpolation
- $z_{BH}$  : Z coordinate, in m, of the upper end of hopper tank with respect to the reference coordinate system defined in Ch 1, Sec 3, [2.6]
- $h_{DS}$  : As defined in the requirements of [4.3.1]
- $h'_{DS}$  : Height of the double side structure between the upper end of hopper tank and the lower end of topside tank at the position under consideration, in m
- $\ell_{DS}$  : As defined in the requirements of [4.3.1]
- $a$  : Depth of transverses at the point under consideration, in m. However, where vertical stiffeners are fitted on the transverse,  $a$  is the distance from the vertical stiffener under consideration to the side shell or the longitudinal bulkhead of double side hull or the distance between the vertical stiffeners under consideration
- $S_1$  : Spacing, in m, of horizontal stiffeners or stringers

- $C'_4$  : Coefficient given in Tab 18 depending on  $S_1/a$ . For intermediate values of  $S_1/a$ ,  $C'_4$  is to be obtained by linear interpolation
- H : Value obtained from the following formulae:
- where the transverse is provided with an unreinforced opening:
 
$$H = 1 + 0,5 \frac{\phi_H}{\alpha}$$
  - in other cases:
 
$$H = 1,0.$$
- $\alpha$  : The greater of a or  $S_1$ , in m.

**Table 17 : Coefficient  $C_4$**

$h_{DS}/\ell_{DS}$	0,5 and under	0,6	0,7	0,8	0,9	1,0	1,1	1,2	1,3 and over
$C_4$	0,62	0,61	0,59	0,55	0,52	0,49	0,46	0,43	0,41

**Table 18 : Coefficient  $C'_4$**

$S_1/a$	0,3 and under	0,4	0,5	0,6	0,7	0,8	0,9	1,0	1,2	1,4 and over
$C'_4$	64	38	25	19	15	12	10	9	8	7

## 4.5 Primary supporting member in bilge hopper tanks and topside tanks

### 4.5.1 Boundary conditions

The requirements of this sub-article apply to primary supporting members considered as clamped at both ends. For boundary conditions deviated from the above, the yielding check is to be considered on a case-by-case basis.

### 4.5.2 Net section modulus, net shear sectional area and web thickness

The net section modulus  $Z$ , in  $\text{cm}^3$ , the net shear sectional area  $A_{shr}$ , in  $\text{cm}^2$ , and the net web thickness  $t_w$ , in mm, subject to lateral pressure are not to be less than the values obtained from the following formulae:

$$Z = \frac{|P| S \ell_{bdg}^2}{f_{bdg} C_s R_{eH}} 10^3$$

$$A_{shr} = \frac{5 |P| S \ell_{shr}}{C_t \tau_{eH}}$$

$$t_w = 1,75 \sqrt[3]{\frac{h_w C_t \tau_{eH} A_{shr}}{10^4 C_5}}$$

where:

- P : Design pressure for the design load set being considered as defined in Ch 7, Sec 2, Tab 3, calculated at the mid-point of span  $\ell$  of a web frame located midway between transverse bulkheads of holds
- S : Spacing of primary supporting members, in m
- $\ell_{bdg}$  : Effective bending span, in m, of primary supporting members, measured between the supporting members as defined in Ch 4, Sec 6, [1.1.6]
- $\ell_{shr}$  : Effective shear span, in m, of primary supporting members, measured between the supporting members as defined in Ch 4, Sec 6, [1.1.7]
- $f_{bdg}$  : Bending moment factor:
- For continuous primary supporting members and where end connections are fitted consistent with idealisation of the primary supporting members as having fixed ends and is not to be taken higher than:
 
$$f_{bdg} = 10$$
  - For primary supporting members with reduced end fixity, the yield check is to be considered on a case-by-case basis
- $C_s$  : Permissible bending stress coefficient for primary supporting members taken equal to:
- $C_s = 0,70$  for AC-1
- $C_s = 0,85$  for AC-2
- $h_w$  : Web height, in mm
- $C_5$  : Coefficient defined in Tab 19 according to  $s_1$  and  $d_0$ . For intermediate values of  $s_1/d_0$ , coefficient  $C_5$  is to be obtained by linear interpolation
- $s_1$  : Spacing of stiffeners or tripping brackets on web plate, in m
- $d_0$  : Spacing of stiffeners parallel to shell plate on web plate, in m.

Table 19 : Coefficient C<sub>5</sub>

s <sub>1</sub> /d <sub>0</sub>	0,3 and less	0,4	0,5	0,6	0,7	0,8	0,9	1,0	1,5	2,0 and over
C <sub>5</sub>	60,0	40,0	26,8	20,0	16,4	14,4	13,0	12,3	11,1	10,2

**4.6 Transverse vertically corrugated bulkheads separating holds assigned as ballast holds and separating hopper wells on dredgers**

**4.6.1 Application**

These requirements apply to:

- transverse vertically corrugated watertight bulkheads of the cargo holds of ships of less than 150m in length intended for the carriage of dry cargoes in bulk and assigned as ballast holds
- transverse vertically corrugated bulkheads fitted on dredgers and forming the boundary of hopper wells subjected to spoil pressure, as detailed in Pt D, Ch 13, Sec 2, [6.4.1].

**4.6.2 Section modulus**

The net section modulus Z at the lower and upper ends, in cm<sup>3</sup>, of transverse vertically corrugated bulkheads subject to lateral pressure are not to be less than the values obtained from the following formula:

$$Z = K \frac{P s_{cg} \ell^2}{f_{bdg} C_s R_Y}$$

where:

K : Coefficient given in Tab 20 and Tab 21, according to the type of end connection. When d<sub>H</sub> < 2,5 d<sub>0</sub> (see Fig 9), both section modulus per half pitch of corrugated bulkhead and section modulus of lower stool at inner bottom are to be calculated

P : Design pressure, in kN/m<sup>2</sup>, for:

- the WB design load sets as defined in Ch 7, Sec 2, Tab 3, or
- the HW-N or HW-Di design load sets as defined in Pt D, Ch 13, Sec 2, Tab 8, and calculated at the load calculation point defined in Ch 4, Sec 6, [3.2]

s<sub>cg</sub> : Half pitch length, in mm, of the corrugation, as defined in Ch 4, Sec 5, Fig 27

ℓ : Length, in m, between the supports, as indicated in Fig 9

C<sub>s</sub> : Coefficient defined in Ch 7, Sec 5, [1.1.2]

f<sub>bdg</sub> : Coefficient defined in Ch 7, Sec 5 for lower and upper ends of corrugation.

The effective width of the corrugation flange in compression is to be considered according to [4.6.3] when the net section modulus of corrugated bulkhead is calculated.

Table 20 : Values of K, in case d<sub>H</sub> ≥ 2,5d<sub>0</sub>

Upper end support	
Welded directly to deck	Welded to stool efficiently supported by ship structure
1,00	0,83

Table 21 : Values of K, in case d<sub>H</sub> < 2,5d<sub>0</sub>

Section modulus of	Upper end support	
	Connected to deck	Connected to stool
Corrugated bulkhead	0,71	0,65
Stool at bottom	1,25	1,13

Figure 9 : Measurement of  $\ell$

#### 4.6.3 Effective flange width

The net section modulus of the corrugations is to be calculated with the compression flange having an effective flange width  $b_{eff}$  not larger than the following formula:

$$b_{eff} = C_E b_{f-cg}$$

where:

$C_E$  : Coefficient taken equal to:

- for  $\beta \geq 1,25$ :

$$C_E = \frac{2,25}{\beta} - \frac{1,25}{\beta^2}$$

- for  $\beta < 1,25$ :

$$C_E = 1,0$$

$\beta$  : Coefficient to be taken equal to:

$$\beta = \frac{b_{f-cg}}{t_f} \sqrt{\frac{R_{eH}}{E}}$$

$b_{f-cg}$  : Width, in mm, of the corrugation flange as shown in Ch 4, Sec 5, Fig 27

$t_f$  : Net flange thickness, in mm.

### 4.7 Transverse vertically corrugated bulkheads in flooded conditions

#### 4.7.1 Application

These requirements apply to vertically corrugated transverse watertight bulkheads of the cargo holds of ships intended for the carriage of dry cargoes in bulk.

#### 4.7.2 Bending capacity and shear capacity

The bending capacity and the shear capacity of the corrugations of transverse watertight corrugated bulkheads separating cargo holds are to comply with the following formulae:

$$0,5W_{LE} + W_M \geq \frac{M}{0,95 R_{eH}} 10^3$$

$$\tau \leq \frac{R_{eH}}{2}$$

where:

$M$  : Bending moment in a corrugation, in kNm, taken as:

$$M = \frac{F_R \ell_C}{8}$$

$F_R$  : Resultant force, in kN, given in Ch 5, Sec 6, [4.1.7]

$\ell_C$  : Span of the corrugations, in m, as given in Ch 4, Sec 5, [10.3.5]

$W_{LE}$  : Net section modulus, in  $cm^3$ , of one half pitch corrugation, to be calculated at the lower end of the corrugations according to [4.6.3], not to be taken greater than:

$$W_{LE,M} = W_G + \frac{Q h_G 10^3 - 0,5 h_G^2 s_{cR} P_R}{R_{eH}}$$

$W_G$  : Net section modulus, in  $cm^3$ , of one half pitch corrugation, to be calculated in way of the upper end of shedder or gusset plates, as applicable, according to [4.6.3]

$Q$  : Shear force, in kN, at the lower end of a corrugation, to be taken as:

$$Q = 0,8 F_R$$

$h_G$  : Height, in m, of shedders or gusset plates, as applicable as shown in Fig 11 to Fig 13

$P_R$  : Resultant pressure, in  $kN/m^2$ , to be calculated in way of the middle of the shedders or gusset plates, as applicable, according to Ch 5, Sec 6, [4.1.7]

$W_M$  : Net section modulus, in  $cm^3$ , of one half pitch corrugation, to be calculated at the mid-span of corrugations according to [4.6.3] without being taken greater than  $1,15 W_{LE}$

$s_{cR}$  : Half pitch, in mm, of the corrugation flange as defined in Ch 4, Sec 5, [10.3.2]

$\tau$  : Shear stress, in  $N/mm^2$ , in the corrugation to be taken as:

$$\tau = 10 \frac{Q}{A_{shr}}$$

$A_{shr}$  : Net shear area, in  $cm^2$ , of one half pitch corrugation. The calculated net shear area is to consider possible reduced shear efficiency due to non-straight angles between the corrugation webs and flanges. In general, the reduced shear area may be obtained by multiplying the web sectional area by  $\sin \phi$

$\phi$  : Angle between the web and the flange, see Ch 4, Sec 5, Fig 27.

The net section modulus of the corrugations in the upper part of the bulkhead, as defined in Fig 10, is not to be taken less than 75% of that of the middle part complying with this requirement and Ch 7, Sec 4, [1.2], corrected for different minimum yield stresses.

**Figure 10 : Parts of corrugation**

### 4.7.3 Shear buckling check of the bulkhead corrugation webs

This requirement is to be applied in lieu of the shear buckling strength criteria for corrugated bulkheads given in NR615, Section 3.

The shear stress  $\tau$ , calculated according to [4.7.2], is to comply with the following formula:

$$\tau \leq \tau_C$$

where:

$\tau_C$  : Critical shear buckling stress, in  $N/mm^2$ , to be taken as:

- $\tau_C = \tau_E$

for

$$\tau_E \leq \frac{R_{eH}}{2 \sqrt{3}}$$

- $\tau_c = \frac{R_{eH}}{\sqrt{3}} \left( 1 - \frac{R_{eH}}{4\sqrt{3} \tau_E} \right)$

for

$$\tau_E > \frac{R_{eH}}{2\sqrt{3}}$$

$\tau_E$  : Euler shear buckling stress, in N/mm<sup>2</sup>, to be taken as:

$$\tau_E = 0,9 k_t E \left( \frac{t_w}{b_{w-cg}} \right)^2$$

$k_t$  : Coefficient, to be taken equal to 6,34

$t_w$  : Net thickness, in mm, of the corrugation webs

$b_{w-cg}$  : Width, in mm, of the corrugation webs as shown in Ch 4, Sec 5, Fig 27.

#### 4.7.4 Webs not supported by local brackets

Unless welded to a sloping stool top plate as defined in [4.7.7], if the corrugation webs are not supported by local brackets below the stool top plate (or below the inner bottom) in the lower part, the section modulus of the corrugations is to be calculated considering the corrugation webs 30% effective.

#### 4.7.5 Effective shedder plates

Provided that effective shedder plates are fitted as shown in Fig 11, when calculating the section modulus at the lower end of the corrugations ("Sections 1" in Fig 11), the net area, in cm<sup>2</sup>, of flange plates may be increased by  $I_{SH}$  to be taken as:

$$I_{SH} = 2,5 \cdot 10^{-3} b_{f-cg} \sqrt{t_f t_{SH}}$$

without being taken greater than  $2,5 b_{f-cg} t_f 10^{-3}$

where:

$b_{f-cg}$  : Width, in mm, of the corrugation flange as shown in Ch 4, Sec 5, Fig 27.

$t_{SH}$  : Net shedder plate thickness, in mm.

$t_f$  : Net flange thickness, in mm.

Effective shedder plates are those which:

- are not knuckled
- are welded to the corrugations and the lower stool top plate according to Ch 13, Sec 3, [3.3.5]
- are fitted with a minimum slope of 45°, their lower edge being in line with the lower stool side plating
- have net thickness not less than 75% of the net required for the corrugation flanges
- have material properties not less than those required for the flanges.

Figure 11 : Symmetrical and unsymmetrical shedder plates

**4.7.6 Effective gusset plates**

Provided that effective gusset plates are fitted, when calculating the section modulus at the lower end of the corrugations (Sections '1' in Fig 12 and Fig 13), the net area, in cm<sup>2</sup>, of flange plates may be increased by  $I_G$  to be taken as:

$$I_G = 7 h_G t_f$$

where:

$h_G$  : Height, in m, of gusset plates as shown in Fig 12 and Fig 13 but not to be taken greater than:

$$\frac{10 S_{GU}}{7}$$

$S_{GU}$  : Width, in m, of gusset plates.

$t_f$  : Net flange thickness, in mm.

Effective gusset plates are those which:

- are in combination with shedder plates having thickness, material properties and welded connections as requested for shedder plates in [4.7.5]
- have a height not less than half of the flange width
- are fitted in line with the lower stool side plating
- are welded to the lower stool top plate, corrugations and shedder plates according to Ch 13, Sec 3, [3.3.5]
- have net thickness and material properties not less than those net required for the flanges.

**Figure 12 : Symmetrical and unsymmetrical gusset / shedder plates**

**Figure 13 : Asymmetrical gusset / shedder plates**

**4.7.7 Sloping stool top plate**

Where the corrugation webs are welded to a sloping stool top plate which has an angle not less than 45° with the horizontal plane, the section modulus at the lower end of the corrugations may be calculated considering the corrugation webs fully effective. For angles less than 45°, the effectiveness of the web may be obtained by linear interpolation between 30% efficient for 0° and 100% efficient for 45°.

Where effective gusset plates are fitted, when calculating the net section modulus of corrugations, the net area of flange plates may be increased as specified in [4.7.6]. No credit may be given to shedder plates only.

**4.7.8 Effective flange width**

The net section modulus of the corrugations is to be calculated with the compression flange having an effective flange width  $b_{eff}$  as defined in [4.6.3].

**4.8 Double bottom capacity in flooded conditions**

**4.8.1 Application**

These requirements apply to the double bottom in cargo holds of ships intended for the carriage of dry cargoes in bulk.

**4.8.2 Shear capacity of the double bottom**

The shear capacity of the double bottom is to be calculated as the sum of the shear strength at each end of:

- Floors connected to hopper tanks, less one half of the shear strength of the two floors adjacent to each stool, or transverse bulkhead if no stool is fitted as shown in Fig 14. The shear strength of floors is to be calculated according to [4.8.3]
- Double bottom girders connected to stools, or transverse bulkheads if no stool is fitted. The shear strength of girders is to be calculated according to [4.8.4].

The floors and girders to be considered when calculating the shear capacity of the double bottom are those inside the hold boundaries formed by the hopper tanks and stools or transverse bulkheads if no stool is fitted. Where both ends of girders or floors are not directly connected to the hold boundaries, their strength is to be evaluated for the connected end only.

The hopper tank side girders and the floors directly below the connection of the stools or transverse bulkheads if no stool is fitted to the inner bottom may not be included.

For special double bottom designs, the shear capacity of the double bottom is to be calculated by means of direct calculations carried out in accordance with requirements specified in [5] Part B, Chapter 8, as applicable.

**Figure 14 : Double bottom structure**

**4.8.3 Floor shear strength**

The floor shear strength, in kN, is to be taken as given in the following formulae:

- in way of the floor panel adjacent to the hopper tank:

$$S_{f1} = A_f \frac{\tau_A}{\eta_1} 10^{-3}$$

- in way of the openings in the outermost bay (i.e., that bay which is closer to the hopper tank):

$$S_{f2} = A_{f,h} \frac{\tau_A}{\eta_2} 10^{-3}$$

where:

- $A_f$  : Net sectional area, in mm<sup>2</sup>, of the floor panel adjacent to the hopper tank  
 $A_{f,h}$  : Net sectional area, in mm<sup>2</sup>, of the floor panels in way of the openings in the outermost bay (i.e., the bay which is closer to the hopper tank)  
 $\tau_A$  : Allowable shear stress, in N/mm<sup>2</sup>, to be taken as the lesser of:

$$\tau_A = 0,645 \frac{R_{eH}^{0,6}}{(s/t)^{0,8}}$$

and

$$\tau_A = \frac{R_{eH}}{\sqrt{3}}$$

For floors adjacent to the stools or transverse bulkheads,  $\tau_A$  is taken as:

$$\frac{R_{eH}}{\sqrt{3}}$$

- $t$  : Floor web net thickness, in mm  
 $s$  : Spacing, in m, of stiffening members of the panel considered  
 $\eta_1$  : Coefficient to be taken equal to 1,1  
 $\eta_2$  : Coefficient to be taken equal to 1,2. It may be reduced to 1,1 where appropriate reinforcements are fitted in way of the openings in the outermost bay, to be examined by the Society on a case-by-case basis.

#### 4.8.4 Girder shear strength

The girder shear strength, in kN, is to be taken as given in the following formulae:

- in way of the girder panel adjacent to the stool or transverse bulkhead, if no stool is fitted:

$$S_{g1} = A_g \frac{\tau_A}{\eta_1} 10^{-3}$$

- in way of the largest opening in the outermost bay (i.e., that bay which is closer to the stool) or transverse bulk-head, if no stool is fitted:

$$S_{g2} = A_{g,h} \frac{\tau_A}{\eta_2} 10^{-3}$$

- $A_g$  : Net sectional area, in mm<sup>2</sup>, of the girder panel adjacent to the stool (or transverse bulkhead, if no stool is fitted)  
 $A_{g,h}$  : Net sectional area, in mm<sup>2</sup>, of the girder panel in way of the largest opening in the outermost bay (i.e. that bay which is closer to the stool) or transverse bulkhead, if no stool is fitted  
 $\tau_A$  : Allowable shear stress, in N/mm<sup>2</sup>, as defined in [4.8.3] where  $t$  is the girder web net thickness  
 $\eta_1$  : Coefficient to be taken equal to 1,1  
 $\eta_2$  : Coefficient to be taken equal to 1,15. It may be reduced to 1.1 where appropriate reinforcements are fitted in way of the largest opening in the outermost bay, to be examined by the Society on a case-by-case basis.

#### 4.8.5 Allowable hold loading

The allowable hold loading, in  $t$ , is to be taken as:

$$W = \rho_C V \frac{1}{F}$$

where:

- $\rho_C$  : Density of the dry bulk cargo, in t/m<sup>3</sup>, as defined Ch 5, Sec 6, [3.3.3]  
 $V$  : Volume, in m<sup>3</sup>, occupied by the cargo up to the level  $h_B$   
 $F$  : Coefficient to be taken as:  
 $F = 1,1$  in general.  
 $F = 1,05$  for steel mill products.

- $h_B$  : Level of cargo, in m, to be taken as:

$$h_B = \frac{P}{\rho_C g}$$

- $P$  : Pressure, in kN/m<sup>2</sup>, to be taken as:

- For dry bulk cargoes, the lesser of:

$$P = \frac{Z + \rho g (z_F - (0,1 D_I) - h_F)}{1 + \frac{\rho}{\rho_C} (\text{perm} - 1)}$$

$$P = Z + \rho g (z_F - (0,1 D_I) - h_F \text{ perm})$$

- For steel mill products:

$$p = \frac{Z + \rho g (z_F - (0,1 D_T) - h_F)}{1 - \frac{\rho}{\rho_{ST}}}$$

- $D_1$  : Distance, in m, from the baseline to the freeboard deck at side amidships
- $h_F$  : Inner bottom flooded height, in m, measured vertically with the ship in the upright position, from the inner bottom to the flooded level  $z_F$
- $z_F$  : Flooded level, in m, as defined in Ch 5, Sec 6, [4.1.3]
- perm : Permeability of cargo, which need not be taken greater than 0,3.
- $\rho_{ST}$  : Density of steel, in t/m<sup>3</sup>, to be taken as 7,85.
- $Z$  : Pressure, in kN/m<sup>2</sup>, to be taken as the lesser of:

$$Z = \frac{C_H}{A_{DB,H}}$$

$$Z = \frac{C_E}{A_{DB,E}}$$

- $C_H$  : Shear capacity of the double bottom, in kN, to be calculated according to [4.8.2], considering, for each floor, the lesser of the shear strengths  $S_{f1}$  and  $S_{f2}$  as defined in [4.8.3] and, for each girder, the lesser of the shear strengths  $S_{g1}$  and  $S_{g2}$  as defined in [4.8.4]

- $A_{DB,H}$  : Area, in m<sup>2</sup>, taken as:

$$A_{DB,H} = \sum_{i=1}^n S_i B_{DB,i}$$

- $C_E$  : Shear capacity of the double bottom, in kN, to be calculated according to [4.8.2], considering, for each floor, the shear strength  $S_{f1}$  as defined in [4.8.3] and, for each girder, the lesser of the shear strengths  $S_{g1}$  and  $S_{g2}$  as defined in [4.8.4]

- $A_{DB,E}$  : Area, in m<sup>2</sup>, taken as:

$$A_{DB,E} = \sum_{i=1}^n S_i (B_{DB} - s)$$

- $n$  : Number of floors between stools or transverse bulkheads, if no stool is fitted.
- $S_i$  : Space of i-th floor, in m.
- $B_{DB,i}$  : Length, in m, to be taken equal to:  
 $B_{DB,i} = B_{DB} - s$  for floors for which  $S_{f1} < S_{f2}$ .  
 $B_{DB,i} = B_{DB,h}$  for floors for which  $S_{f1} \geq S_{f2}$ .
- $B_{DB}$  : Breadth, in m, of double bottom between the hopper tanks as shown in Fig 15
- $B_{DB,h}$  : Distance, in m, between the two openings considered as shown in Fig 15
- $s$  : Spacing, in m, of inner bottom longitudinal ordinary stiffeners adjacent to the hopper tanks.

**Figure 15 : Dimensions  $B_{DB}$  and  $B_{DB,h}$**

## 5 Grillage structure

### 5.1 General

#### 5.1.1 Application

Where the structure is arranged as a grillage, the scantlings are to be checked using beam models in 2 or 3 dimensions, taking into account the requirements in [5.1.2] to [5.1.4].

**5.1.2 Structural modelling**

The model is to be built considering:

- the number and position of intermediate supports (e.g. decks, girders, pillars, etc)
- the conditions of fixity at the model boundaries and at intermediate supports
- the geometrical characteristics of the primary supporting members on the intermediate spans.

**5.1.3 Design loads**

The distribution of static pressures and forces and of still water hull girder stresses, as applicable, are to be applied to the model for all the loading conditions defined in Ch 5, Sec 8 and considered relevant for the assessment of the modeled structure.

Unless otherwise specified by the Society, for each of the considered seagoing loading conditions, the still water and static loads are to be combined with the dynamic pressures and forces and with the wave hull girder stresses, if any of all the dynamic load cases defined in Ch 5, Sec 2.

**5.1.4 Analysis criterion**

The calculated stress values are to comply with the following criterion:

a) For isolated beam analysis:

$$\tau \leq \chi K_{corr} C_t \tau_{eH}$$

$$\sigma \leq \chi K_{corr} C_s R_{eH}$$

b) For grillage analysis:  $\sigma_{eq} \leq \chi K_{corr} C_{comb} R_{eH}$

where:

$\sigma_{eq}$  : Equivalent Von Mises stress, in N/mm<sup>2</sup>:

$$\sigma_{eq} = \sqrt{\sigma^2 + 3\tau^2}$$

$C_t, C_s, C_{comb}$ : Permissible stress coefficients defined in Tab 2 for the acceptance criteria selected according to Tab 22

**Table 22 : Acceptance criterias for grillage structure analysis**

Acceptance criteria	Loading condition
AC-1	Harbour condition
AC-2	Any seagoing condition
AC-3	Tank testing condition Flooded condition

# Appendix 1      Analyses of Primary Supporting Members Subject to Wheeled Loads

## 1 General

### 1.1 Scope

**1.1.1** The requirements of this Appendix apply to the analysis criteria, structural modelling, load modelling and stress calculation of primary supporting members subject to wheeled loads.

**1.1.2** The purpose of these structural analyses is to determine:

- the distribution of the forces induced by the vertical acceleration acting on wheeled cargoes, among the various primary supporting members of decks, sides and possible bulkheads
- the behaviour of the above primary supporting members under the racking effects due to the transverse forces induced by the transverse acceleration acting on wheeled cargoes, when the number or location of transverse bulkheads are not sufficient to avoid such effects,

and to calculate the stresses in primary supporting members.

The above calculated stresses are to be used in the yielding and buckling checks.

In addition, the results of these analyses may be used, where deemed necessary by the Society, to determine the boundary conditions for finer mesh analyses of the most highly stressed areas.

**1.1.3** When the behaviour of primary supporting members under the racking effects, due to the transverse forces induced by the transverse acceleration, is not to be determined, the stresses in deck primary supporting members may be calculated according to the simplified analysis in [6], provided that the conditions for its application are fulfilled (see [6.1]).

### 1.2 Application

**1.2.1** The requirements of this Appendix apply to ships whose structural arrangement is such that the following assumptions may be considered as being applicable:

- primary supporting members of side and possible bulkheads may be considered fixed in way of the double bottom (this is generally the case when the stiffness of floors is at least three times that of the side primary supporting members)
- under transverse inertial forces, decks behave as beams loaded in their plane and supported at the ship ends; their effect on the ship transverse rings (side primary supporting members and deck beams) may therefore be simulated by means of elastic supports in the transverse direction or transverse displacements assigned at the central point of each deck beam.

**1.2.2** When the assumptions in [1.2.1] are considered by the Society as not being applicable, the analysis criteria are defined on a case by case basis, taking into account the ship's structural arrangement and loading conditions. In such cases, the analysis is generally to be carried out on the basis of a finite element model of the whole ship, built according to the requirements in Ch 8, App 3, as far as applicable.

### 1.3 Information required

**1.3.1** To perform these structural analyses, the following characteristics for every vehicle to be loaded are necessary:

- load per axle
- arrangement of wheels on axles
- tyre dimensions.

### 1.4 Lashing of vehicles

**1.4.1** The presence of lashing for vehicles is generally to be disregarded, but may be given consideration by the Society, on a case by case basis, at the request of the interested parties.

## 2 Analysis criteria

### 2.1 Finite element model analyses

#### 2.1.1 General

Areas which appear, from the primary supporting member analysis, to be highly stressed may be required to be further analysed through local FE models according to Ch 8, App 2.

**2.1.2 Criteria**

Primary supporting members analyzed through FE models are to comply with the criteria in Ch 8, App 1, [5] or Ch 8, App 3, [5] as relevant.

**2.2 Beam model analyses**

**2.2.1 General**

Beam models, built according to Ch 7, Sec 6, [5.1], may be adopted in lieu of the finite element models, provided that:

- primary supporting members are not so stout that the beam theory is deemed inapplicable by the Society
- their behaviour is not substantially influenced by the transmission of shear stresses through the shell plating.

In any case, FE models may need to be adopted when deemed necessary by the Society on the basis of the ship’s structural arrangement.

**2.2.2 Criteria**

Primary supporting members analyzed through beam models are to comply with the criteria in Ch 7, Sec 6, [5.1.4].

**3 Primary supporting members structural modelling**

**3.1 Model construction**

**3.1.1 Elements**

The structural model is to represent the primary supporting members with the plating to which they are connected. In particular, the following primary supporting members are to be included in the model:

- deck beams
- side primary supporting members
- primary supporting members of longitudinal and transverse bulkheads, if any
- pillars
- deck beams, deck girders and pillars supporting ramps and deck openings, if any.

**3.1.2 Net scantlings**

All the elements in [3.1.1] are to be modelled with their net scantlings according to Ch 4, Sec 2.

**3.2 Model extension**

**3.2.1** The structural model is to represent a hull portion which includes the zone under examination and which is repeated along the hull. The non-modelled hull parts are to be considered through boundary conditions as specified in [3.3].

In addition, the longitudinal extension of the structural model is to be such that the results in the areas to be analysed are not influenced by the unavoidable inaccuracy in the modelling of the boundary conditions.

**3.2.2** Double bottom structures are not required to be included in the model, based on the assumptions in [1.2.1].

**3.3 Boundary conditions of the three dimensional model**

**3.3.1 Boundary conditions at the lower ends of the model**

The lower ends of the model (i.e. the lower ends of primary supporting members of side and possible bulkheads) are to be considered as being clamped in way of the inner bottom.

**3.3.2 Boundary conditions at the fore and aft ends of the model**

Symmetry conditions are to be applied at the fore and aft ends of the model, as specified in Tab 1.

**3.3.3 Additional boundary conditions at the fore and aft ends of models subject to transverse loads**

When the model is subject to transverse loads, i.e. when load cases corresponding to beam and oblique sea (as defined in Ch 5, Sec 2) are applied to the model, the transverse displacements of the deck beams are to be obtained by means of a racking analysis and applied at the fore and aft ends of the model, in way of each deck beam.

**Table 1 : Symmetry conditions at the model fore and aft ends**

DISPLACEMENTS in directions (1):			ROTATION around axes (1):		
X	Y	Z	X	Y	Z
fixed	free	free	free	fixed	fixed
(1) X, Y and Z directions and axes are defined with respect to the reference co-ordinate system in Ch 1, Sec 3, [2.6].					

Figure 1 : Springs at the fore and aft ends of models subject to transverse loads

For ships with a traditional arrangement of fore and aft parts, a simplified approximation may be adopted, when deemed acceptable by the Society, defining the boundary conditions without taking into account the racking calculation and introducing springs, acting in the transverse direction, at the fore and aft ends of the model, in way of each deck beam (see Fig 1). The stiffness of each spring, simulating the effects of the deck in way of which it is modelled, is to be obtained, in kN/m, from the following formula:

$$R_{D,i} = \frac{24EJ_{D,i}s_a10^3}{2x^4 - 4L_{D,i}x^3 + L_{D,i}^2\left(x^2 + 15,6\frac{J_{D,i}}{A_{D,i}}\right) + L_{D,i}^3x}$$

where:

- $J_{D,i}$  : Net moment of inertia, in  $m^4$ , of the average cross-section of the deck  $i$ , with the attached side shell plating, about its vertical neutral axis
- $A_{D,i}$  : Net area, in  $m^2$ , of the average cross-section of deck  $i$  plating
- $s_a$  : Spacing of side vertical primary supporting members, in  $m$
- $x_i$  : Longitudinal distance, in  $m$ , measured from the transverse section at mid-length of the model to any end of deck  $i$
- $L_{D,i}$  : Length of the deck  $i$ , in  $m$ , to be taken equal to the ship's length. Special cases in which such value may be reduced will be considered by the Society on a case by case basis.

## 4 Load model

### 4.1 General

#### 4.1.1 Hull girder and local loads

Only local loads are to be directly applied to the structural model.

The stresses induced by hull girder loads are to be calculated separately and added to the stresses induced by local loads.

#### 4.1.2 Loading conditions and load cases: wheeled cargoes

The still water and dynamic loads are to be calculated for the most severe loading conditions as given in the loading manual, with a view on maximising the stresses in primary supporting members.

The loads transmitted by vehicles are to be applied taking into account the most severe axle positions for the ship structures.

The dynamic local loads and hull girder loads are to be calculated for the following sets of dynamic load cases defined in Ch 5, Sec 2, maximizing the vertical and transverse accelerations  $a_x$  and  $a_y$  according to Ch 5, Sec 3, [3.3]:

- BP2-P, BP2-S, OVA2-P and OVA2-S load cases for maximum vertical acceleration (OVA2-P and OVA2-S load cases are only relevant for models extending forward of 0,6L)
- BR2-P and BR1-S load cases for maximum transverse acceleration.

Other load cases may be disregarded for the purposes of the structural analyses dealt with in this Appendix.

#### 4.1.3 Loading conditions and load cases: dry uniform cargoes

When the ship's decks are also designed to carry dry uniform cargoes, the loading conditions foreseeing the transportation of such cargoes are also to be considered. The still water and dynamic loads induced by these cargoes are to be calculated for the most severe loading conditions, with a view to maximising the stresses in primary supporting members.

The dynamic local loads and hull girder loads are to be calculated for the dynamic load cases specified in [4.1.2].

## **4.2 Local loads**

### **4.2.1 General**

Still water loads include:

- the still water sea pressure, defined in Ch 5, Sec 5, [1.2]
- the static forces defined in Ch 5, Sec 6, [7] and Ch 5, Sec 6, [6] for wheeled cargoes and dry uniform cargoes when relevant.

Dynamic loads include:

- the dynamic pressures, defined in Ch 5, Sec 5, [1], Ch 5, Sec 5, [3] and Ch 5, Sec 5, [5]
- the dynamic forces defined in Ch 5, Sec 6, [7] and Ch 5, Sec 6, [6] for wheeled cargoes and dry uniform cargoes when relevant.

### **4.2.2 Tyred vehicles**

For the purpose of primary supporting members analyses, the forces transmitted through the tyres may be considered as concentrated loads in the tyre print centre.

The forces acting on primary supporting members are to be determined taking into account the area of influence of each member and the way ordinary stiffeners transfer the forces transmitted through the tyres.

### **4.2.3 Non-tyred vehicles**

The requirements in [4.2.2] also apply to tracked vehicles. In this case, the print to be considered is that below each wheel or wheelwork.

For vehicles on rails, the loads transmitted are to be applied as concentrated loads.

### **4.2.4 Distributed loads**

In the analyses carried out on the basis of beam models or membrane finite element models, the loads distributed perpendicularly to the plating panels are to be applied on the primary supporting members proportionally to their areas of influence.

## **5 Stress calculation**

### **5.1 Normal stress induced by hull girder loads**

**5.1.1** The normal stress  $\sigma_L$ , in N/mm<sup>2</sup>, induced by the hull girder loads is to be calculated according to Ch 6, Sec 1, [2.1] for the relevant load cases and added to the stresses induced by local loads as calculated by the direct strength analysis.

### **5.2 Analyses based on beam models**

#### **5.2.1 Stress calculation points**

Stresses are to be calculated at least in the following points of each primary supporting member:

- in the primary supporting member span where the maximum bending moment occurs
- at the connection of the primary supporting member with other structures, assuming as resistant section that formed by the member, the bracket (if any and if represented in the model) and the attached plating
- at the toe of the bracket (if any and if represented in the model) assuming as resistant section that formed by the member and the attached plating.

The values of the stresses calculated in the above points are to be used for carrying out the checks required.

## **6 Grillage analysis of primary supporting members of decks**

### **6.1 Application**

**6.1.1** For the sole purpose of calculating the stresses in deck primary supporting members due to the forces induced by the vertical accelerations acting on wheeled cargoes (the racking effect is not to be considered), the simplified two dimensional analysis described in [6.2] may be considered.

This analysis is generally considered as being acceptable for standard structural typology where there are neither pillar lines nor longitudinal bulkheads, but sufficient transverse bulkheads to prevent racking effect.

### **6.2 Structural model**

#### **6.2.1 Members to be modelled**

The structural model used to represent the deck primary supporting members is a beam grillage model.

**6.2.2 Model extension**

The structural model is to represent a hull portion which includes the zone under examination and which is repeated along the hull. The non-modelled hull parts are to be considered through boundary conditions as specified in [6.3].

**6.3 Boundary conditions**

**6.3.1 Boundary conditions at the fore and aft ends of the model**

Symmetry conditions are to be applied at the fore and aft ends of the model, as specified in Tab 1.

**6.3.2 Boundary conditions at the connections of deck beams with side vertical primary supporting members**

Vertical supports are to be fitted at the nodes positioned in way of the connection of deck beams with side primary supporting members.

The contribution of flexural stiffness supplied by the side primary supporting members to the deck beams is to be simulated by springs, applied at their connections, having rotational stiffness, in the plane of the deck beam webs, obtained, in kN.m/rad, from the following formulae:

- for intermediate decks:

$$R_F = \frac{3E(J_1 + J_2)(l_1 + l_2)}{l_1^2 + l_2^2 - l_1 l_2} 10^{-5}$$

- for the uppermost deck:

$$R_F = \frac{6EJ_1}{l_1} 10^{-5}$$

where:

$l_1, l_2$  : Height, in m, of the ‘tweendecks, respectively below and above the deck under examination (see Fig 2)

$J_1, J_2$  : Net moments of inertia, in  $cm^4$ , of side primary supporting members with attached shell plating, relevant to the ‘tweendecks, respectively below and above the deck under examination.

**Figure 2 : Heights of ‘tweendecks for grillage analysis of deck primary supporting members**

**6.4 Load model**

**6.4.1 Hull girder and local loads are to be calculated and applied to the model according to [4].**

The dynamic local loads and hull girder loads are to be calculated for the load cases maximizing the vertical acceleration according to Ch 5, Sec 3, [3.3], and are to be applied to the model according to [4].

**6.5 Stress calculation**

**6.5.1 Stress components are to be calculated according to [5.1] and [5.2].**

### CHAPTER 8

## DIRECT STRENGTH ANALYSIS

---

Section 1	Direct Strength Assessment
Appendix 1	Cargo Hold Structural Strength Analysis
Appendix 2	Local Structural Strength Analysis
Appendix 3	Full Length Structural Strength Analysis

# Section 1 Direct Strength Assessment

## 1 General

### 1.1 Application

**1.1.1** This Chapter provides requirements to assess the scantlings of the hull structure using finite element analysis, mandatory only for ships defined in Ch 7, Sec 6, [1.1.1].

**1.1.2** Direct strength assessment may cover the following types of analysis:

- cargo hold analysis to assess the strength of longitudinal hull girder structural members, primary supporting structural members and bulkheads, performed according to Ch 8, App 1
- complete ship structural analysis to assess the primary supporting members, performed according to Ch 8, App 3
- fine mesh analysis to assess detailed stress levels in local structural details, performed according to Ch 8, App 2
- very fine mesh analysis to assess the fatigue capacity of the structural details according to Part B, Chapter 10.

**1.1.3** The analysis is to verify that:

- stress levels are within the acceptance criteria for yielding
- buckling capability of plates and stiffened panels are within the acceptance criteria for buckling defined in Ch 9, Sec 1
- fatigue capacity of the structural details is within the acceptance criteria defined in Ch 10, Sec 1.

**1.1.4** A flow diagram showing the minimum requirement of finite element analysis is shown in Fig 1.

**Figure 1 : Flow diagram of finite element analysis**

## 2 Net scantling

### 2.1 Net scantling application

**2.1.1** Models for cargo hold FE analyses, local fine mesh FE analyses and very fine mesh FE analyses are to be based on the net scantling approach, applying the corrosion addition as defined in Ch 4, Sec 2, Tab 1.

All the buckling capacity assessments are to be based on the net scantling approach, applying the corrosion addition as defined in Ch 4, Sec 2, Tab 1.

## 3 Finite element types

### 3.1 Finite element types to be used

**3.1.1** The structural assessment is to be based on linear finite element analysis of three-dimensional structural models. The general types of finite elements to be used in the finite element analysis are given in Tab 1.

**Table 1 : Types of finite elements**

Type of finite element	Description
Rod (or truss) element	Line element with axial stiffness only and constant cross-sectional area along the length of the element
Beam element	Line element with axial, torsional and bi-directional shear and bending stiffness and with constant properties along the length of the element
Shell (or plate) element	Shell element with in-plane stiffness and out-of-plane bending stiffness with constant thickness

**3.1.2** Two node line elements and four node shell elements are, in general, considered sufficient for the representation of the hull structure. The mesh requirements given in this Chapter are based on the assumption that these elements are used in the finite element models. However, higher order elements may also be used.

## 4 Acceptance criteria

### 4.1 Definition

**4.1.1** Acceptance criteria are to be selected as defined in Tab 2.

**Table 2 : Acceptance criteria**

Acceptance criteria	Design load scenario / Loading condition (1)
AC-1	Harbour condition
AC-2	Any seagoing condition
AC-3	Tank testing condition Flooded condition (2) Static heel 30° condition Collision condition

(1) The detailed loading conditions are defined in Ch 5, Sec 8.  
 (2) In this Chapter, flooded condition is to be considered for watertight boundaries of compartments not intended to carry liquid (except for corrugated bulkheads).

## 5 Submission of results

### 5.1 Detailed report

**5.1.1** A detailed report of the structural analysis is to be submitted by the designer/builder to demonstrate compliance with the specified structural design criteria. This report is to include the following information:

- a) list of plans used including dates and versions
- b) detailed description of structural modeling including all modeling assumptions and any deviations in geometry and arrangement of structure compared with plans
- c) plots to demonstrate correct structural modeling and assigned properties
- d) details of material properties, plate thickness, beam properties used in the model
- e) details of boundary conditions
- f) details of all loading conditions reviewed with calculated hull girder shear force, bending moment and torsional moment distributions
- g) details of applied loads and confirmation that individual and total applied loads are correct
- h) plots and results that demonstrate the correct behaviour of the structural model under the applied loads
- i) summaries and plots of global and local deflections
- j) summaries and sufficient plots of stresses to demonstrate that the design criteria are not exceeded in any member
- k) plate and stiffened panel buckling analysis and results
- l) tabulated results showing compliance, or otherwise, with the design criteria
- m) proposed amendments to structure where necessary, including revised assessment of stresses, buckling and fatigue properties showing compliance with design criteria
- n) reference of the finite element computer program, including its version and date.

## 6 Computer programs

### 6.1 Use of computer programs

**6.1.1** Any finite element computation program may be employed to determine the stress and deflection of the hull structure, provided that the combined effects of bending, shear, axial and torsional deformations are considered.

# Appendix 1 Cargo Hold Structural Strength Analysis

## Symbols

For symbols not defined in this Section, refer to Ch 1, Sec 3.

- $M_{sw}$  : Permissible vertical still water bending moment, in kN·m, as defined in Ch 5, Sec 4  
 $M_{ww}$  : Vertical wave bending moment, in kN·m, in hogging or sagging condition, as defined in Ch 5, Sec 4  
 $M_{wh}$  : Horizontal wave bending moment, in kN·m, as defined in Ch 5, Sec 4  
 $M_{wt}$  : Wave torsional moment in seagoing condition, in kNm, as defined in Ch 5, Sec 4.  
 $Q_{sw}$  : Permissible still water shear force, in kN, at the considered bulkhead position, as provided in Ch 5, Sec 4  
 $Q_{ww}$  : Vertical wave shear force, in kN, as defined in Ch 5, Sec 4  
 $X_{b-aft}$ ,  $X_{b-fwd}$  : X-coordinate, in m, of, respectively, the aft and forward bulkheads of the mid-hold  
 $x_{aft}$  : X-coordinate, in m, of the aft end support of the FE model  
 $x_{fore}$  : X-coordinate, in m, of the fore end support of the FE model  
 $x_i$  : X-coordinate, in m, of web frame station  $i$   
 $Q_{aft}$  : Vertical shear force, in kN, at the aft bulkhead of the mid-hold, as defined in [4.4.6]  
 $Q_{fwd}$  : Vertical shear force, in kN, at the forward bulkhead of the mid-hold, as defined in [4.4.6]  
 $Q_{targ-aft}$  : Target shear force, in kN, at the aft bulkhead of the mid-hold, as defined in [4.3.3]  
 $Q_{targ-fwd}$  : Target shear force, in kN, at the forward bulkhead of the mid-hold, as defined in [4.3.3].

## 1 Objective and scope

### 1.1 General

**1.1.1** This Section gives the requirements for cargo hold structural strength analysis used for the assessment of scantlings of longitudinal hull girder structural members, primary supporting members and bulkheads within the cargo hold region.

**1.1.2** For the purpose of FE structural assessment and load application, the cargo hold region contains the following cargo hold regions, which may vary depending on the ship length and cargo hold arrangement, as defined in Fig 1:

- midship cargo hold region
- forward cargo hold region
- after cargo hold region
- foremost cargo hold(s)
- aftmost cargo hold(s).

**Figure 1 : Definition of the cargo hold regions for FE structural assessment**

Holds in the forward cargo hold region are defined as holds having their longitudinal centre of gravity position located forward of 0.7 L from AE, except foremost cargo hold.

Holds in the midship cargo hold region are defined as holds having their longitudinal centre of gravity position located at or forward of 0.3 L from AE and at or aft of 0.7 L from AE.

Holds in the after cargo hold region are defined as holds having their longitudinal centre of gravity position located aft of 0.3 L from AE, except aftmost hold.

Foremost cargo hold(s) is (are) defined as hold(s) in the foremost location of the cargo hold region.

Aftmost cargo hold(s) is (are) defined as hold(s) in the aftmost location of the cargo hold region.

**1.1.3** Cargo hold structural strength analysis is mandatory for each typical cargo tank or cargo hold representative of the cargo hold regions defined in [1.1.2] including the aft bulkhead of the aftmost cargo hold and the collision bulkhead.

The evaluation areas are defined in [5.1].

## 1.2 Cargo hold structural strength analysis procedure

### 1.2.1 Procedure description

The structural FE analysis is to be performed in accordance with the following:

- model: three cargo hold model with:
  - extent as given in [2.2]
  - finite element types as given in [2.3]
  - structural modeling as defined in [2.4]
- boundary conditions as defined in [2.5]
- FE load combinations as defined in [3]
- load application as defined in [4]
- evaluation area as defined in [5.1]
- strength assessment as defined in [5.2] and [5.3].

### 1.2.2 Mid-hold definition

For the purpose of the FE analysis, the mid-hold is defined as the middle hold(s) of the three cargo hold length FE model.

### 1.2.3 Scantling assessment

The scantling assessment is carried out according to Ch 8, Sec 1 for each individual cargo hold of the covered regions using the FE load combinations defined in [3] applicable to the considered cargo hold. The FE analysis results are applicable to the evaluation area, as defined in [5.1.1], of the considered cargo hold.

The individual transverse bulkhead structural elements, including plating, stiffeners and horizontal stringers, are to be assessed considering two cargo hold finite element analyses, i.e. the analysis for the hold forward and the one for the hold aft of the considered transverse bulkhead.

For ships having the service notation **container ship**, when the results of the full length model are not deemed sufficient by the Society, in particular to account for conditions with one bay empty, results from the midship cargo hold region analysis may also be extrapolated with special care to the other cargo hold areas.

## 2 Structural model

### 2.1 Members to be modeled

**2.1.1** All the main longitudinal and transverse structural elements are to be modeled. These ones include:

- inner and outer shell
- upper deck
- double bottom floors and girders
- transverse and vertical web frames
- hatch coamings
- stringers and lower decks
- transverse and longitudinal bulkheads structures
- other primary supporting members
- other structural members which contribute to hull girder strength.

All plates and stiffeners on the structure, including web stiffeners, are to be modeled. Brackets which contribute to the primary supporting member strength and the size of which is not less than the typical mesh size (s-by-s) described in [2.4.2] are to be modeled.

### 2.2 Extent of model

#### 2.2.1 Longitudinal extent

Except the foremost and aftermost cargo hold models, the longitudinal extent of the cargo hold FE model is to cover three cargo hold lengths. The transverse bulkheads at the ends of the model are to be modeled. Where corrugated bulkheads are fitted, the model is to include the extent of the bulkhead steel structure forward and aft of the tanks/holds at the model ends. Typical finite element models representing the midship cargo hold region are shown in Fig 2 to Fig 4.

The foremost and the aftmost cargo holds are located at the middle of the FE models as follows:

- foremost cargo hold: from the after bulkhead of the cargo hold no. 2 to the ship's foremost cross section where the reinforced ring or web frame remains continuous from the base line to the strength deck
- aftermost cargo hold: from the after bulkhead of the engine room to the forward bulkhead of no. N-1 cargo hold, where N is the number of holds or sets of holds numbered from forward to aft.

Examples of finite element models representing the foremost and aftermost cargo holds of different ship type configurations are shown in Fig 5 and Fig 6

**Figure 2 : Example of 3 cargo hold model within midship region of oil tankers**

Example of cargo hold model of a container ship (shows only port side of the full breadth model)

Figure 5 : Example of FE model for the foremost cargo hold structure of an oil tanker

Figure 6 : Example of FE model for the aftermost cargo hold structure of a bulk carrier

### 2.2.2 Hull form modeling

In general, the finite element model is to represent the geometry of the hull form. In the midship cargo hold region, the finite element model may be prismatic, provided the mid-hold has a prismatic shape.

In the foremost cargo hold model, the hull form forward of the transverse section at the middle of the fore part up to the model end as defined in [2.2.1] may be modeled with a simplified geometry. The transverse section at the middle of the fore part up to the model end may be extruded out to the fore model end.

In the aftmost cargo hold model, the hull form aft of the middle of the machinery space may be modeled with a simplified geometry. The section at the middle of the machinery space may be extruded out to its aft bulkhead.

### 2.2.3 Transverse extent

Both port and starboard sides of the ship are to be modeled.

### 2.2.4 Vertical extent

The full depth of the ship is to be modeled including primary supporting members above the upper deck, trunks, forecastle and/or cargo hatch coaming, if any.

The superstructure or deck house in way of the machinery space, if any, and the bulwark are not required to be included in the model.

## 2.3 Finite element types

**2.3.1** Shell elements are to be used to represent plating.

**2.3.2** All the stiffeners are to be modeled with beam elements. The eccentricity of the neutral axis is to be modeled.

**2.3.3** Face plates of primary supporting members and brackets are to be modeled using rod or beam elements.

## 2.4 Structural modeling

### 2.4.1 Aspect ratio

The aspect ratio of the shell elements is in general not to exceed 3. The use of triangular shell elements is to be kept to a minimum. Where possible, the aspect ratio of the shell elements, in areas where there are likely to be high stresses or a high stress gradient, is to be kept close to 1 and the use of triangular elements is to be avoided.

### 2.4.2 Mesh

The shell element mesh is to follow the stiffening system as far as practicable, hence representing the actual plate panels between stiffeners. In general, the shell element mesh is to satisfy the following requirements:

- a) One element between every ordinary stiffener, see Fig 7 and Fig 8. Longitudinally, the element length is not to be greater than two longitudinal spaces, with a minimum of three elements between primary supporting members
- b) At least three elements over the height of primary supporting members webs, see Fig 7 and Fig 8  
For primary supporting members with a small web depth, modeling using two elements over the depth is acceptable provided that there is at least one element between every web stiffener. The mesh size of adjacent structure is to be adjusted accordingly
- c) The curvature of the free edge on large brackets of primary supporting members is to be modeled to avoid unrealistic high stress due to geometry discontinuities. In general, a mesh size equal to the stiffener spacing is acceptable. The bracket toe may be terminated at the nearest nodal point, provided that the modeled length of the bracket arm does not exceed the actual bracket arm length. The bracket flange is not to be connected to the plating, as shown in Fig 9. The modeling of the tapering part of the flange is to be in accordance with [2.4.8]. An example of acceptable mesh is shown in Fig 9. A finer mesh is to be used for the determination of detailed stress at the bracket toe, as given in Ch 8, App 2.

Figure 7 : Typical finite element mesh on web frame of an oil tanker and a bulk carrier

Figure 8 : Typical finite element mesh on web frame of a container ship

Figure 9 : Typical finite element mesh on large brackets of primary supporting member

### 2.4.3 Finer mesh

Where the geometry cannot be adequately represented in the cargo hold model and the stress exceeds the cargo hold mesh acceptance criteria, a finer mesh may be used for such geometry, to demonstrate satisfactory scantlings. The mesh size required for such analysis can be governed by the geometry. In such cases, the average stress within an area equivalent to that specified in [2.4] is to comply with the requirements given in [5.2].

### 2.4.4 Corrugated bulkhead

Diaphragms in the stools, supporting structure of corrugated bulkheads and internal longitudinal and vertical stiffeners on the stool plating are to be included in the model. Modeling is to be carried out as follows:

- the corrugation is to be modeled with its geometric shape
- the mesh on the flange and web of the corrugation is in general to follow the stiffener spacing inside the bulkhead stool
- the mesh on the longitudinal corrugated bulkhead is to follow longitudinal positions of transverse web frames where the corrections to hull girder vertical shear forces are applied in accordance with [4.4.7]
- the aspect ratio of the mesh in the corrugation is not to exceed 2 with a minimum of 2 elements for the flange breadth and the web height
- where difficulty occurs in matching the mesh on the corrugations directly with the mesh on the stool, it is acceptable to adjust the mesh on the stool in way of the corrugations
- for a corrugated bulkhead without an upper stool and/or lower stool, it may be necessary to adjust the geometry in the model. The adjustment is to be made such that the shape and position of the corrugations and primary supporting members are retained. Hence, the adjustment is to be made on stiffeners and plate seams if necessary
- when corrugated bulkhead is subjected to liquid cargo or ballast, dummy rod elements with a cross sectional area of 1 mm<sup>2</sup> are to be modeled at the corrugation knuckle between the flange and the web. Dummy rod elements are to be used as minimum at the two corrugation knuckles closest to the intersection between:
  - transverse and longitudinal bulkheads
  - transverse bulkhead and inner hull
  - transverse bulkhead and side shell.
- manholes in diaphragms are to be modeled according to [2.4.9].

2.4.5 Examples of mesh arrangement of the cargo hold structure are shown in Fig 10 to Fig 13.

### 2.4.6 Sniped stiffener

Non continuous stiffeners are to be modeled as continuous stiffeners, i.e. the height web reduction in way of the sniped ends are not to be modeled.

### 2.4.7 Web stiffeners of primary supporting members

Web stiffeners of primary supporting members are to be modeled. Where these stiffeners are not in line with the primary FE mesh, it is sufficient to place the line element along the nearby nodal points, provided that the adjusted distance does not exceed 0,2 times the stiffener spacing under consideration. The stresses and buckling utilisation factors obtained need not be corrected for the adjustment. Buckling stiffeners on large brackets, deck transverses and stringers parallel to the flange are to be modeled. These stiffeners may be modeled using rod elements.

Figure 10 : Example of FE cargo hold structure mesh arrangements for a container ship

Figure 11 : Example of FE mesh arrangements of cargo hold structure for a bulk carrier

Figure 12 : Example of FE mesh on transverse corrugated bulkhead structure

Figure 13 : Example of FE mesh arrangements of cargo tank structure for an aframax tanker

**2.4.8 Face plate of primary supporting member**

The effective cross-sectional area at the curved part of the face plate of primary supporting members and brackets is to be calculated in accordance with Ch 4, Sec 6. The cross-sectional area of a rod or beam element representing the tapering part of the face plate is to be based on the average cross-sectional area of the face plate in way of the element length.

**2.4.9 Openings**

Methods of representing openings and manholes in webs of primary supporting members are to be in accordance with Tab 1. Regardless of size, manholes are to be modeled by removing the appropriate elements.

**Figure 14 : Openings in web**

**Figure 15 : Length  $l_o$  for sequential openings with  $d_o < h/4$**

**Table 1 : Representation of openings in primary supporting member webs**

Criteria	Modeling decision	Analysis
$h_o/h < 0,5$ and $g_o < 2,0$	Openings do not need to be modeled	–
Manholes	The geometry of the opening is to be modeled by removing the adequate elements	To be evaluated by fine mesh if listed in Ch 8, App 2, [1.2.1]
$h_o/h \geq 0,5$ or $g_o \geq 2,0$	The geometry of the opening is to be modeled	

**Note 1:**

$$g_o = \left( 1 + \frac{l_o^2}{2,6(h - h_o)^2} \right)$$

- $l_o$  : Length, in m, of the opening parallel to the primary supporting member web direction, see Fig 14. For sequential openings where the distance  $d_o$  between openings is less than  $(0,25 h)$ ,  $l_o$  is to be taken as the length across openings, as shown in Fig 15
- $h_o$  : Height of the opening parallel to the web depth, in m, see Fig 14 and Fig 15
- $h$  : Web height of the primary supporting member in way of the opening, in m, see Fig 14 and Fig 15.

## 2.5 Boundary conditions

### 2.5.1 General

All boundary conditions described in this Section are in accordance with the global coordinate system defined in Ch 5, Sec 1.

### 2.5.2 Application

The boundary conditions given in [2.5.3] are applicable to cargo hold finite element model analyses in cargo hold region.

### 2.5.3 Boundary conditions

The boundary conditions consist of rigid links, point constraints and end-beams at model ends. The rigid links connect the nodes on the longitudinal members at the model ends to an independent point at neutral axis in centreline.

The boundary conditions to be applied at the ends of the cargo hold FE model are given in Tab 2, except for the foremost cargo hold model, for which they are given in Tab 3.

**Table 2 : Boundary constraints at model ends except the foremost cargo hold model**

Location	Translation			Rotation		
	$\delta_x$	$\delta_y$	$\delta_z$	$\theta_x$	$\theta_y$	$\theta_z$
Independent point (1) at aft end	–	fix	fix	$M_{T-end}$	–	–
Independent point (1) at fore end	–	fix	fix	fix	–	–
Intersection of centerline and inner bottom (1) at fore end	fix	–	–	–	–	–
Cross section at both ends	–	rigid link	rigid link	rigid link	–	–
	End beam, see [2.5.4]					

**Note 1:** [–] means no constraint applied (free).  
**(1)** See Fig 16.

**Table 3 : Boundary constraints at model ends of the foremost cargo hold model**

Location	Translation			Rotation		
	$\delta_x$	$\delta_y$	$\delta_z$	$\theta_x$	$\theta_y$	$\theta_z$
Independent point (1) at aft end	–	fix	fix	fix	–	–
Intersection of centerline and inner bottom (1) at aft end	fix	–	–	–	–	–
Independent point (1) at fore end	–	fix	fix	$M_{T-end}$	–	–
Cross section at aft end	–	rigid link	rigid link	rigid link	–	–
	End beam, see [2.5.4]					
Cross section at fore end	–	rigid link	rigid link	rigid link	–	–

**Note 1:** [–] means no constraint applied (free).  
**Note 2:** The fore end constraints are to be located at the most forward reinforced ring or web frame which remains continuous from the base line to the strength deck.  
**(1)** See Fig 16.

**Figure 16 : Boundary conditions applied at the model end sections**

NA : neutral axis of the model end sections

**2.5.4 End constraint beams**

End constraint beams are to be modeled at both end sections of the model along all longitudinally continuous structural members and along the cross deck plating of ships with large deck openings. An example of end beams at one end for a double hull bulk carrier is shown in Fig 17.

The properties of beams are calculated at fore and after sections separately and all beams at each end section have identical properties as follows:

- Net moment of inertia:  $I_{yy-n50} = I_{zz-n50} = I_{xx-n50} (J) = 1/25$  of the vertical hull girder moment of inertia of fore/aft end cross sections based on the net FE model
- Net cross sectional area:  $A_{y-n50}$  and  $A_{z-n50} = 1/80$  of the fore/aft end cross sectional areas based on the net FE model.

where:

- $I_{yy-n50}$  : Moment of inertia about local beam Y axial, in  $m^4$
- $I_{zz-n50}$  : Moment of inertia about local beam Z axial, in  $m^4$
- $I_{xx-n50} (J)$  : Torsional inertia, in  $m$ .
- $A_{y-n50}$  : Shear area in local beam Y direction, in  $m^2$
- $A_{z-n50}$  : Shear area in local beam Z direction, in  $m^2$ .

**Figure 17 : End constraint beams**

**3 FE load combinations**

**3.1 Design load combinations**

**3.1.1 FE load combination definition**

A FE load combination is defined as a loading pattern, a draught, a roll radius of gyration, a metacentric height, a value of still water bending moment and of still water shear force, associated with a given dynamic load case.

**3.1.2 Mandatory load combinations**

For cargo hold structural strength analysis, the design load combinations specified in the applicable Part D or Part E chapter are to be used for the considered ship type and cargo hold regions.

Each load combination requires the application of the structural weight, internal and external loads and hull girder loads. For seagoing condition, both static and dynamic load components are applied. For tank testing and flooding condition, only the static load components are applied.

**3.1.3 Additional loading conditions**

Where the loading conditions specified by the designer are not covered by the load combinations given the applicable Part D or Part E chapter, these additional loading conditions are to be examined according to the procedure in [4].

**4 Load application**

**4.1 General**

**4.1.1 Structural weight**

Effect of the weight of hull structure is to be included in the static loads, but is not to be included in the dynamic loads. Density of steel is to be taken as given in Ch 5, Sec 6.

**4.1.2 Sign convention**

Unless otherwise mentioned in this Section, the sign of the moments and shear forces is to be in accordance with the sign convention defined in Ch 5, Sec 1.

## 4.2 External and internal loads

### 4.2.1 External loads

The external pressures are to be calculated for each load case in accordance with Ch 5, Sec 5. They include static sea pressure, wave pressure and green sea pressure.

The effect of the hatch cover self weight is to be ignored in the loads applied to the ship structure.

### 4.2.2 Internal loads

The internal loads are to be calculated for each load case in accordance with Ch 5, Sec 6 for design load scenarios given in Ch 5, Sec 7, Tab 1. They include static dry and liquid cargo (including containers on deck if any), ballast and other liquid pressure, setting pressure on relief valve and dynamic pressure of dry and liquid cargo (including containers on deck if any), ballast and other liquid pressure due to acceleration.

### 4.2.3 Pressure application on FE element

A constant pressure, calculated at the element's centroid, is applied to the shell element of the loaded surfaces, e.g. outer shell and deck for the external pressure and tank/hold boundaries for the internal pressure. Alternately, the pressure can be calculated at the element nodes applying linear pressure distribution within the elements.

## 4.3 Hull girder loads

### 4.3.1 General

Each loading condition is to be associated with the corresponding hull girder loads to be applied to the model according to the procedure described in [4.4] for shear force and bending moment and in [4.5] for torsional moment.

The hull girder loads are the combinations of the still water hull girder loads and the wave induced hull girder loads as specified in Ch 5, Sec 8.

For each required FE load combination:

- the combination between still water bending moment and still water shear force may be adjusted by the use of relevant coefficients, in line with the loading manual and to the satisfaction of the Society
- the wave induced hull girder loads are to be calculated with the load combination factors (LCFs) specified in Ch 5, Sec 2.

### 4.3.2 Target hull girder vertical bending moment

The target hull girder vertical bending moment  $M_{v-targ}$ , in kN·m, at a longitudinal position for a given FE load combination, is taken as:  $M_{v-targ} = M_{sw} + M_{wv-LC}$

where:

$M_{sw}$  : Maximum and minimum permissible vertical still water bending moments at the considered longitudinal position, in seagoing conditions, in kN·m, as defined in Ch 5, Sec 4

$M_{wv-LC}$  : Vertical wave bending moment, in kN·m, for the dynamic load case under consideration, calculated in accordance with Ch 5, Sec 4, [3.6.1].

Within the midship cargo hold region, the value of  $M_{v-targ}$  is taken as the maximum hull girder bending moment within the mid-hold, for each given FE load combination.

Outside the midship cargo hold region, the values of  $M_{v-targ}$  are taken at all web frames and transverse bulkhead positions of the FE model under consideration.

### 4.3.3 Target hull girder vertical shear forces

The target hull girder vertical shear forces  $Q_{targ-aft}$  and  $Q_{targ-fwd}$  at the aft and forward transverse bulkheads of the mid-hold, in kN, for a given FE load combination, are taken as:

- if  $Q_{fwd} \geq Q_{aft}$  :
 
$$Q_{targ-aft} = Q_{sw-aft} - \Delta Q_{sw-aft} + |C_{QV}| Q_{wv-neg}$$

$$Q_{targ-fwd} = Q_{sw-fwd} + \Delta Q_{sw-fwd} + |C_{QV}| Q_{wv-pos}$$
- if  $Q_{fwd} < Q_{aft}$  :
 
$$Q_{targ-aft} = Q_{sw-aft} + \Delta Q_{sw-aft} + |C_{QV}| Q_{wv-pos}$$

$$Q_{targ-fwd} = Q_{sw-fwd} - \Delta Q_{sw-fwd} + |C_{QV}| Q_{wv-neg}$$

where:

$Q_{fwd}$ ,  $Q_{aft}$  : Vertical shear forces, in kN, due to the local loads, respectively at the forward and aft bulkhead positions of the mid-hold, as defined in [4.4.6]

$Q_{sw-aft}$ ,  $Q_{sw-fwd}$  : Aft and forward permissible still water shear forces, in kN, at any longitudinal position for seagoing conditions as defined in Ch 5, Sec 4

$C_{QV}$  : Load combination factor for vertical wave shear force, as given in Ch 5, Sec 2

$Q_{wv-pos}$ ,  $Q_{wv-neg}$  : Positive and negative vertical wave shear forces, in kN, as defined in Ch 5, Sec 4, [3.2.1].

$\Delta Q_{sw-fwd}$  : Shear force correction, in kN, for the considered FE loading pattern at the forward bulkhead taken as:

- For bulk carriers and ore carriers:

Minimum of the absolute values of  $\Delta Q_{md-fwd}$  as defined in [4.3.4] calculated at forward bulkhead for the mid-hold and the value calculated at aft bulkhead of the forward cargo hold taken as:

$$\Delta Q_{sw-fwd} = \text{Min}(|\Delta Q_{md-fwd}|_{\text{Mid}}, |\Delta Q_{md-fwd}|_{\text{Fwd}})$$

- For other ships:

$$\Delta Q_{sw-fwd} = 0$$

$\Delta Q_{sw-aft}$  : Shear force correction, in kN, for the considered FE loading pattern at the aft bulkhead taken as:

- For bulk carriers and ore carriers:

Minimum of the absolute values of  $\Delta Q_{md-fwd}$  as defined in [4.3.4] calculated at aft bulkhead for the mid-hold and the value calculated at forward bulkhead of the aft cargo hold taken as:

$$\Delta Q_{sw-aft} = \text{Min}(|\Delta Q_{md-fwd}|_{\text{Mid}}, |\Delta Q_{md-fwd}|_{\text{Aft}})$$

- For other ships:

$$\Delta Q_{sw-aft} = 0$$

The values of  $Q_{\text{targ-aft}}$  and  $Q_{\text{targ-fwd}}$  are to be taken at the aft and forward transverse bulkheads of the mid-hold under consideration.

#### 4.3.4 Shear force correction for bulk carriers and ore carriers

For bulk carriers and ore carriers, shear force correction, which takes into account the portion of loads transmitted by the double bottom longitudinal girders to the transverse bulkheads, is to be considered.

For the considered cargo hold, the shear force correction at the considered transverse section is to be obtained, in kN, from the following formula:

$$\Delta Q_{md-fwd} = C_d \alpha \left( \frac{M}{B_H \ell_H} - \rho T_{LC, mh} \right)$$

where:

$C_d$  : Distribution coefficient taken as:

- $C_d = -1$  at the aft end of the considered cargo hold except for aftmost cargo hold
- $C_d = 1$  at the fore end of the considered cargo hold except for foremost cargo hold
- $C_d = 0$  at mid-length of the cargo hold
- $C_d = 0$  at the aft bulkhead of the aftmost cargo hold
- $C_d = 0$  at the fore bulkhead of the foremost cargo hold
- $C_d$  : Linearly distributed at other locations

$\alpha$  : Coefficient taken as:

$$\alpha = g \frac{\ell_o b_o}{2 + \varphi \frac{\ell_o}{b_o}}$$

$M$  : Mass, in t, in the hold in way of the considered transverse section for the considered loading condition.  $M$  is to include the mass of ballast water and fuel oil located directly below the flat portion of the inner bottom, if any, excluding the portion under the bulkhead stool

$\varphi$  : Coefficient taken as:

$$\varphi = 1,38 + 1,55 \frac{\ell_o}{b_o}$$

without being taken greater than 3,7

$B_H$  : Breadth of the cargo hold, in m, as defined in Ch 5, Sec 6

$\ell_H$  : Length of the cargo hold, in m, as defined in Ch 5, Sec 6

$\ell_o, b_o$  : Length and breadth, respectively, in m, of the flat portion of the double bottom in way of the hold considered;  $b_o$  is to be measured on the hull transverse section at the middle of the hold

$T_{LC, mh}$  : Draught, in m, measured vertically on the hull transverse section at the middle of the hold considered, from the moulded baseline to the waterline in the loading condition considered

$\Delta Q_{CF}$  : Shear force correction for the full hold (see Fig 18)

$\Delta Q_{CE}$  : Shear force correction for the empty hold (see Fig 18).

Figure 18 : Shear force correction,  $\Delta Q_C$

**4.3.5 Target hull girder horizontal bending moment**

The target hull girder horizontal bending moment  $M_{h-targ}$ , in kN-m, for a given FE load combination is taken as:

$$M_{h-targ} = M_{wh-LC}$$

where:

$M_{wh-LC}$  : Horizontal wave bending moment, in kN-m, for the dynamic load case under consideration, calculated in accordance with Ch 5, Sec 4, [3.6.3].

Within the midship cargo hold region, the value of  $M_{wh-LC}$  is taken as the maximum hull girder bending moment within the mid-hold(s) for each individual cargo hold for each given FE load combination.

Outside the midship cargo hold region, the values of  $M_{wh-LC}$  are taken at all web frames and transverse bulkhead positions of the FE model under consideration.

**4.3.6 Target hull girder torsional moment**

For ships with large deck openings only, the target hull girder torsional moment,  $M_{wt-targ}$ , in kNm, for the dynamic load cases OHM, OHS and OVA is the value at the target location taken as:

$$M_{wt-targ} = M_{wt-LC}(x_{targ})$$

where:

$M_{wt-LC}(x)$ : Wave torsional moment, in kNm, for the dynamic load cases OHM, OHS and OVA, defined in Ch 5, Sec 4, [3.6.5], calculated at x position

$x_{targ}$  : Target location for hull girder torsional moment taken as:

- For midship cargo hold region:
  - If  $x_{mid} \leq 0,5 L$ : after bulkhead of the mid-hold
  - If  $x_{mid} > 0,5 L$ : forward bulkhead of the mid-hold
- Outside midship cargo hold region:

The transverse bulkhead of mid-hold where the following formula is minimum:

$$\frac{M_{wt-LC}(x_{bhd})}{|M_{wt-LC}(x_{bhd})|} \cdot [M_{wt-LC}(x_{bhd}) - M_{T-FEM}(x_{bhd})]$$

$x_{mid}$  : X-coordinate, in m, of the mid-hold centre

$x_{bhd}$  : X-coordinate, in m, of the after or forward transverse bulkhead of mid-hold.

For dynamic load cases of ships with large deck openings other than OHM, OHS and OVA and for all dynamic load cases of other types of ships, the hull girder torsional moment  $M_{wt-targ}$  at middle of mid-hold is to be adjusted to zero.

**4.4 Procedure to adjust hull girder shear forces and bending moments**

**4.4.1 General**

The procedure given in this sub-article describes how to adjust the hull girder horizontal bending moment, vertical shear force and vertical bending moment distribution on the three cargo hold FE model, in order to achieve the required target values defined in [4.3] at the following target locations:

- at the transverse bulkheads of the mid-hold for vertical shear force
- at the centre of the mid-hold, in general, for hull girder bending moments.

The final adjusted loads at the target location should not exceed the target loads.

#### 4.4.2 Local load distribution

The following local loads are to be applied:

- ship structural steel weight distribution over the length of the cargo hold model (static loads)
- static sea pressure, dynamic wave pressure and, where applicable, green sea load
- weight of cargo/containers, ballast and fuel oil (static loads)
- dynamic loads for cargo/containers, ballast and fuel oil in seagoing operation.

The 3D nodal forces obtained by applying the above local loads to the FE model are lumped to each longitudinal station, in order to generate the one dimension local load distribution.

The longitudinal stations are located at transverse bulkheads/frames and typical nodal locations in between the frames according to the cargo hold model mesh size requirement.

Any intermediate nodes created for modeling structural details are not treated as longitudinal stations for the purpose of local load distribution.

The nodal forces are to be lumped to the nearest longitudinal station, the lumping process being done separately for vertical and horizontal nodal forces in order to obtain both vertical and horizontal local loads  $f_{vi}$  and  $f_{hi}$  at each longitudinal station  $i$ .

#### 4.4.3 Hull girder forces and bending moments due to local loads

The model is considered simply supported at both ends. The reaction forces at model ends and the hull girder shear forces and bending moments induced by local loads at any longitudinal station are determined by the following formulae:

$$R_{V\_fore} = - \frac{\sum_i (x_i - x_{aft}) f_{vi}}{x_{fore} - x_{aft}}$$

$$R_{V\_aft} = \sum_i f_{vi} + R_{V\_fore}$$

$$R_{H\_fore} = \frac{\sum_i (x_i - x_{aft}) f_{hi}}{x_{fore} - x_{aft}}$$

$$R_{H\_aft} = -\sum_i f_{hi} + R_{H\_fore}$$

$$F_l = \sum_i f_{li}$$

and, when  $x_i < x_j$ :

$$Q_{V\_FEM}(x_j) = R_{V\_aft} - \sum_i f_{vi}$$

$$Q_{H\_FEM}(x_j) = R_{H\_aft} + \sum_i f_{hi}$$

$$M_{V\_FEM}(x_j) = (x_j - x_{aft}) R_{V\_aft} - \sum_i (x_j - x_i) f_{vi}$$

$$M_{H\_FEM}(x_j) = (x_j - x_{aft}) R_{H\_aft} + \sum_i (x_j - x_i) f_{hi}$$

where:

$R_{V\_aft}$ ,  $R_{V\_fore}$ ,  $R_{H\_aft}$ ,  $R_{H\_fore}$ : Vertical and horizontal reaction forces at the aft and fore ends, in kN

$x_{aft}$ : X-coordinate of the aft end support, in m

$x_{fore}$ : X-coordinate of the fore end support, in m

$f_{vi}$ : Lumped vertical local load at longitudinal station  $i$ , in kN, as defined in [4.4.2]

$f_{hi}$ : Lumped horizontal local load at longitudinal station  $i$ , in kN, as defined in [4.4.2]

$F_l$ : Total longitudinal force of the model, in kN

$f_{li}$ : Lumped longitudinal local load at longitudinal station  $i$ , in kN, as defined in [4.4.2]

$x_j$ : X-coordinate, in m, of the considered longitudinal station  $j$

$x_i$ : X-coordinate, in m, of longitudinal station  $i$

$Q_{V\_FEM}(x_j)$ ,  $Q_{H\_FEM}(x_j)$ ,  $M_{V\_FEM}(x_j)$ ,  $M_{H\_FEM}(x_j)$ : Vertical and horizontal shear forces, in kN, and bending moments, in kN-m, at longitudinal station  $x_j$  created by the local loads applied on the FE model. According to the sign convention, positive reaction forces create a positive shear force.

#### 4.4.4 Longitudinal unbalanced force

In case the total longitudinal force of the model  $F_1$  is not equal to zero, the counter longitudinal force  $(F_x)_j$  is to be applied at the model end where the translation in X-direction  $\delta_x$  is fixed.  $(F_x)_j$  is to be distributed among all the bending effective hull girder longitudinal elements, as follows:

$$(F_x)_j = \frac{F_1}{A_{x-n50}} \frac{A_{j-n50}}{n_j}$$

where:

- $(F_x)_j$  : Axial force, in kN, applied to a node of the j-th element
- $F_1$  : Total longitudinal force of the model, in kN, as defined in [4.4.3]
- $A_{j-n50}$  : Net cross-sectional area of the j-th element, in m<sup>2</sup>
- $A_{x-n50}$  : Net cross-sectional area of the fore end section, in m<sup>2</sup>:

$$A_{x-n50} = \sum_j A_{j-n50}$$

- $n_j$  : Number of nodal points of the j-th element on the cross-section:
  - $n_j = 1$  for beam element
  - $n_j = 2$  for 4-node shell element.

#### 4.4.5 Hull girder shear force adjustment procedure

The hull girder shear force adjustment procedure defined in this requirement applies to all the FE load combinations. The FE load combinations not directly covered by the applicable Part D or Part E chapter are to be considered on a case-by-case basis.

The two following methods are used for shear force adjustment:

- method 1 (M1): shear force adjustment at one of the mid-hold bulkheads, as given in [4.4.6]
- method 2 (M2): shear force adjustment at both mid-hold bulkheads, as given in [4.4.7]

The method to be applied for one given FE load combination is to be selected as follows:

- no shear force adjustment is requested when the shear forces at both bulkheads are lower than, or equal to, the target values. This applies to cargo hold analysis in whole cargo area except for aft most and foremost cargo hold.

For aft most and foremost cargo hold analyses, the shear force adjustment is to be applied with method 1. The target hull girder vertical shear force at the aft and forward transverse bulkheads,  $Q_{\text{targ-aft}}$  and  $Q_{\text{targ-fwd}}$  are to be set to values of vertical shear force due to local loads  $Q_{\text{aft}}$  and  $Q_{\text{fwd}}$  accordingly:

$$Q_{\text{targ-fwd}} = Q_{\text{fwd}}$$

$$Q_{\text{targ-aft}} = Q_{\text{aft}}$$

- method 1 applies when the shear force exceeds the target value at one bulkhead. At the other bulkhead, the shear force adjusted according to method 1 is not to exceed the target value, otherwise method 2 is to be applied
- method 2 applies when the shear forces exceed the target values at both bulkheads.

#### 4.4.6 Method 1 for vertical shear force adjustment at one bulkhead

The required adjustments in shear force at aft or forward transverse bulkhead of the mid-hold are to be made by applying vertical bending moments,  $M_{y\text{-aft}}$ ,  $M_{y\text{-fore}}$  at model ends. For aft most cargo and foremost cargo hold models, the following additional vertical loads are to be applied at the transverse frame positions as shown in Tab 7:

- for aft most cargo hold model:  $\delta w'_1$
- for foremost cargo hold model:  $\delta w'_3$

The required adjustments in shear force at mid-hold aft and forward bulkheads are given by:

- aft bulkhead:

$$M_{y\text{-aft}} = M_{y\text{-fore}} = \frac{(X_{\text{fore}} - X_{\text{aft}})}{2} (Q_{\text{targ-aft}} - Q_{\text{aft}}) - M'_{1\text{-aft}}$$

$$\Delta Q_{\text{aft}} = \Delta Q_{\text{fwd}} = 0$$

- for aftmost cargo hold model only:

$$\delta w'_1 = \frac{Q_{\text{targ-aft}} - Q_{\text{aft}} + R_{y\text{-aft}}}{(n_1 - 1)}$$

- for foremost cargo hold model only:

$$\delta w'_3 = \frac{Q_{\text{targ-aft}} - Q_{\text{aft}} + R_{y\text{-fore}}}{(n_3 - 1)}$$

- forward bulkhead:

$$M_{y\text{-aft}} = M_{y\text{-fore}} = \frac{(X_{\text{fore}} - X_{\text{aft}})}{2} (Q_{\text{targ-fwd}} - Q_{\text{fwd}}) - M'_{1\text{-fwd}}$$

$$\Delta Q_{aft} = \Delta Q_{fwd} = 0$$

- for aftmost cargo hold model only:

$$\delta w'_1 = \frac{Q_{targ-fwd} - Q_{fwd} + R_{v-aft}}{(n_1 - 1)}$$

- for foremost cargo hold model only:

$$\delta w'_3 = \frac{Q_{targ-fwd} - Q_{fwd} + R_{v-fore}}{(n_3 - 1)}$$

where:

$M_{Y\_aft}$ ,  $M_{Y\_fore}$ : Vertical bending moments, in kN-m, to be applied at the aft and fore ends in accordance with [4.4.10], in order to enforce the hull girder vertical shear force adjustment as shown in Tab 4. The sign convention is that of the FE model.

$Q_{aft}$ : Vertical shear force, in kN, due to the local loads at mid-hold aft bulkhead location  $x_{b\_aft}$  resulting from the local loads calculated according to [4.4.3]

Since the vertical shear force is discontinued at the transverse bulkhead location,  $Q_{aft}$  is the maximum absolute shear force between the stations located right after and right forward the mid-hold aft bulkhead

$Q_{fwd}$ : Vertical shear force, in kN, due to the local loads at mid-hold forward bulkhead location  $x_{b\_fwd}$  resulting from the local loads calculated according to [4.4.3]

Since the vertical shear force is discontinued at the transverse bulkhead location,  $Q_{fwd}$  is the maximum absolute shear force between the stations located right after and right forward the mid-hold forward bulkhead.

$M'_{1-aft}$ ,  $M'_{1-fwd}$ : Additional vertical bending moment, in kNm, applicable for aftmost and foremost cargo hold analysis only, taken as:

- aft most cargo hold model:

$$M'_{1-aft} = \frac{\ell_1}{4}(Q_{targ-aft} - Q_{aft} + R_{v-aft})$$

$$M'_{1-fwd} = \frac{\ell_1}{4}(Q_{targ-fwd} - Q_{fwd} + R_{v-aft})$$

- foremost cargo hold model:

$$M'_{1-aft} = \frac{\ell_3}{4}(Q_{targ-aft} - Q_{aft} + R_{v-fore})$$

$$M'_{1-fwd} = \frac{\ell_3}{4}(Q_{targ-fwd} - Q_{fwd} + R_{v-fore})$$

$\delta w'_1$ : Distributed load, in kN, at frame in the modelled engine room of aftmost cargo hold model, see also Tab 7

$\delta w'_3$ : Distributed load, in kN, at frame in the modelled forepeak of foremost cargo hold model, see also Tab 7

$\Delta Q_{aft}$ ,  $\Delta Q_{fwd}$ : Shear force adjustments, as given in Tab 7

$R_{v\_aft}$ ,  $R_{v\_fore}$ : Reaction forces at the aft and fore end, in kN, as defined in [4.4.3]

$\ell_1$ : Length of the modelled engine room in aftmost cargo hold model, in m. (see also Tab 7)

$\ell_3$ : Length of the modelled forepeak in foremost cargo hold model, in m. (see also Tab 7)

$n_1$ ,  $n_3$ : Number of frame spaces (see also Tab 7)

**Table 4 : Vertical shear force adjustment by application of vertical bending moments  $M_{Y\_aft}$  and  $M_{Y\_fore}$  for method**

**4.4.7 Method 2 for vertical shear force adjustment at both bulkheads**

The required adjustments in shear force at both mid-hold transverse bulkheads are to be made by applying:

- vertical bending moments  $M_{Y\_aft}$  and  $M_{Y\_fore}$  at model ends, and
- vertical loads at the transverse frame positions as shown in Tab 6, in order to generate vertical shear forces  $\Delta Q_{aft}$  and  $\Delta Q_{fwd}$  at the transverse bulkhead positions.
- for aft most cargo and foremost cargo hold models, the following additional vertical loads are to be applied at the transverse frame positions as shown in Tab 6:
  - for aft most cargo hold model:  $\delta w'_1$
  - for foremost cargo hold model:  $\delta w'_3$

Tab 5 shows application examples of the shear force adjustment by means of vertical bending moments and vertical loads.

$$M_{Y\_aft} = M_{Y\_fore} = \frac{(x_{fore} - x_{aft})(Q_{targ\_fwd} - Q_{fwd} + Q_{targ\_aft} - Q_{aft})}{2} - M'_2$$

$$M_{Y\_fore} = M_{Y\_aft}$$

$$\Delta Q_{fwd} = \frac{Q_{targ\_fwd} - Q_{fwd} - (Q_{targ\_aft} - Q_{aft})}{2}$$

$$\Delta Q_{aft} = -\Delta Q_{fwd}$$

For aft most cargo hold model:

$$\delta w'_1 = \frac{\left[ \frac{(Q_{targ\_aft} - Q_{aft})(l - l_2 - l_1) + (Q_{targ\_fwd} - Q_{fwd})(l - l_2 - l_3)}{2l - l_1 - 2l_2 - l_3} + R_{V\_aft} \right]}{n_1 - 1}$$

For foremost cargo hold model:

$$\delta w'_3 = \frac{\left[ \frac{(Q_{targ\_fwd} - Q_{fwd})(l - l_2 - l_3) + (Q_{targ\_aft} - Q_{aft})(l - l_2 - l_1)}{2l - l_1 - 2l_2 - l_3} + R_{V\_fore} \right]}{n_3 - 1}$$

where:

$M_{Y\_aft}$ ,  $M_{Y\_fore}$ : Vertical bending moments, in kN-m, to be applied at the aft and fore ends in accordance with [4.4.10], in order to enforce the hull girder vertical shear force adjustment. The sign convention is that of the FE model

$\Delta Q_{aft}$ : Shear force adjustment, in kN, at mid-hold aft bulkhead

$\Delta Q_{fwd}$ : Shear force adjustment, in kN, at mid-hold forward bulkhead.

**Table 5 : Target and required shear force adjustment by applying vertical forces**

Vertical shear force diagram	Aft bulkhead	Forward bulkhead
	Target shear force	Target shear force
	$Q_{targ\_aft} (-ve)$	$Q_{targ\_fwd} (+ve)$
	$Q_{targ\_aft} (+ve)$	$Q_{targ\_fwd} (-ve)$
<p><b>Note 1:</b> -ve means negative, +ve means positive.</p> <p>———— Vertical shear force after both adjustments</p> <p>----- Vertical shear force after adjustment by use of <math>M_{Y\_aft}</math> and <math>M_{Y\_fore}</math></p> <p>..... Vertical shear force due to local loads</p>		

$M'_2$  : Additional vertical bending moment, in kNm, applicable for aftmost and foremost cargo hold analysis only, taken as:

- aftmost cargo hold model

$$M'_2 = \frac{\ell_1(n_1-1)\delta w'_1}{4}$$

- foremost cargo hold model

$$M'_2 = \frac{\ell_3(n_3-1)\delta w'_3}{4}$$

$\delta w'_1$  : Distributed load, in kN, at frame in the modelled engine room of aftmost cargo hold model, see also Tab 7

$\delta w'_3$  : Distributed load, in kN, at frame in the modelled forepeak of foremost cargo hold model, see also Tab 7

$R_{v\_aft}$ ,  $R_{v\_fore}$  : Reaction forces at the aft and fore ends, in kN, as defined in [4.4.3]

$\ell_1$  : Length of the modelled engine room in aftmost cargo hold model, in m. (see also Tab 7)

$\ell_3$  : Length of the modelled forepeak in foremost cargo hold model, in m. (see also Tab 7)

$n_1$ ,  $n_3$  : Number of frame spaces (see also Tab 7)

The shear force adjustments  $\Delta Q_{aft}$  and  $\Delta Q_{fore}$  are to be generated at transverse bulkhead positions by applying vertical loads at the transverse frame positions, as shown in Tab 6.

Vertical correction loads are not to be applied to any transverse tight bulkheads, any frames forward of the forward cargo hold nor any frames aft of the aft cargo hold of the FE model.

The vertical loads applied to each transverse frame in order to generate the increase/decrease in shear force at bulkheads may be calculated as shown in Tab 6.

In case of uniform frame spacing, the amount of vertical force to be distributed at each transverse frame may be calculated in accordance with Tab 7.

Where non-uniform frame spacing is used within a hold  $i$ , the average frame spacing  $\ell_{av-i}$  is used to calculate the average frame load  $\delta w_{av-i}$  according to Tab 7.  $\delta w_{av-i}$  is then redistributed among the non-uniform frames, as follows:

$$\delta w_i^k = \delta w_{av-i} \frac{\ell_{av-i}^k}{\ell_{av-i}}$$

where:

$k = 1, 2, \dots, n_i-1$ , for each frame in cargo hold  $i$ , with  $i = 1, 2, 3$

$\ell_{av-i}$  : Average frame spacing, in m, equal to:  $\ell_{av-i} = \ell_i / n_i$ , in cargo hold  $i$ , with  $i = 1, 2, 3$

$\ell_i$  : Length, in m, of the cargo hold  $i$ , with  $i = 1, 2, 3$ , as defined in Tab 7

$n_i$  : Number of frame spacings in cargo hold  $i$ , with  $i = 1, 2, 3$ , as defined in Tab 7

$\delta w_{av-i}$  : Average frame load calculated, according to Tab 7, with the average frame spacing  $\ell_{av-i}$  in cargo hold  $i$ , with  $i = 1, 2, 3$

$\delta w_i^k$  : Distributed load, in kN, for non-uniform frame  $k$  in cargo hold  $i$

$\ell_{av-i}^k$  : Equivalent frame spacing, in m, for each frame  $k$ , with  $k = 1, 2, \dots, n_i-1$ , in cargo hold  $i$ , taken equal to:

- for  $k = 1$  (first frame), in cargo hold  $i$ :

$$\ell_{av-i}^k = \ell_i - \frac{\ell_{av-i} \ell_i^1}{\ell_i^1 + \ell_i^{n_i}} + \frac{\ell_i^2}{2}$$

- for  $k = 2, 3, \dots, n_i-2$ , in cargo hold  $i$ :

$$\ell_{av-i}^k = \frac{\ell_i^k}{2} + \frac{\ell_i^{k+1}}{2}$$

- for  $k = n_i-1$  (last frame), in cargo hold  $i$ :

$$\ell_{av-i}^k = \ell_i - \frac{\ell_{av-i} \ell_i^{n_i}}{\ell_i^1 + \ell_i^{n_i}} + \frac{\ell_i^{n_i-1}}{2}$$

$\ell_i^k$  : Frame spacing, in m, between the frames  $k-1$  and  $k$ , in the cargo hold  $i$ .

The vertical correction loads,  $\delta w_i$  for a uniform frame spacing or  $\delta w_i^k$  for a non-uniform frame spacing, are to be applied, following the shear flow distribution at the considered cross-section, as described in Ch 6, App 1. For a frame section under the vertical load  $\delta w_i$ , the shear flow  $q_{i-k}$ , at the middle point of the element, is calculated as follows:

$$q_{i-k} = \frac{\delta w_i}{I_{y-n50} \cdot 10^{12}} Q_{k-n50}$$

where:

$q_{i-k}$  : Shear flow calculated at the middle of the  $k$ -th element of the transverse frame, in N/mm

$\delta w_i$  : Distributed load at each transverse frame location, in N, for the  $i$ -th cargo hold ( $i = 1, 2, 3$ ), as defined in Tab 7

$Q_{k-n50}$  : First moment, about the neutral axis, of the accumulative section area starting from the open end (shear stress free end) of the cross-section to the point  $s_k$  for shear flow  $q_{i-k}$ , in  $\text{mm}^3$ , taken as:

$$Q_{k-n50} = \int_0^{S_k} z_{neu} t_{n50} ds$$

$z_{neu}$  : Vertical distance, in mm, from the integral point  $s$  to the vertical neutral axis

$t_{n50}$  : Net thickness, in mm, of the plate at the integral point of the cross-section

The distributed shear force  $F_{j-grid}$  at the  $j$ -th FE grid of the transverse frame, in N, is obtained from the shear flow of the connected elements, as follows:

$$F_{j-grid} = \sum_{k=1}^n q_{t-k} \frac{\ell_k}{2}$$

where:

$\ell_k$  : Length, in mm, of the  $k$ -th element of the transverse frame connected to grid  $j$

$n$  : Total number of elements connected to grid  $j$ .

The shear flow has direction along the cross-section and therefore the distributed force  $F_{j-grid}$  is a vector force. For vertical hull girder shear correction, the vertical and horizontal force components calculated with the above mentioned shear flow method need to be applied to the cross-section.

#### 4.4.8 Procedure to adjust vertical and horizontal bending moments for midship cargo hold region

In case the target vertical bending moment needs to be reached, an additional vertical bending moment  $M_{v-end}$  is to be applied at both FE model ends, according to [4.4.10], in order to generate this target value within the mid-hold. This additional vertical bending moment is to be taken, in kN-m, equal to:

$$M_{v-end} = M_{v-targ} - M_{v-peak}$$

where:

$M_{v-targ}$  : Hogging (positive) or sagging (negative) vertical bending moment, in kN-m, as specified in [4.3.2]

$M_{v-peak}$  : Maximum or minimum bending moment, in kN-m, within the mid-hold length induced by the local loads as described in [4.4.3] and the shear force adjustment as defined in [4.4.5].

$M_{v-peak}$  is to be taken as the maximum bending moment if  $M_{v-targ}$  is hogging (positive) and as the minimum bending moment if  $M_{v-targ}$  is sagging (negative).

$M_{v-peak}$  is to be calculated as follows, based on a simply supported beam model:

$$M_{v-peak} = \text{Extremum} \left\{ M_{V\_FEM}(x) + M_{lineload} + M_{Y\_aft} \left( 2 \frac{x - X_{aft}}{X_{fore} - X_{aft}} - 1 \right) \right\}$$

$M_{V\_FEM}(x)$ : Vertical bending moment, in kN-m, at position  $x$ , induced by the local loads as described in [4.4.3]

$M_{Y\_aft}$  : Aft bending moment, in kN-m, to be taken equal to:

- when method 1 is applied: the value defined in [4.4.6]
- when method 2 is applied: the value defined in [4.4.7]
- otherwise:  $M_{Y\_aft} = 0$

$M_{lineload}$  : Vertical bending moment, in kN-m, at position  $x$ , induced by the application of vertical loads at frames according to method 2, to be taken equal to:

$$M_{lineload} = -(x - X_{aft})F - \sum_i (x - x_i) \delta w_i \text{ when } x_i < x$$

$F$  : Reaction force, in kN, at model ends induced by the application of vertical loads to frames as defined in Tab 6

$x$  : X-coordinate, in m, of frame in way of the mid-hold

$\delta w_i$  : Vertical load, in kN, at web frame station  $i$  applied to generate required shear force.

In case the target horizontal bending moment needs to be reached, an additional horizontal bending moment  $M_{h-end}$  is to be applied at both FE model ends, according to [4.4.10], in order to generate this target value within the mid-hold. The additional horizontal bending moment, in kN-m, is to be taken equal to:  $M_{h-end} = M_{h-targ} - M_{h-peak}$

where:

$M_{h-targ}$  : Horizontal bending moment, as defined in [4.3.5]

$M_{h-peak}$  : Maximum or minimum horizontal bending moment, in kN-m, within the mid-hold length induced by the local loads described in [4.4.3].

$M_{h-peak}$  is to be taken as the maximum horizontal bending moment if  $M_{h-targ}$  is positive (starboard side in tension) and as the minimum horizontal bending moment if  $M_{h-targ}$  is negative (port side in tension).

$M_{h-peak}$  is to be calculated as follows, based on a simply supported beam model:

$$M_{h-peak} = \text{Extremum} \{ M_{H\_FEM}(x) \}$$

$M_{H\_FEM}(x)$ : Horizontal bending moment, in kN-m, at position  $x$ , induced by the local loads as described in [4.4.3].

The vertical and horizontal bending moments are to be calculated over the mid-hold length in order to identify the position and value of each maximum/minimum bending moment.

Table 6 : Distribution of adjusting vertical force at frames and resulting shear force distributions

**Table 7 : Formulae for calculation of vertical loads for adjusting vertical shear forces**

$\delta w_1$	: Distributed load, in kN, at frame in the aft cargo hold of the FE model $\delta w_1 = \frac{\Delta Q_{aft} (2\ell - \ell_2 - \ell_3) + \Delta Q_{fwd} (\ell_2 + \ell_3)}{(n_1 - 1) (2\ell - \ell_1 - 2\ell_2 - \ell_3)} + \delta w'_1$
$\delta w_2$	: Distributed load, in kN, at frame in the mid-hold of the FE model $\delta w_2 = \frac{(W1 + W3)}{(n_2 - 1)} = \frac{(\Delta Q_{aft} - \Delta Q_{fwd})}{(n_2 - 1)}$
$\delta w_3$	: Distributed load, in kN, at frame in the forward cargo hold of the FE model $\delta w_3 = \frac{-\Delta Q_{fwd} (2\ell - \ell_1 - \ell_2) - \Delta Q_{aft} (\ell_1 + \ell_2)}{(n_3 - 1) (2\ell - \ell_1 - 2\ell_2 - \ell_3)} = \delta w'_3$
F	: End reactions, in kN, due to application of vertical loads to frames: <ul style="list-style-type: none"> <li>In general  <math display="block">F = F_{aft} = F_{fwd} = 0,5 \left( \frac{W1 \ell_2 + \ell_1 - W3 \ell_2 + \ell_3}{\ell} \right)</math></li> <li>For aftmost and foremost cargo hold FE model  <math display="block">F = F_{aft} = \frac{W1(\Delta \ell_{fore} + \ell_3 + \ell_2 + 0,5\ell_1) + W2(\Delta \ell_{fore} + \ell_3 + 0,5\ell_2) + W3(\Delta \ell_{fore} + 0,5\ell_3)}{\ell}</math></li> </ul>
where:	
$\Delta Q_{aft}$	: Required adjustment in shear force, in kN, at the aft bulkhead of the mid-hold, see [4.4.7]
$\Delta Q_{fwd}$	: Required adjustment in shear force, in kN, at fore bulkhead of the mid-hold, see [4.4.7]
$\ell$	: Total length, in m, of FE model including portions beyond end bulkheads: $\ell = \ell_1 + \ell_2 + \ell_3 + \Delta \ell_{end} + \Delta \ell_{fore}$
$\ell_1$	: Length of the aft cargo hold of the model, in m
$\ell_2$	: Length of the mid-hold of the model, in m
$\ell_3$	: Length of the forward cargo hold of the model, in m
$n_1$	: Number of frame spaces in the aft cargo hold of the FE model
$n_2$	: Number of frame spaces in the mid-hold of the FE model
$n_3$	: Number of frame spaces in the forward cargo hold of the FE model
$\delta w'_1$	: Additional distributed load, in kN, at frame in the modelled engine room of aftmost cargo hold model. Formulae of $\delta w'_1$ are given in [4.4.6] and [4.4.7] for shear force adjustment method 1 and method 2 accordingly
$\delta w'_3$	: Additional distributed load, in kN, at frame in the modelled forepeak of foremost cargo hold model. Formulae of $\delta w'_3$ are given in [4.4.6] and [4.4.7] for shear force adjustment method 1 and method 2 accordingly
W1	: Total evenly distributed vertical load, in kN, applied to the aft hold of the FE model: $W1 = (n_1 - 1) \delta w_1$
W2	: Total evenly distributed vertical load, in kN, applied to the mid-hold of the FE model: $W2 = (n_2 - 1) \delta w_2$
W3	: Total evenly distributed vertical load, in kN, applied to the forward hold of the FE model: $W3 = (n_3 - 1) \delta w_3$
$\Delta \ell_{end}$	: Distance, in m, between the aft bulkhead of the aft cargo hold to the aft end of the FE model $\Delta \ell_{end} = 0$ in the aftmost cargo hold model
$\Delta \ell_{fore}$	: Distance, in m, between the forward bulkhead of the forward cargo hold to the forward end of the FE model $\Delta \ell_{fore} = 0$ in the foremost cargo hold model
<b>Note 1:</b> In the above formulae, positive direction of loads, shear forces and adjusting vertical forces is in accordance with Tab 5 and Tab 6.	
<b>Note 2:</b> $W1 + W3 = W2$ (not applicable for aftmost and foremost cargo FE model)	
<b>Note 3:</b> The above formulae are applicable only if a uniform frame spacing is used within each hold. The length and frame spacing of individual cargo holds may be different.	

**4.4.9 Procedure to adjust vertical and horizontal bending moments outside midship cargo hold region**

To reach the vertical hull girder target values at each frame and transverse bulkhead position, as defined in [4.3.2], the vertical bending moment adjustments,  $m_{vi}$ , are to be applied at web frames and transverse bulkhead positions of the finite element model, as shown in Fig 19. The vertical bending moment adjustment at each longitudinal location,  $i$ , is to be calculated as follows:

$$f(i) = M_{v-targ}(i) - M_{v-FEM}(i) - M_{lineload}(i) - M_{Y-aft} \cdot \left( \frac{2(x_i - x_{aft})}{x_{fore} - x_{aft}} - 1 \right)$$

$$m_{vi} = \frac{f(i) + f(i+1)}{2} - \sum_{j=0}^{i-1} m_{vj}$$

$$m_{v\_end} = - \sum_{j=0}^{n_t} m_{vj}$$

where:

- $i$  : Index corresponding to the  $i$ -th station, starting from  $i=1$  at the aft end section up to  $n_t$
- $n_t$  : Total number of longitudinal stations where the vertical bending moment adjustment,  $m_{vi}$ , is applied
- $m_{vi}$  : Vertical bending moment adjustment, in kN.m, to be applied at transverse frame or bulkhead at station  $i$
- $m_{v\_end}$  : Vertical bending moment adjustment, in kN.m, to be applied, at the fore end section ( $n_t+1$  station)
- $m_{vj}$  : Argument of summation to be taken as:
  - $m_{v0} = 0$  when  $j = 0$
  - $m_{vj} = m_{vi}$  when  $j = i$
- $M_{v-targ}(i)$  : Required target vertical bending moment, in kN.m, at station  $i$ , calculated in accordance with [4.3.2]
- $M_{v-FEM}(i)$  : Vertical bending moment distribution, in kN.m, at station  $i$  due to local loads as given in [4.4.3]
- $M_{lineload}(i)$  : Vertical bending moment, in kN.m, at station  $i$ , due to the line load for the vertical shear force correction as required in [4.4.8].

To reach the horizontal hull girder target values at each frame and transverse bulkhead position as defined in [4.3.4], the horizontal bending moment adjustments,  $m_{hi}$ , are to be applied at web frames and transverse bulkhead positions of the finite element model, as shown in Fig 19. The horizontal bending moment adjustment at each longitudinal location,  $i$ , is to be calculated as follows:

$$f(i) = M_{h-targ}(i) - M_{h-FEM}(i)$$

$$m_{hi} = \frac{f(i) + f(i+1)}{2} - \sum_{j=0}^{i-1} m_{hj}$$

$$m_{h\_end} = - \sum_{j=0}^{n_t} m_{hj}$$

where:

- $i$  : Longitudinal location for bending moment adjustments,  $m_{hi}$ .
- $n_t$  : Total number of longitudinal stations where the horizontal bending moment adjustment,  $m_{hi}$ , is applied.
- $m_{hi}$  : Horizontal bending moment adjustment, in kN.m, to be applied at transverse frame or bulkhead at station  $i$ .
- $m_{h\_end}$  : Horizontal bending moment adjustment, in kN.m, to be applied at the fore end section ( $n_t+1$  station).
- $m_{hj}$  : Argument of summation to be taken as:
  - $m_{h0} = 0$  when  $j = 0$
  - $m_{hj} = m_{hi}$  when  $j = i$

**Figure 19 : Adjustments of bending moments outside midship cargo hold region.**

$m_{hi}$  can be substituted to  $m_{vi}$  in this figure and  $m_i$  is the positive bending moment in FE coordinate system.

$M_{h-targ}(i)$  : Required target horizontal bending moment, in kN.m, at station  $i$ , calculated in accordance with [4.3.5].

$M_{H-FEM}(i)$  : Horizontal bending moment distribution, in kN.m, at station  $i$  due to local loads as given in [4.4.3].

The vertical and horizontal bending moment adjustments,  $m_{vi}$  and  $m_{hi}$ , are to be applied at all web frames and bulkhead positions of the FE model. The adjustments are to be applied in FE model by distributing longitudinal axial nodal forces to all hull girder bending effective longitudinal elements in accordance with [4.4.10].

#### 4.4.10 Application of bending moment adjustments on the FE model

The required vertical and horizontal bending moment adjustments are to be applied by distributing the longitudinal axial nodal forces among all the bending effective hull girder longitudinal elements of the considered FE model cross-section according to Ch 6, Sec 1, [1.2], as follows:

- for vertical bending moment:

$$(F_x)_i = \frac{M_v}{I_{y-n50}} \frac{A_{i-n50}}{n_i} Z_i$$

- for horizontal bending moment:

$$(F_x)_i = \frac{M_h}{I_{z-n50}} \frac{A_{i-n50}}{n_i} Y_i$$

where:

$M_v$  : Vertical bending moment adjustment, in kN.m, to be applied to the considered cross-section of the model

$M_h$  : Horizontal bending moment adjustment, in kN.m, to be applied to the considered cross-section of the model

$(F_x)_i$  : Axial force, in kN, applied to a node of the  $i$ -th element

$Z_i$  : Vertical distance, in m, from the neutral axis to the centre of the cross-sectional area of the  $i$ -th element

$Y_i$  : Horizontal distance, in m, from the neutral axis to the centre of the cross-sectional area of the  $i$ -th element

$A_{i-n50}$  : Cross-sectional area, in  $m^2$ , of the  $i$ -th element

$n_i$  : Number of nodal points of the  $i$ -th element on the cross-section:

- $n_i = 1$  for a beam element
- $n_i = 2$  for a 4-node shell element.

For cross-sections not located at the model ends, the average area of the corresponding  $i$ -th elements forward and aft of the considered cross-section is to be used.

## 4.5 Procedure to adjust hull girder torsional moments

### 4.5.1 General

The procedure in this sub-article describes how to adjust the hull girder torsional moment distribution on the cargo hold FE model to achieve the target torsional moment at the target location. The hull girder torsional moment target values are given in [4.3.6].

### 4.5.2 Torsional moment due to local loads

Torsional moment, in kN.m, at longitudinal station  $i$  due to local loads,  $M_{T-FEMi}$  in kN.m, is determined by the following formula (see Fig 20):

$$M_{T-FEMi} = \sum_k [f_{hik}(Z_{ik} - Z_T)] - \sum_k (f_{vik} Y_{ik})$$

where:

$M_{T-FEMi}$  : Lumped torsional moment, in kN.m, due to local load at longitudinal station  $i$

$Z_T$  : Vertical coordinate from baseline, in m, of the horizontal shear centre at the transverse section under consideration, as defined in Ch 5, Sec 4, [3.5.1]

$f_{hik}$  : Horizontal nodal force, in kN, of node  $k$  at longitudinal station  $i$

$f_{vik}$  : Vertical nodal force, in kN, of node  $k$  at longitudinal station  $i$

$Y_{ik}$  : Y--coordinate, in m, of node  $k$  at longitudinal station  $i$

$Z_{ik}$  : Z-coordinate, in m, of node  $k$  at longitudinal station  $i$

$M_{T-FEM0}$  : Lumped torsional moment, in kN.m, due to local load at aft end of the FE model (forward end for foremost cargo hold model), taken as:

- For the foremost cargo hold model:

$$M_{T-FEM0} = \sum_k [f_{hok}(Z_{ok} - Z_T)] - \sum_k (f_{vok} Y_{ok}) + R_{H\_fore}(Z_{ind} - Z_T)$$

- For the other cargo hold models:

$$M_{T-FEM0} = \sum_k [f_{hok}(Z_{ok} - Z_T)] - \sum_k (f_{vok} Y_{ok}) + R_{H\_aft}(Z_{ind} - Z_T)$$

$R_{H\_fore}$  : Horizontal reaction forces, in kN, at the forward end, as defined in [4.4.3]

$R_{F\_aft}$  : Horizontal reaction forces, in kN, at the aft end, as defined in [4.4.3]  
 $Z_{ind}$  : Vertical coordinate, in m, of independent point as defined in [2.5.3].

**Figure 20 : Station forces and acting location of torsional moment at section**

**4.5.3 Hull girder torsional moment**

The hull girder torsional moment,  $M_{T-FEM}(x_j)$ , in kN.m, is obtained by accumulating the station torsional moment from the aft end section (forward end for foremost cargo hold model) as follows:

$$M_{T-FEM}(x_j) = \sum_i M_{T-FEMi}$$

- when  $x_i \geq x_j$  for foremost cargo hold model,
- when  $x_i < x_j$  otherwise.

where:

$M_{T-FEM}(x_j)$ : Hull girder torsional moment, in kN.m, at longitudinal station  $x_j$

$x_j$  : X-coordinate, in m, of considered longitudinal station j.

The torsional moment distribution given in [4.5.2], has a step at each longitudinal station.

**4.5.4 Procedure to adjust hull girder torsional moment to target value**

The torsional moment is to be adjusted by applying a hull girder torsional moment  $M_{T-end}$ , in kN.m, at the independent point of the aft end section of the model (forward end for foremost cargo hold model), given as follows:

$$M_{T-end} = M_{wt-targ} - M_{T-FEM}(x_{targ})$$

where:

$x_{targ}$  : X-coordinate, in m, of the target location for hull girder torsional moment, as defined in [4.3.6]

$M_{wt-targ}$  : Target hull girder torsional moment, in kN.m, specified in [4.3.6], to be achieved at the target location

$M_{T-FEM}(x_{targ})$ : Hull girder torsional moment, in kN.m, at target location due to local loads.

Due to the step of hull girder torsional moment at each longitudinal station, the hull girder torsional moment is to be selected from the values aft and forward of the target location as follows: Maximum value for positive torsional moment and minimum value for negative torsional moment.

**4.6 Summary of hull girder load adjustments**

**4.6.1** The required methods of hull girder load adjustments for different cargo hold regions are given in Tab 8.

**Table 8 : Overview of hull girder load adjustments in FE analyses**

	Midship cargo hold region	After and Forward cargo hold region	Aft most cargo holds	Foremost cargo holds

## 5 Analysis criteria

### 5.1 General

#### 5.1.1 Evaluation areas

Verification of results against the acceptance criteria is to be carried out within the longitudinal extent of the mid-hold, as shown in Fig 21.

Figure 21 : Longitudinal extent of evaluation area

#### 5.1.2 Structural members

The following structural elements within the evaluation area are to be verified with the criteria given in [5.2] and [5.3]:

- all the hull girder longitudinal structural members
- all the primary supporting structural members and bulkheads within the mid-hold
- all the structural members being part of the transverse bulkheads
- all structural members being part of the collision bulkhead and extending to one web frame spacing forward of the collision bulkhead
- all structural members being part of the forward transverse bulkhead of the machinery space and all hull girder longitudinal structural members aft of this transverse bulkhead within the extent of 15% of the aftmost cargo hold length excluding slop tanks if any.

## 5.2 Yield strength assessment

### 5.2.1 Von Mises stress

For all the plates of the structural members defined in [5.1.2], the Von Mises stress  $\sigma_{vm}$ , in N/mm<sup>2</sup>, is to be calculated based on the membrane normal and shear stresses of the shell element. The stresses are to be evaluated at the element centroid of the mid-plane, as follows:

$$\sigma_{vm} = \sqrt{\sigma_x^2 - \sigma_x \sigma_y + \sigma_y^2 + 3\tau_{xy}^2}$$

where:

$\sigma_x$   $\sigma_y$  : Element normal membrane stresses, in N/mm<sup>2</sup>

$\tau_{xy}$  : Element shear stress, in N/mm<sup>2</sup>.

### 5.2.2 Axial stress in beams and rod elements

For beams and rod elements, the axial stress  $\sigma_{axial}$ , in N/mm<sup>2</sup>, is to be calculated based on the axial force alone. The axial stress is to be evaluated at the middle of the element length.

### 5.2.3 Yield criteria

The structural elements given in [5.1.2] are to comply with the following criterion:

$$\lambda_y \leq \lambda_{yperm}$$

where:

$\lambda_y$  : Yield utilisation factor:

$$\lambda_y = \frac{\sigma_{vm}}{R_Y} \text{ for shell elements}$$

$$\lambda_y = \frac{|\sigma_{axial}|}{R_Y} \text{ for rod or beam elements}$$

$\sigma_{vm}$  : Von Mises stress, in N/mm<sup>2</sup>

$\sigma_{axial}$  : Axial stress in rod or beam element, in N/mm<sup>2</sup>

$\lambda_{yperm}$  : Standard mesh permissible yield utilisation factor defined in Tab 9.

**5.2.4 Corrugation of corrugated bulkhead**

The stress in corrugation of corrugated bulkheads is to be evaluated based on:

- a) the von Mises stress,  $\sigma_{vm}$ , in shell elements on the flange and web of the corrugation
- b) the axial stress,  $\sigma_{axial}$ , in dummy rod elements, modeled with unit cross sectional properties at the intersection between the flange and web of the corrugation.

**5.3 Buckling strength assessment**

**5.3.1** All the structural elements in FE analysis carried out in accordance with this Section are to be assessed individually against the buckling requirements as defined in Ch 9, Sec 1.

**Table 9 : Standard mesh permissible yield utilisation factor  $\lambda_{yperm}$**

Structural component	Acceptance criteria (1)	$\lambda_{yperm}$
Plating of all the longitudinal hull girder structural members, primary supporting structural members and bulkheads Face plate of the primary supporting members Dummy rod of corrugated bulkhead	AC-1	0,8
	AC-2	1,0
	AC-3	$1,0 \cdot R_{eH} / R_y$
Corrugation of vertically corrugated bulkheads with lower stool and horizontally corrugated bulkhead, under lateral pressure from liquid loads, for shell elements only Supporting structure in way of lower end of corrugated bulkheads without lower stool (2)	AC-1	0,72
	AC-2	0,9
	AC-3	$0,9 \cdot R_{eH} / R_y$
Corrugation of vertically corrugated bulkheads without lower stool under lateral pressure from liquid loads and without lower stool, for shell elements only	AC-1	0,65
	AC-2	0,81
	AC-3	$0,81 \cdot R_{eH} / R_y$
Supports and keys of independent cargo tanks	AC-1	0,8
	AC-2	0,9
	AC-3	$1,0 \cdot R_{eH} / R_y$
(1) See Ch 8, Sec 1, [4] for the acceptance criteria definition.		
(2) Supporting structure for a transverse corrugated bulkhead refers to the structure in the longitudinal direction within half a web frame space forward and aft of the bulkhead, and within a vertical extent equal to the corrugation depth. Supporting structure for a longitudinal corrugated bulkhead refers to the structure in transverse direction within 3 longitudinal stiffener spacings from each side of the bulkhead, and within a vertical extent equal to the corrugation depth.		

# Appendix 2 Local Structural Strength Analysis

## 1 Objective and scope

### 1.1 General

1.1.1 The local strength analysis of structural details is to be in accordance with the requirements given in this Section.

#### 1.1.2 Fine mesh analysis procedure

The details to be assessed by fine mesh analysis are to be modeled according to the requirements given in Article [2], under the FE load combinations defined in Article [3], and are to comply with the criteria given in Article [4].

### 1.2 Structural details to be assessed by fine mesh analysis

#### 1.2.1 Mandatory structural details

Mandatory structural details subject to fine mesh analysis are listed in Ch 13, Sec 5, [2], as applicable depending on the assigned service notation.

For structural details having the same geometry and the same relative location inside the midship cargo region, one fine mesh model is required. The selection of the location of this fine mesh model is to be based on the detail which has the maximum yield utilisation factor  $\lambda_y$  as defined in Ch 8, App 1, [5.2.3].

Such analysis may also be considered for other details which are considered critical by the Society.

#### 1.2.2 Structural details to be evaluated by screening

The following structural details and areas are to be evaluated by screening according to [1.2.3] in order to determine if a fine mesh analysis is required or not:

- manholes in all areas
- structural details listed in Ch 13, Sec 5, [2], as applicable depending on the assigned service notation

#### 1.2.3 Screening criteria

Stresses in areas defined in [1.2.2], calculated for all the applicable FE load combinations given in Article [3], are to be checked against the following screening criterion:

$$\lambda_{sc} \leq \lambda_{scperm}$$

where:

$\lambda_{sc}$  : Screening factor as defined in Tab 1 and in Part D and Part E for details specific to ship types, as applicable

$\lambda_{scperm}$  : Permissible screening factor as defined in Tab 1 and in Part D and Part E for details specific to ship types, as applicable.

Where the screening criterion is not met, fine mesh analysis of the corresponding structural detail is required and to be performed according to [1.1.2].

**Table 1 : Screening factors and permissible screening factors**

Type of details	Screening factors $\lambda_{sc}$	Permissible screening factors $\lambda_{scperm}$	
		AC-2 (1)	AC-1 (1)
Manholes in all areas (2)	$\lambda_y$ (3)	0,85 $\lambda_{yperm}$ (4)	

(1) See Ch 8, Sec 1, [4] for acceptance criteria definition.  
 (2) The representative element which has the maximum yield utilisation factor around the manhole is to be verified against criteria.  
 (3)  $\lambda_y$  : Standard mesh yield utilisation factor, as defined in Ch 8, App 1, [5.2.3]  
 (4)  $\lambda_{yperm}$  : Standard mesh permissible yield utilisation factor, as defined in Ch 8, App 1, [5.2.3].

## 2 Structural modeling

### 2.1 General

2.1.1 Evaluation of detailed stresses requires the use of refined finite element mesh in way of areas of high stress. This fine mesh analysis can be carried out by fine mesh zones incorporated into the cargo hold model. Alternatively, separate local FE model with fine mesh zones in conjunction with the boundary conditions obtained from the cargo hold model may be used.

## 2.2 Extent of model

2.2.1 If a separate local fine mesh model is used, its extent is to be such that the calculated stresses at the areas of interest are not significantly affected by the imposed boundary conditions. The boundary of the fine mesh model is to coincide with primary supporting members in the cargo hold model, such as web frame, girders, stringers and floors.

## 2.3 Mesh size

2.3.1 The mesh size in the fine mesh zones is not to be greater than 50 x 50 mm.

## 2.4 Elements

2.4.1 All plating within the fine mesh zone is to be represented by shell elements. The aspect ratio of elements within the fine mesh zone is to be kept as close to 1 as possible. Variation of mesh density within the fine mesh zone and the use of triangular elements are to be avoided. In all cases, the elements within the fine mesh model are to have an aspect ratio not exceeding 3. Distorted elements, with element corner angles less than 45° or greater than 135°, are to be avoided. Stiffeners inside the fine mesh zone are to be modeled using shell elements. Stiffeners outside the fine mesh zones may be modeled using beam elements.

2.4.2 The extent of the fine mesh zone is not to be less than 10 elements in all directions from the area under investigation. A smooth transition of mesh density from fine mesh zone to the boundary of the fine mesh model is to be maintained, see Fig 1 and Fig 2.

2.4.3 Where a fine mesh analysis is required for an opening, the first two layers of elements around the opening are to be modeled with mesh size not greater than 50 x 50 mm. A smooth transition from the fine mesh to the coarser mesh is to be maintained. Edge stiffeners which are welded directly to the edge of an opening are to be modeled with shell elements. Web stiffeners close to an opening may be modeled using rod or beam elements located at a distance of at least 50 mm from the edge of the opening. Example of fine mesh zone around an opening is shown in Fig 3.

2.4.4 Face plates of openings, primary supporting members and associated brackets are to be modeled with at least two elements across their width on either side.

Figure 1 : Fine mesh zone around bracket toes

Figure 2 : Example of local model for the analysis of hatch opening structures

Figure 3 : Fine mesh zone around an opening

## 2.5 Transverse web frames

**2.5.1** In addition to the requirements of [2.2] to [2.4], the modeling requirements in this sub-article are applicable to the analysis of a typical transverse web frame.

**2.5.2** Where a FE sub-model is used, the model is to have an extent of at least 1+1 web frame spaces, i.e. one web frame space extending on either side of the transverse web frame under investigation. The transverse web frames forward and aft of the web frame under investigation need not be included in the sub-model.

**2.5.3** The full depth and full breadth of the ship are to be modeled, see Fig 4.

Figure 4 : Example of extent of local model for fine mesh analysis of web frame bracket connections and openings

## 2.6 Transverse bulkhead stringers, buttress and adjacent web frame

**2.6.1** In addition to the requirements of [2.2] to [2.4], the modeling requirements in this sub-section are applicable to the analysis of transverse bulkhead structures and adjacent web frame.

**2.6.2** Due to the structural interaction among the transverse bulkhead, horizontal stringers, web frames, deck and double bottom, it is recommended that the FE local model represents a full section of the hull. Longitudinally, the ends of the model should extend over at least one web frame space beyond the areas that require investigation, see Fig 5.

**2.6.3** Alternatively, it is acceptable to use a number of local models, as shown in Fig 6, to analyse different parts of the structure. For the analysis of the transverse bulkhead horizontal stringers the full breadth of the ship are to be modeled. For the analysis of buttress structure, the local model width should be at least 4+4 longitudinal spaces, i.e. four longitudinal spaces at each side of the buttress.

## 2.7 Deck, double bottom longitudinal and adjoining transverse bulkhead vertical stiffeners

**2.7.1** In addition to the requirements of [2.2] to [2.4], the modeling requirements in this sub-section are applicable specifically to the analysis of longitudinal and vertical stiffener end connections and attached web stiffeners.

**2.7.2** Where a local FE model is used, its length is to be of at least 2 web frame spaces on each side of the area under investigation. The model width is to extend over at least 2 longitudinal stiffeners spaces on each side the area under investigation.

**2.7.3** The web of the longitudinal stiffeners outside of the fine mesh zone should be represented by at least 3 shell elements across its depth. Similar size elements should be used to represent the plating of the bottom shell and inner bottom. The flange of the longitudinal stiffeners and face plate of brackets should be modeled with at least 2 shell elements across its width at one side.

**2.7.4** The mesh size and extent of the fine mesh zone is to be in accordance with [2.3] and [2.4].

**Figure 5 : Example of local model for fine mesh analysis of transverse bulkhead and adjacent structure**

Figure 6 : Example of local analysis of transverse bulkhead structure using local models

## 2.8 Corrugated bulkheads

2.8.1 In addition to the requirements of [2.2] to [2.4], the modeling requirements in this sub-article are applicable to the analysis of connections of corrugated bulkheads to lower stool and the connection between lower stool and inner bottom.

2.8.2 The minimum extents of the local model are as follows, see also Fig 7:

- Vertically, the model is to extend from the bottom of the ship to a level of at least 2 m above the connection between the corrugation and the lower stool.
- For transverse corrugated bulkheads, the local model is to extend transversally to the nearest diaphragm web in the lower stool on each side of the fine mesh zone (i.e. the local model covers two lower stool transverse web/diaphragm spaces). The end diaphragms do not need to be modeled.
- For longitudinal corrugated bulkheads, the local model is to extend to the nearest web frame on each side of the fine mesh zone (i.e. the local model covers two frame spaces). The end web frames do not need to be modeled.
- For connection between the corrugation and the lower stool located close to the intersection of transverse and longitudinal corrugated bulkheads (such as for product tankers), the local model is to cover the structure between the diaphragms (in transverse direction) and web frames (in longitudinal direction) closest to the detail, whichever is relevant. In addition, the local model is to extend over at least one diaphragm/web frame outside the intersection between the transverse stool and the longitudinal stool.
- For lower stool to inner bottom connection, the connection between inner bottom, lower stool plate, diaphragm and double bottom girder, where applicable, is to be at the centre of the fine mesh zone.

2.8.3 The fine mesh zone is to cover at least the corrugation flange under investigation, the adjacent corrugation webs and at least 500 mm on each side of the corrugation webs (i.e. the fine mesh zone covers at least four corrugation knuckles, see Fig 7).

2.8.4 Diaphragm webs, brackets inside the lower stool and all stiffeners on the stool plate and diaphragm are to be modeled at their actual positions within the extent of the local model. Shell elements are to be used for the modeling of diaphragm, web and flange of vertically orientated stiffeners, and brackets in the fine mesh zone.

2.8.5 Horizontally orientated stiffeners within the fine mesh zone are to be represented by either shell or beam elements.

Figure 7 : Extent of local model and fine mesh zone for the analysis of corrugated bulkhead connection to lower stool and inner bottom

### 3 FE load combinations

#### 3.1 General

**3.1.1** The fine mesh detailed stress analysis is to be carried out for all the FE load combinations as defined in Ch 8, App 1, [3] required according to the applicable Part D or Part E chapter, except tank testing and flooding conditions, applied to the corresponding cargo hold analysis.

#### 3.2 Application of loads and boundary conditions

##### 3.2.1 General

Where a separate local model is used for the fine mesh detailed stress analysis, the nodal displacements from the global model are to be applied to the corresponding boundary nodes on the local model as prescribed displacements. Alternatively, equivalent nodal forces from the global model may be applied to the boundary nodes.

Where there are nodes on the local model boundaries which are not coincident with the nodal points on the global model, it is acceptable to impose prescribed displacements on these nodes using multi-point constraints. The use of linear multi-point constraint equations connecting two neighbouring coincident nodes is considered sufficient.

At the exception of flooding loads, all the local loads, including any loads applied for hull girder bending moment and/or shear force adjustments, in way of the structure represented by the separate local finite element model are to be applied to the model.

### 4 Analysis criteria

#### 4.1 Yield strength assessment

##### 4.1.1 Reference stress

Reference stress is Von Mises stress  $\sigma_{vm}$  as defined in Ch 8, App 1, [5.2.1], which is to be calculated based on the membrane normal and shear stresses of the shell element evaluated at the element centroid. The stresses are to be evaluated at the mid-plane of the element.

##### 4.1.2 Permissible stress

The maximum permissible stresses are based on the mesh size of 50 x 50 mm, as specified in [2.1] to [2.4].

Where a smaller mesh size is used, an area weighted Von Mises stress  $\sigma_{vm-av}$  calculated over an area equal to the specified mesh size may be used to compare with the permissible stresses. The averaging is to be based only on elements with their entire boundary located within the desired area:

$$\sigma_{vm-av} = \frac{\sum_1^n A_i \sigma_{vm-i}}{\sum_1^n A_i}$$

The average stress is to be calculated based on stresses at the element centroid; stress values obtained by interpolation and/or extrapolation are not to be used.

Stress averaging is not to be carried across structural discontinuities and abutting structure.

##### 4.1.3 Yield criteria

The structural assessment is to demonstrate that the stress complies with the following criterion:  $\lambda_f \leq \lambda_{fperm}$

where:

$\lambda_f$  : Fine mesh yield utilisation factor:

- for shell elements:

$$\lambda_f = \frac{\sigma_{vm}}{R_Y}$$

- for rod or beam elements:

$$\lambda_f = \frac{|\sigma_{axial}|}{R_Y}$$

$\sigma_{vm}$  : Von Mises stress, in N/mm<sup>2</sup>

$\sigma_{axial}$  : Axial stress in rod element, in N/mm<sup>2</sup>

$\lambda_{fperm}$  : Fine mesh permissible yield utilisation factor as defined in Tab 2.

In addition, the average Von Mises stress over a standard mesh size as per Ch 8, App 1, [2.4.2] is not to exceed the permissible stress as defined in Ch 8, App 1, [5.2].

**Table 2 : Fine mesh permissible yield utilisation factor  $\lambda_{\text{perm}}$**

Structural component		Acceptance criteria (1)	$\lambda_{\text{perm}}$
All components Supports and keys of independent cargo tanks	Elements not adjacent to welding	AC-1	$1,36 f_i$
		AC-2	$1,70 f_i$
		AC-3	$1,70 f_i \cdot R_{eH} / R_y$
	Elements adjacent to welding	AC-1	$1,20 f_i$
		AC-2	$1,50 f_i$
		AC-3	$1,50 f_i \cdot R_{eH} / R_y$
<p>(1) See Ch 8, Sec 1, [4] for the acceptance criteria definition.  <b>Note 1:</b> <math>f_i</math> : Fatigue factor, taken as:</p> <ul style="list-style-type: none"> <li><math>f_i = 1,0</math> in general, including the free edge of base material</li> <li><math>f_i = 1,2</math> for details assessed by very fine mesh analysis complying with the fatigue assessment criteria given in Ch 10, Sec 1.</li> </ul>			

# Appendix 3 Full Length Structural Strength Analysis

## 1 Objective and scope

### 1.1 General

**1.1.1** This Section gives the requirements for full length structural strength analysis to be used for the assessment of primary supporting members.

**1.1.2** The structural analysis aims at calculating the stresses in the primary supporting members and in the hull plating, to be used for yielding and buckling checks.

### 1.2 Full length structural strength analysis procedure

#### 1.2.1 Procedure description

The structural FE analysis is to be performed in accordance with the following:

- full length model with:
  - extent as given in [2.2]
  - finite element types as given in [2.3]
  - structural modeling as defined in [2.4]
- boundary conditions as defined in [2.5]
- loading conditions and load cases as defined in [3]
- load application as defined in [4]
- strength assessment as defined in [5].

## 2 Structural model

### 2.1 Model construction

#### 2.1.1 Elements

The structural model is to represent the primary supporting members with the plating to which they are connected.

Ordinary stiffeners are also to be represented in the model in order to reproduce the stiffness and inertia of the actual hull girder structure.

#### 2.1.2 Net scantlings

All the elements are to be modeled with their net scantlings according to Ch 4, Sec 3. Therefore, the hull girder stiffness and inertia to be reproduced by the model are also those obtained considering the net scantlings of the hull structures.

### 2.2 Extent of model

**2.2.1** The complete ship is to be modeled so that the coupling between torsion and horizontal bending is properly taken into account in the structural analysis.

Superstructures are to be modeled in order to reproduce the correct lightweight distribution.

### 2.3 Finite element types

**2.3.1** See Ch 8, App 1, [2.3].

### 2.4 Structural modeling

**2.4.1** See Ch 8, App 1, [2.4].

Note 1: Openings modeling defined in Ch 8, App 1, Tab 1 are not applicable to complete ship models.

#### 2.4.2 Lightweight and deadweight

The finite element model is to include both the lightweight and the deadweight mass and inertia distributions.

The lightweight can be adjusted using one of the following techniques:

- modification of the density properties of plate and beam elements
- additional nodal masses fitted on the structural model.

Massive items (main engine, hatch covers) are preferably be excluded of the lightweight distribution and modeled similarly to deadweight items.

Deadweight items (such as container stacks or liquids) are to be modeled as nodal masses linked to the model through additional elements designed in order to transfer loads without introducing artificial stiffness (interpolation elements). Nodal masses are also to include the inertia properties of the items they represent.

## 2.5 Boundary conditions of the model

### 2.5.1 General

All the boundary conditions described in this Section are in accordance with the global coordinate system defined in Ch 5, Sec 1.

### 2.5.2 Boundary conditions

In order to prevent the rigid body motions of the overall model, the constraints specified in Tab 1 are to be applied to full length finite element model analyses.

**Table 1 : Boundary conditions to prevent rigid body motion of the model**

Location	Translation			Rotation		
	$\delta_x$	$\delta_y$	$\delta_z$	$\theta_x$	$\theta_y$	$\theta_z$
One node on the fore end of the ship	free	fixed	fixed	free	free	free
One node on the port side shell at aft end of the ship <b>(1)</b>	fixed	free	fixed	free	free	free
One node on the starboard side shell at aft end of the ship <b>(1)</b>	free	fixed	fixed	free	free	free

**(1)** The nodes on the port side shell and that on the starboard side shell are to be symmetrical with respect to the ship's longitudinal plane of symmetry.

## 3 Load combinations

### 3.1 General

**3.1.1** The combination of loading conditions and load cases to be considered are given in Part D and Part E depending on the ship type.

## 4 Load application

### 4.1 General

#### 4.1.1 Design wave method

The various load components which occur simultaneously may be combined by setting the characteristics of waves defined in [4.2.4] that maximise the dominant load effects given in [4.2.2].

Any other method may be used, provided relevant documentation is submitted to the Society for review.

#### 4.1.2 Model loading

The loads are applied to the finite element model according to the following indications:

- a) Still water loads include:
  - The still water sea pressure, defined in Ch 5, Sec 5, [1]
  - The still water internal loads, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast
- b) Wave loads, determined by means of hydrodynamic calculations, include:
  - The wave pressure
  - The inertial loads
- c) The fluid pressure in tanks is affected by the change of direction of the total acceleration vector defined in Ch 5, Sec 3
- d) For dry unit cargoes, inertial forces are computed at the centre of mass, taking into account the mass moment of inertia
- e) Inertial loads for structure weight and dry uniform cargo are computed using local accelerations calculated at their location.

#### 4.1.3 Equilibrium check

The convergence of the displacement, trim and vertical bending moment is deemed satisfactory within the following tolerances:

- 2% of the displacement
- 0,1 degree of the trim angle
- 10% of the still water bending moment.

## 4.2 Procedure for the selection of design waves

### 4.2.1 Summary of the loading procedure

The determination of the design wave characteristics for each load case includes the following steps:

- computation of the response operators (amplitude and phase) of the dominant load effect
- selection of the wave length and heading according to [3]
- determination of the wave phase such that the dominant load effect reaches its maximum
- computation of the wave amplitude corresponding to the design value of the dominant load effect.

### 4.2.2 Dominant load effects

Each load case maximises the value of one of the following load effects having a dominant influence on the strength of some parts of the structure:

- vertical wave bending moment in hogging and sagging condition amidships
- horizontal wave bending moment amidships
- wave torsional moment around 0,25L and 0,75L
- vertical acceleration at fore body sections
- roll motion
- wave pressure at the waterline amidships.

Additional loads might be investigated when deemed relevant by the Society.

### 4.2.3 Response Amplitude Operators

The Response Amplitude Operators (RAO's) and associated phase characteristics are to be computed for wave periods between 4 and 22 seconds, using a seakeeping program, for the following motions and load effects:

- heave, sway, pitch, roll and yaw motions
- vertical wave bending moment at 0,5L or at the longitudinal position where the bending moment RAO is maximum
- vertical wave shear force at 0,25L and 0,75L
- horizontal wave bending moment at 0,5L
- wave torsional moment at 0,25L and 0,75L.

The response amplitude operators are to be calculated for wave headings ranging from 0° (following seas) to 180° (head seas) by increment of 15°, using a ship speed of 5 knots.

The amplitude and phase of other dominant load effects may be computed at relevant wave period, using the RAO's listed above.

### 4.2.4 Design waves

For each load case, the ship is considered to encounter a Response Conditioned Wave (RCW). The RCW is an irregular wave train composed by at least 60 uni-directional waves. For each wave, the range of time is to be taken between  $-\pi/\Delta\omega$  and  $\pi/\Delta\omega$ , where  $\Delta\omega$  is the wave frequency step as defined in [4.2.6].

### 4.2.5 Design wave amplitude and phase

For each wave contributing to the RCW, the amplitude  $A_i$  and phase  $\phi_i$  can be computed from the RAO and the wave spectrum, using the following relationships:

$$A_i = S(\omega_i) |RAO(\omega_i, \beta)| \frac{D}{m_0} \Delta\omega_i$$

$$\phi_i = -RAO_\phi(\omega_i, \beta)$$

where:

D : Design value of the dominant load effect

RAO : Response amplitude operator of the dominant load effect computed for the relevant wave heading and wave frequency

RAO<sub>φ</sub> : Phase of the response amplitude operator of the dominant load effect for the relevant wave heading and wave frequency

ω<sub>i</sub> : Wave frequency

β : Wave heading

S : Wave spectrum (Pierson-Moskowitz) with the peak period T<sub>p</sub>

m<sub>0</sub> : Spectral moment of order 0, defined as:

$$m_0 = \int_0^\infty S(\omega) RAO(\omega, \beta)^2 d\omega$$

Δω<sub>i</sub> : Wave frequency step.

The wave heading β, peak period T<sub>p</sub> and design value D of the dominant load effect are given, for each load case, in [3].

When positioning the finite element model of the ship on the design wave, the amplitude of the wave is to be corrected to obtain the design value of the dominant load effect in order to take into account the non linear effects due to the hull shape and to the pressure distribution above the mean waterline.

#### 4.2.6 Seakeeping assumptions

When a direct seakeeping analysis is used to derive long-term values of hull girder loads, Response Amplitude Operators are to be computed, considering:

- a linear analysis
- a ship speed of 5 knots
- at least 36 headings (10° steps)
- frequencies in the range [0:2] rad/s
- a frequency step  $\Delta\omega$  equal to:

$$\Delta\omega = 0,3 \sqrt{\frac{g}{L}}$$

## 5 Analysis criteria

### 5.1 Yield strength assessment

#### 5.1.1 Von Mises stress

The Von Mises stress  $\sigma_{vm}$ , in N/mm<sup>2</sup>, is to be calculated based on the membrane normal and shear stresses of the shell element. The stresses are to be evaluated at the element centroid of the mid plane, as follows:

$$\sigma_{vm} = \sqrt{\sigma_x^2 - \sigma_x \sigma_y + \sigma_y^2 + 3\tau_{xy}^2}$$

where:

- $\sigma_x, \sigma_y$  : Element normal membrane stresses, in N/mm<sup>2</sup>
- $\tau_{xy}$  : Element shear stress, in N/mm<sup>2</sup>.

#### 5.1.2 Axial stress in beams and rod elements

For beams and rod elements, the axial stress  $\sigma_{axial}$ , in N/mm<sup>2</sup>, is to be calculated based on the axial force alone. The axial stress is to be evaluated at mid-length of the element.

#### 5.1.3 Yield criteria

The structural elements are to comply with the following criterion:  $\lambda_y \leq \lambda_{yperm}$

where:

- $\lambda_y$  : Yield utilisation factor:

$$\lambda_y = \frac{\sigma_{vm}}{R_Y} \text{ for shell elements}$$

$$\lambda_y = \frac{|\sigma_{axial}|}{R_Y} \text{ for rod or beam elements}$$

- $\sigma_{vm}$  : Von Mises stress, in N/mm<sup>2</sup>
- $\sigma_{axial}$  : Axial stress in rod or beam element, in N/mm<sup>2</sup>
- $\lambda_{yperm}$  : Permissible yield utilisation factor defined in Ch 8, App 1, Tab 9.

Where the Von Mises stress of the elements under investigation by fine mesh exceeds the yield criteria, the average Von Mises stress obtained from the fine mesh analysis, calculated over an area equivalent to the mesh size of the full length finite element model, is to satisfy the yield criterion above.

### 5.2 Buckling strength assessment

5.2.1 All the structural elements in FE analysis carried out in accordance with this Section are to be assessed individually against the buckling requirements as defined in Ch 9, Sec 1.

## 6 Refined analysis

### 6.1 Application

6.1.1 When a refined analysis is deemed necessary on a given detail, the requirements of this Article are to be applied.

### 6.2 Structural modeling

6.2.1 See Ch 8, App 2, [2].

**6.3 Loading conditions and load cases**

**6.3.1** The loading conditions and load cases considered are to be similar to those applied for the full length model.

**6.4 Load application**

**6.4.1** See Ch 8, App 2, [3.2].

**6.5 Analysis criteria**

**6.5.1** See Ch 8, App 2, [4].

# Part B

## Hull and Stability

---

### CHAPTER 9

## BUCKLING

---

#### Section 1      Buckling

# Section 1 Buckling

## Symbols

For symbols not defined in this Section, refer to Ch 5, Sec 4.

## 1 General

### 1.1 Application

**1.1.1** The buckling check of plating, stiffeners, primary supporting members and other structures such as pillars and brackets is to be performed according to the applicable requirements of NR615 Buckling Assessment of Plated Structures, taking into account, in addition, the requirements of this Section.

### 1.2 Allowable buckling utilisation factor

#### 1.2.1 General structural elements

The allowable buckling utilisation factor  $\eta_{all}$  is defined in Tab 1.

**Table 1 : Allowable buckling utilisation factor  $\eta_{all}$**

Structural component	Acceptance criteria	$\eta_{all}$
Plates and stiffeners	AC-1	0,80
Stiffened and unstiffened panels	AC-2	1,00
Vertically stiffened side shell plating of single side skin ship	AC-3	
Web plate in way of openings	AC-4	
Web and flange of primary supporting members		
Pillars	AC-1	0,75
	AC-2	0,85
	AC-3	
Struts and cross ties	AC-1	0,65
	AC-2	0,75
	AC-3	
Corrugation of vertically corrugated bulkheads with lower stool and horizontally corrugated bulkhead, under lateral pressure from liquid loads, for shell elements only.	AC-1	0,72
	AC-2	0,90
	AC-3	
Supporting structure in way of lower end of corrugated bulkheads without lower stool		
	AC-1	0,65
	AC-2	0,81
AC-3		
<p><b>Note 1:</b> Supporting structure for a transverse corrugated bulkhead refers to the structure in longitudinal direction within half a web frame space forward and aft of the bulkhead, and within a vertical extent equal to the corrugation depth.</p> <p><b>Note 2:</b> Supporting structure for a longitudinal corrugated bulkhead refers to the structure in transverse direction within three longitudinal stiffener spacings from each side of the bulkhead, and within a vertical extent equal to the corrugation depth.</p>		

## 2 Slenderness requirements

### 2.1 Application

**2.1.1** The slenderness requirements defined in NR615, Sec 2 are to be applied to all structural members including plating, web and face plate, if any, of stiffeners and tripping brackets, web plating and flange of primary supporting members.

Slenderness requirements are not to be applied to corrugations of bulkheads.

When the buckling capacity of a plate element is assessed according to NR615, Sec 5, its associated slenderness requirement may be disregarded.

### 3 Prescriptive buckling requirements

#### 3.1 Application

3.1.1 The requirements in this Article are to be taken into account for application of NR615, Sec 3.

#### 3.1.2 Partial safety factor

The partial safety factor  $S$ , defined in NR615, Sec 5, is to be replaced by:

$$\frac{S}{K_{\text{corr}}}$$

where:

$K_{\text{corr}}$  : Coefficient to take into account the corrosion:

- In general:  $K_{\text{corr}} = 1,0$
- For tank testing:  $K_{\text{corr}} = 1,1$

#### 3.2 Design load sets

##### 3.2.1 General

Unless otherwise specified, the buckling checks are to be performed for all the design load sets defined in Ch 7, Sec 2, [2], with pressure combination defined in Ch 7, Sec 2, [1].

For each design load set defined in Ch 7, Sec 2, except the one associated to accidental design load scenario, the hull girder stress given in [3.3] is to be applied together with the lateral pressure determined according to Part B, Chapter 5, at the load calculation point defined in Ch 4, Sec 6.

Note 1: The still water loads  $Q_{\text{sw}}$  and  $M_{\text{sw}}$  need not be considered simultaneously but independently from each other when combined with wave loads, except in the following specific cases:

- where the minimum vertical still water bending moment  $M_{\text{sw-min}}$  is positive, it is to be considered simultaneously with  $Q_{\text{sw}}$  when combined with the vertical wave bending moment in sagging condition  $M_{\text{wv-s}}$
- where the minimum vertical still water shear force  $Q_{\text{sw-min}}$  is positive, it is to be considered simultaneously with  $M_{\text{sw}}$  when combined with the negative vertical wave shear force  $Q_{\text{wv-neg}}$
- where the maximum vertical still water shear force  $Q_{\text{sw-max}}$  is negative, it is to be considered simultaneously with  $M_{\text{sw}}$  when combined with the positive vertical wave shear force  $Q_{\text{wv-pos}}$ .

##### 3.2.2 Deckhouses side bulkheads

The buckling checks of structural members of deckhouses sides contributing to the longitudinal strength are to be performed for the design load set SEA-1 with a combined lateral pressure  $P_{\text{ex}}$  taken equal to 2,5 kN/m<sup>2</sup>.

#### 3.3 Hull girder stress

3.3.1 The hull girder bending stress  $\sigma_{\text{hg}}$ , in N/mm<sup>2</sup>, is to be taken equal to  $\sigma_{\text{L}}$  as defined in Ch 6, Sec 1, [2.1.1] or Ch 6, Sec 1, [2.1.2] as applicable.

3.3.2 The hull girder shear stress  $\tau_{\text{hg}}$ , in N/mm<sup>2</sup>, is to be taken equal to  $\tau_{\text{L}}$  as defined in Ch 6, Sec 1, [2.2.1] or Ch 6, Sec 1, [2.2.2] as applicable.

# Part B

## Hull and Stability

---

# CHAPTER 10

## FATIGUE

---

### Section 1      Fatigue

# Section 1 Fatigue

## Symbols

- $T_{DF}$  : Design fatigue life, in year, specified by the designer, but not to be taken less than 25 years.  
For ships granted with additional class notation **FAT xx years**,  $T_{DF}$  is to be taken equal to xx years
- $T_f$  : Calculated fatigue life, determined in accordance with NI611.

## 1 General

### 1.1 Application

**1.1.1** The requirements of this Section apply to ships having a length equal to or greater than 150 m.

**1.1.2** Fatigue assessment is performed on the applicable special structural details listed in Ch 13, Sec 5, [2] in order to prevent the following types of fatigue failure:

- fatigue cracks initiating from the weld toe and propagating into the base material
- fatigue cracks initiating from the free edge of non-welded details.

**1.1.3** When the structural arrangement is such that some of the listed details listed are not relevant, specific requirements are defined by the Society on a case by case basis, depending on the arrangement adopted.

### 1.2 Reference

**1.2.1** When reference is made to NI611 "Guidelines for Fatigue Assessment of Steel Ships and Offshore Units", the latest version of this Guidance Note is applicable.

### 1.3 Fatigue due to loading and unloading

**1.3.1** The additional fatigue damage that may be induced by the loading and unloading cycles is to be considered for ships assigned with one of the following service notations:

- **hopper dredger**
- **hopper unit**
- **split hopper unit**
- **split hopper dredger.**

**1.3.2** Wave loads associated to loading and unloading fatigue assessment are to be obtained using the specific  $f_p$  coefficient defined in Ch 5, Sec 3.

**1.3.3** The detailed operational loading / unloading sequence is to be provided by the Designer (loading/unloading cycle period, loading conditions involved, number of loading / unloading cycles per year).

## 2 Loading conditions

### 2.1 Design loading conditions for fatigue assessment

#### 2.1.1 General

Loading conditions representative of the intended operation and the fraction of time spent in each condition are to be considered for fatigue analysis.

Unless otherwise specified, the following loading conditions are to be considered:

- full load condition 50% of the time
- normal ballast condition 50% of the time

Tanks filling levels associated to each loading condition are detailed in Tab 1.

#### 2.1.2 Ro-ro and passenger ships

For ships with the service notation **ro-ro cargo ship**, **PCTC**, **PCC**, **passenger ship** or **ro-ro passenger ship**, the full load condition is to be considered 100% of the time.

Table 1 : Tanks filling levels for fatigue loading conditions

Type of tank	Filling level	
	Full load condition	Normal ballast condition
Cargo holds (2)	100 %	0 %
Ballast tanks	0 %	100 %
Consumable tanks (1)	50 %	50 %
(1) Consumable tanks are to be filled at 100% in case of FE fatigue analysis		
(2) If applicable		

### 2.1.3 Container ships

For ships with the service notation **container ship**, the loading condition to be considered for fatigue is defined in Pt D, Ch 2, Sec 2, [11.2].

### 2.1.4 Bulk carriers, ore carriers and combination carriers

For ships with the service notation **bulk carrier**, **bulk carrier ESP**, **self-unloading bulk carrier ESP**, **ore carrier ESP** or **combination carrier ESP**, the following loading conditions are to be considered:

- full load homogeneous condition: 25% of the time
- partially filled alternate loading condition: 25% of the time if allowed by the loading manual. Otherwise, the full load homogeneous condition is to be increased to 50%.
- normal ballast condition: 25% of the time
- heavy ballast 25% of the time.

## 3 Corrosion model

### 3.1 General

#### 3.1.1 Corrosion model

The fatigue assessment is to be performed based on net thicknesses according to Ch 4, Sec 2.

Unless otherwise specified in Part D or Part E, the following values of stress correction factor as defined in NI611 are to be considered:

a) for analytical approach for longitudinal stiffeners:

- $f_{c,a} = 0,95$
- $f_{c,b} = 1,0$

b) for FEA calculations:

$$f_{c,FEA} = 0,95$$

## 4 Fatigue assessment based on a deterministic approach

### 4.1 Longitudinal stiffener connections

#### 4.1.1 Application

The fatigue strength of connections of longitudinal stiffeners with stiffeners of transverse primary supporting members is to be checked according to the methodology of NI611 as applicable to the “simplified rule based approach”.

For application of this methodology, requirements [4.1.2] to [4.1.6] are to be taken into account.

#### 4.1.2 Loading conditions

The design fatigue loading conditions as defined in [2.1] are to be considered.

#### 4.1.3 Hull girder loads

The vertical still water bending moment distribution defined in Ch 5, Sec 4, [2.1.3] is to be considered for the fatigue assessment.

The torsional still water moment is to be taken equal to zero.

#### 4.1.4 Load cases

The dynamic load cases to be considered are given in Ch 5, Sec 2, [3].

The design load scenario for fatigue assessment is defined in Ch 5, Sec 7, [3].

For the loading conditions defined in [4.1.2], all the fatigue load cases are to be considered for fatigue assessment in accordance with NI611.

#### **4.1.5 Fatigue damage calculation**

The fatigue damage is to be calculated according to NI611 as applicable, considering:

- a simplified rule based approach
- a single period design life pattern
- the corrosion protection.

#### **4.1.6 Acceptance criteria**

The acceptance criteria is defined in [6].

### **4.2 Other structural details**

#### **4.2.1 Application**

When the structural details other than longitudinal connections to primary supporting members are assessed by deterministic fatigue analysis, they are to be checked according to the methodology of NI611 as applicable to the “rule based approach”, taking into account requirements [4.2.2] to [4.2.7].

#### **4.2.2 Loading conditions**

The design fatigue loading conditions as defined in [2.1] are to be considered.

#### **4.2.3 Hull girders loads**

The vertical still water bending moment and shear force distribution are to be taken as the maximum permissible value in seagoing operation.

The torsional still water moment is to be taken equal to zero.

#### **4.2.4 Load cases**

The dynamic load cases to be considered are given in Ch 5, Sec 2, [3].

The design load scenario for fatigue assessment is defined in Ch 5, Sec 7, [3].

For the loading conditions defined in [4.2.2], all the fatigue load cases are to be considered for fatigue assessment in accordance with NI611.

#### **4.2.5 Hot spot stress calculation for welded details**

For hot spot stress calculation of ordinary welded details as defined in NI611, the “hot spot stress without stress extrapolation” method is to be considered.

#### **4.2.6 Fatigue damage calculation**

The fatigue damage is to be calculated according to NI611 as applicable, considering:

- a simplified rule based approach
- a single period design life pattern
- the corrosion protection.

#### **4.2.7 Acceptance criteria**

The acceptance criterion is defined in [6].

## **5 Fatigue assessment based on spectral fatigue analysis**

### **5.1 General**

**5.1.1** Fatigue strength of details subject to spectral fatigue analysis is to be assessed following the provisions of NI611 considering the assumptions given in [5.1.2] to [5.1.6].

#### **5.1.2 Seakeeping assumptions**

The seakeeping analysis necessary to the spectral fatigue assessment is to be based on:

- linear analysis
- ship speed, to be taken as 75% of the design speed
- at least 36 headings, 10° steps
- frequencies, to be taken in the range [0:2] rad/s
- frequency step, to be about  $0,3 (g / L)^{0,5}$
- intermittent wetting, to be accounted for, where relevant.

#### **5.1.3 Loading conditions**

The design fatigue loading conditions as defined in [2.1] are to be considered.

#### **5.1.4 Environmental conditions**

The long term analysis of stress RAOs is to be carried out considering the North Atlantic scatter diagram.

### 5.1.5 Fatigue damage calculation

The fatigue damage is to be calculated according to NI611 as applicable, considering:

- a spectral analysis
- a single period design life pattern
- the corrosion protection.

### 5.1.6 Acceptance criteria

The acceptance criterion is defined in [6].

## 6 Acceptance criteria

### 6.1 Fatigue life and acceptance criteria

#### 6.1.1 General

For each considered detail, the calculated fatigue life  $T_f$  is to be greater than  $T_{DF}$ .

# Section 1 Fore Part

## Symbols

For symbols not defined in this Section, refer to Ch 1, Sec 3.

$a_p$  : Correction factor for panel aspect ratio to be taken as:

$$\alpha_p = 1,2 - \frac{b}{2,1a}$$

but not to be taken greater than 1,0

$b_i$  : Breadth of impact area supported by primary supporting member, in m, as defined in Ch 7, Sec 6, [2.3.1]

$c_E$  : Coefficient to be taken equal to:

$$c_E = 1 \quad \text{for } L \leq 65 \text{ m}$$

$$c_E = 3 - L / 32,5 \quad \text{for } 65 \text{ m} < L < 90 \text{ m}$$

$$c_E = 0 \quad \text{for } L \geq 90 \text{ m}$$

$c_F$  : Coefficient to be taken equal to:

$$c_F = 0,9 \quad \text{for forecastle sides}$$

$$c_F = 1,0 \quad \text{in other cases}$$

$f_{bdg}$  : Bending moment factor taken as:

$$f_{bdg} = 8 \left( 1 + \frac{n_s}{2} \right)$$

$n_s$  : End fixation factor taken as:

- for both ends with low end fixity (simply supported):  $n_s = 0$
- for one end fixed and one end simply supported:  $n_s = 1$
- for continuous members or members with brackets fitted at both ends:  $n_s = 2$ .

## 1 General

### 1.1 Application

1.1.1 The requirements of this Section apply to the following structures of the fore part as defined in Ch 1, Sec 1, [2.1.2]:

- fore peak structures
- stem.

In addition, the requirements of this Section apply to structure subjected to impact loads:

- flat bottom forward, according to [3.2]
- bow area, according to [3.3].

## 2 Structural arrangement

### 2.1 Bottom Structure

#### 2.1.1 Plating and ordinary stiffeners

The net scantlings of plating and ordinary stiffeners are to be not less than the values specified in Tab 1.

**Table 1 : Scantling of bottom plating and ordinary stiffeners**

Element	Minimum value
Plating	Net minimum thickness, in mm: in general: $t = c_F (0,03 L_3 + 5,5) k^{1/2} - c_E$ for inner bottom: $t = 2 + 0,017 L_3 k^{1/2} + 4,5$ s
Ordinary stiffeners	Web net minimum thickness, in mm, to be not less than the lesser of: <ul style="list-style-type: none"> <li>• <math>t = 1,5 L_0^{1/3} k^{1/6}</math></li> <li>• the net thickness of the attached plating.</li> </ul>

**2.1.2 Floors**

In case of transverse framing, solid floors are to be fitted at each web frame location.

In case of longitudinal framing, the spacing of solid floors is not to be greater than 3,5 m or four transverse frame spaces, whichever is smaller.

The floors dimensions and scantlings are to be not less than those specified in Tab 2 and Tab 3.

**Table 2 : Longitudinally framed bottom - Floors and girders dimensions and scantlings**

Dimension or scantling	Specified value
Web height, in m	$h_M = 0,085 D + 0,15$
Web net thickness, in mm	$t = \min(10\text{mm}; 1,5L_0^{1/3} k^{1/6})$
Floor face plate net sectional area, in cm <sup>2</sup>	$A_p = 3,15 D$
Floor face plate net thickness, in mm	$t_p = 0,4 D + 5$ may be assumed not greater than 14 mm

**Table 3 : Transversely framed bottom - Floors dimensions and scantlings**

Dimension or scantling	Specified value
Web height, in m	$h_M = 0,085 D + 0,15$
Web net thickness, in mm	$t = \min(10\text{mm}; 1,5L_0^{1/3} k^{1/6})$
Floor face plate net sectional area, in cm <sup>2</sup>	$A_p = 1,67 D$

**2.1.3 Bottom girders**

A supporting structure is to be provided at the centreline, either by extending the centreline girder to the stem, or by providing a deep girder or a centreline bulkhead.

The centre bottom girder is to be connected to the collision bulkhead by means of a large end bracket.

The spacing of bottom girders is not to exceed:

- 2,5 m in case of transverse framing
- 3,5 m in case of longitudinal framing.

The bottom girders dimensions are to be not less than those specified in Tab 2.

**2.1.4 Alternative design verification**

The spacing of solid floors and bottom girders, defined in [2.1.2] and [2.1.3] respectively, may be increased, if the designer performs a verification of the bottom structure by means of grillage analysis or FE analysis and provides the full corresponding documentation.

The acceptance criteria to be applied are defined in Ch 7, Sec 6, [5.1.4]. A FE analysis is to be performed, considering the requirements provided in Part B, Chapter 8.

**2.2 Centreline wash bulkheads**

**2.2.1 General**

Except for dry peaks, a centreline longitudinal wash bulkhead may be required in liquid compartments for which there is a risk of resonance in the transverse direction.

**2.2.2 Extension**

In the case of a bulbous bow, such bulkhead is generally to extend for the whole length and depth of the fore peak.

Where hull structures are flared, such as those situated above the bulb and in the fore part of the peak, the bulkhead may be locally omitted.

Similarly, the extension of the bulkhead may be limited for bows without a bulb, depending on the shape of the hull. However, the bulkhead is to be fitted in the higher part of the peak.

**2.2.3 Plating thickness**

The net plating thickness of the lower part of the longitudinal bulkhead over a height at least equal to  $h_M$  defined in Tab 2 is to be not less than that required for the centre girder in [2.1.3].

Elsewhere, the net thickness of the longitudinal bulkhead plating is to be not less than the value obtained, in mm, from the following formula:  $t = 6,5 + 0,013 L_1$

**2.2.4 Ordinary stiffeners**

The net section modulus of ordinary stiffeners is to be not less than the value obtained, in cm<sup>3</sup>, from the following formula:

$$w = 3,5 s \ell^2 k (z_{TOP} - z_M) 10^{-3}$$

where:

$z_{TOP}$  : Z co-ordinate, in m, of the highest point of the tank

$z_M$  : Z co-ordinate, in m, of the stiffener mid-span.

**2.2.5 Primary supporting members**

Vertical and longitudinal primary supporting members, to be made preferably with symmetrical type sections, are to have a section modulus not less than 50% of that required for the corresponding side transverse or side girder.

The vertical and longitudinal webs are to be provided with adequate fairing end brackets and to be securely connected to the struts, if any.

**2.2.6 Openings**

Bulkhead openings are to be limited in the zone corresponding to the centre girder to approximately 2% of the total area of the bulkhead, and, in the zone above, to not less than 10% of the total area of the bulkhead. Openings are to be located such as to affect as little as possible the plating sections adjacent to primary supporting members.

**2.3 Side shell structure**

**2.3.1 Plating and ordinary stiffeners**

The net scantlings of plating and ordinary stiffeners are to be not less than the values specified in Tab 4.

**Table 4 : Scantling of side plating and ordinary stiffeners**

Element	Minimum value
Plating	Net minimum thickness, in mm: $t = c_F (0,03 L_3 + 5,5) k^{1/2} - c_E$
Ordinary stiffeners	Web net minimum thickness, in mm, to be not less than the lesser of: <ul style="list-style-type: none"> <li>• <math>t = 1,5 L_0^{1/3} k^{1/6}</math></li> <li>• the net thickness of the attached plating</li> </ul>

**2.3.2 Web frames**

The spacing S of web frames, in m, as defined in Ch 1, Sec 3, Tab 4, is generally not to be taken greater than:

$$S = 2,6 + 0,005 L$$

**2.3.3 Stringers**

Stringers are to have an effective span not greater than 10 m and are to be adequately supported by web frame structures.

Moreover, the depth  $b_A$ , in mm, and the net thickness  $t_A$ , in mm, of the stringer webs of transversely framed side are generally to be not less than the values obtained from the following formulae:

$$b_A = 2,5 (180 + L)$$

$$t_A = (6 + 0,018 L) k^{1/2}$$

**2.3.4 Alternative design verification**

The spacing of web frames and stringers may be increased, if the designer performs a verification of the side shell supporting structure by means of beam analysis or FE analysis and provides the full corresponding documentation.

The acceptance criteria to be applied are defined in Ch 7, Sec 6, [5.1.4]. A FE analysis is to be performed, considering the requirements provided in Part B, Chapter 8.

**2.3.5 Panting structures**

In order to withstand the panting loads, horizontal structures are to be provided. These structures are to be fitted at a spacing generally not exceeding 2 m and consist of side girders supported by panting beams or side transverses whose ends are connected to deck transverses, located under the tank top, so as to form a strengthened ring structure.

Panting beams, which generally consist of sections having the greater side vertically arranged, are to be fitted every two frames.

Each panting beam is to be connected to the side frames by means of brackets whose arms are generally to be not less than twice the panting beam depth.

Side frames not supporting panting beams are to be connected to side girders by means of brackets having the same thickness as that of the side girder and arms which are to be not less than one half of the depth of the side girder.

The net area  $A_B$ , in cm<sup>2</sup>, and the net inertia  $J_B$ , in cm<sup>4</sup>, of the panting beam section are to be not less than the values obtained from the following formulae:

$$A_B = 0,5 L - 18$$

$$J_B = 0,34 (0,5 L - 18) b_B^2$$

where:

$b_B$  : Beam length, in m, measured between the internal edges of side girders or the internal edge of the side girder and any effective central or lateral support.

Where side girder spacing is other than 2 m, the values  $A_B$  and  $J_B$  are to be modified according to the relation between the actual spacing and 2 m.

Panting beams of considerable length are generally to be supported at the centreline by a wash bulkhead or pillars arranged both horizontally and vertically.

Non-tight platforms may be fitted in lieu of side girders and panting beams. Their openings and scantlings are to be in accordance with [2.6.1].

Their spacing is to be not greater than 2,5 m.

If the peak exceeds 10 m in depth, a non-tight platform is to be arranged at approximately mid-depth.

Where the peak exceeds 10 m in length and the frames are supported by panting beams or non-tight platforms, additional transverse wash bulkheads or side transverses are to be fitted.

## 2.4 Tripping brackets

**2.4.1** For side shell and tank walls located forward of the collision bulkhead and vertically framed, tripping brackets spaced not more than 2,6 m are to be fitted, according to Fig 1, between primary supporting members, decks and/or platforms.

The as-built thickness of the tripping brackets is not to be less than the as-built thickness of the side frame webs to which they are connected.

**Figure 1 : Tripping brackets**

## 2.5 Decks

### 2.5.1 Plating and ordinary stiffeners

The net scantlings of deck plating and ordinary stiffeners, up to the bulkhead deck, are to be not less than the values obtained from the values specified in Tab 5.

**Table 5 : Scantling of deck plating and ordinary stiffeners**

Element	Minimum value
Plating	Net minimum thickness, in mm: $t = 2,1 + 0,013 L_3 k^{1/2} + 4,5 s$
Ordinary stiffeners	Web net minimum thickness, in mm, to be not less than the lesser of: <ul style="list-style-type: none"> <li><math>t = 1,5 L_0^{1/3} k^{1/6}</math></li> <li>the net thickness of the attached plating.</li> </ul>

## 2.6 Platforms

### 2.6.1 Non-tight platforms

Non-tight platforms located inside the peak are to be provided with openings having a total area not less than 10% of that of the platforms. Moreover, the thickness of the plating and the section modulus of ordinary stiffeners are to be not less than those required in [2.2] for the non-tight central longitudinal bulkhead.

The number and depth of non-tight platforms within the peak is considered by the Society on a case by case basis.

The platforms may be replaced by equivalent horizontal structures whose scantlings are to be supported by direct calculations.

### 2.6.2 Platform transverses

The net sectional area of platform transverses, calculated considering a width of attached plating whose net sectional area is equal to that of the transverse flange, is to be not less than the value obtained, in  $cm^2$ , from the following formula:

$$A = \frac{10P_{ex}d_s h_s}{C_p R_y}$$

where:

$P_{ex}$  : Sea pressure, defined in Ch 5, Sec 5, [1], acting at the ends of the platform transverse in the direction of its axis.

- $d_s$  : Half of the longitudinal distance between the two adjacent transverses, in m  
 $h_s$  : Half of the vertical distance between the two adjacent platforms, in m  
 $C_p$  : Coefficient, to be taken equal to:

$$C_p = 1 \quad \text{for} \quad \frac{d_p}{r_p} \leq 70$$

$$C_p = 1,7 - 0,01 \frac{d_p}{r_p} \quad \text{for} \quad 70 < \frac{d_p}{r_p} \leq 140$$

When  $d_p/r_p > 140$ , the scantlings of the struts are considered by the Society on a case by case basis

- $d_p$  : Distance, in cm, from the face plate of the side transverse and that of the bulkhead vertical web, connected by the strut, measured at the level of the platform transverse  
 $r_p$  : Radius of gyration of the strut, to be obtained, in cm, from the following formula:

$$r_p = \sqrt{\frac{J}{A_E}}$$

- $A_E$  : Actual net sectional area, in cm<sup>2</sup>, of the transverse section of the strut considered  
 $J$  : Minimum net moment of inertia, in cm<sup>4</sup>, of the strut considered

### 2.6.3 Breasthooks

Breasthooks are to have the same thickness of that required for platforms. They are to be arranged on the stem, in way of every side longitudinal, or at equivalent spacing in the case of transverse framing, extending aft for a length equal to approximately twice the breasthook spacing.

## 2.7 Bulbous bow

### 2.7.1 General

Where a bulbous bow is fitted, the structural arrangements are to be such that the bulb is adequately supported and integrated into the fore peak structure.

### 2.7.2 Diaphragm plates

At the forward end of the bulb, the structure is generally to be supported by horizontal diaphragm plates, spaced about 1 m apart, in conjunction with a deep centreline web.

In general, vertical transverse diaphragm plates are to be arranged in way of the transition from the peak framing to the bulb framing.

### 2.7.3 Special bulbous bow designs

In way of a wide bulb, additional strengthening in the form of a centreline wash bulkhead is generally to be fitted.

In way of a long bulb, additional strengthening in the form of transverse wash bulkheads or substantial web frames is to be fitted.

### 2.7.4 Strengthening for anchor and chain cable contact

The shell plating is to be increased in thickness at the forward end of the bulb and also in areas likely to be subjected to contact with anchors and chain cables during anchor handling. The increased plate thickness is to be the same as that required for plated stems given in [2.8.1].

## 2.8 Stems

### 2.8.1 Plate stem

The net thickness  $t_{stm}$ , in mm, from keel line to  $T_{SC} + 0,6$  m, is not to be less than:

$$t_{stm} = (0,6 + 0,4 S_B) (0,08 L + 2,7) k^{0,5}$$

but need not be greater than:

$$t_{stm} = 22 k^{0,5} - 1$$

where:

$S_B$  : Spacing, in m, between horizontal stringers (partial or not), breasthooks, or equivalent horizontal stiffening members.

Starting from 0,6 m above  $T_{SC}$  up to  $(T_{SC} + C_w)$ , the net thickness may gradually be reduced to  $0,8 t_{stm}$ .

The plating forming the stems is to be supported by horizontal diaphragms spaced not more than 1200 mm apart and connected, as far as practicable, to the adjacent frames and side stringers.

**2.8.2 Bar stems**

The gross area of bar stems constructed of forged or rolled steel is to be not less than the value obtained, in cm<sup>2</sup>, from the following formulae:

$$A_p = \left(0,40 + \frac{10T}{L}\right)(0,009L^2 + 20)\sqrt{k} \quad \text{for } L \leq 90$$

$$A_p = \left(0,40 + \frac{10T}{L}\right)(1,8L - 69)\sqrt{k} \quad \text{for } 90 < L \leq 200$$

where the ratio T/L in the above formulae is to be taken not less than 0,05 or greater than 0,075.

The gross thickness  $t_b$  of the bar stem is to be not less than the value obtained, in mm, from the following formula:

$$t_b = (0,4L + 13)\sqrt{k}$$

The cross-sectional area of the stem may be gradually tapered from the load waterline to the upper end, where it may be equal to the two thirds of the value as calculated above.

The lower part of the stem may be constructed of cast steel subject to the examination by the Society; where necessary, a vertical web is to be fitted for welding of the centre keelson.

Welding of the bar stem with the bar keel and the shell plating is to be in accordance with Ch 13, Sec 3, [5.6].

**2.9 Thruster tunnel****2.9.1 General**

The net thickness of the tunnel plating  $t_{\text{tun}}$ , in mm, is not to be less than the net thickness required for the shell plating in the vicinity of the bow thruster.

In addition,  $t_{\text{tun}}$  is not to be taken less than:

$$t_{\text{tun}} = 0,008 d_{\text{tun}} + 1,8$$

where:

$d_{\text{tun}}$  : Inside diameter of the tunnel, in mm, not to be taken less than 970 mm.

Where the outboard ends of the tunnel are provided with bars or grids, the bars or grids are to be effectively secured.

**3 Structures subject to impact loads****3.1 General****3.1.1 Application**

This Article covers the strengthening requirements for local impact loads that may occur on the forward structures.

**3.1.2 General scantling requirements**

Local scantling increase due to impact loads is to be made with due consideration given to the details, provide effective continuity of strength and avoid hard spots, notches and other harmful stress concentrations.

**3.1.3 Design to resist impact loads**

- a) The design of end connections of stiffeners in the impact regions is to provide end fixity, either by making the stiffeners continuous through supports, or by providing end brackets complying with Ch 4, Sec 5, [3.2]. Where it is not practical to comply with this requirement, the net plastic section modulus,  $Z_{\text{pl-alt}}$ , in cm<sup>3</sup>, for alternative end fixity arrangements is not to be less than:

$$Z_{\text{pl-alt}} = \frac{16Z_{\text{pl}}}{f_{\text{bdg}}}$$

where:

$Z_{\text{pl}}$  : Net plastic section modulus, in cm<sup>3</sup>, as required by Ch 7, Sec 5, [1.3.1].

- b) Scantlings and arrangements of primary supporting members, including decks and bulkheads in way of the stiffeners, are to comply with Ch 7, Sec 6, [2.3]. In areas where impact load is maximum, the web stiffeners are to be arranged perpendicular to the hull envelope plating and double sided lug connections are to be provided.
- c) End brackets of primary supporting members are to be suitably stiffened along their edge. Consideration is to be given to the design of bracket toes to minimise abrupt changes of cross-section.
- d) Tripping arrangements are to comply with Part B, Chapter 9. In addition, tripping brackets are to be fitted at the toe of end brackets and at locations where the primary supporting member flange is knuckled or curved.

**3.1.4 Shell plating**

The net thickness  $t$ , in mm, of the hull envelope plating subjected to bottom slamming or bow impact according to [3.2] and [3.3] is to comply with the requirements in Ch 7, Sec 4, [4], considering the impact pressure  $P_{\text{SL}}$  or  $P_{\text{FI}}$  as applicable, defined respectively in Ch 5, Sec 5, [4.2] and in Ch 5, Sec 5, [4.3].

**3.1.5 Shell stiffeners**

The shell stiffeners subjected to bottom slamming or bow impact according to [3.2] and [3.3] are to comply with the requirements in Ch 7, Sec 5, [1.3] considering the impact pressure  $P_{SLI}$  or  $P_{FI}$  as applicable, defined respectively in Ch 5, Sec 5, [4.2] and in Ch 5, Sec 5, [4.3].

**3.1.6 Primary supporting members**

The primary supporting members subjected to bottom slamming or bow impact according to [3.2] and [3.3] are to comply with the requirements in Ch 7, Sec 6, [2.3], considering the impact pressure  $P_{SLI}$  or  $P_{FI}$  as applicable, defined respectively in Ch 5, Sec 5, [4.2] and in Ch 5, Sec 5, [4.3].

**3.2 Bottom slamming**

**3.2.1 Application**

Where the minimum forward draught  $T_F$ , as specified in Ch 1, Sec 2, [1.6.1], is less than  $0,04 L$ , the bottom forward is to be additionally strengthened to resist bottom slamming pressures.

The draughts for which the bottom has been strengthened are to be indicated on the shell expansion plan and loading guidance information, as required in Ch 1, Sec 5.

The load calculation point of the primary supporting members is specified in Ch 4, Sec 6, [4].

**3.2.2 Extent of strengthening**

The strengthening is to extend between  $0,7L$  to the fore end, over the flat bottom and adjacent plating with attached stiffeners up to a height of 500 mm above the baseline, see Fig 2.

Outside the region strengthened to resist bottom slamming, the scantlings are to be tapered to maintain continuity of longitudinal and/or transverse strength.

**Figure 2 : Extent of strengthening against bottom slamming**

**3.3 Bow impact**

**3.3.1 Application**

The side structure in the ship forward area is to be strengthened against bow impact pressures. The strengthening is to extend forward of  $0,1 L$  from the FP and, vertically, from the minimum design ballast draught  $T_{BAL}$  defined in Ch 1, Sec 3, [2.1.6] up to the forecastle deck, if any, or to the level at which a knuckle with an angle greater than  $15^\circ$  is located on the side shell. See Fig 3.

Outside the strengthening area, scantlings are to be tapered to maintain continuity of longitudinal and/or transverse strength.

**Figure 3 : Extent of strengthening against bow impact**

**3.3.2 Buckling check of primary supporting members**

The buckling check of the webs and flanges of primary members is to be performed according to the requirements for plate panels as defined in Ch 9, Sec 1. The normal stress  $\sigma$  and the shear stress  $\tau$  as defined below are to be considered independently.

The normal bending stress  $\sigma$ , in  $N/mm^2$ , is to be taken equal to:

- In way of the attached plating:

$$\sigma = 0$$

- In way of the flange:

$$\sigma = \frac{f_{cb} P_{FI} f_{pb} \ell_{bdg}^2 b_1}{f_{bdg} Z_{n50}} 10^3$$

where:

- $f_{cb}$  : Correction factor for the bending moment at the ends considering the patch load, as defined in Ch 7, Sec 6, [2.3.1]
- $\ell_{bdg}$  : Effective bending span, in m, as defined in Ch 4, Sec 6, [1.1.6]
- $f_{pb}$  : Patch load modification factor for bending, as defined in Ch 7, Sec 6, [2.3.1]
- $f_{bdg}$  : Coefficient for end connection of primary supporting members, as defined in Ch 7, Sec 6, [2.3.1].

The shear stress  $\tau$ , in N/mm<sup>2</sup>, is to be taken equal to:

$$\tau = 10 \frac{Q_I}{A_{shr-n50}}$$

where:

- $Q_I$  : Shear force in kN, as defined in Ch 7, Sec 6, [2.3.1].

When the structure is arranged as a grillage, direct analysis (finite element analysis or beam models) is to be applied. Plate panels are to be considered as simply supported along the edges, except for flanges free edges which are to be considered as free. The stresses obtained from direct analysis are to be mutually considered accounting for the following:

- Beam model analysis:
  - Normal bending stress  $\sigma$  is to be calculated in way of flange and attached plating.
  - Shear stress  $\tau$  is to be taken equal to the mean stress acting within the web.
  - Stresses are to be calculated along the span of the primary supporting member at the point where the worst combination of  $\sigma$  and  $\tau$  occurs and at least at the ends and the middle of the span.
- Finite element analysis:
  - Normal stresses  $\sigma_x$ ,  $\sigma_y$  and shear stress  $\tau$  are to be taken as obtained from the finite element analysis.

### 3.3.3 Decks, bulkheads and webs of primary supporting members

Unless buckling check of primary supporting members and decks/bulkhead panels is performed according to 3.3.2 b), the net web thickness  $t_w$ , in mm, of each primary supporting member, including decks and bulkheads directly welded to the side shell, is not to be less than:

$$t_w = \frac{P_{FI} b_1}{\sin \phi_w \sigma_{cr}}$$

where:

- $\phi_w$  : Angle, in deg, between the primary supporting member web and the shell plate, as shown in Fig 4
- $\sigma_{cr}$  : Critical buckling stress in compression, in N/mm<sup>2</sup>, of the web of the primary supporting member or deck/bulkhead panel in way of the applied load, as given in Part B, Chapter 9. In the calculation, either  $\sigma_{cx'}$  or  $\sigma_{cy'}$  is to be considered, depending on the orientation of the normal stress induced in the plate panel by the lateral pressure acting on the side shell and UP-B or SP-B is to be applied respectively for webs of primary supporting members or for decks and bulkheads.

### 3.3.4 Breasthooks and diaphragm plating

The net thickness of breasthooks/diaphragm plates in way of bow impact strengthening area defined in [3.3.1]  $t_w$ , in mm, is not to be less than:

$$t_w = \frac{s}{70} \sqrt{\frac{R_{eH}}{235}}$$

where:

- $s$  : Spacing of stiffeners on the web, in mm, as defined in Ch 1, Sec 3, Tab 4. Where no stiffeners are fitted,  $s$  is to be taken as the depth of the web.

Figure 4 : Angle between shell primary member and shell plate

# Section 2 Machinery Space

## Symbols

P	: Maximum power, in kW, of the engine
$n_r$	: Number of revolutions per minute of the engine shaft at power equal to P
$L_E$	: Effective length, in m, of the engine foundation plate required for bolting the engine to the seating, as specified by the engine manufacturer.

## 1 General

### 1.1 Application

**1.1.1** The requirements of this Section apply to the scantlings and arrangement of structures located in the machinery space. It is the shipyard responsibility to design the ship in accordance with the machinery manufacturer's requirements.

## 2 Machinery space arrangement

### 2.1 Structural arrangement

**2.1.1** All parts of the machinery, shafting, etc, are to be supported to properly transfer the loads to the ship structure. The adjacent structure is to be suitably stiffened.

**2.1.2** Decks which are interrupted in the machinery space are to be tapered on the side by means of horizontal brackets.

**2.1.3** In case of change of framing system between machinery space and adjacent hull areas, abrupt structural discontinuities are to be avoided.

**2.1.4** The spacing of web frames in way of transversely framed machinery spaces is generally not to exceed five transverse frame spaces. Web frames are to be connected at the top and bottom to members of suitable stiffness.

Side transverses are to be aligned with floors.

For a longitudinally framed side, the side transverse spacing is to be not greater than 4-frame spacing.

**2.1.5** Side shell longitudinal stiffeners are to be efficiently connected to transverse bulkheads to provide proper fixity and lateral support. When the stiffener is not continuous through the bulkhead, a soft-toe bracket is to be fitted. Brackets lapped onto the longitudinals are not satisfactory.

**2.1.6** Where a transverse framing system is adopted, deck stiffeners are to be supported by a suitable arrangement of longitudinal girders in association with pillars or pillar bulkheads. Where fitted, deck transverses are to be arranged in line with web frames to provide end fixity and transverse continuity of strength.

Where a longitudinal framing system is adopted, deck longitudinals are to be supported by deck transverses in line with web frames in association with pillars or pillar bulkheads.

#### 2.1.7 Machinery casing

Machinery casings are to be supported by a suitable arrangement of deck transverses and longitudinal girders in association with pillars or pillar bulkheads. In way of particularly large machinery casing openings, cross ties may be required. These are to be arranged in line with deck transverses.

The net thickness of bulkheads is to be not less than:

- 5,5 mm for bulkheads in way of cargo holds
- 4 mm for bulkheads in way of accommodation spaces.

**2.1.8** The foundations of main propulsion units, reduction gears, shaft and thrust bearings, and the structure supporting those foundations are to maintain the required alignment and rigidity in all anticipated loading conditions. The following drawings are to be submitted to the machinery manufacturer for review:

- foundations of main propulsion units
- foundations of reduction gears
- foundations of thrust bearings
- structures supporting a), b) and c).

**2.1.9 Platforms**

The location and extension of platforms in machinery spaces are preferably to be arranged so as to be a continuation of the structure of side longitudinals, as well as of platforms and side girders located in the adjacent hull areas.

In general, platform transverses are to be arranged in way of side or longitudinal bulkhead transverses.

The net thickness of platforms is to be not less than that obtained, in mm, from the following formula:

$$t = 0,018 L_0 k^{1/2} + 4,5$$

**2.2 Double bottom**

**2.2.1 General**

Where the machinery space is immediately forward of the after peak, the double bottom is to be transversely framed. In all other cases it may be transversely or longitudinally framed.

**2.2.2 Minimum thicknesses**

The net thicknesses of inner bottom, floor and girder webs are to be not less than the values given in Tab 1.

**Table 1 : Double bottom - Minimum net thicknesses of inner bottom, floor and girder webs**

Element	Minimum net thickness, in mm	
	Machinery space within 0,4L amidships	Machinery space outside 0,4L amidships
Inner bottom	3,0 + 0,024 L k <sup>1/2</sup> + 0,0045b The Society may require the thickness of the inner bottom in way of the main machinery seatings and on the main thrust blocks to be increased, on a case by case basis.	
Margin plate	L <sup>1/2</sup> k <sup>1/4</sup> + 1	0,9 L <sup>1/2</sup> k <sup>1/4</sup> + 1
Centre girder	1,8 L <sup>1/3</sup> k <sup>1/6</sup> + 4	1,55 L <sup>1/3</sup> k <sup>1/6</sup> + 3,5
Floors and side girders	1,7 L <sup>1/3</sup> k <sup>1/6</sup> + 1	
Girder bounding a duct keel	0,8 L <sup>1/2</sup> k <sup>1/4</sup> + 2,5 to be taken not less than that required for the centre girder	

**2.2.3** Lower net thickness values for floor and web girder web can be accepted, if based on direct calculations.

**2.2.4 Double bottom height**

The double bottom height at the centreline, irrespective of the location of the machinery space, is to be not less than the value defined in Ch 2, Sec 2, [3]. This depth may need to be considerably increased, depending on the type and depth of main machinery seatings.

Where the double bottom height in the machinery space differs from that in adjacent spaces, structural continuity of longitudinal members is to be provided by sloping the inner bottom over an adequate longitudinal extent. The knuckles in the sloped inner bottom are to be located in way of floors. A lesser double bottom height may be accepted in local areas provided that the overall strength of the double bottom structure is not thereby impaired.

**2.2.5 Centreline girder**

The double bottom is to be arranged with a centreline girder. Manholes in the centreline girder are only to be fitted where absolutely necessary for double bottom access and maintenance. Local strengthening in way of such manholes is to be provided.

**2.2.6 Side bottom girders**

In the machinery space, the number of side bottom girders is to be adequately increased, with respect to the adjacent areas, to provide adequate rigidity of the structure. The side bottom girders, in longitudinal stiffened double bottom, are to be in line with bottom longitudinals in adjacent areas. The spacing of such girders is generally not to be greater than 3 times that of the longitudinals and in no case greater than 3 m.

**2.2.7 Girders in way of machinery seatings**

Bottom girders are to be fitted in way of machinery seatings.

Bottom girders arranged in way of main machinery seatings are to be extended over the full length of the machinery space.

Where the machinery space is situated amidships, the bottom girders are to extend aft of the after bulkhead of such space for at least three frame spaces, and beyond to be connected to the hull structure by tapering.

Where the machinery space is situated aft, the bottom girders are to extend as far as practicable and be supported by floors and side primary supporting members at the ends.

Forward of the machinery space forward bulkhead, the bottom girders are to be tapered for at least three frame spaces and are to be effectively connected to the hull structure.

**2.2.8 Floors in longitudinally stiffened double bottom**

Where the double bottom is longitudinally stiffened, plate floors are to be fitted at every frame under the main engine and thrust bearing. Outboard of the engine and bearing seatings, the floors may be fitted at alternate frames.

**2.2.9 Floors in transversely framed double bottom**

Where the double bottom in the machinery space is transversely stiffened, floors are to be arranged at every frame.

Boilers and other important machinery are to be supported by means of structural elements of adequate strength.

**2.2.10 Manholes and wells**

The number and size of manholes in floors located in way of seatings and adjacent areas are to be kept to the minimum necessary for double bottom access and maintenance.

The depth of manholes is generally to be not greater than 40% of the floor local depth.

In general, manhole edges are to be stiffened with flanges; failing this, the floor plate is to be adequately stiffened with flat bars at manhole sides.

Manholes with perforated portable plates are to be fitted in the inner bottom in the vicinity of wells arranged close to the aft bulkhead of the engine room.

Drainage of the tunnel is to be arranged through a well located at the aft end of the tunnel.

**2.2.11 Inner bottom plating**

Where main engines or thrust bearings are bolted directly to the inner bottom, the net thickness of the inner bottom plating is to be at least 19 mm. The hold-down bolts are to be arranged as close as possible to floors and longitudinal girders. Plating thickness and arrangements of hold-down bolts are also to consider the manufacturer’s recommendations.

**2.2.12 Heavy equipment**

Where an heavy equipment is mounted directly on the inner bottom, the thickness of the floors and girders is to be suitably increased.

**2.3 Single bottom**

**2.3.1 Floors in longitudinally framed single bottom**

Where the single bottom is longitudinally framed, the floor spacing is to be not greater than:

- 1-frame spacing in way of the main engine and thrust bearing
- 2-frame spacing in other areas of the machinery spaces.

Boilers and other important machinery are to be supported by means of structural elements of adequate strength.

**2.3.2 Floors in transversely framed single bottom**

Where the single bottom is transversely framed, the floors are to be arranged at every frame.

Boilers and other important machinery are to be supported by means of structural elements of adequate strength.

**2.3.3 Floor height**

The height of floors in way of machinery spaces located amidships is to be not less than  $B/14,5$ . Where the top of the floors is recessed in way of main machinery, the height of the floors in way of this recess is generally to be not less than  $B/16$ . Lower values will be considered by the Society on a case by case basis.

Where the machinery space is situated aft or where there is considerable rise of floor, the depth of the floors will be considered by the Society on a case by case basis.

**2.3.4 Floor flanging**

Floors are to be fitted with welded face plates in way of:

- engine bed plates
- thrust blocks
- auxiliary seatings.

**2.3.5 Minimum thicknesses**

The net thicknesses of floor and girder webs are to be not less than the values given in Tab 2.

**Table 2 : Single bottom - Minimum net thicknesses of floor and girder webs**

Element	Minimum net thickness, in mm	
	Machinery space within 0,4L amidships	Machinery space outside 0,4L amidships
Centre girder	$7 + 0,05 L_0 k^{1/2}$	$6 + 0,05 L_0 k^{1/2}$
Floors and side girder	$6,5 + 0,05 L_0 k^{1/2}$	$5 + 0,05 L_0 k^{1/2}$

### 3 Machinery foundations

#### 3.1 General

**3.1.1** Main engines and thrust bearings are to be effectively secured to the hull structure by foundations having a strength sufficient to resist the various gravitational, thrust, torque, dynamic, and vibratory forces which may be imposed on them.

**3.1.2** In the case of higher power internal combustion engines or turbine installations, the foundations are generally to be integrated within the double bottom structure. Consideration is to be given to substantial increase of the inner bottom plating thickness in way of the engine foundation plate or the turbine gear case and the thrust bearing, see Fig 1.

**Figure 1 : Machinery foundations type 1**

Seat integral with tank top

Note 1: Brackets are to be as large as possible. Brackets may be omitted to avoid interference with the girders of the engine foundation, in accordance with the recommendations of the engine manufacturer.

**3.1.3** For main machinery supported on foundations of Type 2, as shown in Fig 2, the forces from the engine into the adjacent structure are to be distributed as uniformly as possible. Longitudinal members supporting the foundation are to be aligned with girders in the double bottom, and transverse stiffening is to be arranged in line with the floors, see Fig 2.

**Figure 2 : Machinery foundations type 2**

Built-up seat

Note 1: Brackets are to be as large as possible. Brackets may be omitted to avoid interference with the girders of the engine foundation, in accordance with the recommendations of the engine manufacturer.

#### 3.1.4 Supporting structure above the double bottom plating

Girders in way of seatings are to be fitted with flanged brackets, generally located at each frame and extending towards both the centre of the ship and the sides.

The extension of the seatings above the double bottom plating is to be limited as far as practicable while ensuring adequate spaces for the fitting of bedplate bolts. Bolt holes are to be located such that they do not interfere with supporting structures.

#### 3.1.5 Seatings in a single bottom structure

For ships having a single bottom structure within the machinery space, seatings are to be located above the floors and to be adequately connected to the latter and to the girders located below.

### 3.2 Scantlings

**3.2.1** The net scantlings of the structural elements in way of the seatings of engines are to be determined by the engine manufacturer. They are to be checked on the basis of justificative calculations supplied by the engine manufacturer. If these calculations are not supplied, the net scantlings of the structural elements in way of the seatings of engines are to be not less than those obtained from the formulae in Tab 3.

### 3.3 Foundations for internal combustion engines and thrust bearings

**3.3.1** The general rigidity of the engine is to be considered in the determination of the foundations scantlings, as it may have an incidence on the loads balance.

**3.3.2** Generally, two girders are to be fitted in way of the foundation for internal combustion engines and thrust bearings.

**3.3.3 Number of longitudinal members in way of seatings of engines**

In general, at least two longitudinal members are to be fitted in way of seatings of main engines.

One longitudinal member may be fitted only where the following three formulae are complied with:

$$L < 150 \text{ m}$$

$$P < 7100 \text{ kW}$$

$$P < 2,3 n_R L_E$$

**3.4 Auxiliary machinery foundations**

**3.4.1** Auxiliary machinery is to be secured on foundations that are of suitable size and arrangement to distribute the loads from the machinery evenly into the supporting structure.

**Table 3 : Scantlings of the structural elements in way of seatings of engines**

Scantling	Minimum value
Net cross-sectional area, in cm <sup>2</sup> , of each bedplate of the seatings	$40 + 70 \frac{P}{n_r L_E}$
Net thickness, in mm, of each bedplate of the seatings	<ul style="list-style-type: none"> <li>Bedplate supported by two or more longitudinal members:  <math>\sqrt{240 + 175 \frac{P}{n_r L_E}}</math></li> <li>Bedplate supported by one longitudinal member:  <math>5 + \sqrt{240 + 175 \frac{P}{n_r L_E}}</math></li> </ul>
Web net thickness, in mm, of girders fitted in way of each bedplate of the seatings	<ul style="list-style-type: none"> <li>Bedplate supported by two or more longitudinal members:  <math>\frac{1}{n_G} \sqrt{320 + 215 \frac{P}{n_r L_E}}</math>                      where <math>n_G</math> is the number of longitudinal members in way of the bedplate considered</li> <li>Bedplate supported by one longitudinal member:  <math>\sqrt{95 + 65 \frac{P}{n_r L_E}}</math></li> </ul>
Web net thickness, in mm, of transverse members fitted in way of bedplates of the seating <b>(1)</b>	$\sqrt{55 + 40 \frac{P}{n_r L_E}}$
<b>(1)</b> When intermediate transverse members welded to the bedplate are fitted, the web minimum net thickness may be reduced on a case-by-case basis.	

# Section 3 Aft Part

## Symbols

$F_C$  : Force, in kN, taken equal to:

$$F_C = \left(\frac{2\pi N}{60}\right)^2 R_p P$$

$P$  : Mass of a propeller blade, in t

$N$  : Number of revolutions per minute of the propeller

$R_p$  : Distance, in m, of the centre of gravity of a blade in relation to the rotation axis of the propeller

$\sigma_{ALL}$  : Allowable stress, in N/mm<sup>2</sup>:  $\sigma_{ALL} = 70 / k$

where:

$k$  : Material factor, as defined in Ch 4, Sec 1, [2.2]

$w_A$  : Section modulus, in cm<sup>3</sup>, of the arm at the level of the connection to the hull with respect to a transversal axis

$w_B$  : Section modulus, in cm<sup>3</sup>, of the arm at the level of the connection to the hull with respect to a longitudinal axis

$A$  : Sectional area, in cm<sup>2</sup>, of the arm

$A_S$  : Shear sectional area, in cm<sup>2</sup>, of the arm

$d_p$  : Propeller shaft diameter, in mm, measured inside the liner, if any

$b$  : Breadth of the plate panel, in mm, as defined in Ch 4, Sec 6, [2.1.1].

## 1 General

### 1.1 Application

**1.1.1** The requirements of this Section apply to the scantlings and arrangement of structures located aft of the aft peak bulkhead. In addition, the requirements of this Section apply to structures subjected to stern impact loads according to Article [6].

## 2 Aft peak

### 2.1 Structural arrangement

#### 2.1.1 Floors

Floors are to be fitted at each frame space in the aft peak. They are to extend at least above the stern tube. Where floors do not extend up to a platform or a deck, they are to be stiffened by flanges at their upper end.

Heavy plate floors are to be fitted in way of, and near, the rudder post, propeller post and rudder horn. They are to extend up to the peak tank top or platform. In this area, cut outs, scallops and other openings are to be kept to a minimum.

#### 2.1.2 Platforms and side girders

Platforms and side girders within the peak are to be arranged in line with those located in the area immediately forward.

Where this arrangement is not possible due to the shape of the hull and access needs, structural continuity between the peak and the structures of the area immediately forward is to be ensured with wide tapering brackets.

Where the aft peak is adjacent to a longitudinally framed side machinery space, the side girders in the aft peak are to be fitted with tapering brackets.

#### 2.1.3 Longitudinal bulkheads

A longitudinal non-tight bulkhead is to be fitted at the centreline of the ship, in general in the upper part of the peak, and stiffened at each frame spacing.

Where either the stern overhang is very large or the maximum breadth of the space divided by watertight and wash bulkheads is greater than 20 m, additional longitudinal wash bulkheads may be required.

#### 2.1.4 Alternative design verification

Spacings and arrangements other than those required in [2.1.1], [2.1.2] and [2.1.3] may be agreed, provided the designer performs a verification by means of grillage analysis or FE analysis and provides the full corresponding documentation. The acceptance criteria to be applied are defined in Ch 7, Sec 6, [5.1.4]. A FE analysis is to be performed under consideration of the requirements provided in Part B, Chapter 8.

## 2.2 Stiffening of floors and girders

**2.2.1** Stiffeners on the floors and girders in aft peak ballast or fresh water tanks above propeller are to be designed in accordance with [2.2.2] and [2.2.3]. This applies for stiffeners located in an area extending longitudinally between the forward edge of the rudder and the after end of the propeller boss and transversely within the diameter of the propeller.

**2.2.2** The height of stiffeners  $h_{stf}$ , in mm, on the floors and girders in aft peak is not to be less than:

- for flat bar stiffeners:  $h_{stf} = 80 l_{stf}$
- for bulb profiles and flanged stiffeners:  $h_{stf} = 70 l_{stf}$

where:

$l_{stf}$  : Stiffener length, in m, as shown in Fig 1.  $l_{stf}$  need not be taken greater than 5 m.

**2.2.3** End brackets are to be provided as follows:

- at the lower and upper ends when  $l_{stf-t}$  exceeds 4 m
- at the lower end when  $l_{stf-t}$  exceeds 2,5 m

where:

$l_{stf-t}$  : Total length of the stiffener, in m, as shown in Fig 1.

**Figure 1 : Stiffening of floors and girders in the aft peak tank**

## 3 Connection of hull structures with the rudder horn

### 3.1 Connection of after peak structures with the rudder horn

#### 3.1.1 General

The requirement of this sub-article apply to the connection between peak structure and rudder horn where the sternframe is of an open type and is fitted with the rudder horn.

#### 3.1.2 Rudder horn

Horn design is to be such as to enable sufficient access for welding and inspection.

The scantlings of the rudder horn, which are to comply with Ch 12, Sec 1, [8.2], may be gradually tapered inside the hull.

Connections by slot welds are not acceptable.

#### 3.1.3 Hull structures

Direct calculations are to be performed to check the connection of the rudder horn to the structure of the vessel, taking account of the reactions induced by the rudder on the rudder horn.

The thickness of the structures adjacent to the rudder horn, such as shell plating, floors, platforms and side girders, the centreline bulkhead and any other structures, is to be adequately increased in relation to the horn scantlings.

### 3.2 Structural arrangement above the after peak

#### 3.2.1 Side transverses

Where a rudder horn is fitted, side transverses, connected to deck beams, are to be arranged between the platform forming the peak tank top and the weather deck.

The side transverse spacing is to be not greater than:

- 2-frame spacing in way of the horn
- 4-frame spacing for and aft of the rudder horn
- 6-frame spacing in the area close to the after peak bulkhead.

The side transverses are to be fitted with end brackets and located within the poop.

**3.2.2 Side girders**

Where the depth from the peak tank top to the weather deck is greater than 2,6 m and the side is transversely framed, one or more side girders are to be fitted, preferably in line with similar structures existing forward.

**4 Stern frames**

**4.1 General**

**4.1.1** Stern frames are to be fabricated from steel plates or made of cast steel with a hollow section. For applicable material specifications and steel grades, see Ch 4, Sec 1. Stern frames of other material or construction will be specially considered.

**4.1.2** Cast steel and fabricated stern frames are to be strengthened by adequately spaced horizontal plates with gross thickness not less than 80% of the required thickness for stern frames. Abrupt changes of section are to be avoided in castings; all sections are to have adequate tapering radius.

**4.1.3** In the upper part of the propeller aperture, where the hull form is full and centreline supports are provided, the thickness of stern frames may be reduced to 80% of the applicable requirement in [4.2.1].

**4.2 Propeller posts**

**4.2.1 Gross scantlings of propeller posts**

The gross scantlings of propeller posts are not to be less than those obtained from the formulae in Tab 1 for single screw ships and in Tab 2 for twin screw ships.

Scantlings and proportions of the propeller post which differ from those above may be considered acceptable, provided the section modulus of the propeller post section about its longitudinal axis is not less than the value calculated with the propeller post scantlings in Tab 1 or Tab 2, as applicable.

**4.2.2 Propeller shaft bossing**

In single screw ships, the thickness of the propeller shaft bossing, over the whole shaft bearing length and included in the propeller post, is not to be less than 60% of the thickness *b* required in [4.2.1] for bar propeller posts with a rectangular section.

**4.3 Connections**

**4.3.1 Connections with hull structure**

Stern frames are to be effectively attached to the aft structure and the required scantling for the lower part of the propeller post is to be extended from the aft end of propeller post, at the centerline of the propeller shaft, to a length not less than  $(1500 + 6 L_3)$  mm, in order to provide an effective connection with the keel. However, the stern frame need not extend beyond the aft peak bulkhead.

**Table 1 : Single screw ships - Gross scantlings of propeller posts**

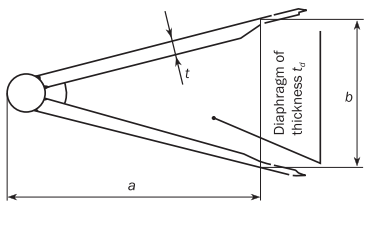

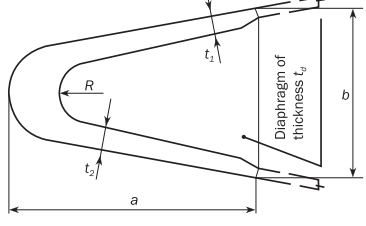

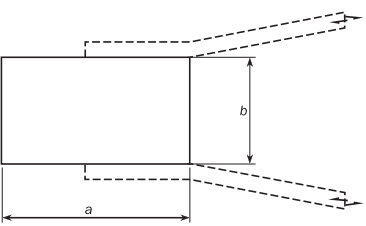

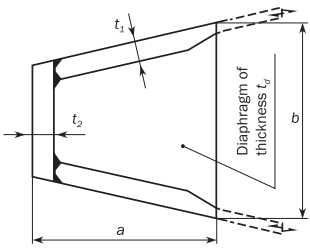

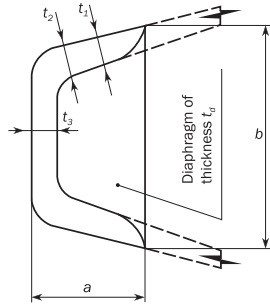

Gross scantlings of propeller posts, in mm	Fabricated propeller post	Cast propeller post	Bar propeller post, cast or forged, having a rectangular section
			
a	$50 L_2^{1/2}$	$33 L_2^{1/2}$	$10\sqrt{7, 2L - 256}$
b	$35 L_2^{1/2}$	$23 L_2^{1/2}$	$10\sqrt{4, 6L - 164}$
<i>t</i> <sub>1</sub>	$2,5 L_2^{1/2}$	$3,2 L_2^{1/2}$	–
<i>t</i> <sub>2</sub>	–	$4,4 L_2^{1/2}$	–
<i>t</i> <sub>d</sub>	$1,3 L_2^{1/2}$	$2,0 L_2^{1/2}$	–
R	–	50 mm	–

Table 2 : Twin screw ships - Gross scantlings of propeller posts

Gross scantlings of propeller posts, in mm	Fabricated propeller post	Cast propeller post	Bar propeller post, cast or forged, having a rectangular section
			
a	$25 L_2^{1/2}$	$12,5 L_2^{1/2}$	$2,4 L + 6$
b	$25 L_2^{1/2}$	$25 L_2^{1/2}$	$0,8 L + 2$
t <sub>1</sub>	$2,5 L_2^{1/2}$	$2,5 L_2^{1/2}$	–
t <sub>2</sub>	$3,2 L_2^{1/2}$	$3,2 L_2^{1/2}$	–
t <sub>3</sub>	–	$4,4 L_2^{1/2}$	–
t <sub>d</sub>	$1,3 L_2^{1/2}$	$2,0 L_2^{1/2}$	–

**4.3.2 Connection with keel plate**

The thickness of the lower part of the stern frames is to be gradually tapered to that of the solid bar keel or keel plate.

Where a keel plate is fitted, the lower part of the stern frame is to be designed to ensure an effective connection with the keel.

**4.3.3 Connection with transom floors**

Rudder posts and propeller posts are to be connected with transom floors having a height not less than the double bottom height and a net thickness not less than the value obtained, in mm, from the following formula:

$$t = 9 + 0,023 L_1$$

**4.3.4 Connection with centre keelson**

Where the stern frame is made of cast steel, the lower part of the stern frame is to be fitted, as far as practicable, with a longitudinal web for connection with the centre keelson.

**4.4 Rudder gudgeons**

**4.4.1** In general, gudgeons are to be solidly forged or cast with the sternframe.

The height of the gudgeon is to be not greater than 1,2 times the pintle diameter. In any case, the height and diameter of the gudgeons are to be suitable to house the rudder pintle.

The thickness of the metal around the finished bore of the gudgeons is to be not less than half the diameter of the pintle.

**4.5 Sterntubes**

**4.5.1** The sterntube thickness is considered by the Society on a case by case basis. In no case, however, may it be less than the thickness of the side plating adjacent to the sternframe.

Where the materials adopted for the sterntube and the plating adjacent to the sternframe are different, the sterntube thickness is to be at least equivalent to that of the plating.

**5 Shell structure**

**5.1 Shell plating**

**5.1.1 Minimum net thickness**

The minimum net thickness of plating are to be not less than values specified in Tab 3.

**5.1.2 Shell plating connected with stern frame**

The net thickness of shell plating connected with the stern frame is not to be less than the value obtained, in mm, from the following formula:  $t = 0,094 (L_3 - 43) + 0,009 b$

In way of the boss and heel plate, the net thickness t of shell plating, in mm, is not to be less than:

$$t = 0,105 (L_3 - 47) + 0,011 b$$

**5.1.3 Heavy shell plates**

Heavy shell plates are to be fitted locally in way of the heavy plate floors as required in [2.1.1]. The net thickness of heavy shell plates is not to be less than the value given in [5.1.1]. Outboard of the heavy floors, the heavy shell plates may be reduced in thickness in as gradual a manner as practicable. Where the rudder horn plating is radiused into the shell plating, the radius *r* at the shell connection, in mm, is not to be less than:  $r = 150 + 0,8 L_3$

**5.1.4 Thruster tunnel plating**

The net thickness  $t_{un}$  of the tunnel plating, in mm, is to comply with the requirements in Ch 11, Sec 1, [2.9].

**Table 3 : Net thickness of plating**

Plating location	Net minimum thickness, in mm
Bottom and side	$c_F (0,03 L_3 + 5,5) k^{1/2} - c_E$
Inner bottom	$2 + 0,017 L_3 k^{1/2} + 0,0045 b$
Deck	For strength deck: $2,1 + 0,013 L_3 k^{1/2} + 0,0045 b$
Platform and wash bulkhead	<ul style="list-style-type: none"> <li><math>1,3 + 0,004 L_3 k^{1/2} + 0,0045 b</math> for <math>L &lt; 120</math> m</li> <li><math>2,1 + 2,2 k^{1/2} + 0,001b</math> for <math>L \geq 120</math> m</li> </ul>
<b>Note 1:</b> Where $c_F$ and $c_E$ are coefficient defined in Ch 11, Sec 1.	

**5.2 Ordinary stiffeners**

**5.2.1 Web net minimum thicknesses**

The web net minimum thickness of ordinary stiffeners are to be not less than values specified in Tab 3.

**Table 4 : Net scantlings of ordinary stiffeners**

Ordinary stiffener location	Minimum value
Bottom, side and deck Platform and wash bulkhead	Web net minimum thickness, in mm, to be not less than the lesser of: <ul style="list-style-type: none"> <li><math>t = 1,5 L_0^{1/3} k^{1/6}</math></li> <li>the net thickness of the attached plating.</li> </ul>

**6 Structure subject to stern impact loads**

**6.1 General**

**6.1.1 Application**

This Article covers the strengthening requirements for local impact loads that may occur on the flat area of the bottom aft structure having a maximum deadrise angle of 30° and located at a distance not greater than  $h_{SL}$  from the design waterline, for ships having a length *L* at least equal to 150 m, where:

$h_{SL}$  : Maximum relative wave elevation, in m, for stern impact pressure, as defined in Ch 5, Sec 5, [4.2.2].

**6.1.2 General scantling requirements**

Local scantling increase due to impact loads is to be made with due consideration given to the details, provide effective continuity of strength and avoid hard spots, notches and other harmful stress concentrations.

**6.1.3 Design to resist impact loads**

a) The design of end connections of stiffeners in the impact regions is to provide end fixity, either by making the stiffeners continuous through supports, or by providing end brackets complying with Ch 4, Sec 5, [3.2]. Where it is not practical to comply with this requirement, the net plastic section modulus,  $Z_{pl-alt}$ , in cm<sup>3</sup>, for alternative end fixity arrangements is not to be less than:

$$Z_{pl-alt} = \frac{16Z_{pl}}{f_{bdg}}$$

where:

$Z_{pl}$  : Net plastic section modulus, in cm<sup>3</sup>, as required by Ch 7, Sec 5, [1.3.1].

- b) Scantlings and arrangements of primary supporting members, including decks and bulkheads in way of the stiffeners, are to comply with Ch 7, Sec 6, [2.3]. In areas where impact load is maximum, the web stiffeners are to be arranged perpendicular to the hull envelope plating and double sided lug connections are to be provided.
- c) End brackets of primary supporting members are to be suitably stiffened along their edge. Consideration is to be given to the design of bracket toes to minimise abrupt changes of cross-section.
- d) Tripping arrangements are to comply with Part B, Chapter 9. In addition, tripping brackets are to be fitted at the toe of end brackets and at locations where the primary supporting member flange is knuckled or curved.

**6.1.4 Shell plating**

The net thickness  $t$ , in mm, of the hull envelope plating subject to stern impact according to [6.1.1] is to comply with the requirements in Ch 7, Sec 4, [4], considering the impact pressure  $P_{SLI}$  defined in Ch 5, Sec 5, [4.2].

**6.1.5 Shell stiffeners**

The shell stiffeners subject to stern impact according to [6.1.1] are to comply with the requirements in Ch 7, Sec 5, [1.3] considering the impact pressure  $P_{SLI}$  defined in Ch 5, Sec 5, [4.2]

**6.1.6 Primary supporting members**

The primary supporting members subject to stern impact according to [6.1.1] are to comply with the requirements in Ch 7, Sec 6, [2.3], considering the impact pressure  $P_{SLI}$  defined in Ch 5, Sec 5, [4.2].

# Section 4 Tanks Subject to Sloshing

## Symbols

For symbols not defined in this Section, refer to Ch 1, Sec 3.

$\alpha_p$  : Correction factor for the panel aspect ratio to be taken as:

$$\alpha_p = 1,2 - \frac{b}{2,1 a}$$

but not to be taken greater than 1,0

$a$  : Length of plate panel, in mm, as defined in Ch 4, Sec 6

$b$  : Breadth of plate panel, in mm, as defined in Ch 4, Sec 6

$l_{bdg}$  : Effective bending span, in m, as defined in Ch 4, Sec 6

$l_{shr}$  : Effective shear span, in m, as defined in Ch 4, Sec 6

$H$  : Height of a tank, in m, to be taken as the vertical distance from the bottom to the top of the tank, excluding any small hatchways

$l_C$  : Longitudinal distance, in m, between transverse watertight bulkheads or transverse wash bulkheads, if any, or between a transverse watertight bulkhead and the adjacent transverse wash bulkhead

$b_C$  : Transverse distance, in m, between longitudinal watertight bulkheads or longitudinal wash bulkheads, if any, or between a longitudinal watertight bulkhead and the adjacent longitudinal wash bulkhead

$d_F$  : Filling level of a tank, in m, to be taken as the vertical distance, measured with the ship at rest, from the tank bottom to the free surface of the liquid

$l_S$  : Length, in m, of the free surface of the liquid, measured horizontally with the ship at rest and depending on the filling level  $d_F$ , as shown in Fig 1. In this figure, wash bulkheads are those satisfying the requirements in Ch 4, Sec 5, [10.4.1]

$b_S$  : Breadth, in m, of the free surface of the liquid, measured horizontally with the ship at rest and depending on the filling level  $d_F$ , as shown in Fig 2 for ships without longitudinal watertight or wash bulkheads.

For ships fitted with longitudinal watertight or wash bulkheads (see Fig 3),  $b_S$  is delimited by these bulkheads (to this end, wash bulkheads are those satisfying the requirements in Ch 4, Sec 5, [10.4.1])

$\sigma_L$  : Hull girder normal stress, in N/mm<sup>2</sup>, as defined in Ch 6, Sec 1, [2.1.2], calculated at the load calculation point as defined in Ch 4, Sec 6, [2.2] or Ch 4, Sec 6, [3.2].

## 1 Application

### 1.1 General

**1.1.1** The requirements of this Section cover the strengthening requirements for localised loads that may occur in partly filled tanks intended for the carriage of liquid.

**1.1.2** Sloshing and impact pressures are to be considered as applicable according to respectively [1.3] and [1.4].

**1.1.3** Sloshing and impact pressures may be disregarded for filling levels lower than 0,50 H.

**Figure 1 : Length  $l_S$  of the free surface of the liquid**

Figure 2 : Breadth  $b_s$  of the free surface of the liquid for ships without longitudinal bulkheads

Figure 3 : Breadth  $b_s$  of the free surface of the liquid for ships with longitudinal bulkheads

## 1.2 Liquefied gas carriers

1.2.1 Sloshing in cargo containment tanks of liquefied gas carriers is to be checked according to Pt D, Ch 9, Sec 4, or Pt D, Ch 9, Sec 20, as applicable.

### 1.3 Sloshing loads

#### 1.3.1 Longitudinal motion

Where there is a risk of longitudinal resonance according to [1.5] for a filling level  $d_F$ , the sloshing pressure  $P_{sl}$  calculated according to Ch 5, Sec 6, [2.2.1] is to be considered as acting on transverse bulkheads which form tank boundaries, in the area extended vertically  $0,2 d_F$  above and below  $d_F$  (see Ch 5, Sec 6, Fig 2).

Where tank bottom transverses or wash transverse bulkheads are fitted, the sloshing pressure calculated according to Ch 5, Sec 6, [2.4.2] is to be considered as acting on them.

The Society may also require the sloshing pressure to be considered when there is no risk of resonance, but the tank arrangement is such that  $\ell_C / L > 0,15$ .

#### 1.3.2 Transverse motion

Where there is a risk of transverse resonance according to [1.5] for a filling level  $d_F$ , the sloshing pressure  $P_{st}$  calculated according to Ch 5, Sec 6, [2.2.1] is to be considered as acting on longitudinal bulkheads, inner sides or sides which, as the case may be, form tank boundaries, in the area extended vertically  $0,2 d_F$  above and below  $d_F$  (see Ch 5, Sec 6, Fig 2).

If sloped longitudinal topsides are fitted, they are to be considered as subjected to the sloshing pressure if their height is less than  $0,30 H$ .

Where wash longitudinal bulkheads are fitted, the sloshing pressure calculated according to Ch 5, Sec 6, [2.4.2] is to be considered as acting on them.

## 1.4 Impact loads

#### 1.4.1 Longitudinal motion

Where there is a risk of longitudinal resonance in tanks with arrangements such that  $\ell_s$  is greater than  $0,13 L$  at any filling level  $d_F$  from  $0,10 H$  to  $0,95 H$ , the dynamic impact pressure  $P_{w-1}$  due to liquid motions calculated according to Ch 5, Sec 6, [2.5.1] is to be considered as acting on:

- transverse bulkheads which form tank boundaries, in the area extended vertically 0,15 H from the tank top
- the tank top in the area extended longitudinally 0,3  $\ell_c$  from the above transverse bulkheads.

Where the upper part of a transverse bulkhead is sloped, the impact pressure is to be considered as acting on the sloped part of the transverse bulkhead and the tank top (as the case may be) in the area extended longitudinally 0,3  $\ell_c$  from the transverse bulkhead.

**1.4.2 Transverse motion**

Where there is a risk of transverse resonance in tanks with arrangements such that  $b_s$  is greater than 0,56 B at any filling level  $d_f$  from 0,10 H to 0,95 H, the dynamic impact pressure  $P_{W-1}$  due to liquid motions calculated according to Ch 5, Sec 6, [2.5.1] is to be considered as acting on:

- longitudinal bulkheads, inner sides or sides which, as the case may be, form tank boundaries, in the area extended vertically 0,15 H from the tank top
- the tank top in the area extended transversely 0,3  $b_c$  from the above longitudinal bulkheads, inner sides or sides.

Where the upper part of a longitudinal bulkhead, inner side or side is sloped, the impact pressure is to be considered as acting on this sloped part and the tank top (as the case may be) in the area extended transversely 0,3  $b_c$  from the longitudinal bulkhead, inner side or side.

**1.4.3 Static pressure**

The static pressure  $P_{S-1}$ , acting on the full tank boundary and calculated according to Ch 5, Sec 6, [2.3.2], is to be combined with  $P_{W-1}$  according to Ch 5, Sec 6, [2.2.2].

**1.5 Evaluation of the risk of resonance**

**1.5.1** Where tanks are partly filled at a level  $d_f$  such as  $0,10 H \leq d_f \leq 0,95 H$ , the risk of resonance between:

- the ship pitch motion and the longitudinal motion of the liquid inside the tank
- the ship roll motion and the transverse motion of the liquid inside the tank,

is to be evaluated on the basis of the criteria specified in Tab 1

where:

$T_x$  : Natural period, in s, of the liquid motion in the longitudinal direction:

$$T_x = \sqrt{\frac{4\pi\ell_s}{g \tanh \frac{\pi d_f}{\ell_s}}}$$

$T_y$  : Natural period, in s, of the liquid motion in the transverse direction:

$$T_y = \sqrt{\frac{4\pi b_s}{g \tanh \frac{\pi d_f}{b_s}}}$$

$T_\phi$  : Pitch period, in s, defined in Ch 5, Sec 3, [2.1.2]

$T_\theta$  : Roll period, in s, defined in Ch 5, Sec 3, [2.2.1].

**1.5.2** The Society may accept that the risk of resonance is evaluated on the basis of dynamic calculation procedures, where deemed necessary in relation to the tank dimensions and the ship characteristics. The calculations are to be submitted to the Society for approval.

**Table 1 : Criteria for the evaluation of the risk of resonance**

Liquid motion direction	Risk of resonance when:	Resonance due to:
Longitudinal	$0,6 < \frac{T_x}{T_\phi} < 1,3$ and $\frac{d_f}{\ell_c} > 0,1$	Pitch
Transverse	$0,8 < \frac{T_y}{T_\theta} < 1,2$ and $\frac{d_f}{b_c} > 0,1$	Roll

## 2 Scantling of elements subject to sloshing loads

### 2.1 Plating

#### 2.1.1 Net thickness

The net thickness of plating  $t$ , in mm, subject to sloshing pressures is not to be less than:

$$t = 0,0158 \alpha_p b \sqrt{\frac{P_{sl}}{C_a R_{eH}}}$$

where:

$C_a$  : Permissible bending stress coefficient to be taken as:

$$C_a = \beta_a - \alpha_a \frac{|\sigma_l|}{R_{eH}}$$

without being taken greater than  $C_{a-max}$

with  $\beta_a$ ,  $\alpha_a$  and  $C_{a-max}$  as defined in Tab 2

$\sigma_l$  : Hull girder bending stress, in N/mm<sup>2</sup>, corresponding to the greater of the still water sagging and hogging bending moments in absolute value

$P_{sl}$  : Sloshing pressure, in kN/m<sup>2</sup>, calculated according to Ch 5, Sec 6, [2.2.1].

**Table 2 : Definition of  $\beta_a$ ,  $\alpha_a$  and  $C_{a-max}$**

Acceptance criteria set	Structural member	$\beta_a$	$\alpha_a$	$C_{a-max}$
AC-1	Longitudinal strength members in the cargo hold region including, but not limited to:	0,9	0,5	0,8
	<ul style="list-style-type: none"> <li>• deck</li> <li>• longitudinal bulkhead</li> <li>• longitudinal girders and stringers</li> </ul>			
	<ul style="list-style-type: none"> <li>• transversely or vertically stiffened plating</li> </ul>	0,9	1,0	0,8
	Other strength members including:	0,8	0	0,8
	<ul style="list-style-type: none"> <li>• transverse bulkhead</li> <li>• transverse stringers and web frames</li> <li>• plating of tank boundaries and primary supporting members</li> </ul>			

### 2.2 Stiffeners

#### 2.2.1 Net section modulus of horizontal stiffeners

The net section modulus  $Z$ , in cm<sup>3</sup>, of horizontal stiffeners subjected to sloshing pressures is not to be less than:

$$Z = \frac{P_{sl} S_{bdg}^2}{f_{bdg} C_s R_{eH}}$$

where:

$f_{bdg}$  : Bending moment factor:

- $f_{bdg} = 12$

for stiffeners fixed against rotation at each end. This is generally to be applied for scantlings of all continuous stiffeners

- $f_{bdg} = 8$

for stiffeners with one or both ends not fixed against rotation. This is generally to be applied to discontinuous stiffeners

$C_s$  : Permissible bending stress coefficient, to be taken as:

- For members subject to hull girder stress: coefficient to be taken as defined in Tab 3
- $C_s = C_{s-max}$  for other cases

$P_{sl}$  : Sloshing pressure, in kN/m<sup>2</sup>, calculated according to Ch 5, Sec 6, [2.2.1].

$C_{s-max}$  : Coefficient as defined in Tab 4.

#### 2.2.2 Vertical stiffeners

Vertical stiffeners subject to sloshing loads are to be assessed by means of direct calculation according to Ch 7, Sec 5, [1.7] considering the permissible stress coefficient  $C_s$  as defined in [2.2.1].

**2.3 Primary supporting members**

**2.3.1 Web plating**

The web plating net thickness  $t$  of primary supporting members, in mm, is not to be less than:

$$t = 0,0158\alpha_p b \sqrt{\frac{P_{sl}}{C_a R_{eH}}}$$

where:

- $P_{sl}$  : Sloshing pressure, in kN/m<sup>2</sup>, calculated according to Ch 5, Sec 6, [2.2.1]. The pressure is to be calculated at the load application point, defined in Ch 4, Sec 6, [4.1], taking into account the distribution over the height of the member
- $C_a$  : Permissible plate bending stress coefficient, as given in [2.1.1].

**2.3.2 Stiffeners on web plating**

The net section modulus  $Z$ , in cm<sup>3</sup>, of each individual stiffener on the web plating of primary supporting members subjected to sloshing pressures is not to be less than:

$$Z = \frac{P_{sl} S_{bdg}^2}{f_{bdg} C_s R_{eH}}$$

where:

- $P_{sl}$  : Sloshing pressure, in kN/m<sup>2</sup>, calculated according to Ch 5, Sec 6, [2.2.1]. The pressure is to be calculated at the load application point, defined in Ch 4, Sec 6, [3.2], taking into account the distribution over the height of the member
- $C_s$  : Permissible bending stress coefficient, as given in Tab 3
- $f_{bdg}$  : Bending moment factor, as given in [2.2.1].

**Table 3 : Permissible bending stress coefficient  $C_s$**

Sign of hull girder bending stress $\sigma_L$ (1)	Lateral pressure acting on (2)	Stiffener boundary condition (3)	$f_{bdg}$	Coefficient $C_s$ (4)
Tension (positive)	Stiffener side	F - F	12	$C_s = \beta_s - \alpha_s \frac{ \sigma_L }{R_{eH}}$ with $C_s \leq C_{s-max}$
		F - S	8	$C_s = \beta_s - \alpha_s \frac{ \sigma_L }{R_{eH}}$ with $C_s \leq C_{s-max}$
		S - S	8	$C_s = C_{s-max}$
	Plate side	F - F	12	$C_s = C_{s-max}$
		F - S	8	$C_s = C_{s-max}$
		S - S	8	$C_s = \beta_s - \alpha_s \frac{ \sigma_L }{R_{eH}}$ with $C_s \leq C_{s-max}$
Compression (negative)	Stiffener side	F - F	12	$C_s = C_{s-max}$
		F - S	8	$C_s = C_{s-max}$
		S - S	8	$C_s = \beta_s - \alpha_s \frac{ \sigma_L }{R_{eH}}$ with $C_s \leq C_{s-max}$
	Plate side	F - F	12	$C_s = \beta_s - \alpha_s \frac{ \sigma_L }{R_{eH}}$ with $C_s \leq C_{s-max}$
		F - S	8	$C_s = \beta_s - \alpha_s \frac{ \sigma_L }{R_{eH}}$ with $C_s \leq C_{s-max}$
		S - S	8	$C_s = C_{s-max}$

- (1)  $\sigma_L$  is to be considered for the hogging and sagging situations.
- (2) For primary supporting members located inside the considered tank and for wash bulkheads, the sloshing pressure is to be applied on both stiffener side and plate side.
- (3) F - F stands for both ends of the stiffener fixed against rotation  
 F - S stands for one end of the stiffener fixed and the other not fixed against rotation  
 S - S stands for both ends of the stiffener not fixed against rotation.
- (4) See Tab 4 for definition of  $\beta_s$ ,  $\alpha_s$  and  $C_{s-max}$ .

Table 4 : Definition of  $\beta_s$ ,  $\alpha_s$  and  $C_{s-max}$

Acceptance criteria set	Structural member	$\beta_s$	$\alpha_s$	$C_{s-max}$	
AC-1	Longitudinal strength members in the cargo hold region including, but not limited to:				
	<ul style="list-style-type: none"> <li>deck stiffeners</li> <li>stiffeners on longitudinal bulkheads</li> <li>stiffeners on longitudinal girders and stringers</li> </ul>	Longitudinal stiffeners	0,85	1,0	0,75
		Transverse or vertical stiffeners	0,70	0	0,70
	Other strength members including:				
	<ul style="list-style-type: none"> <li>stiffeners on transverse bulkheads</li> <li>stiffeners on transverse stringers and web frames</li> <li>stiffeners on tank boundaries and primary supporting members</li> </ul>		0,75	0	0,75

2.3.3 Tripping brackets supporting primary supporting members

The net section modulus  $Z$ , in  $cm^3$ , in way of the base within the effective length  $d$  of tripping brackets, and the net shear sectional area  $A_{shr}$ , in  $cm^2$ , after deduction of cut-outs and slots, of the tripping brackets supporting primary supporting members are not to be less than:

$$Z = \frac{1000 P_{sl} s_{trip} h^2}{2 C_s R_{eH}}$$

$$A_{shr} = 10 \frac{P_{sl} s_{trip} h}{C_t \tau_{eH}}$$

where:

- $P_{sl}$  : Sloshing pressure, in  $kN/m^2$ , calculated according to Ch 5, Sec 6, [2.2.1]. The average pressure may be calculated at mid-point of the tripping bracket, taking into account the distribution over the height of the bracket
- $s_{trip}$  : Mean spacing, in m, between tripping brackets or other primary supporting members or bulkheads
- $h$  : Height of tripping bracket, in m (see Fig 4)
- $C_s$  : Permissible bending stress coefficient for tripping brackets, to be taken as 0,75
- $C_t$  : Permissible shear stress coefficient for tripping brackets, to be taken as 0,75.

The effective breadth of the attached plate to be used for the calculation of the section modulus of the tripping bracket is to be taken as  $h/3$ .

Figure 4 : Effective length  $d$  of tripping bracket

3 Scantling of elements subject to impact loads

3.1 Plating

3.1.1 Plate panels subject to impact loads according to [1.4] are to comply with the requirements of Ch 7, Sec 4, [4].

3.2 Ordinary stiffeners

3.2.1 Ordinary stiffeners subject to impact loads according to [1.4] are to comply with the requirements of Ch 7, Sec 5, [1.3].

### **3.2.2 Stiffeners partly located in the impact area**

For stiffeners partly located within the application area defined in [1.4.1] and [1.4.2], the static pressure  $P_{S-1}$  and the dynamic impact pressure  $P_{W-1}$  are to be taken as follows:

- the static pressure  $P_{S-1}$  is to be considered as acting over the full span of the stiffener, and taken equal to  $P_{S-1,eq}$
- the dynamic impact pressure  $P_{W-1}$  is to be considered as acting only on the portion of the stiffener span located within the application area, and taken equal to  $P_{W-1,eq}$ ,

where

$$P_{S-1,eq} = \frac{(P_{S-1} + P_{S-2})}{2}$$

$$P_{W-1,eq} = \frac{\ell_1}{\ell} \cdot P_{W-1}$$

$P_{S-1}$ ,  $P_{S-2}$ : Static pressures, in kN/m<sup>2</sup>, calculated at both ends of the stiffener span.

$\ell_1$  : Portion of the stiffener span, in m, located within the application area.

### **3.3 Primary supporting members**

**3.3.1** Primary supporting members subject to impact loads according to [1.4] are to comply with the requirements of Ch 7, Sec 6, [2.3].

# Section 5 Superstructures and Deckhouses

## Symbols

$k$	: Material factor, defined in Ch 4, Sec 1, [2.2] or Ch 4, Sec 1, [4.4] as applicable
$P_{sd}$	: Lateral pressure, in kN/m <sup>2</sup> , defined in Ch 5, Sec 5, [5.4] calculated at midpoint of stiffener span, or at the middle of the plate field.
$s$	: Stiffener spacing, in mm
$t_c$	: Corrosion addition, defined in Ch 4, Sec 3

## 1 General

### 1.1 Application

**1.1.1** The requirements of this Section apply for the scantling of plating and associated structures of fore, side and aft bulkheads and decks of superstructures and deckhouses.

**1.1.2** The requirements of this Section comply with the applicable regulations of the 1966 International Convention on Load Lines, as amended, with regard to the strength of enclosed superstructures.

**1.1.3** In addition to the requirements of this Section, structural elements of superstructures and deckhouses forming tank boundaries are to comply with the applicable requirements of Part B, Chapter 7.

### 1.2 Net scantlings

**1.2.1** Except for the stiffeners section modulus in [3.3.1], and as specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

The gross scantlings are obtained as specified in Ch 4, Sec 3, [1.2].

### 1.3 Definitions

#### 1.3.1 Superstructures

Superstructures are defined in Ch 1, Sec 3.

#### 1.3.2 Deckhouses

Deckhouses are defined in Ch 1, Sec 3.

#### 1.3.3 Tiers of superstructures and deckhouses

Tiers of superstructures and deckhouses are defined in Ch 1, Sec 3, [2.2.10].

The lowest tier is normally that tier which is directly situated above the uppermost continuous deck to which the moulded depth  $D$  is measured. However, when  $(D - T_{sc})$  exceeds the minimum non-corrected tabular freeboard (according to ICLL as amended) by at least one standard superstructure height (as defined in Ch 1, Sec 3, Tab 5), then this tier may be defined as the 2nd tier and the tier above as the 3rd tier.

### 1.4 Connections of superstructures and deckhouses with the hull structure

**1.4.1** Superstructure and deckhouse frames are to be fitted as far as practicable as extensions of those underlying and are to be effectively connected to both the latter and the deck beams above.

Fore and aft bulkheads of superstructures and deckhouses are to be efficiently supported by bulkheads, diaphragms, webs or pillars.

Where hatchways are fitted close to the ends of superstructures, additional strengthening may be required.

**1.4.2** Connection to the deck of corners of superstructures and deckhouses is considered by the Society on a case by case basis. Where necessary, doublers or reinforced welding may be required.

**1.4.3** As a rule, the frames of side bulkheads of superstructures and deckhouses are to have the same spacing as the beams of the supporting deck.

Web frames are to be arranged to support the side, fore and aft bulkheads of superstructures and deckhouses.

**1.4.4** The side plating at fore and aft bulkheads of superstructures is to be tapered into the bulwark or sheerstrake of the strength deck.

Where a raised deck is fitted, this arrangement is to extend over at least a 3-frame spacing.

## **1.5 Structural arrangement of superstructures and deckhouses**

### **1.5.1 Strengthening in way of superstructures and deckhouses**

Web frames, transverse partial bulkheads or other equivalent strengthening are to be fitted inside deckhouses of at least 0,5 B in breadth extending more than 0,15 L in length within 0,4 L amidships. These transverse strengthening reinforcements are to be spaced approximately 9 m apart and are to be arranged, where practicable, in line with the transverse bulkheads below.

Web frames are also to be arranged in way of large openings, boats davits and other areas subjected to point loads.

Web frames, pillars, partial bulkheads and similar strengthening are to be arranged, in conjunction with deck transverses, at fore and aft bulkheads of superstructures and deckhouses.

### **1.5.2 Strengthening of the raised quarter deck stringer plate**

When a superstructure is located above a raised quarter deck, the thickness of the raised quarter deck stringer plate is to be increased by 30% and is to be extended within the superstructure.

The increase above may be reduced when the raised quarter deck terminates outside 0,5 L amidships.

### **1.5.3 Openings**

Openings are to be in accordance with Ch 6, Sec 1, [1].

Continuous coamings are to be fitted above and below doors or similar openings.

### **1.5.4 Access and doors**

Access openings cut in sides of enclosed superstructures are to be fitted with doors made of steel or other equivalent material, and permanently attached.

Special consideration is to be given to the connection of doors to the surrounding structure.

Securing devices which ensure watertightness are to include tight gaskets, clamping dogs or other similar appliances, and are to be permanently attached to the bulkheads and doors. These doors are to be operable from both sides.

Unless otherwise permitted by the Society, doors open outwards to provide additional security against the impact of the sea.

### **1.5.5 Strengthening of deckhouses in way of lifeboats and rescue boats**

Sides of deckhouses are to be strengthened in way of lifeboats and rescue boats and the top plating is to be reinforced in way of their lifting appliances.

### **1.5.6 Construction details**

Lower tier stiffeners are to be welded to the decks at their ends.

Brackets are to be fitted at the upper and preferably also the lower ends of vertical stiffeners of exposed front bulkheads of engine casings and superstructures or deckhouses protecting pump room openings.

### **1.5.7 Use of aluminium alloys**

Unprotected front bulkheads of first tier superstructures or deckhouses are generally to be built of steel and not of aluminium alloy.

Aluminium alloys may be adopted for front bulkheads of superstructures or deckhouses above the first tier.

## **2 Superstructures side bulkheads**

### **2.1 Plating**

**2.1.1** The net thickness of plating of superstructures side bulkheads is to be determined in accordance with the applicable requirements of Ch 7, Sec 4, considering the lateral pressure defined in Ch 5, Sec 5, [5.3].

### **2.2 Stiffeners**

**2.2.1** The net scantlings of stiffeners of superstructures side bulkheads are to be determined in accordance with the applicable requirements of Ch 7, Sec 5, considering the lateral pressure defined in Ch 5, Sec 5, [5.3].

### **2.3 Primary supporting members**

**2.3.1** The net scantlings of primary supporting members of superstructures side bulkheads are to be determined in accordance with the applicable requirements of Ch 7, Sec 6, using the lateral pressure defined in Ch 5, Sec 5, [5.3].

### 3 Fore and aft bulkheads of superstructures and deckhouses, side bulkheads of deckhouses

#### 3.1 Application

##### 3.1.1 Buckling

In addition to the requirements in [3.2.1] to [3.4.1], the structural members of deckhouses side bulkheads contributing to the longitudinal strength are to be checked for buckling according to Ch 9, Sec 1, [3.2.2].

#### 3.2 Plating

**3.2.1** The net plating thickness of fore and aft bulkheads of superstructures and deckhouses, and of side bulkheads of deckhouses is to be not less than the value obtained, in mm, from the following formula:

$$t = 0,95 s_{\sqrt{kP_{sd}}} \cdot 10^{-3} - t_c$$

This net thickness is to be not less than:

- the values given in Tab 1 for steel superstructures,
- the following values for aluminium superstructures:
  - 4 mm for rolled products
  - 2,5 mm for extruded products.

**Table 1 : Minimum thicknesses of superstructures and deckhouses**

Location	Minimum thickness, in mm
Lowest tier (1)	$(5 + 0,01 L_3) k^{1/2} - t_c$
Second tier and above (2)	$(4 + 0,01 L_4) k^{1/2} - t_c$
(1) $L_3$ :	As defined in Ch 1, Sec 3, Tab 1
(2) $L_4$ :	Rule length L, but not less than 100 m and not greater than 300 m

#### 3.3 Stiffeners

**3.3.1** The gross section modulus of single span stiffeners of fore and aft bulkheads of superstructures and deckhouses, and of side bulkheads of deckhouses is to be not less than the value obtained, in  $\text{cm}^3$ , from the following formula:

$$Z = k \frac{P_{sd} s \ell^2}{f_{bdg} 235}$$

where:

- $\ell$  : Span of the ordinary stiffener, in m.  
For vertical stiffeners,  $\ell$  is to be taken equal to the tweendeck height but not less than 2 m.
- $f_{bdg}$  : Coefficient depending on the stiffener end connections, and taken equal to:
  - 12 for continuous horizontal stiffeners with at least one fixed end and for lower tier vertical stiffeners
  - 8 for horizontal stiffeners simply supported at both ends
  - value defined in Tab 2 for vertical stiffeners of upper tiers.

The section modulus of side ordinary stiffeners need not be greater than that of the side ordinary stiffeners of the tier situated directly below considering spacing and span.

**Table 2 : Coefficient n for vertical stiffeners of fore and aft bulkheads of superstructures and deckhouses, and of side bulkheads of deckhouses**

Coefficient $f_{bdg}$	Upper end welded to deck	Bracketed upper end	Sniped upper end
Lower end welded to deck	12	14	10
Bracketed lower end	14	14	12
Sniped lower end	10	12	10

#### 3.4 Primary supporting members

**3.4.1** It is to be checked that the stress values in primary supporting members of fore and aft bulkheads of superstructures and deckhouses, and of side bulkheads of deckhouses, calculated using the lateral pressure  $P_{sd}$ , in  $\text{kN/m}^2$ , defined in Ch 5, Sec 5, [5.4], comply with the following criterion:

$$\sigma_{eq} \leq \frac{235}{k}$$

where:

$\sigma_{eq}$  : equivalent Von Mises stress, in N/mm<sup>2</sup>:

$$\sigma_{eq} = \sqrt{\sigma^2 + 3\tau^2}$$

## 4 Decks

### 4.1 Plating

**4.1.1** The net thickness of decks plating is to be determined in accordance with the applicable requirements of Ch 7, Sec 4, considering the loads defined in Ch 5, Sec 5, [3] or in Ch 5, Sec 6, [6] as applicable.

**4.1.2** For decks sheathed with wood, the net thickness obtained from [4.1.1] may be reduced by 10 percent.

### 4.2 Stiffeners

**4.2.1** The net scantlings of decks ordinary stiffeners are to be determined in accordance with the applicable requirements of Ch 7, Sec 5, considering the loads defined in Ch 5, Sec 5, [3] or in Ch 5, Sec 6, [6] as applicable.

### 4.3 Primary supporting members

**4.3.1** The net scantlings of decks primary supporting members are to be determined in accordance with the applicable requirements of Ch 7, Sec 6, considering the loads defined in Ch 5, Sec 5, [3] or in Ch 5, Sec 6, [6] as applicable.

## 5 Additional requirements applicable to movable wheelhouses

### 5.1 General

**5.1.1** The requirements of this Article apply in addition of those in [1] to [4].

**5.1.2** The structures of movable wheelhouses are to be checked in low and in high position.

**5.1.3** Mechanical locking devices are to be fitted in addition to hydraulic systems.

### 5.2 Supports and guides, connections with the deck, under deck reinforcements, locking devices

#### 5.2.1 Still water and inertial forces

The supports or guides of movable wheelhouses, connections with the deck, under deck reinforcements and locking devices are to be checked considering the sum of the following forces:

- still water and inertial forces, determined according to Ch 5, Sec 6, [6.2]
- wind forces, corresponding to a lateral pressure of 1,2kN/m<sup>2</sup>.

#### 5.2.2 Checking criteria

It is to be checked that the calculated stress values comply with the following criterion:

$$\sigma_{eq} \leq \frac{235}{k\gamma_R\gamma_m}$$

where:

$\sigma_{eq}$  : equivalent Von Mises stress, in N/mm<sup>2</sup>:

$$\sigma_{eq} = \sqrt{\sigma^2 + 3\tau^2}$$

$\gamma_R$  : Partial safety factor covering uncertainties regarding resistance, to be taken equal to:

- 1,10 in general
- 1,40 for checking locking devices

$\gamma_m$  : Partial safety factor covering uncertainties regarding material, to be taken equal to 1,02.

# Section 6 Bow Doors and Inner Doors

## 1 General

### 1.1 Application

**1.1.1** The requirements of this Section apply to the arrangement, strength and securing of bow doors and inner doors leading to a complete or long forward enclosed superstructure or to a long non-enclosed superstructure, where fitted to attain minimum bow height equivalence.

The requirements apply to ships engaged on international voyages and also to ships engaged only in domestic (non international) voyages, except where specifically indicated otherwise in this Section.

**1.1.2** Two types of bow door are provided for:

- visor doors opened by rotating upwards and outwards about a horizontal axis through two or more hinges located near the top of the door and connected to the primary supporting members of the door by longitudinally arranged lifting arms
- side-opening doors opened either by rotating outwards about a vertical axis through two or more hinges located near the outboard edges or by horizontal translation by means of linking arms arranged with pivoted attachments to the door and the ship. It is anticipated that side-opening bow doors are arranged in pairs.

Other types of bow door are considered by the Society on a case by case basis in association with the applicable requirements of this Section.

### 1.2 Gross scantlings

**1.2.1** With reference to Ch 4, Sec 2, [1.1.2], all scantlings and dimensions referred to in this Section are gross, i.e. they include the margins for corrosion.

### 1.3 Arrangement

**1.3.1** Bow doors are to be situated above the freeboard deck. A watertight recess in the freeboard deck located forward of the collision bulkhead and above the deepest waterline fitted for arrangement of ramps or other related mechanical devices may be regarded as a part of the freeboard deck for the purpose of this requirement.

**1.3.2** An inner door is to be fitted as part of the collision bulkhead. The inner door need not be fitted directly above the bulkhead below, provided it is located within the limits specified for the position of the collision bulkhead, as per.

A vehicle ramp may be arranged for this purpose, provided its position complies with Ch 2, Sec 1, [3.1].

If this is not possible, a separate inner weathertight door is to be installed, as far as practicable within the limits specified for the position of the collision bulkhead.

**1.3.3** Bow doors are to be so fitted as to ensure tightness consistent with operational conditions and to give effective protection to inner doors.

Inner doors forming part of the collision bulkhead are to be weathertight over the full height of the cargo space and arranged with fixed sealing supports on the aft side of the doors.

**1.3.4** Bow doors and inner doors are to be arranged so as to preclude the possibility of the bow door causing structural damage to the inner door or to the collision bulkhead in the case of damage to or detachment of the bow door. If this is not possible, a separate inner weathertight door is to be installed, as indicated in [1.3.2].

**1.3.5** The requirements for inner doors are based on the assumption that vehicles are effectively lashed and secured against movement in stowed position.

### 1.4 Definitions

#### 1.4.1 Securing device

A securing device is a device used to keep the door closed by preventing it from rotating about its hinges.

#### 1.4.2 Supporting device

A supporting device is a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship's structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, which transmits loads from the door to the ship's structure.

### 1.4.3 Locking device

A locking device is a device that locks a securing device in the closed position.

## 2 Design loads

### 2.1 Bow doors

2.1.1 The design loads to be considered for the scantlings of bow doors are defined in Ch 5, Sec 5, [7.1].

### 2.2 Inner doors

#### 2.2.1 Design external pressure

The design external pressure to be considered for the scantlings of primary supporting members, securing and supporting devices and surrounding structure of inner doors is to be taken as the greater of the values obtained, in kN/m<sup>2</sup>, from the following formulae:

$$p_E = 0,45 L_1$$

$$p_E = 10 h$$

where:

$h$  : Distance, in m, from the calculation point to the top of the cargo space.

#### 2.2.2 Design internal pressure

The design internal pressure  $p_i$  to be considered for the scantlings of securing devices of inner doors is to be not less than 25 kN/m<sup>2</sup>.

## 3 Scantlings of bow doors

### 3.1 General

3.1.1 The strength of bow doors is to be commensurate with that of the surrounding structure.

3.1.2 Bow doors are to be adequately stiffened and means are to be provided to prevent lateral or vertical movement of the doors when closed.

For visor doors, adequate strength for opening and closing operations is to be provided in the connections of the lifting arms to the door structure and to the ship's structure.

### 3.2 Plating and ordinary stiffeners

#### 3.2.1 Plating

The thickness of the bow door plating is to be not less than that obtained according to the requirements in Ch 11, Sec 1 for the fore part, using the bow door stiffener spacing. In no case may it be less than the minimum required thickness of fore part shell plating.

#### 3.2.2 Ordinary stiffeners

The section modulus of bow door ordinary stiffeners is to be not less than that obtained according to the requirements in Ch 11, Sec 1 for the fore part, using the bow door stiffener spacing.

Consideration is to be given, where necessary, to differences in conditions of fixity between the ends of ordinary stiffeners of bow doors and those of the fore part shell.

### 3.3 Primary supporting members

3.3.1 Bow door ordinary stiffeners are to be supported by primary supporting members constituting the main stiffening of the door.

3.3.2 The primary supporting members of the bow door and the hull structure in way are to have sufficient stiffness to ensure integrity of the boundary support of the door.

3.3.3 Scantlings of primary supporting members are generally to be verified through direct calculations on the basis of the external pressure  $p_E$  in Ch 5, Sec 5, [7.1.1] and the strength criteria in [6.1.1] and [6.1.2].

In general, isolated beam models may be used to calculate the loads and stresses in primary supporting members.

Members are to be considered to have simply supported end connections.

## 4 Scantlings of inner doors

### 4.1 General

**4.1.1** The gross scantlings of the primary supporting members are generally to be verified through direct strength calculations on the basis of the external pressure  $p_E$  in [2.1.1] and the strength criteria in [6.1.1] and [6.1.2].

In general, isolated beam models may be used to calculate the loads and stresses in primary supporting members.

**4.1.2** Where inner doors also serve as vehicle ramps, their scantlings are to be not less than those obtained according to Ch 11, Sec 11.

**4.1.3** The distribution of the forces acting on the securing and supporting devices is generally to be supported by direct calculations taking into account the flexibility of the structure and the actual position and stiffness of the supports.

## 5 Securing and supporting of bow doors

### 5.1 General

**5.1.1** Bow doors are to be fitted with adequate means of securing and supporting so as to be commensurate with the strength and stiffness of the surrounding structure.

The hull supporting structure in way of the bow doors is to be suitable for the same design loads and design stresses as the securing and supporting devices.

Where packing is required, the packing material is to be of a comparatively soft type, and the supporting forces are to be carried by the steel structure only. Other types of packing may be considered by the Society on a case by case basis.

The maximum design clearance between securing and supporting devices is generally not to exceed 3 mm.

A means is to be provided for mechanically fixing the door in the open position.

**5.1.2** Only the active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered to calculate the reaction forces acting on the devices. Small and/or flexible devices such as cleats intended to provide local compression of the packing material may generally not be included in the calculation in [5.2.5].

The number of securing and supporting devices is generally to be the minimum practical while taking into account the requirements for redundant provision given in [5.2.6] and [5.2.7] and the available space for adequate support in the hull structure.

**5.1.3** For visor doors which open outwards, the pivot arrangement is generally to be such that the visor is self-closing under external loads, i.e. it is to be checked that the closing moment  $M_Y$ , defined in Ch 5, Sec 5, [7.1.3], is in compliance with the following formula:

$$M_Y > 0$$

Moreover, the closing moment  $M_Y$  is to be not less than the value  $M_{Y0}$ , in kN.m, obtained from the following formula:

$$M_{Y0} = 10Wc + 0,1 \sqrt{a^2 + b^2} \sqrt{F_X^2 + F_Z^2}$$

**5.1.4** For side-opening doors, a thrust bearing is to be provided in way of girder ends at the closing of the two leaves to prevent one leaf from shifting towards the other under the effect of unsymmetrical pressure (see example in Fig 1).

The parts of the thrust bearing are to be kept secured to each other by means of securing devices.

The Society may consider any other arrangement serving the same purpose.

**Figure 1 : Thrust bearing**

## 5.2 Scantlings

**5.2.1** Securing and supporting devices are to be adequately designed so that they can withstand the reaction forces within the allowable stresses defined in [6.1.1].

**5.2.2** For visor doors, the reaction forces applied on the effective securing and supporting devices assuming the door as a rigid body are determined for the following combination of external loads acting simultaneously together with the self weight of the door:

- Case 1:  $F_X$  and  $F_Z$
- Case 2:  $0,7F_Y$  acting on each side separately together with  $0,7F_X$  and  $0,7F_Z$ ,

where  $F_X$ ,  $F_Y$  and  $F_Z$  are to be calculated as indicated in Ch 5, Sec 5, [7.1.2] and applied at the centroid of projected areas.

**5.2.3** For side-opening doors, the reaction forces applied on the effective securing and supporting devices assuming the door as a rigid body are determined for the following combination of external loads acting simultaneously together with the self weight of the door:

- Case 1:  $F_X$ ,  $F_Y$  and  $F_Z$  acting on both doors
- Case 2:  $0,7F_X$  and  $0,7F_Z$  acting on both doors and  $0,7F_Y$  acting on each door separately,

where  $F_X$ ,  $F_Y$  and  $F_Z$  are to be calculated as indicated in Ch 5, Sec 5, [7.1.2] and applied at the centroid of projected areas.

**5.2.4** The support forces as calculated according to Case 1 in [5.2.2] and Case 1 in [5.2.3] are to generally give rise to a zero moment about the transverse axis through the centroid of the area  $A_X$ .

For visor doors, longitudinal reaction forces of pin and/or wedge supports at the door base contributing to this moment are not to be in the forward direction.

**5.2.5** The distribution of the reaction forces acting on the securing and supporting devices may need to be supported by direct calculations taking into account the flexibility of the hull structure and the actual position and stiffness of the supports.

**5.2.6** The arrangement of securing and supporting devices in way of these securing devices is to be designed with redundancy so that, in the event of failure of any single securing or supporting device, the remaining devices are capable of withstanding the reaction forces without exceeding by more than 20% the allowable stresses defined in [6.1.1].

**5.2.7** For visor doors, two securing devices are to be provided at the lower part of the door, each capable of providing the full reaction force required to prevent opening of the door within the allowable stresses defined in [6.1.1].

The opening moment  $M_0$  to be balanced by this reaction force is to be taken not less than that obtained, in kN.m, from the following formula:  $M_0 = 10 W d + 5 A_X a$

where:

- $d$  : Vertical distance, in m, from the hinge axis to the centre of gravity of the door, as shown in Ch 5, Sec 5, Fig 6
- $a$  : Vertical distance, in m, defined in Ch 5, Sec 5, [7.1.3].

**5.2.8** For visor doors, the securing and supporting devices excluding the hinges are to be capable of resisting the vertical design force ( $F_Z - 10 W$ ), in kN, within the allowable stresses defined in [6.1.1].

**5.2.9** All load transmitting elements in the design load path, from the door through securing and supporting devices into the ship's structure, including welded connections, are to be of the same strength standard as required for the securing and supporting devices. These elements include pins, supporting brackets and back-up brackets.

## 6 Strength criteria

### 6.1 Primary supporting members and securing and supporting devices

#### 6.1.1 Yielding check

It is to be checked that the normal stresses  $\sigma$ , the shear stress  $\tau$  and the equivalent stress  $\sigma_{VM}$ , induced in the primary supporting members and in the securing and supporting devices of bow doors by the design load defined in [2], are in compliance with the following formulae:

$$\sigma \leq \sigma_{ALL}$$

$$\tau \leq \tau_{ALL}$$

$$\sigma_{VM} = (\sigma^2 + 3 \tau^2)^{0,5} \leq \sigma_{VM,ALL}$$

where:

$\sigma_{ALL}$  : Allowable normal stress, in N/mm<sup>2</sup>, equal to:  $\sigma_{ALL} = 120/k$

$\tau_{ALL}$  : Allowable shear stress, in N/mm<sup>2</sup>, equal to:  $\tau_{ALL} = 80/k$

$\sigma_{VM,ALL}$  : Allowable equivalent stress, in N/mm<sup>2</sup>, equal to:  $\sigma_{VM,ALL} = 150/k$

$k$  : Material factor, defined in Ch 4, Sec 1, [2.2], but to be taken not less than 0,72 unless a fatigue analysis is carried out.

**6.1.2 Buckling check**

The buckling check of primary supporting members is to be carried out according to Ch 9, Sec 1.

**6.1.3 Bearings**

For steel to steel bearings in securing and supporting devices, it is to be checked that the nominal bearing pressure  $\sigma_B$ , in N/mm<sup>2</sup>, is in compliance with the following formula:  $\sigma_B \leq 0,8 R_{e,HB}$

where:

$$\sigma_B = 10 \frac{F}{A_B}$$

F : Design force, in kN, defined in Ch 5, Sec 5, [7.1.2]

A<sub>B</sub> : Projected bearing area, in cm<sup>2</sup>

R<sub>e,HB</sub> : Yield stress, in N/mm<sup>2</sup>, of the bearing material.

For other bearing materials, the allowable bearing pressure is to be determined according to the manufacturer's specification.

**6.1.4 Bolts**

The arrangement of securing and supporting devices is to be such that threaded bolts do not carry support forces.

It is to be checked that the tension  $\sigma_T$  in way of threads of bolts not carrying support forces is in compliance with the following formula:  $\sigma_T \leq \sigma_{T,ALL}$

where:

$\sigma_{T,ALL}$  : Allowable tension in way of threads of bolts, in N/mm<sup>2</sup>, equal to:  $\sigma_{T,ALL} = 125/k$

k : Material coefficient defined in [6.1.1].

**7 Securing and locking arrangement****7.1 Systems for operation**

**7.1.1** Securing devices are to be simple to operate and easily accessible.

Securing devices are to be equipped with mechanical locking arrangement (self-locking or separate arrangement), or to be of the gravity type.

The opening and closing systems as well as securing and locking devices are to be interlocked in such a way that they can only operate in the proper sequence.

**7.1.2** Bow doors and inner doors giving access to vehicle decks are to be provided with an arrangement for remote control, from a position above the freeboard deck, of:

- the closing and opening of the doors, and
- associated securing and locking devices for every door.

Indication of the open/closed position of every door and every securing and locking device is to be provided at the remote control stations.

The operating panels for operation of doors are to be inaccessible to unauthorised persons.

A notice plate, giving instructions to the effect that all securing devices are to be closed and locked before leaving harbour, is to be placed at each operating panel and is to be supplemented by warning indicator lights.

**7.1.3** Where hydraulic securing devices are applied, the system is to be mechanically lockable in closed position. This means that, in the event of loss of hydraulic fluid, the securing devices remain locked.

The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits, when in closed position.

**7.2 Systems for indication/monitoring**

**7.2.1** Separate indicator lights and audible alarms are to be provided on the navigation bridge and on the operating panel to show that the bow door and inner door are closed and that their securing and locking devices are properly positioned.

The indication panel is to be provided with a lamp test function. It is not to be possible to turn off the indicator light.

**7.2.2** The indicator system is to be designed on the fail safe principle and is to show by visual alarms if the door is not fully closed and not fully locked and by audible alarms if securing devices become open or locking devices become unsecured.

The power supply for the indicator system for operating and closing doors is to be independent of the power supply for operating and closing the doors and is to be provided with a back-up power supply from the emergency source of power or other secure power supply, e.g. UPS.

The sensors of the indicator system are to be protected from water, ice formation and mechanical damage.

Note 1: The indicator system is considered designed on the fail-safe principal when:

- the indication panel is provided with:
  - a power failure alarm
  - an earth failure alarm
  - a lamp test
  - separate indication for door closed, door locked, door not closed and door not locked
- limit switches electrically closed when the door is closed (when more limit switches are provided they may be connected in series)
- limit switches electrically closed when securing arrangements are in place (when more limit switches are provided they may be connected in series)
- two electrical circuits (also in one multicore cable), one for the indication of door closed/not closed and the other for door locked/not locked
- in case of dislocation of limit switches, indication to show: not closed/not locked/securing arrangement not in place - as appropriate.

**7.2.3** The indication panel on the navigation bridge is to be equipped with a mode selection function “harbour/sea voyage”, so arranged that an audible alarm is given on the navigation bridge if the ship leaves harbour with the bow door or the inner door not closed or with any of the securing devices not in the correct position.

**7.2.4** A water leakage detection system with an audible alarm and television surveillance is to be arranged to provide an indication to the navigation bridge and to the engine control room of leakage through the inner door.

Note 1: The indicator system is considered designed on the fail-safe principal when:

- the indication panel is provided with:
  - a power failure alarm
  - an earth failure alarm
  - a lamp test
  - separate indication for door closed, door locked, door not closed and door not locked
- limit switches electrically closed when the door is closed (when more limit switches are provided they may be connected in series)
- limit switches electrically closed when securing arrangements are in place (when more limit switches are provided they may be connected in series)
- two electrical circuits (also in one multicore cable), one for the indication of door closed/not closed and the other for door locked/not locked
- in case of dislocation of limit switches, indication to show: not closed/not locked/securing arrangement not in place - as appropriate.

**7.2.5** Between the bow door and the inner door a television surveillance system is to be fitted with a monitor on the navigation bridge and in the engine control room.

The system is to monitor the position of the doors and a sufficient number of their securing devices.

Special consideration is to be given for the lighting and contrasting colour of the objects under surveillance.

Note 1: The indicator system is considered designed on the fail-safe principal when:

- the indication panel is provided with:
  - a power failure alarm
  - an earth failure alarm
  - a lamp test
  - separate indication for door closed, door locked, door not closed and door not locked
- limit switches electrically closed when the door is closed (when more limit switches are provided they may be connected in series)
- limit switches electrically closed when securing arrangements are in place (when more limit switches are provided they may be connected in series)
- two electrical circuits (also in one multicore cable), one for the indication of door closed/not closed and the other for door locked/not locked
- in case of dislocation of limit switches, indication to show: not closed/not locked/securing arrangement not in place - as appropriate.

**7.2.6** The indicator system for the closure of the doors and the television surveillance systems for the doors and water leakage detection, and for special category and ro-ro spaces are to be suitable to operate correctly in the ambient conditions on board and to be type approved on the basis of the applicable tests required in Part D, Chapter 1 and/or Part D, Chapter 12.

**7.2.7** A drainage system is to be arranged in the area between bow door and ramp or, where no ramp is fitted, between the bow door and the inner door.

The system is to be equipped with an audible alarm function to the navigation bridge being set off when the water levels in these areas exceed 0,5 m or the high water level alarm, whichever is lesser.

Note 1: The indicator system is considered designed on the fail-safe principal when:

- the indication panel is provided with:
  - a power failure alarm
  - an earth failure alarm
  - a lamp test
  - separate indication for door closed, door locked, door not closed and door not locked
- limit switches electrically closed when the door is closed (when more limit switches are provided they may be connected in series)
- limit switches electrically closed when securing arrangements are in place (when more limit switches are provided they may be connected in series)

- two electrical circuits (also in one multicore cable), one for the indication of door closed/not closed and the other for door locked/not locked
- in case of dislocation of limit switches, indication to show: not closed/not locked/securing arrangement not in place - as appropriate.

**7.2.8** For ro-ro passenger ships on international voyages, the special category spaces and ro-ro spaces are to be continuously patrolled or monitored by effective means, such as television surveillance, so that any movement of vehicles in adverse weather conditions or unauthorized access by passengers thereto, can be detected whilst the ship is underway.

## **8 Operating and Maintenance Manual**

### **8.1 General**

**8.1.1** An Operating and Maintenance Manual for the bow door and inner door is to be provided on board and is to contain the necessary information on:

- a) Main particulars and design drawings:
  - special safety precautions
  - details of ship
  - equipment and design loading (for ramps)
  - key plan of equipment (doors and ramps)
  - manufacturer's recommended testing for equipment
  - description of equipment:
    - bow doors
    - inner bow doors
    - bow ramp/doors
    - central power pack
    - bridge panel
    - engine control room panel
- b) Service conditions:
  - limiting heel and trim of ship for loading/unloading
  - limiting heel and trim for door operations
  - doors/ramps operating instructions
  - doors/ramps emergency operating instructions
- c) Maintenance:
  - schedule and extent of maintenance
  - trouble shooting and acceptable clearances
  - manufacturer's maintenance procedures
- d) Register of inspections, including inspection of locking, securing and supporting devices, repairs and renewals.

This manual is to be submitted to the Society for approval that the above mentioned items are contained in the OMM and that the maintenance part includes the necessary information with regard to inspections, trouble-shooting and acceptance/rejection criteria.

Note 1: It is recommended that inspections of the doors and supporting and securing devices be carried out by ship's personnel at monthly intervals or following any incidents which could result in damage, including heavy weather or contact in the region of the shell doors. A record is to be kept and any damage found during such inspections is to be reported to the Society.

**8.1.2** Documented operating procedures for closing and securing the bow door and inner door are to be kept on board and posted at an appropriate place.

## Section 7 Side Doors and Stern Doors

### 1 General

#### 1.1 Application

**1.1.1** The requirements of this Section apply to the arrangement, strength and securing of side doors located abaft the collision bulkhead, and of stern doors leading to enclosed spaces.

The requirements apply to ships assigned with the service notation **ro-ro passenger ship** or **ro-ro cargo ship** engaged on international voyages and also in domestic (non-international) voyages, except where specifically indicated otherwise in this section.

Shell doors not covered by this Section are dealt with in Ch 11, Sec 8.

#### 1.2 Gross scantlings

**1.2.1** With reference to Ch 4, Sec 2, [1.1.2], all scantlings and dimensions referred to in this Section are gross, i.e. they include the margins for corrosion.

#### 1.3 Arrangement

**1.3.1** Side doors and stern doors are to be so fitted as to ensure tightness and structural integrity commensurate with their location and the surrounding structure.

**1.3.2** Where the sill of any side door is below the uppermost load line, the arrangement is considered by the Society on a case by case basis.

**1.3.3** Doors are preferably to open outwards.

#### 1.4 Definitions

##### 1.4.1 Securing device

A securing device is a device used to keep the door closed by preventing it from rotating about its hinges or about pivoted attachments to the ship.

##### 1.4.2 Supporting device

A supporting device is a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship's structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, which transmits loads from the door to the ship's structure.

##### 1.4.3 Locking device

A locking device is a device that locks a securing device in the closed position.

### 2 Design loads

#### 2.1 Side and stern doors

**2.1.1** The design loads to be considered for the scantlings of side and stern doors are defined in Ch 5, Sec 5, [7.2].

### 3 Scantlings of side doors and stern doors

#### 3.1 General

**3.1.1** The strength of side doors and stern doors is to be commensurate with that of the surrounding structure.

**3.1.2** Side doors and stern doors are to be adequately stiffened and means are to be provided to prevent any lateral or vertical movement of the doors when closed.

Adequate strength is to be provided in the connections of the lifting/manoeuvring arms and hinges to the door structure and to the ship's structure.

**3.1.3** Where doors also serve as vehicle ramps, the design of the hinges is to take into account the ship angle of trim and heel which may result in uneven loading on the hinges.

**3.1.4** Shell door openings are to have well rounded corners and adequate compensation is to be arranged with web frames at sides and stringers or equivalent above and below.

## **3.2 Plating and ordinary stiffeners**

### **3.2.1 Plating**

The thickness of the door plating is to be not less than that obtained according to the requirements in Ch 7, Sec 4, for side plating, using the door stiffener spacing. It is in no case to be less than the minimum required thickness of side plating.

Where doors also serve as vehicle ramps, the thickness of the door plating is to be not less than that obtained according to Ch 11, Sec 11.

### **3.2.2 Ordinary stiffeners**

The scantling of door ordinary stiffeners is to be not less than that obtained according to the requirements in Ch 7, Sec 5, for the side, using the door stiffener spacing.

Consideration is to be given, where necessary, to differences in conditions of fixity between the ends of ordinary stiffeners of doors and those of the side.

Where doors also serve as vehicle ramps, the scantling of ordinary stiffeners is to be not less than that obtained according to Ch 11, Sec 11.

## **3.3 Primary supporting members**

**3.3.1** The door ordinary stiffeners are to be supported by primary supporting members constituting the main stiffening of the door.

**3.3.2** The primary supporting members and the hull structure in way are to have sufficient stiffness to ensure structural integrity of the boundary of the door.

**3.3.3** Scantlings of primary supporting members are generally to be verified through direct strength calculations on the basis of the design forces in [2] and the strength criteria in Ch 11, Sec 6, [6.1.1] and Ch 11, Sec 6, [6.1.2].

In general, isolated beam models may be used to calculate the loads and stresses in primary supporting members.

Members are to be considered to have simply supported end connections.

## **4 Securing and supporting of doors**

### **4.1 General**

**4.1.1** Side doors and stern doors are to be fitted with adequate means of securing and supporting so as to be commensurate with the strength and stiffness of the surrounding structure.

The hull supporting structure in way of the doors is to be suitable for the same design loads and design stresses as the securing and supporting devices.

Where packing is required, the packing material is to be of a comparatively soft type, and the supporting forces are to be carried by the steel structure only. Other types of packing may be considered by the Society on a case by case basis.

The maximum design clearance between securing and supporting devices is generally not to exceed 3 mm.

A means is to be provided for mechanically fixing the door in the open position.

**4.1.2** Only the active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered to calculate the reaction forces acting on the devices. Small and/or flexible devices such as cleats intended to provide local compression of the packing material may generally not be included in the calculation in [4.2.2].

The number of securing and supporting devices is generally to be the minimum practical while taking into account the requirements for redundant provision given in [4.2.3] and the available space for adequate support in the hull structure.

### **4.2 Scantlings**

**4.2.1** Securing and supporting devices are to be adequately designed so that they can withstand the reaction forces within the allowable stresses defined in [5.1.1].

**4.2.2** The distribution of the reaction forces acting on the securing and supporting devices may need to be supported by direct calculations taking into account the flexibility of the hull structure and the actual position of the supports.

**4.2.3** The arrangement of securing and supporting devices in way of these securing devices is to be designed with redundancy so that, in the event of failure of any single securing or supporting device, the remaining devices are capable of withstanding the reaction forces without exceeding by more than 20% the allowable stresses defined in [5.1.1] for normal or damaged conditions.

**4.2.4** All load transmitting elements in the design load path, from the door through securing and supporting devices into the ship's structure, including welded connections, are to be of the same strength standard as required for the securing and supporting devices. These elements include pins, support brackets and back-up brackets.

## **5 Strength criteria**

### **5.1 Primary supporting members and securing and supporting devices**

#### **5.1.1 Yielding check**

It is to be checked that the normal stress  $\sigma$ , the shear stress  $\tau$  and the equivalent stress  $\sigma_{VM}$ , induced in the primary supporting members and in the securing and supporting devices of doors by the design load defined in [2], are in compliance with the following formulae:

$$\sigma \leq \sigma_{ALL}$$

$$\tau \leq \tau_{ALL}$$

$$\sigma_{VM} = (\sigma^2 + 3 \tau^2)^{0,5} \leq \sigma_{VM,ALL}$$

where:

$\sigma_{ALL}$  : Allowable normal stress, in N/mm<sup>2</sup>:  $\sigma_{ALL} = 120 / k$

$\tau_{ALL}$  : Allowable shear stress, in N/mm<sup>2</sup>:  $\tau_{ALL} = 80 / k$

$\sigma_{VM,ALL}$  : Allowable equivalent stress, in N/mm<sup>2</sup>:  $\sigma_{VM,ALL} = 150 / k$

$k$  : Material factor, defined in Ch 4, Sec 1, [2.2], but to be taken not less than 0,72 unless a fatigue analysis is carried out. In case of damaged ship conditions assessment, the above allowable stresses are to be increased by 20%.

#### **5.1.2 Buckling check**

The buckling check of primary supporting members is to be carried out according to Ch 9, Sec 1.

#### **5.1.3 Bearings**

For steel to steel bearings in securing and supporting devices, it is to be checked that the nominal bearing pressure  $\sigma_B$ , in N/mm<sup>2</sup>, is in compliance with the following formula:  $\sigma_B \leq 0,8 R_{eH,B}$

where:

$$\sigma_B = 10 \frac{F}{A_B}$$

with:

$F$  : Design force, in KN, defined in Ch 5, Sec 5, [7.2.1]

$A_B$  : Projected bearing area, in cm<sup>2</sup>

$R_{eH,B}$  : Yield stress, in N/mm<sup>2</sup>, of the bearing material.

For other bearing materials, the allowable bearing pressure is to be determined according to the manufacturer's specification.

#### **5.1.4 Bolts**

The arrangement of securing and supporting devices is to be such that threaded bolts do not carry support forces.

It is to be checked that the tension  $\sigma_T$  in way of threads of bolts not carrying support forces is in compliance with the following formula:  $\sigma_T \leq \sigma_{T,ALL}$

where:

$\sigma_{T,ALL}$  : Allowable tension in way of threads of bolts, in N/mm<sup>2</sup>:  $\sigma_{T,ALL} = 125 / k$

$k$  : Material factor, defined in Ch 11, Sec 6, [6.1.1].

## **6 Securing and locking arrangement**

### **6.1 Systems for operation**

**6.1.1** Securing devices are to be simple to operate and easily accessible.

Securing devices are to be equipped with mechanical locking arrangement (self-locking or separate arrangement), or to be of the gravity type.

The opening and closing systems as well as securing and locking devices are to be interlocked in such a way that they can only operate in the proper sequence.

**6.1.2** Doors which are located partly or totally below the freeboard deck with a clear opening area greater than 6 m<sup>2</sup> are to be provided with an arrangement for remote control, from a position above the freeboard deck, of:

- the closing and opening of the doors
- associated securing and locking devices.

For doors which are required to be equipped with a remote control arrangement, indication of the open/closed position of the door and the securing and locking device is to be provided at the remote control stations.

The operating panels for operation of doors are to be inaccessible to unauthorised persons.

A notice plate, giving instructions to the effect that all securing devices are to be closed and locked before leaving harbour, is to be placed at each operating panel and is to be supplemented by warning indicator lights.

**6.1.3** Where hydraulic securing devices are applied, the system is to be mechanically lockable in closed position. This means that, in the event of loss of hydraulic fluid, the securing devices remain locked.

The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits, when in closed position.

## **6.2 Systems for indication / monitoring**

**6.2.1** The following requirements apply to doors in the boundary of special category spaces or ro-ro spaces, as defined in Pt D, Ch 12, Sec 2, [1.1], through which such spaces may be flooded.

For cargo ships, where no part of the door is below the uppermost waterline and the area of the door opening is not greater than 6m<sup>2</sup>, then the requirements of this sub-article need not be applied.

**6.2.2** Separate indicator lights and audible alarms are to be provided on the navigation bridge and on each operating panel to indicate that the doors are closed and that their securing and locking devices are properly positioned.

The indication panel is to be provided with a lamp test function. It shall not be possible to turn off the indicator light.

**6.2.3** The indicator system is to be designed on the fail safe principle and is to show by visual alarms if the door is not fully closed and not fully locked and by audible alarms if securing devices become open or locking devices become unsecured. The power supply for the indicator system is to be independent of the power supply for operating and closing the doors and is to be provided with a backup power supply from the emergency source of power or secure power supply, e.g. UPS.

The sensors of the indicator system are to be protected from water, ice formation and mechanical damages.

Note 1: See Ch 11, Sec 6, [7.2.2] for fail safe principal design.

**6.2.4** The indication panel on the navigation bridge is to be equipped with a mode selection function "harbour/sea voyage", so arranged that audible alarm is given on the navigation bridge if the ship leaves harbour with any side shell or stern door not closed or with any of the securing devices not in the correct position.

**6.2.5** For passenger ships, a water leakage detection system with audible alarm and television surveillance is to be arranged to provide an indication to the navigation bridge and to the engine control room of any leakage through the doors.

For cargo ships, a water leakage detection system with audible alarm is to be arranged to provide an indication to the navigation bridge.

**6.2.6** For ro-ro passenger ships, on international voyages, the special category spaces and ro-ro spaces are to be continuously patrolled or monitored by effective means, such as television surveillance, so that any movement of vehicles in adverse weather conditions and unauthorized access by passengers thereto, can be detected whilst the ship is underway.

## **7 Operating and Maintenance Manual**

### **7.1 General**

**7.1.1** An Operating and Maintenance Manual for the side doors and stern doors is to be provided on board and is to contain the necessary information on:

- a) main particulars and design drawings:
  - special safety precautions
  - details of ship
  - equipment and design loading (for ramps)
  - key plan of equipment (doors and ramps)
  - manufacturer's recommended testing for equipment
  - description of equipment:
    - side doors
    - stern doors
    - central power pack
    - bridge panel
    - engine control room panel

- b) service conditions:
- limiting heel and trim of ship for loading / unloading
  - limiting heel and trim for door operations
  - doors / ramps operating instructions
  - doors / ramps emergency operating instructions
- c) maintenance:
- schedule and extend of maintenance
  - trouble shooting and acceptable clearances
  - manufacturer's maintenance procedures
- d) register of inspections, including inspection of locking, securing and supporting devices, repairs and renewals.

This manual is to be submitted to the Society for approval that the above mentioned items are contained in the OMM and that the maintenance part includes the necessary information with regard to inspections, trouble-shooting and acceptance / rejection criteria.

Note 1: It is recommended that inspections of the door and supporting and securing devices be carried out by ship's personnel at monthly intervals or following any incidents which could result in damage, including heavy weather or contact in the region of the shell doors. A record is to be kept and any damage recorded during such inspections is to be reported to the Society.

**7.1.2** Documented operating procedures for closing and securing the side and stern doors are to be kept on board and posted at an appropriate place.

# Section 8 Watertight and Weathertight Doors

## 1 General

### 1.1 Application

1.1.1 The requirements of this Section apply to the scantling of shell doors not covered by Ch 11, Sec 7 and doors in bulkheads that are required to be watertight or weathertight.

### 1.2 Definitions

#### 1.2.1 Watertightness

The various degrees of watertightness are defined in NR 467 Ch 3, Sec 3, [3.3.2].

#### 1.2.2 Securing device

A securing device is a device used to keep the door closed by preventing it from rotating about its hinges, or from sliding open.

#### 1.2.3 Supporting device

A supporting device is a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship's structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, which transmits loads from the door to the ship's structure.

#### 1.2.4 Locking device

A locking device is a device locking the securing device in the closed position.

## 2 Design loads

### 2.1 General

2.1.1 Doors are to be designed to offer equivalent strength compared to the adjacent bulkhead in which they are fitted. Therefore, they are to be assessed considering the same design loads, as per the examples given in the following requirements.

### 2.2 Side shell doors

2.2.1 Doors fitted in side shell are to be checked with the outside sea pressures defined in Ch 5, Sec 5, and whenever relevant, with the internal flooding pressure defined in Ch 5, Sec 6, [1.4].

### 2.3 Internal bulkheads doors

2.3.1 Doors fitted in watertight bulkheads are to be checked with the flooding pressures defined in Ch 5, Sec 6, [1.4], for spaces on both sides of the bulkhead.

### 2.4 Superstructure doors

2.4.1 Doors fitted in superstructure walls are to be checked with the loads defined in Ch 5, Sec 5, [5].

## 3 Door leaf scantling

### 3.1 Plating

3.1.1 The net thickness of watertight and weathertight doors is to be not less than that calculated according to Ch 7, Sec 4 or to Ch 11, Sec 5, [2.1] or Ch 11, Sec 5, [3.2], as relevant.

### 3.2 Stiffeners

3.2.1 The net scantling of doors stiffeners is to be not less than that calculated according to Ch 7, Sec 5 or to Ch 11, Sec 5, [2.2] or Ch 11, Sec 5, [3.3], as relevant, considering that doors stiffeners are generally to be considered as simply supported at ends instead of clamped.

### 3.3 Glass

3.3.1 If permitted, when glazing is fitted in the door leaf, its thickness is to be in line with the requirements of Ch 11, Sec 12, [3.3].

## 4 Securing and supporting

### 4.1 General

**4.1.1** Doors are to be fitted with adequate means of securing and supporting so as to be commensurate with the strength and stiffness of the surrounding structure.

The hull supporting structure in way of the doors is to be suitable for the same design loads and design stresses as the securing and supporting devices.

Where packing is required, the packing material is to be of a comparatively soft type, and the supporting forces are to be carried by the steel structure only. Other types of packing may be considered by the Society on a case by case basis.

In order to prevent damage to the packing material, the edges of the part of the door frame in contact with the seal should be rounded or chamfered.

The maximum design clearance between securing and supporting devices is generally not to exceed 3 mm.

**4.1.2** Only the active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered to calculate the reaction forces acting on the devices. Small and/or flexible devices such as cleats intended to provide local compression of the packing material may generally not be included in the calculation in [4.2].

The number and distribution of securing and supporting devices is to be set to achieve the scantling criteria in [4.2] and the required degree of watertightness.

### 4.2 Scantlings

**4.2.1** Securing and supporting devices are to be adequately designed so that they can comply with the checking criteria defined in Ch 7, Sec 6, [5.1.4] for primary members, using AC-2 or AC-3 acceptance criteria as relevant.

**4.2.2** In addition to the requirements in [4.2.1], every element transmitting loads by means of direct contact must be checked against bearing. In that respect, the maximum normal compressive stress  $\sigma_c$  distributed over the contact area between the two elements is not to be higher than  $R_{eH}$ .

**4.2.3** The distribution of the reaction forces acting on the securing and supporting devices is generally to be supported by direct calculations taking into account the flexibility of the hull structure, the actual position of the supports and the design load pattern. In case of homogeneously distributed supports and uniform design pressure, the total force acting on the door may be considered as evenly divided amongst the supports.

**4.2.4** All load transmitting elements in the design load path, from the door through securing and supporting devices into the ship's structure, including welded connections, are to be of the same strength standard as required for the securing and supporting devices. These elements include pins, support brackets and back-up brackets.

## 5 Inspection and testing

### 5.1 General

**5.1.1** Watertight and semi-watertight doors which become immersed by an equilibrium or intermediate waterplane are to be subjected to a hydrostatic pressure test.

**5.1.2** For large doors of more than 6 m<sup>2</sup> intended for use in the watertight subdivision boundaries of cargo spaces, structural analysis may be accepted in lieu of pressure testing. Where such doors utilize gasket seals, a prototype pressure test to confirm that the compression of the gasket material is capable of accommodating any deflection, revealed by the structural analysis, is to be carried out.

**5.1.3** Watertight doors above the freeboard or bulkhead deck which are not immersed by an equilibrium or intermediate waterplane but become intermittently immersed at angles of heel in the required range of positive stability beyond the equilibrium position may be only hose tested (required only to be weathertight according to Ch 3, Sec 3, [3.3.2]).

### 5.2 Hydrostatic pressure testing

**5.2.1** The head of water used for the pressure test shall correspond at least to the head measured from the lower edge of the door opening, at the location in which the door is to be fitted in the vessel, to the bulkhead deck or freeboard deck, as applicable, or to the most unfavourable damage waterplane, if that be greater. Testing may be carried out at the factory or other shore based testing facility prior to installation in the ship. The duration of the test is to be at least 30 min.

**5.2.2** For cargo ships not covered by damage stability requirements, watertight doors are to be tested by water pressure to a head of water measured from the lower edge of the opening to one meter above the freeboard deck.

### **5.2.3 Leakage criteria for watertight doors**

The following acceptable leakage criteria should apply:

- doors with gaskets: no leakage
- doors with metallic sealing: max leakage 1 litre/min.

Limited leakage may be accepted for pressure tests on large doors located in cargo spaces employing gasket seals or guillotine doors located in conveyor tunnels, in accordance with the following value, in litre/min:

$$\frac{(P + 4,572) \times h^3}{6568}$$

where:

P : Perimeter of door opening (m)

h : Test head of water (m).

However, in the case of doors where the water head taken for the determination of the scantling does not exceed 6,10 m, the leakage rate may be taken equal to 0,375 litre/min if this value is greater than that calculated by the above-mentioned formula.

### **5.2.4 Leakage criteria for semi-watertight doors**

A leakage quantity of approximately 100 l/hour is to be considered as being acceptable for a 1,35 m<sup>2</sup> opening.

**5.2.5** For doors on passenger ships which are used at sea or which become submerged by the equilibrium or intermediate waterplane, a prototype test shall be conducted, on each side of the door, to check the satisfactory closing of the door against a force equivalent to a water height of at least 1 m above the sill on the centre line of the door.

## **5.3 Hose testing**

**5.3.1** All watertight, semi-watertight and weathertight doors shall be subject to a hose test after installation in a ship. Hose testing is to be carried out:

- from both sides of a watertight or semi-watertight door unless, for a specific application, exposure to floodwater is anticipated only from one side
- from both sides of internal bulkheads weathertight doors (fitted above bulkhead deck)
- from the exposed side of external weathertight doors (superstructures).

Where a hose test is not practicable because of possible damage to machinery, electrical equipment insulation or outfitting items, it may be replaced by means such as an ultrasonic leak test or an equivalent test.

## **6 Type approval procedure**

### **6.1 General**

**6.1.1** Type approval certificates of doors may be issued to applicant manufacturers to certify that the design of the door has been assessed against a given strength level.

**6.1.2** The documents and information listed in [6.2.1] must allow for the door strength to be checked against the applied design load.

**6.1.3** In case a type approved door is fitted onboard a vessel, the hull supporting structure in way of the door is to be checked to have adequate strength according to [4].

**6.1.4** A type approved door fitted onboard a vessel is to be selected to have a design load at least equivalent to the adjacent bulkhead in which it is fitted.

### **6.2 Documents and information to be submitted**

**6.2.1** Prior to issuance of type approval certificate, the following documents and information must be submitted to the Society for review, for each door model and variant:

- maximum considered design load
- tightness level (weathertight, semi-watertight or watertight)
- door dimensions
- structural drawings of the door, including securing devices
- material and mechanical properties of each part of the door
- test and inspection procedure (if relevant, see [6.3]).

### **6.3 Prototype test**

**6.3.1** *Where testing of individual doors is not carried out because of possible damage to insulation or outfitting items, testing of individual doors may be replaced by a prototype pressure test of each type and size of door with a test pressure corresponding at least to the head required for the individual location. The prototype test is to be carried out before the door is fitted. The installation method and procedure for fitting the door on board is to correspond to that of the prototype test. When fitted on board, each door is to be checked for proper seating between the bulkhead, the frame and the door.*

The corresponding test reports are to be annexed to the type approval certificate.

**6.3.2** In such a case, the test procedure is to be submitted to the Society for review and is to be in line with the relevant requirements in [5].

## Section 9 Large Hatch Covers

### Symbols

For symbols not defined in this section, refer to Ch 1, Sec 3.

$P_S$  : Still water pressure, in  $\text{kN/m}^2$ , as defined in [4.1]

$P_W$  : Wave pressure, in  $\text{kN/m}^2$ , as defined in [4.1]

$P_C$  : Pressure acting on the hatch coaming, in  $\text{kN/m}^2$ , as defined in [6.2]

$F_S, F_W$  : Coefficients taken equal to:

$F_S = 0$  and  $F_W = 0,9$  for ballast water loads on hatch covers of the ballast hold

$F_S = 1.0$  and  $F_W = 1,0$  in other cases

$b_p$  : Effective breadth, in mm, of the plating attached to the stiffener or primary supporting member, as defined in [3]

$A_{shr}$  : Net shear sectional area, in  $\text{cm}^2$ , of the stiffener or primary supporting member

$f_{bc}$  : Boundary coefficient for stiffeners and primary supporting members, taken equal to:

$f_{bc} = 8$ , in the case of stiffeners and primary supporting members simply supported at both ends or supported at one end and clamped at the other end

$f_{bc} = 12$ , in the case of stiffeners and primary supporting members clamped at both ends

$t_c$  : Total corrosion addition, in mm, as defined in [1.5]

$\sigma_a, \tau_a$  : Allowable stresses, in  $\text{N/mm}^2$ , as defined in [1.6].

## 1 General

### 1.1 Application

**1.1.1** The requirements of this Section apply to large cargo hatch covers and coamings on weather decks, as defined in Ch 1, Sec 3, [2.4].

### 1.2 Definitions

#### 1.2.1 Large hatches

Large hatches are hatches with openings greater than  $2,5 \text{ m}^2$ .

#### 1.2.2 ICLL

Where ICLL is referred to in the text, this is to be taken as the International Convention on Load Lines, 1966 as amended by the 1988 protocol, as amended in 2003.

#### 1.2.3 Single skin cover

A hatch cover made of steel or equivalent material which has continuous top and side plating, but is open underneath with the stiffening structure exposed. The cover is weathertight and fitted with gaskets and clamping devices unless such fittings are specifically excluded.

#### 1.2.4 Double skin cover

A hatch cover as above but with continuous bottom plating such that all the stiffening structure and internals are protected from the environment.

#### 1.2.5 Pontoon type cover

A special type of portable cover, secured weathertight by tarpaulins and battening devices.

## 1.3 Materials

### 1.3.1 Steel

The formulae for scantlings given in [5] are applicable to steel hatch covers.

The materials used for construction of the steel large hatch covers, stoppers, securing devices and their weldings are to comply with the applicable requirements of Ch 4, Sec 1 and Part B, Chapter 13 respectively.

Specifications of the materials are to be shown in the drawings of the hatch covers.

**1.3.2 Other materials**

The use of materials other than steel is to be considered by the Society on a case-by-case basis, by checking that criteria adopted for scantlings are such as to ensure strength and stiffness equivalent to those of steel hatch covers.

**1.4 Net scantlings**

**1.4.1 Corrosion additions for steel other than stainless steel**

All scantlings referred to in this section are net, i.e. they do not include any margin for corrosion.

When calculating the stresses  $\sigma$  and  $\tau$  in [5.3] and [5.4], the net scantlings are to be used.

The gross scantlings are obtained as specified in Ch 4, Sec 2.

The corrosion additions are given in [1.5].

**1.4.2 Corrosion additions for aluminium alloys**

For structural members made of aluminium alloys, the corrosion addition  $t_c$  is to be taken equal to 0.

**1.5 Corrosion additions**

**1.5.1** The total corrosion addition for both sides to be considered for the plating and internal members of hatch covers is equal to the value specified in Tab 1.

The corrosion addition for hatch coamings and coaming stays is defined according to Ch 4, Sec 3.

**1.6 Allowable stresses**

**1.6.1** The allowable stresses  $\sigma_a$  and  $\tau_a$ , in N/mm<sup>2</sup>, are to be obtained from Tab 2.

The allowable buckling utilisation factors are given in Tab 3:

**Table 1 : Corrosion additions  $t_c$  for hatch covers and hatch coamings**

Application	Structure	$t_c$ , in mm
Weather deck hatches of container ships, car carriers, paper carriers, passenger ships	Hatch covers	1,0
	Hatch coamings	1,5
Hatch covers of ships having the service notation <b>bulk carrier, self-unloading bulk carrier ESP, ore carrier ESP or combination carrier ESP</b>	Plating and stiffeners of single skin hatch cover	2,0
	Top and bottom plating of double skin hatch cover	2,0
	Internal structures of double skin hatch cover	1,5
Weather deck hatches of all other ship types covered by this Section	Hatch covers in general	2,0
	Weather exposed plating and bottom plating of double skin hatch covers	1,5
	Internal structure of double skin hatch covers and closed box girders	1,0

## 2 Arrangements

### 2.1 Height of hatch coamings

2.1.1 The height of hatch coamings is not to be less than:

- 600 mm in position 1
- 450 mm in position 2.

2.1.2 The height of hatch coamings in positions 1 and 2 closed by steel covers provided with gaskets and securing devices may be reduced with respect to the above values or the coamings may be omitted entirely, on condition that the Administration is satisfied that the safety of the ship is not thereby impaired in any sea conditions.

In such cases the scantlings of the covers, their gasketing, their securing arrangements and the drainage of recesses in the deck are considered by the Society on a case-by-case basis.

### 2.2 Hatch covers

2.2.1 The stiffeners and primary supporting members of the hatch covers are to be continuous over the breadth and length of the hatch covers, as far as practical. When this is impractical, sniped end connections are not to be used and appropriate arrangements are to be adopted to ensure sufficient load carrying capacity.

2.2.2 The spacing of primary supporting members parallel to the direction of stiffeners is not to be greater than 1/3 of the span of primary supporting members.

2.2.3 The breadth of the primary supporting member face plate is not to be less than 40% of their depth for laterally unsupported spans greater than 3 m. Tripping brackets attached to the face plate may be considered as a lateral support for primary supporting members.

The face plate outstand is not to exceed 15 times the gross face plate thickness.

2.2.4 Efficient retaining arrangements are to be provided to prevent translation of the hatch cover under the action of the longitudinal and transverse forces exerted by cargoes on the cover, if any. These retaining arrangements are to be located in way of the hatch coaming side brackets.

2.2.5 The width of each bearing surface for hatch covers is to be at least 65 mm.

### 2.3 Hatch coamings

2.3.1 Coamings, stiffeners and brackets are to be capable of withstanding the local forces in way of the clamping devices and handling facilities necessary for securing and moving the hatch covers as well as those due to cargo stowed on the latter.

2.3.2 Special attention is to be paid to the strength of the fore transverse coaming of the forward hatch and to the scantlings of the closing devices of the hatch cover on this coaming.

**Figure 1 : Example of extension to lower edge of deck beams of longitudinal coaming by fitting a hatch side girder**

**2.3.3** Longitudinal coamings are to be vertically extended at least to the lower edge of deck beams or hatch side girders below deck are to be fitted in line with longitudinal coamings. Extended coaming plates are to be flanged or fitted with face bars or half-round bars at the level of lower edge of the deck beams (see Fig 1).

- where they are not part of continuous deck girders, the lower edge of longitudinal coamings including below deck structure as an extension measure above are to extend for at least two frame spaces beyond the end of the hatch openings.
- where they are part of continuous deck girders, their scantlings are to be as required in Ch 7, Sec 6 and Ch 9, Sec 1.

**2.3.4** A web frame or a similar structure is to be provided below the deck in line with the transverse coaming. Transverse coamings are to extend below the deck and to be connected with the web frames.

### 3 Width of Attached Plating

#### 3.1 Stiffeners

**3.1.1** The width of the attached plating  $b_p$ , in mm, to be considered for the check of stiffeners is to be taken as:

- where the attached plating extends on both sides of the stiffener:

$$b_p = s$$

- where the attached plating extends on one side of the stiffener:

$$b_p = 0,5 s$$

#### 3.2 Primary supporting members

**3.2.1** The effective breadth, in mm, of the attached plating to be considered for the yielding and buckling checks of primary supporting members analysed through isolated beam or grillage model is to be taken as:

- where the plating extends on both sides of the primary supporting member:

$$b_p = b_{eff}$$

- where the plating extends on one side of the primary supporting member:

$$b_p = 0,5b_{eff}$$

where:

$b_{eff}$  : Effective breadth of attached plating, in m, as defined in Ch 4, Sec 6, [1.3.2].

For structural evaluations based on isolated beam or grillage models, the areas of stiffeners are not to be included in the idealisation of the attached plating of the primary members.

### 4 Load Model

#### 4.1 Lateral pressures and forces

##### 4.1.1 General

The lateral pressures and forces to be considered as acting on hatch covers are given in [4.1.2] to [4.1.8]. When two or more panels are connected by hinges, each individual panel is to be considered separately.

In any case, the green sea loads defined in [4.1.2] and [4.1.3] are to be considered for hatch covers located on exposed decks.

Additionally, when the hatch cover is intended to carry uniform cargoes, special cargoes or containers, the pressures and forces defined in [4.1.4] to [4.1.8] are to be considered independently from the sea pressures.

##### 4.1.2 Vertical weather design load

The vertical weather design load acting on exposed hatch covers is to be considered and is defined in Ch 5, Sec 5, [6.2.1].

##### 4.1.3 Horizontal weather design load

The horizontal weather design load acting on coamings of exposed hatches is to be considered and taken as given in Tab 4.

**Table 4 : Horizontal weather loads**

Application		$P_A$ , in kN/m <sup>2</sup>
Ships having the service notation <b>bulk carrier, self-unloading bulk carrier ESP, ore carrier ESP or combination carrier ESP</b>	Most forward transverse coaming of ships not fitted with a forecandle according to Pt D, Ch 4, Sec 2, [2]; Pt D, Ch 5, Sec 2, [3] and Pt D, Ch 6, Sec 2, [1] depending on the service notation.	290
	All other coamings	220
All other ship types covered by this Section		as defined in Ch 5, Sec 5, [6.2.2]

**4.1.4 Internal pressures due to ballast water**

If applicable, the internal static and dynamic lateral pressures due to ballast water are to be considered and are defined in Ch 5, Sec 6, [1].

**4.1.5 Pressures due to uniform or unit cargoes**

If applicable, the static and dynamic pressures or forces due to uniform or unit cargoes are to be considered and are defined in Ch 5, Sec 6, [6].

**4.1.6 Pressures and forces due to wheel loads**

If applicable, the static and dynamic pressures or forces due to uniform or unit cargoes are to be considered and are defined in Ch 5, Sec 6, [7].

**4.1.7 Pressures or forces due to special cargoes**

In the case of carriage of special cargoes (e.g. pipes, etc) on the hatch covers which may temporarily retain water during navigation, the lateral pressures or forces to be applied are considered by the Society on a case-by-case basis.

**4.1.8 Forces due to containers**

In the case of carriage of containers on the hatch covers, the concentrated forces under the containers corners are to be considered and are defined in Ch 5, Sec 6, [8].

**4.1.9 Self weight**

The effect of the hatch cover structure weight is to be included in the static loads but not in the dynamic loads.

**4.2 Load point**

**4.2.1 Wave lateral pressure for hatch covers on exposed decks**

The wave lateral pressure to be considered as acting on each hatch cover is to be calculated at a point located:

- Longitudinally, at the hatch cover mid-length.
- Transversely, on the longitudinal plane of symmetry of the ship.
- Vertically, at the top of the hatch cover.

**4.2.2 Lateral pressures other than the wave pressure**

The lateral pressure is to be calculated at the level of the tight boundary of the cover:

- In way of the geometrical centre of gravity of the plate panel, for plating.
- At mid-span, for stiffeners and primary supporting members.

**5 Strength Check**

**5.1 General**

**5.1.1 Application**

The strength check is applicable to rectangular hatch covers subjected to a lateral pressure and/or concentrated loads, designed with primary supporting members arranged in one direction or as a grillage of longitudinal and transverse primary supporting members.

In the latter case, i.e. when the hatch cover is arranged as a grillage of longitudinal and transverse primary supporting members, or when the Society deems it necessary, the stresses in the primary supporting members are to be determined by a grillage or a finite element analysis.

It is to be checked that stresses induced by concentrated loads are in accordance with the criteria in [5.4.5].

When FE analysis is carried out, the buckling assessment as described in [5.2.4], [5.3.4] and [5.4.7] can be made considering only the stresses given by the FE analysis.

The hatch covers fitted with U type stiffeners as shown in Fig 2 are to be checked by means of FE analysis. In transverse section of the stiffener, nodes are to be located at the connection between the web of the U type stiffener and the hatch cover plate as well as at the connection between the web and the flange of the U type stiffener. The buckling assessment as described in [5.2.4], [5.3.4] and [5.4.7] can be made considering only the stresses given by the FE analysis.

**5.1.2 Hatch covers supporting containers**

The scantlings of hatch covers supporting containers are to comply with the applicable requirements of the Society.

**5.1.3 Hatch covers supporting wheel loads**

The scantlings of hatch covers supporting wheeled loads are to be obtained in accordance with the applicable requirements of:

- Ch 7, Sec 4, for plating
- Ch 7, Sec 5, or by direct calculations under consideration of the permissible stresses given in [5.4.5], for ordinary stiffeners
- Ch 7, Sec 6, for primary supporting members.

Figure 2 : Example of hatch cover fitted with U type stiffener

### 5.1.4 Hatch covers subjected to special cargoes

For hatch covers supporting special cargoes, stiffeners and primary supporting members are generally to be checked by direct calculations, taking into account the stiffener arrangements and their relative inertia. It is to be checked that stresses induced by special cargoes are in accordance with the criteria in [5.4.5].

## 5.2 Plating

### 5.2.1 Net thickness

The net thickness, in mm, of steel hatch cover top plating is not to be taken less than:

$$t = 0,0158 F_p b \sqrt{\frac{F_s P_s + F_w P_w}{0,95 R_{eH}}}$$

where:

$F_p$  : Factor for combined membrane and bending response, equal to:

- $F_p = 1,5$  in general
- $F_p = 1,9 \sigma / \sigma_a$  for the attached plating of primary supporting members and for  $\sigma \geq 0,8 \sigma_a$

$\sigma$  : Normal stress, in N/mm<sup>2</sup>, in the attached plating of primary supporting members, calculated according to [5.4.3] or determined through a grillage analysis or a finite element analysis.

### 5.2.2 Minimum net thickness

In addition to [5.2.1], the net thickness, in mm, of the plating forming the top of the hatch cover is not to be taken less than the greater of the following values:

$$t = \frac{b}{100}$$

$$t = 6$$

### 5.2.3 Lower plating of double skin hatch covers and box girders

The thickness to fulfil the strength requirements is to be obtained from the calculations according to [5.4].

When the lower plating is taken into account as a strength member of the hatch cover, its net thickness, in mm, is not to be less than 5 mm.

When project cargo is intended to be carried on a hatch cover, the net thickness must not be less than:  $t = 6,5 s$

When the lower plating is not considered as a strength member of the hatch cover, the thickness of the lower plating is to be determined according to Ch 7, Sec 4.

Note 1: Project cargo means especially large or bulky cargo lashed to the hatch cover. Examples are parts of cranes or wind power stations, turbines, etc. Cargoes that can be considered as uniformly distributed over the hatch cover, e.g., timber, pipes or steel coils need not to be considered as project cargo.

### 5.2.4 Buckling strength

The buckling strength of the hatch cover plating subjected to loading conditions as defined in [4.1] is to comply with the requirements in Ch 9, Sec 1, considering the following stresses:

a) For beam theory calculation, i.e. not calculated by means of finite element analysis:

- $\sigma_x$  or  $\sigma_y$  is selected for the uniaxial check of the plate in the direction parallel to the primary supporting member,
- $\tau = 0$ .

b) For finite element analysis:  $\sigma_x, \sigma_y, \tau$  obtained from FE analysis.

For hatch covers fitted with U type stiffeners, the buckling panels  $b_1, b_2$  and  $c$  (see Fig 2) are to be assessed separately.

## 5.3 Stiffeners

5.3.1 Stiffeners are to comply with the applicable slenderness and proportion requirements given in Ch 9, Sec 1.

### 5.3.2 Minimum net thickness of web

The net thickness, in mm, of the stiffener web is to be taken not less than 4 mm.

### 5.3.3 Net section modulus and net shear sectional area

The net section modulus  $Z$ , in  $\text{cm}^3$ , and the net shear sectional area  $A_{\text{shr}}$ , in  $\text{cm}^2$ , of a stiffener subject to lateral pressure are to be taken not less than given by the following formulae:

$$Z = \frac{(F_s P_s + F_w P_w) s \cdot \ell_s^2}{f_{bc} \sigma_a}$$

$$A_{\text{shr}} = \frac{5(F_s P_s + F_w P_w) s \ell_s}{\tau_a} 10^{-3}$$

where:

$\ell_s$  : Stiffener span, in m, to be taken as the spacing, in m, of primary supporting members or the distance between a primary supporting member and the edge support, as applicable. When brackets are fitted at both ends of all stiffener spans, the stiffener span may be reduced by an amount equal to 2/3 of the minimum brackets arm length, but not greater than 10% of the gross span, for each bracket.

### 5.3.4 Buckling strength

The buckling strength of the hatch cover stiffeners subjected to loading conditions as defined in [4.1] is to comply with the requirements in Ch 9, Sec 1, considering the following stresses:

- a) For uniaxial stresses obtained by beam theory, i.e. not calculated by means of finite element analysis:
  - $\sigma_x$  : stiffener axial stress
  - $\sigma_y = 0$
  - $\tau = 0$ .
- b) For stresses calculated by means of finite element analysis:
  - $\sigma_x$  : stiffener axial stress from FE analysis
  - $\sigma_y$  : stress perpendicular to the stiffener
  - $\tau$  : shear stress in the attached plate.

The buckling strength of the hatch cover fitted with U type stiffeners subjected to loading conditions as defined in [4.1] is to be checked as detailed above, considering the U type as an equivalent T-bar profile as follows:

- web height taken equal to  $d$  as defined in Ch 4, Sec 5, Fig 27
- web thickness equal to  $2 t_w$
- flange breadth taken as  $b_{3r}$ , as shown on Fig 2
- flange thickness taken as  $t_{fr}$ , as shown on Fig 2
- effective width of the attached plating,  $b_{\text{effr}}$ , taken as:

$$b_{\text{eff}} = C_{x1} b_1 + C_{x2} b_2$$

where:

$C_{x1}, C_{x2}$  : Reduction factor defined in NR615, calculated for the EPP  $b_1$  and  $b_2$  according to case 1.

## 5.4 Primary supporting members

### 5.4.1 Application

The requirements in [5.4.3] to [5.4.6] apply to primary supporting members which may be analysed through isolated beam models. Primary supporting members whose arrangement is of a grillage type and which cannot be analysed through isolated beam models are to be checked by direct calculations, using the checking criteria in [5.4.5].

### 5.4.2 Minimum net thickness of web

The web net thickness of primary supporting members, in mm, is not to be less than 6 mm.

### 5.4.3 Normal and shear stress for isolated beam

In case that grillage analysis or finite element analysis are not carried out, according to the requirements in [5.1.1], the maximum normal stress  $\sigma$  and shear stress  $\tau$ , in  $\text{N/mm}^2$ , in the primary supporting members are to be taken as given by the following formulae:

$$\sigma = \frac{S(F_s P_s + F_w P_w) \ell_m^2}{f_{bc} Z}$$

$$\tau = \frac{5 S(F_s P_s + F_w P_w) \ell_m}{A_{\text{shr}}}$$

where:

$\ell_m$  : Bending span, in m, of the primary supporting member.

**5.4.4 Edge girders (skirt plates)**

Scantlings of edge girders are obtained from the calculations according to [5.4] under consideration of the permissible stresses defined in [1.6].

The net thickness, in mm, of the outer edge girders exposed to wash of sea is not to be less than the greatest of:

- $t = 15,8 b \sqrt{\frac{p_A}{0,95 R_{eH}}}$
- $t = 8,5 \beta$
- $t_{min} = 5 \text{ mm,}$

where:

$p_A$  : Horizontal pressure, in kN/m<sup>2</sup>, as defined in Ch 5, Sec 5, [6.2.2].

The stiffness of edge girders is to be sufficient to maintain adequate sealing pressure between securing devices. The moment of inertia  $I$ , in cm<sup>4</sup>, of edge girders is not to be less than:

$$I = 6 \theta \sigma_{SD}^4$$

where:

$q$  : Packing line pressure, in N/mm, to be taken not less than 5 N/mm

$s_{SD}$  : Spacing, in m, of securing devices.

**5.4.5 Checking criteria**

The normal stress  $\sigma$  and the shear stress  $\tau$ , calculated according to [5.4.3] or determined through a grillage analysis or finite element analysis, as the case may be, are to comply with the following formulae:

$$\sigma \leq \sigma_a$$

$$\tau \leq \tau_a$$

**5.4.6 Deflection limit**

The net moment of inertia of a primary supporting member, when loaded by sea pressure, excluding the self-weight of the structure, is to be such that the deflection does not exceed  $\mu \ell_{max}$ .

where:

$\mu$  : Coefficient taken equal to:  $\mu = 0,0056$  for weathertight hatch covers.

$\ell_{max}$  : Greatest span, in m, of primary supporting members.

**5.4.7 Buckling strength of the web panels of the primary supporting members**

The buckling strength of the web of primary supporting members subjected to loading conditions as defined in [4.1] is to comply with the requirements in Ch 9, Sec 1, considering the following stresses:

- Shear stress obtained by beam theory (i.e. calculated according to [5.4.3] or determined through a grillage analysis), or
- $\sigma_x, \sigma_y, \tau$  obtained by FE analysis.

**5.4.8 Slenderness criteria**

For buckling stiffeners on webs of primary supporting members, the ratio  $h_w/t_w$  is to comply with the following formula:

$$\frac{h_w}{t_w} \leq 15 \sqrt{\frac{235}{R_{eH}}}$$

**5.5 Stiffeners and primary supporting members of variable cross section**

**5.5.1** The net section modulus  $Z$ , in cm<sup>3</sup>, of stiffeners and primary supporting members with a variable cross section is to be taken not less than the greater of the values given by the following formulae:

$$Z = Z_{CS}$$

$$Z = \left(1 + \frac{3,2\alpha - \psi - 0,8}{7\psi + 0,4}\right) Z_{CS}$$

where:

$Z_{CS}$  : Net section modulus, in cm<sup>3</sup>, for a constant cross section, complying with the checking criteria in [5.4.5]

$a$  : Coefficient taken equal to:

$$\alpha = \frac{\ell_1}{\ell_0}$$

$\psi$  : Coefficient taken equal to:

$$\psi = \frac{Z_1}{Z_0}$$

Figure 3 : Variable cross section stiffener

- $l_1$  : Length of the variable section part, in m, as shown in Fig 3
- $l_0$  : Span measured, in m, between end supports, as shown in Fig 3
- $Z_1$  : Net section modulus at end, in  $\text{cm}^3$ , as shown in Fig 3
- $Z_0$  : Net section modulus at mid-span, in  $\text{cm}^3$ , as shown in Fig 3.

Moreover, the net moment of inertia, in  $\text{cm}^4$ , of stiffeners and primary supporting members with a variable cross section is to be taken not less than the greater of the values given by the following formulae:

$$I = I_{CS}$$

$$I = \left[ 1 + 8\alpha^3 \left( \frac{1 - \varphi}{0,2 + 3\sqrt{\varphi}} \right) \right] I_{CS}$$

where:

- $I_{CS}$  : Net moment of inertia, in  $\text{cm}^4$ , with a constant cross section complying with [5.4.6]
- $\varphi$  : Coefficient taken equal to:

$$\varphi = \frac{I_1}{I_0}$$

- $I_1$  : Net moment of inertia at end, in  $\text{cm}^4$  Fig 3
- $I_0$  : Net moment of inertia at mid-span, in  $\text{cm}^4$ , as shown in Fig 3.

The use of these formulae is limited to the determination of the strength of stiffeners and primary supporting members in which abrupt changes in the cross section do not occur along their length.

## 6 Hatch Coamings

### 6.1 Stiffening

- 6.1.1** The stiffeners of the hatch coamings are to be continuous over the breadth and length of the hatch coamings.
- 6.1.2** Coamings are to be stiffened on their upper edges with a stiffener suitably shaped to fit the hatch cover closing appliances.
- 6.1.3** Where the height of the coaming exceeds 900 mm, additional strengthening may be required. However, reductions may be granted for transverse coamings in protected areas.
- 6.1.4** When two hatches are close to each other, under deck stiffeners are to be fitted to connect the longitudinal coamings in order to maintaining the continuity of their strength. Similar stiffening is to be provided over 2 frame spacings at ends of hatches exceeding 9 frame spacings in length. In some cases, the Society may require the continuity of coamings to be maintained above the deck.
- 6.1.5** Where watertight metallic hatch covers are fitted, other arrangements of equivalent strength may be adopted.

### 6.2 Load model

- 6.2.1** The wave lateral pressure,  $P_A$  in  $\text{kN/m}^2$ , to be considered as acting on the hatch coamings is defined in [4.1.3].
- 6.2.2** For cargo holds intended for the carriage of ballast water, the liquid internal pressures applied on hatch coaming is also to be determined according to Ch 5, Sec 6.

### 6.3 Scantlings

#### 6.3.1 Plating

The net thickness, in mm, of the hatch coaming plate is not to be taken less than the greater value given by the following formulae:

$$t = 0,016b \sqrt{\frac{P_A}{0,95R_{eH}}}$$

$$t = 9,5$$

**6.3.2 Stiffeners**

The net section modulus,  $Z$ , in  $\text{cm}^3$ , of longitudinal or transverse stiffeners fitted on hatch coamings is not to be taken less than:

$$Z = 1,21 \frac{P_A s \ell^2}{f_{bc} c_p R_{eH}}$$

where:

- $f_{bc}$  : Coefficient taken equal to:
  - $f_{bc} = 16$  in general
  - $f_{bc} = 12$  for the end span of stiffeners sniped at the coaming corners
- $c_p$  : Ratio of the plastic section modulus to the elastic section modulus of the stiffeners with an attached plate breadth, in mm, equal to  $40t$ , where  $t$  is the plate net thickness.
  - $c_p = 1,16$  in the absence of more precise evaluation.

**6.3.3 Coaming stays**

At the connection with deck, the net section modulus  $Z$ , in  $\text{cm}^3$ , and the net thickness  $t_w$ , in mm, of the coaming stays designed as beams with flange connected to the deck or sniped and fitted with a bracket (examples shown in Fig 4 and Fig 5) are to be taken not less than:

$$Z = \frac{s_c P_A H_C^2}{1,9 R_{eH}}$$

$$t_w = \frac{s_c P_A H_C}{0,5h R_{eH}}$$

where:

- $H_C$  : Stay height, in m
- $s_c$  : Stay spacing, in mm
- $h$  : Stay depth, in mm, at the connection with deck.

For calculating of offered section modulus of coaming stays, the face plate area may be taken into account only when it is welded with full penetration welds to the deck plating and provided with adequate under deck structure supporting the coaming stay in the deck structure.

**Figure 4 : Coaming stay (example 1)**

**Figure 5 : Coaming stay (example 2)**

For other designs of coaming stays, such as those shown in Fig 6 and Fig 7, the stress levels determined through a grillage analysis or finite element analysis, as the case may be, apply and are to be checked at the highest stressed locations. The stress levels are to comply with the following formulae:

$$\sigma \leq 0,95 R_{eH}$$

$$\tau \leq 0,5 R_{eH}$$

**Figure 6 : Coaming stay (example 3)**

**Figure 7 : Coaming stay (example 4)**

### 6.3.4 Local details

The design of local details is to comply with the requirements in this section ensuring adequate structural continuity from the hatch covers into the supporting deck structure.

Hatch coamings and supporting structures are to be adequately stiffened to accommodate the loading from hatch covers, in longitudinal, transverse and vertical directions.

The normal stress  $\sigma$  and the shear stress  $\tau$ , in  $N/mm^2$ , induced in the under deck structures by the loads transmitted by stays are to comply with the following formulae:

$$\sigma \leq 0,95 R_{eH}$$

$$\tau \leq 0,5 R_{eH}$$

Unless otherwise stated, weld connections and materials are to be dimensioned and selected in accordance with the requirements of the Society.

Double continuous fillet welding is to be adopted for the connections of stay webs with deck plating and the weld leg length is not to be less than  $0,62 t_w$  where  $t_w$  is the gross thickness of the stay web.

Toes of stay webs are to be connected to the deck plating with partial penetration double bevel welds extending over a distance not less than 15% of the stay width.

## 7 Container foundations on hatch covers

### 7.1 Strength requirements

**7.1.1** The substructures of container foundations are to be designed for cargo and container loads according to Ch 5, Sec 6, [9.2], applying the permissible stresses according to [5.4.5].

## 8 Weathertightness, closing arrangement, securing devices, stoppers and supports

### 8.1 Weathertightness

**8.1.1** Where the hatchway is exposed, the weathertightness is to be ensured by gaskets and clamping devices sufficient in number and quality.

Weathertightness may also be ensured by means of tarpaulins.

**8.1.2** In general, a minimum of two securing devices or equivalent is to be provided on each side of the hatch cover.

### 8.2 Gaskets

**8.2.1** The weight of hatch covers and any cargo stowed thereon, together with inertia forces generated by ship motions, are to be transmitted to the ship's structure.

**8.2.2** The sealing is to be obtained by a continuous gasket of relatively soft elastic material compressed to achieve the necessary weathertightness. Similar sealing is to be arranged between cross-joint elements.

Where fitted, compression flat bars or angles are to be well rounded where in contact with the gasket and to be made of a corrosion-resistant material.

**8.2.3** The gasket and the securing arrangements are to maintain their efficiency when subjected to large relative movements between the hatch cover and the ship's structure or between hatch cover elements.

If necessary, suitable devices are to be fitted to limit such movements.

**8.2.4** The gasket material is to be of a quality suitable for all environmental conditions likely to be encountered by the ship, and is to be compatible with the cargoes transported.

The material and form of gasket selected are to be considered in conjunction with the type of hatch cover, the securing arrangement and the expected relative movement between the hatch cover and the ship's structure.

The gasket is to be effectively secured to the hatch cover.

**8.2.5** Coamings and steel parts of hatch covers in contact with gaskets are to have no sharp edges.

**8.2.6** Metallic contact is required to ensure earthing connection between the hatch cover and the hull structures.

#### 8.2.7 Dispensation of weathertight gaskets

For hatch covers of cargo holds solely for the transport of containers, upon request by the Owner and subject to compliance with the following conditions, the fitting of weathertight gaskets according to [8.2.1] to [8.2.6] may be dispensed:

- the hatchway coamings are to be not less than 600 mm in height
- the exposed deck on which the hatch covers are located is situated above a depth  $H(x)$ .  $H(x)$ , in m, is to be shown to comply with the following criterion:

$$H(x) \geq T + f_b + h$$

where:

$f_b$  : Minimum required freeboard, in m, determined according to ICLL Reg.28, as amended

$h$  : Distance, in m, taken equal to:

- for  $x / L_{LL} \leq 0,75$ :  $h = 2 h_s$

- for  $x / L_{LL} > 0,75$ :  $h = 3 h_s$

$h_s$  : Standard height of superstructure, defined in Ch 1, Sec 3, Tab 5

- labyrinths, gutter bars or equivalent are to be fitted near the edges of each panel in way of the gaps to minimise the amount of water that can enter the container hold from the top surface of each panel
- the labyrinths and gaps between hatch cover panels are to be considered as unprotected openings with respect to the requirements of intact and damage stability calculations
- the non-weathertight gaps between hatch cover panels are to be as small as possible commensurate with the capacity of the bilge system and expected water ingress, and the capacity and operational effectiveness of the fire-fighting system and, in general, not greater than 50 mm
- with regard to drainage of cargo holds and the necessary fire-fighting system, reference is made to applicable requirements in Part C, Chapter 1 and Part C, Chapter 4

- bilge alarms are to be provided in each hold fitted with non-weather-tight covers
- scantlings of the hatch cover panels are to be equivalent to those for weather-tight covers and in accordance with the applicable requirements of the present Section.

### **8.3 Closing arrangement, securing devices and stoppers**

#### **8.3.1 General**

Panel hatch covers are to be secured by appropriate devices (bolts, wedges or similar) suitably spaced along the coamings and between cover elements.

Hatch covers provided with special sealing devices, insulated hatch covers, flush hatch covers and those having coamings of a reduced height according to [2.1.2] are to be considered by the Society on a case-by-case basis.

#### **8.3.2 Arrangements**

The securing and stopping devices are to be arranged so as to ensure sufficient compression on gaskets between hatch covers and coamings and between adjacent hatch covers.

Arrangement and spacing are to be determined with due attention to the effectiveness for weather-tightness, depending on the type and the size of the hatch cover, as well as on the stiffness of the hatch cover edges between the securing devices.

At cross-joints of multi-panel covers, (male/female) vertical guides are to be fitted to prevent excessive relative vertical deflections between loaded/unloaded panels.

The location of stoppers is to be compatible with the relative movements between hatch covers and the ship's structure in order to prevent damage to them. The number of stoppers is to be as small as possible.

Towards the ends of the ship, vertical acceleration forces may exceed the gravity force. The resulting lifting forces are to be considered when dimensioning the securing devices according to [8.3.5]. Lifting forces from cargo secured on the hatch cover during rolling are also to be taken into account.

Hatch covers provided with special sealing devices, insulated hatch covers, flush hatch covers and those having coamings of a reduced height (see [2.1]) are considered by the Society on a case by case basis.

In the case of hatch covers carrying containers, the scantlings of the closing devices are to take into account the possible upward vertical forces transmitted by the containers.

#### **8.3.3 Spacing**

The spacing of the securing arrangements is not to be greater than 6 m.

#### **8.3.4 Construction**

Securing arrangements with reduced scantlings may be accepted provided it can be demonstrated that the possibility of water reaching the deck is negligible.

Securing devices are to be of reliable construction and securely attached to the hatchway coamings, decks or hatch covers.

Individual securing devices on each hatch cover are to have approximately the same stiffness characteristics.

#### **8.3.5 Area of securing devices**

The gross cross area of each securing device is not to be less than the value obtained, in cm<sup>2</sup>, from the following formula:

$$A = 1,4 S_s \left( \frac{235}{R_{eH}} \right)^\alpha$$

where:

$S_s$  : Spacing, in m, of securing devices.

$\alpha$  : Coefficient taken equal to:

$$\alpha = 0,75 \text{ for } R_{eH} > 235 \text{ N/mm}^2$$

$$\alpha = 1,0 \text{ for } R_{eH} \leq 235 \text{ N/mm}^2.$$

In the above calculations,  $R_{eH}$  may not be taken greater than 0,7  $R_m$ .

Between hatch cover and coaming and at cross-joints, a packing line pressure sufficient to obtain weather-tightness is to be maintained by securing devices. For packing line pressures exceeding 5 N/mm, the net cross area A is to be increased in direct proportion. The packing line pressure is to be specified.

In the case of securing arrangements which are particularly stressed due to the unusual width of the hatchway, the net cross area A of the above securing arrangements is to be determined through direct calculations.

#### **8.3.6 Anti lifting devices**

The securing devices of hatch covers, on which cargo is to be lashed, are to be designed for the lifting forces resulting from loads according to Ch 5, Sec 6, [9.2.4] (see Fig 8). Unsymmetrical loadings, which may occur in practice, are to be considered. Under these loadings, the equivalent stress, in N/mm<sup>2</sup>, in the securing devices is not to exceed:

$$\sigma_v = 150/k_t$$

Note 1: The partial load cases given in Ch 5, Sec 6, Tab 15 may not cover all unsymmetrical loadings, critical for hatch cover lifting.

Figure 8 : Lifting forces at a hatch cover

### 8.3.7 Inertia of edges elements

The hatch cover edge stiffness is to be sufficient to maintain adequate sealing pressure between securing devices.

The moment of inertia of edge elements is not to be less than the value obtained, in  $\text{cm}^4$ , from the following formula:

$$I = 6 P_L S_s^4$$

where:

$P_L$  : Packing line pressure, in N/mm, to be taken not less than 5

$S_s$  : Spacing, in m, of securing devices.

### 8.3.8 Diameter of rods or bolts

Rods or bolts are to have a gross diameter not less than 19 mm for hatchways exceeding  $5 \text{ m}^2$  in area.

### 8.3.9 Stoppers

Hatch covers are to be effectively secured, by means of stoppers, against the transverse forces arising from a pressure of  $175 \text{ kN/m}^2$ .

With the exclusion of No. 1 hatch cover, hatch covers are to be effectively secured, by means of stoppers, against the longitudinal forces acting on the forward end arising from a pressure of  $175 \text{ kN/m}^2$ .

No. 1 hatch cover is to be effectively secured, by means of stoppers, against the longitudinal forces acting on the forward end arising from a pressure of  $230 \text{ kN/m}^2$ . This pressure may be reduced to  $175 \text{ kN/m}^2$  if a forecastle is fitted in accordance with Ch 4, Sec 2, [3], Ch 5, Sec 2, [3] and Ch 6, Sec 2, [2] depending on the service notation.

The equivalent stress in stoppers, their supporting structures and calculated in the throat of the stopper welds is to be equal to or less than the allowable value, equal to  $0,8 R_{eH}$ .

## 8.4 Cleats

**8.4.1** Where rod cleats are fitted, resilient washers or cushions are to be incorporated.

**8.4.2** Where hydraulic cleating is adopted, a positive means is to be provided to ensure that it remains mechanically locked in the closed position in the event of failure of the hydraulic system.

## 8.5 Tarpaulins

**8.5.1** Where weathertightness of hatch covers is ensured by means of tarpaulins, at least two layers of tarpaulins are to be fitted.

Tarpaulins are to be free from jute and waterproof and are to have adequate characteristics of strength and resistance to atmospheric agents and high and low temperatures.

The mass per unit surface of tarpaulins made of vegetable fibres, before the waterproofing treatment, is to be not less than:

- $0,65 \text{ kg/m}^2$  for waterproofing by tarring
- $0,60 \text{ kg/m}^2$  for waterproofing by chemical dressing
- $0,55 \text{ kg/m}^2$  for waterproofing by dressing with black oil.

In addition to tarpaulins made of vegetable fibres, those of synthetic fabrics or plastic laminates may be accepted by the Society provided their qualities, as regards strength, waterproofing and resistance to high and low temperatures, are equivalent to those of tarpaulins made of vegetable fibres.

## 8.6 Wedges, battens and locking bars

### 8.6.1 Wedges

Wedges are to be of tough wood, generally not more than 200 mm in length and 50 mm in width.

They are generally to be tapered not more than 1 in 6 and their thickness is to be not less than 13 mm.

**8.6.2 Battens and locking bars**

For all hatchways in exposed positions, battens or transverse bars in steel or other equivalent means are to be provided in order to efficiently secure the portable covers after the tarpaulins are battened down.

Portable covers of more than 1,5 m in length are to be secured by at least two such securing appliances.

**8.7 Hatch covers supports****8.7.1 Horizontal forces**

For the design of hatch cover supports, the horizontal force  $F_h$ , in kN, to be considered is given by the following formula:

$$F_h = m \alpha$$

where:

$\alpha$  : Acceleration taken equal to:

- in longitudinal direction:  $\alpha_x = 0,2 \text{ g}$
- in transverse direction:  $\alpha_y = 0,5 \text{ g}$

$m$  : Sum of mass of cargo lashed on the hatch cover and mass of hatch cover, in t.

The accelerations in longitudinal and transverse direction do not need to be considered as acting simultaneously.

**8.7.2 Allowable pressure**

For the transmission of the support forces resulting from the load cases specified in [4] and of the horizontal mass forces specified in [8.7.1], supports are to be provided which are to be designed such that the nominal surface pressures, in N/mm<sup>2</sup>, do not exceed in general the following values:

$$p_{n \max} = d p_n$$

where:

$d$  : Parameter taken equal to:

$$d = 3,75 - 0,015 L,$$

to be taken not greater than  $d_{\max} = 3,0$  and not less than  $d_{\min}$

$\delta_{\text{uv}}$  : Parameter defined as follows:

- $d_{\min} = 1,0$  in general
- $d_{\min} = 2,0$  for partial loading conditions, see Ch 5, Sec 6, [9.2.5]

$p_n$  : Permissible nominal surface pressure, in N/mm<sup>2</sup>, as defined in Tab 5.

For metallic supporting surfaces not subjected to relative displacements, the nominal surface pressure, in N/mm<sup>2</sup>, is to be taken equal to:

$$p_{n \max} = 3 \pi_n$$

Note 1: When the vertical hatch cover support material manufacturer can provide proof that the material is sufficient for the increased surface pressure, not only statically but under dynamic conditions including relative motion for adequate number of cycles, permissible nominal surface pressure may be relaxed on a case-by-case basis, pending realistic long term distribution of spectra for vertical loads and relative horizontal motion.

Drawings of the supports are to be submitted, specifying the permitted maximum pressure given by the material manufacturer related to long time stress.

Where large relative displacements of the supporting surfaces are to be expected, the use of material having low wear and frictional properties is recommended.

The substructures of the supports are to be of such a design, that a uniform pressure distribution is achieved.

Irrespective of the arrangement of stoppers, the supports are to be able to transmit the following force  $P_h$ , in kN, in the longitudinal and transverse directions:

$$P_h = \mu_1 \frac{P_v}{\sqrt{d}}$$

where:

$P_v$  : Vertical supporting force, in kN.

$\mu_1$  : Frictional coefficient, taken equal generally to 0,5

For non-metallic, low-friction support materials on steel,  $\mu_1$  may be reduced, without being taken less than 0,35.

Supports as well as the adjacent structures and substructures are to be designed such that the permissible stresses according to [5.4.5] are not exceeded.

For substructures and adjacent structures of supports subjected to horizontal forces  $P_h$ , fatigue strength may be checked.

**Table 5 : Permissible nominal surface pressure  $p_n$**

Support material	$p_n$ , in N/mm <sup>2</sup> , when loaded by:	
	vertical force	horizontal force (on stoppers)
Hull structural steel	25	40
Hardened steel	35	50
Plastic materials on steel	50	–

## 9 Drainage

### 9.1 Arrangement

**9.1.1** Drainage is to be arranged inside the line of gaskets by means of a gutter bar or vertical extension of the hatch side and end coaming.

**9.1.2** Drain openings are to be arranged at the ends of drain channels and are to be provided with efficient means for preventing ingress of water from outside, such as non-return valves or equivalent.

**9.1.3** Cross-joints of multi-panel hatch covers are to be arranged with drainage of water from the space above the gasket and a drainage channel below the gasket.

**9.1.4** If a continuous outer steel contact is arranged between the cover and the ship's structure, drainage from the space between the steel contact and the gasket is also to be provided.

## 10 Testing

### 10.1 Initial test of watertight hatches

**10.1.1** Watertight hatches are to be tested by water pressure to the maximum head of water they might sustain in a final or intermediate stage of flooding.

For cargo ships not covered by damage stability requirements, watertight hatches are to be tested by water pressure to a head of water measured from the lower edge of the opening to one metre above the freeboard deck.

### 10.2 Prototype test

**10.2.1** *Where testing of individual hatches is not carried out because of possible damage to insulation or outfitting items, testing of individual hatches may be replaced by a prototype pressure test of each type and size of hatch with a test pressure corresponding at least to the head required for the individual location. The prototype test is to be carried out before the hatch is fitted. The installation method and procedure for fitting the hatch on board is to correspond to that of the prototype test. When fitted on board, each door is to be checked for proper seating between the deck, the coaming and the hatch.*

# Section 10 Small Hatches

## 1 General

### 1.1 Definition

**1.1.1** Small hatches are hatches designed for access to spaces below the deck and are capable to be closed weathertight or watertight, as applicable. Their opening is generally equal to or less than 2,5 m<sup>2</sup>.

### 1.2 Application

**1.2.1** The requirements in Article [2] apply to small hatch covers fitted on exposed decks.

**1.2.2** The requirements in Article [3] apply to small hatch covers fitted on the exposed fore deck over the forward 0,25 L, for ships equal to or greater than 80 m in length, where the height of the exposed deck in way of the hatch is less than 0,1 L or 22 m above the summer load waterline, whichever is the lesser.

**1.2.3** The requirements in Article [4] apply to small hatch covers fitted on non-exposed decks.

### 1.3 Materials

#### 1.3.1 Steel

Materials used for the construction of steel small hatch covers are to comply with the applicable requirements of NR216 Materials and Welding, Chapter 3 or Chapter 5, as applicable.

#### 1.3.2 Other materials

The use of materials other than steel is considered by the Society on a case-by-case basis, by checking that criteria adopted for scantlings are such as to ensure strength and stiffness equivalent to those of steel hatch covers.

## 2 Small hatches fitted on exposed decks

### 2.1 General

**2.1.1** Hatch covers on exposed decks are to be weathertight.

**2.1.2** The height of small hatch coamings is to be not less than 600 mm if located in position 1, and 450 mm if located in position 2. Where the closing appliances are secured weathertight by gaskets and swing bolts, the height of the coamings may be reduced or the coamings may be omitted altogether.

**2.1.3** In any case the gross thickness of covers is to be not less than that of the adjacent plating, based on the same spacing and the same steel.

**2.1.4** Securing arrangements and stiffening of hatch cover edges are to be such that weathertightness can be maintained in any sea condition.

At least one securing device is to be fitted at each side. Circular hole hinges are considered equivalent to securing devices.

**2.1.5** Hatches of special design are considered by the Society on a case-by-case basis.

**2.1.6** Hold access points located on the weather deck are to be provided with watertight metallic hatch covers, unless they are protected by a closed superstructure. The same applies to access points located on the forecastle deck and leading directly to a dry cargo hold through a trunk.

**2.1.7** Access points to cofferdams and ballast tanks are to be manholes-fitted with watertight covers fixed with bolts sufficiently closely spaced.

### 2.2 Gaskets

**2.2.1** The sealing is to be obtained by a continuous gasket of relatively soft elastic material compressed to achieve the necessary weathertightness.

**2.2.2** Coamings and steel parts of hatch covers in contact with gaskets are to have no sharp edges.

**2.2.3** For non-bolted hatch covers, metal-to-metal contacts are to be provided in order to prevent over compression of the gasket. They are to be designed in order to withstand the bearing force induced by any relevant lateral load on the hatch cover.

### 3 Small hatches fitted on the exposed fore deck

#### 3.1 Application

**3.1.1** Small hatches designed for emergency escape need not comply with the requirements in [3.4.1], items a) and b), [3.4.3] and [3.5.1].

Securing devices of hatches designed for emergency escape are to be of a quick-acting type (e.g. one action wheel handles are provided as central locking devices for latching/unlatching of hatch cover) operable from both sides of the hatch cover.

#### 3.2 Strength

**3.2.1** The gross thickness of covers is to be not less than that of the adjacent plating based on the same spacing and the same steel.

**3.2.2** For small rectangular steel hatch covers, the gross plate thickness, stiffener arrangement and scantlings are to be not less than those obtained, in mm, from Tab 1 and Fig 1.

Ordinary stiffeners, where fitted, are to be aligned with the metal-to-metal contact points, required in [3.3.1] (see also Fig 1).

Primary stiffeners are to be continuous.

All stiffeners are to be welded to the inner edge stiffener (see Fig 2).

**3.2.3** The upper edge of the hatch coamings is to be suitably reinforced by an horizontal section, generally not more than 170 to 190 mm from the upper edge of the coamings.

**3.2.4** For small hatch covers of circular or similar shape, the cover plate thickness and reinforcement are to comply with Ch 11, Sec 9, [5].

**3.2.5** For small hatch covers constructed of materials other than steel, the required scantlings are to provide equivalent strength.

#### 3.3 Weathertightness

**3.3.1** The hatch cover is to be fitted with a gasket of elastic material. This is to be designed to allow a metal-to-metal contact at a designed compression and to prevent over compression of the gasket by green sea forces that may cause the securing devices to be loosened or dislodged. The metal-to-metal contacts are to be arranged close to each securing device in accordance with Fig 1 and of a sufficient capacity to withstand the bearing force.

#### 3.4 Primary securing devices

**3.4.1** Small hatches located on exposed fore deck are to be fitted with primary securing devices such that their hatch covers can be secured in place and made weathertight by means of a mechanism employing any one of the following methods:

- a) butterfly nuts tightening onto forks (clamps)
- b) quick acting cleats
- c) central locking device.

Dogs (twist tightening handles) with wedges are not acceptable.

**3.4.2** The primary securing method is to be designed and manufactured such that the designed compression pressure is achieved by one person without the need of any tools.

**3.4.3** For a primary securing method using butterfly nuts, the forks (clamps) are to be of robust design. They are to be designed to minimize the risk of butterfly nuts being dislodged while in use by means of curving the forks upwards, a raised surface on the free end, or a similar method. The plate thickness of unstiffened steel forks is to be not less than 16 mm. An example arrangement is shown in Fig 2.

**Table 1 : Gross scantlings for small steel hatch covers on the fore deck**

Nominal size (mm x mm)	Cover plate thickness (mm)	Primary stiffeners	Ordinary stiffeners
		Flat bar (mm x mm) ; number	
630 x 630	8	–	–
630 x 830	8	100 x 8 ; 1	–
830 x 630	8	100 x 8 ; 1	–
830 x 830	8	100 x 10 ; 1	–
1030 x 1030	8	120 x 12 ; 1	80 x 8 ; 2
1330 x 1330	8	150 x 12 ; 2	100 x 10 ; 2

**3.4.4** For small hatch covers located on the exposed deck forward of the foremost cargo hatch, the hinges are to be fitted such that the predominant direction of green seas is to cause the cover to close, which means that the hinges are normally to be located on the fore edge.

**3.4.5** On small hatches located between the main hatches, for example between Nos. 1 and 2, the hinges are to be placed on the fore edge or outboard edge, whichever is practicable for protection from green water in beam sea and bow quartering conditions.

**Figure 1 : Arrangement of stiffeners**

Figure 2 : Example of a primary securing method

- 1 : Butterfly nut
- 2 : Bolt
- 3 : Pin
- 4 : Centre of pin
- 5 : Fork (clamp) plate
- 6 : Hatch cover
- 7 : Gasket
- 8 : Hatch coaming
- 9 : Bearing pad welded on the bracket of a toggle bolt for metal to metal contact
- 10 : Stiffener
- 11 : Inner edge stiffener.

### 3.5 Secondary securing devices

**3.5.1** Small hatches on the fore deck are to be fitted with an independent secondary securing device, e.g. by means of a sliding bolt, a hasp or a backing bar of slack fit, which is capable of keeping the hatch cover in place, even in the event that the primary securing device became loosened or dislodged. It is to be fitted on the side opposite to the hatch cover hinges.

## 4 Small hatch covers fitted on non-exposed decks

### 4.1 General

**4.1.1** Hatch covers on non-exposed decks may not be weathertight.

**4.1.2** Small hatch covers fitted on non-exposed decks are to have strength equivalent to that required for the adjacent deck (see Part B, Chapter 7).

**4.1.3** Small hatch covers fitted on non-exposed decks are to have a level of tightness equivalent to that required for adjacent compartment(s).

**4.1.4** If the hatch cover is weathertight or watertight and non-bolted, metal-to-metal contacts are to be provided in order to prevent over compression of the gasket. They are to be designed in order to withstand the bearing force induced by any relevant lateral load on the hatch cover.

## **5 Testing**

### **5.1 Initial test of watertight hatches**

**5.1.1** Watertight hatches are to be tested by water pressure to the maximum head of water they might sustain in a final or intermediate stage of flooding.

For cargo ships not covered by damage stability requirements, watertight hatches are to be tested by water pressure to a head of water measured from the lower edge of the opening to one metre above the freeboard deck.

### **5.2 Prototype test**

**5.2.1** *Where testing of individual hatches is not carried out because of possible damage to insulation or outfitting items, testing of individual hatches may be replaced by a prototype pressure test of each type and size of hatch with a test pressure corresponding at least to the head required for the individual location. The prototype test is to be carried out before the hatch is fitted. The installation method and procedure for fitting the hatch on board is to correspond to that of the prototype test. When fitted on board, each door is to be checked for proper seating between the deck, the coaming and the hatch.*

# Section 11 Movable Decks, Inner Ramps and External Ramps

## 1 Movable decks and inner ramps

### 1.1 Application

**1.1.1** The requirements of this Section apply to movable decks and inner ramps when the additional class notation **ALP** is not granted and when no cargo gear register is issued.

**1.1.2** On special request of the owner the movable inner ramps under load may be examined by the Society in the scope of application of additional class notation **ALP** (see Pt A, Ch 1, Sec 2, [6.12.1]).

### 1.2 Materials

**1.2.1** The decks and inner ramps are to be made of steel or aluminium alloys complying with the requirements of NR216 Materials. Other materials of equivalent strength may be used, subject to a case by case examination by the Society.

### 1.3 Plating

**1.3.1** The net thickness of plate panels subjected to wheeled loads is to be not less than the value obtained from Ch 7, Sec 4, [3.3], where  $nP_0$  is not to be taken less than 5 kN.

### 1.4 Ordinary stiffeners

**1.4.1** The net section modulus and the net shear sectional area of ordinary stiffeners subjected to wheeled loads is to be not less than the value obtained from Ch 7, Sec 5, [1.2].

### 1.5 Primary supporting members

#### 1.5.1 General

The supporting structure of movable decks and inner ramps is to be verified through direct calculation, considering the following cases:

- movable deck stowed in upper position, empty and locked, at sea
- movable deck in service, loaded, in lower position, resting on supports or supporting legs and locked, at sea
- movable inner ramp in sloped position, supported by hinges at one end and by a deck at the other, with possible intermediate supports, loaded, at harbour
- movable inner ramp in horizontal position, loaded and locked, at sea.

#### 1.5.2 Loading cases

The scantlings of the supporting structure are to be verified for the design load sets DL-1 and DL-2, considering the following cases:

- loaded movable deck or inner ramp under loads according to the load distribution indicated by the Designer
- loaded movable deck or inner ramp under uniformly distributed loads corresponding to a pressure, in kN/m<sup>2</sup>, equal to  $P_1 + P_2$
- empty movable deck under uniformly distributed masses corresponding to a pressure, in kN/m<sup>2</sup>, equal to  $P_1$

where:

$$P_1 = \frac{P_p}{A_p}$$

$$P_2 = n_v \frac{P_v}{A_p}$$

$P_p$  : Mass of the movable deck, in kN

$P_v$  : Mass of a vehicle, in kN

$n_v$  : Maximum number of vehicles loaded on the movable deck

$A_p$  : Effective area of the movable deck, in m<sup>2</sup>.

### 1.5.3 Lateral pressure

The total pressure  $P$ , in  $\text{kN/m}^2$ , for both the static and the static + dynamic design load scenarios is to be derived for each dynamic load case and is to be taken as:  $P = P_s + P_w$

where:

$P_s, P_d$  : Still water and inertial pressures transmitted to the movable deck or inner ramp structures, obtained, in  $\text{kN/m}^2$ , from Tab 1.

### 1.5.4 Checking criteria

Combined stress  $\sigma_{VM}$  is to be checked in accordance with the criteria defined in Ch 7, Sec 6, [5.1.4].

### 1.5.5 Allowable deflection

The scantlings of main stiffeners and the distribution of supports are to be such that the deflection of the loaded movable deck or loaded inner ramp does not exceed 5 mm/m.

## 1.6 Supports, suspensions and locking devices

**1.6.1** Scantlings of wire suspensions are to be determined by direct calculation on the basis of the loads in [1.5.2] and [1.5.3], taking account of a safety factor at least equal to 5.

**1.6.2** Combined stress  $\sigma_{VM}$  in rigid supports and locking devices is to be checked in accordance with the criteria defined in Ch 7, Sec 6, [5.1.4].

## 1.7 Tests and trials

**1.7.1** Tests and trials defined in [1.7.2] to [1.7.4] are to be carried out in the presence of the Surveyor. Upon special request, these conditions of tests and trials may be modified to comply with any relevant national regulations in use.

**1.7.2** The wire ropes are to be submitted to a tensile test on test-piece.

**1.7.3** The loose gears used for the platform and ramp handling (chain, shackles, removable blocks, etc.) are to be indicated with a safe working load (SWL) compatible with the loads to be supported. The loose gears are to be individually tested before lifting onboard.

The test of these loose gears are to be in accordance with the applicable requirements of Rule Note NR 526, Rules for the classification of lifting appliances onboard ships and offshore units.

**1.7.4** A trial to verify the correct operation of lowering and lifting devices of the platform is to be carried out before going into service.

This trial is made without overload unless special requirement of National Authorities.

## 2 External ramps

### 2.1 General

**2.1.1** The external ramps are to be examined for their watertightness, if applicable.

**2.1.2** The locking of external ramps in stowage position at sea is examined by the Society on a case by case basis.

**2.1.3** The ship's structure under the reactions due to the ramp is examined by the Society on a case by case basis.

### 2.2 Plating

**2.2.1** The net thickness of plate panels subjected to wheeled loads is to be not less than the value obtained from Ch 7, Sec 4, [3.3], where  $nP_0$  is not to be taken less than 5 kN, and considering only the design load set DL-2 (harbour condition).

### 2.3 Ordinary stiffeners

**2.3.1** The net section modulus and the net shear sectional area of ordinary stiffeners subjected to wheeled loads is to be not less than the value obtained from Ch 7, Sec 5, [1.2] considering only the design load set DL-2 (harbour condition).

### 2.4 Primary supporting members

**2.4.1** The scantlings of ordinary stiffeners and primary supporting members are to be determined under vehicle loads in harbour condition at rest, as defined in Tab 1.

**Table 1 : Still water pressure  $P_s$  and inertial pressure  $P_w$  for primary supporting members of movable decks and ramps**

Ship condition	Item	Design load set	Acceptance criteria	$P_s$ and $P_w$ , in kN/m <sup>2</sup>
Seagoing conditions	<ul style="list-style-type: none"> <li>Movable decks</li> <li>Inner ramps</li> </ul>	DL-1	AC-2	$P_s = P_1 + P_2$ $P_{w,x} = \frac{a_x}{g}(P_1 + P_2)$ for x direction $P_{w,y} = \frac{a_y}{g}(P_1 + P_2)$ for y direction $P_{w,z} = \frac{a_z}{g}(P_1 + \alpha P_2)$ for z direction
Harbour condition during lifting (1)	<ul style="list-style-type: none"> <li>Movable decks</li> <li>Inner ramps</li> </ul>	DL-2	AC-1	$P_s = P_1$
Harbour condition at rest (1)	<ul style="list-style-type: none"> <li>Movable decks</li> <li>Inner ramps</li> <li>External ramps</li> </ul>	DL-2	AC-1	$P_s = P_1 + P_2$

(1) For harbour conditions, a heel angle of 5° and a trim angle of 2° are taken into account. In case the designer is proposing a heel angle of less than 5° based on specific operational conditions, the used angle is to be clearly specified on the loading manual.

**Note 1:**

$P_1, P_2$  : Pressures, in kN/m<sup>2</sup>, to be calculated according to [1.5.2] for the condition considered.

$\alpha$  : Coefficient taken equal to 0,5

$a_x$  : Longitudinal acceleration, in m/s<sup>2</sup>, at the load position being considered, for the considered load case, to be obtained according to Ch 5, Sec 3, [3]

$a_y$  : Transverse acceleration, in m/s<sup>2</sup>, at the load position being considered, for the considered load case, to be obtained according to Ch 5, Sec 3, [3]

$a_z$  : Vertical acceleration, in m/s<sup>2</sup>, at the load position being considered, for the considered load case, to be obtained according to Ch 5, Sec 3, [3]

# Section 12 Arrangement of Hull and Superstructure Openings

## 1 General

### 1.1 Application

1.1.1 The requirements of this Section apply to the arrangement of hull and superstructure openings excluding hatchways, for which the requirements in Ch 11, Sec 9 and Ch 11, Sec 10 apply.

### 1.2 Definitions

#### 1.2.1 Standard height of superstructure

The standard height of superstructure is that defined in Ch 1, Sec 3, Tab 5.

#### 1.2.2 Standard sheer

The standard sheer is that defined according to regulation 38 of the International Load Line Convention 1966, as amended.

#### 1.2.3 Exposed zones

Exposed zones are the boundaries of superstructures or deckhouses set in from the ship's side at a distance equal to or less than 0,04 B.

#### 1.2.4 Unexposed zones

Unexposed zones are the boundaries of deckhouses set in from the ship's side at a distance greater than 0,04 B.

## 2 External openings

### 2.1 General

2.1.1 *All external openings leading to compartments assumed intact in the damage analysis, which are below the final damage waterline, are required to be watertight.*

2.1.2 *External openings required to be watertight in accordance with [2.1.1] are to be of sufficient strength and, except for cargo hatch covers, are to be fitted with indicators on the bridge.*

2.1.3 *No openings, be they permanent openings, recessed promenades or temporary openings such as shell doors, windows or ports, are allowed on the side shell between the embarkation station of the marine evacuation system and the waterline in the lightest seagoing condition. Windows and sidescuttles of the non-opening type are allowed if complying with Pt C, Ch 4, Sec 5, [3.2.3], item c).*

2.1.4 *Openings in the shell plating below the deck limiting the vertical extent of damage shall be fitted with a device that prevents unauthorized opening if they are accessible during the voyage.*

2.1.5 *Other closing appliances which are kept permanently closed at sea to ensure the watertight integrity of external openings are to be provided with a notice affixed to each appliance to the effect that it is to be kept closed. Manholes fitted with closely bolted covers need not be so marked.*

## 3 Sidescuttles, windows and skylights

### 3.1 General

#### 3.1.1 Application

The requirements in [3.1] to [3.4] apply to sidescuttles and rectangular windows providing light and air, located in positions which are exposed to the action of sea and/or bad weather.

#### 3.1.2 Sidescuttle definition

*Sidescuttles are round or oval openings with an area not exceeding 0,16 m<sup>2</sup>. Round or oval openings having areas exceeding 0,16 m<sup>2</sup> are to be treated as windows.*

### **3.1.3 Window definition**

Windows are rectangular openings generally, having a radius at each corner relative to the window size in accordance with recognised national or international standards, and round or oval openings with an area exceeding 0,16 m<sup>2</sup>.

### **3.1.4 Number of openings in the shell plating**

The number of openings in the shell plating are to be reduced to the minimum compatible with the design and proper working of the ship.

### **3.1.5 Material and scantlings**

Sidescuttles and windows together with their glasses, deadlights and storm covers, if fitted, are to be of approved design and substantial construction in accordance with, or equivalent to, recognised national or international standards.

Non-metallic frames are not acceptable. The use of ordinary cast iron is prohibited for sidescuttles below the freeboard deck.

### **3.1.6 Means of closing and opening**

The arrangement and efficiency of the means for closing any opening in the shell plating are to be consistent with its intended purpose and the position in which it is fitted is to be generally to the satisfaction of the Society.

### **3.1.7 Opening of sidescuttles**

All sidescuttles, the sills of which are below the bulkhead deck for passenger ships or the freeboard deck for cargo ships, are to be of such construction as to prevent effectively any person opening them without the consent of the Master of the ship.

## **3.2 Opening arrangement**

### **3.2.1 General**

Sidescuttles are not to be fitted in such a position that their sills are below a line drawn parallel to the freeboard deck at side and having its lowest point 0,025B or 0,5 m, whichever is the greater distance, above the summer load waterline (or timber summer load waterline if assigned).

### **3.2.2 Sidescuttles below (1,4 + 0,025 B) m above the water**

Where in 'tweendecks the sills of any of the sidescuttles are below a line drawn parallel to the bulkhead deck at side of passenger ships and the freeboard deck at side of cargo ships, and having its lowest point 1,4+0,025B m above the water when the voyage commences, all the sidescuttles in that 'tweendecks are to be closed watertight and locked before the voyage commences, and they may not be opened before the ship arrives at the next port. In the application of this requirement, the appropriate allowance for fresh water may be made when applicable.

For any ship that has one or more sidescuttles so placed that the above requirements apply when it is floating at its deepest subdivision load line, the Society may indicate the limiting mean draught at which these sidescuttles are to have their sills above the line drawn parallel to the bulkhead deck at side of passenger ships and the freeboard deck at side of cargo ships, and having its lowest point 1,4+0,025B above the waterline corresponding to the limiting mean draught, and at which it is therefore permissible for the voyage to commence without them being closed and locked and to be opened during navigation on the responsibility of the master. In tropical zones as defined in the International Convention on Load Lines in force, this limiting draught may be increased by 0,3 m.

### **3.2.3 Cargo spaces**

No sidescuttles may be fitted in any spaces which are appropriated exclusively for the carriage of cargo.

Sidescuttles may, however, be fitted in spaces appropriated alternatively for the carriage of cargo or passengers, but they are to be of such construction as to prevent effectively any person opening them or their deadlights without the consent of the Master.

### **3.2.4 Non-opening type sidescuttles**

Sidescuttles are to be of the non-opening type in the following cases:

- where they become immersed by any intermediate stage of flooding or the final equilibrium waterplane in any required damage case for ships subject to damage stability regulations
- where they are fitted outside the space considered flooded and are below the final waterline for those ships where the freeboard is reduced on account of subdivision characteristics.

### **3.2.5 Manholes and flush scuttles**

Manholes and flush scuttles in positions 1 or 2, or within superstructures other than enclosed superstructures, are to be closed by substantial covers capable of being made watertight. Unless secured by closely spaced bolts, the covers are to be permanently attached.

### **3.2.6 Ships with several decks**

In ships having several decks above the bulkhead deck, such as passenger ships, the arrangement of sidescuttles and rectangular windows is considered by the Society on a case by case basis.

Particular consideration is to be given to the ship side up to the upper deck and the front bulkhead of the superstructure.

### 3.2.7 Automatic ventilating scuttles

Automatic ventilating sidescuttles are not to be fitted in the shell plating below the bulkhead deck of passenger ships and the freeboard deck of cargo ships without the special agreement of the Society.

### 3.2.8 Window arrangement

Windows may not be fitted below the freeboard deck, in first tier end bulkheads or sides of enclosed superstructures and in first tier deckhouses considered as being buoyant in the stability calculations or protecting openings leading below.

### 3.2.9 Skylights

Fixed or opening skylights are to have glass thickness appropriate to their size and position as required for sidescuttles and windows. Skylight glasses in any position are to be protected from mechanical damage and, where fitted in positions 1 or 2, to be provided with permanently attached robust deadlights or storm covers.

### 3.2.10 Gangway, cargo and fuelling ports

Cargo ports and other similar openings (e.g. gangway and fuelling ports) in the side of ships below the bulkhead deck of passenger ships and the freeboard deck of cargo ships are to be fitted with doors so designed as to ensure the same watertightness and structural integrity as the surrounding shell plating. Unless otherwise granted by the Society, these openings are to open outwards. The number of such openings is to be the minimum compatible with the design and proper working of the ship. In no case must these openings be so fitted as to have their lowest point below the summer load line.

## 3.3 Glasses

### 3.3.1 General

In general, toughened glasses with frames of special type are to be used in compliance with, or equivalent to, recognised national or international standards.

Direct metal to glass contact is to be avoided.

The use of clear plate glasses is considered by the Society on a case by case basis.

### 3.3.2 Design loads

Design loads are to be determined in accordance with the applicable requirements of Ch 5, Sec 5, [5].

In damaged ship conditions, where windows or sidescuttles are located below the deepest equilibrium waterline, the design pressure  $p$ , in  $\text{kN/m}^2$ , is to be taken equal to:

$$p = p_s$$

where:

$p_s$  : Still water pressure, taken equal to:

$$p_s = r g d_f$$

$d_f$  : Distance, in m, from the calculation point to the deepest equilibrium waterline.

The deepest equilibrium waterlines are to be provided by the Designer under his own responsibility.

### 3.3.3 Scantling

The windows and sidescuttles assessment methodology defined in this Article is equivalent to Standard ISO 11336-1:2012.

The scantling of windows and sidescuttle defined in this sub-article are provided for the following types of window or sidescuttle:

- monolithic window or sidescuttle (see [3.3.4])
- laminated window or sidescuttle (see [3.3.5])
- double windows unit with gap (see [3.3.6]).

All the window and sidescuttle edges are considered as simply supported.

### 3.3.4 Thickness of monolithic window

The thicknesses, in mm, of monolithic windows and sidescuttles are to be obtained from the following formula:

- rectangular window or sidescuttle:

$$t = 31,6s \sqrt{\frac{\beta p_s}{R_m}}$$

- circular window or sidescuttle:

$$t = 17,4d \sqrt{\frac{p_s}{R_m}}$$

where:

$s$  : Shorter side, in m, of rectangular window or sidescuttle

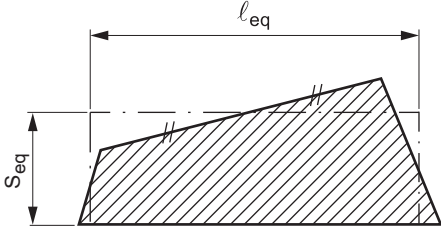

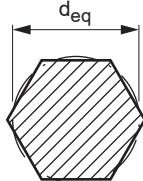

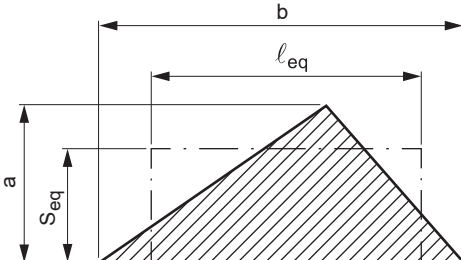

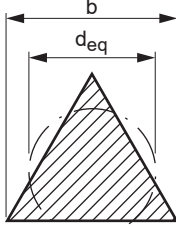

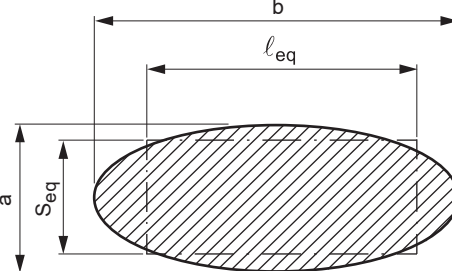

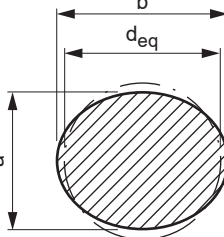

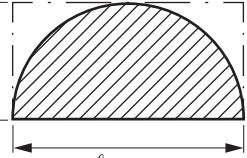

Where the window is supported only on 2 edges,  $s$  is to be taken as the unsupported side

$\ell$  : Longer side, in m, of rectangular window or sidescuttle

- d : Diameter, in m, of circular window or sidescuttle
- R<sub>m</sub> : Guaranteed minimum flexural strength, in N/mm<sup>2</sup>, of material used. For guidance only, the guaranteed minimum flexural strength R<sub>m</sub> for glass window is:
  - for thermally or chemically toughened glass: R<sub>m</sub> = 120 N/mm<sup>2</sup>
  - for polymethylmethacrylate (PMMA) glass: R<sub>m</sub> = 100 N/mm<sup>2</sup>
  - for polycarbonate (PC) glass: R<sub>m</sub> = 90 N/mm<sup>2</sup>
- S<sub>f</sub> : Safety factor taken equal to:
  - 3,0 for thermally or chemically toughened glass:
  - 3,5 for polymethylmethacrylate (PMMA) or polycarbonate (PC) glass:
- β : Aspect ratio coefficient of the rectangular window or sidescuttle, obtained in Tab 2  
 Where the window is supported only by 2 edges, β is to be taken equal to 1,0.

The thickness of windows or sidescuttles having other shapes may be obtained by considering rectangles or circles of equivalent dimensions s<sub>eq</sub>, l<sub>eq</sub> or d<sub>eq</sub> as defined in Tab 1.

**Table 1 : Equivalent dimensions for windows having other shapes**

<p>a) Quadrangle</p>  <p>The equivalent rectangle has the same area</p>	<p>b) Polygon</p>  <p>The equivalent circle has the same area</p>	<p>c) Triangle</p>  <p>s<sub>eq</sub> = 2a/3 l<sub>eq</sub> = 3b/4</p>	
<p>d) Equilateral triangle</p>  <p>d<sub>eq</sub> = 3b/4</p>	<p>e) Flat ellipse</p>  <p>s<sub>eq</sub> = 0,87a l<sub>eq</sub> = 0,87b</p>	<p>f) Round ellipse</p>  <p>d<sub>eq</sub> = √ab</p>	<p>g) Semi circle</p>  <p>s<sub>eq</sub> = d/2 l<sub>eq</sub> = d</p>

**Table 2 : Coefficient β**

l/s	β
1,0	0,284
1,5	0,475
2,0	0,608
2,5	0,684
3,0	0,716
3,5	0,734
≥ 4,0	0,750

**3.3.5 Laminated window**

Laminated windows are windows realized by placing an interlayer of resin (polyvinyl butyral as a general rule) between plies of same or different materials.

For laminated windows made with plies of the same material:

- When the mechanical properties of the interlayer material (the laminating adhesive material) are not known, the plies of the laminated window are considered as mechanically independent, and the equivalent thickness is to be calculated as defined in [3.3.6].
- When the mechanical properties of the interlayer material are known in terms of shear modulus,  $G$ , in  $N/mm^2$ , the plies of the laminated window are considered as mechanically collaborating, and the equivalent thickness is to be calculated as defined in [3.3.7].

When the laminated window is made with plies of different materials, they are considered as mechanically independent, and the equivalent thickness is to be calculated as defined in [3.3.8].

**3.3.6 Thickness of laminated window with independent plies**

The equivalent thickness  $t_{eq}$ , in mm, of laminates made of  $n$  independent plies of thicknesses  $t_{p,1}, t_{p,2}, \dots, t_{p,n}$ , is to comply with the following formula:

$$t_{eq} \geq t$$

where:

$$t_{eq} = \min[t_{eq,j}]$$

$$t_{eq,j} = \sqrt[n]{\frac{\sum_{j=1}^n t_{p,j}^3}{t_{p,j}}}$$

$j$  : Ply index, ranging from 1 to  $n$

$t$  : Thickness, in mm, of a monolithic window, calculated according to [3.3.4].

**3.3.7 Thickness of laminated window with collaborating plies**

The equivalent thickness  $t_{eq}$ , in mm, of laminates made of two collaborating plies of the same material, and of thicknesses  $t_1$  and  $t_2$  separated by an interlayer of thickness  $t_i$  is to comply with the following formula:

$$t_{eq} \geq t$$

where:

$$t_{eq} = \min[t_{1eq,s}, t_{2eq,s}]$$

$t_{1eq,s}, t_{2eq,s}$ : Equivalent thickness for strength as obtained from the following formulae:

$$t_{1eq,s} = \sqrt{\frac{t_{eq,d}^3}{t_1 + 2\Gamma t_2}}$$

$$t_{2eq,s} = \sqrt{\frac{t_{eq,d}^3}{t_2 + 2\Gamma t_1}}$$

$t_{eq,d}$  : Equivalent thickness for deflection as obtained from the following formula:

$$t_{1eq,d} = \sqrt[3]{t_1^3 + t_2^3 + 12\Gamma I_s}$$

$\Gamma$  : Shear transfer coefficient as obtained from the following formula, without being taken less than 0 (independent plies behaviour) and more than 1,0 (monolithic behaviour):

$$\Gamma = \frac{1}{1 + 9,6 \frac{E I_s t_i}{G h s^2 10^6}}$$

$$t_{s1} = \frac{hs \cdot t_1}{t_1 + t_2}$$

$$t_{s2} = \frac{hs \cdot t_2}{t_1 + t_2}$$

$$I_s = t_1 t_{s2}^2 + t_2 t_{s1}^2$$

$$hs = 0,5(t_1 + t_2) + t_i$$

$G$  : Shear modulus of the interlayer at 25 °C, in  $N/mm^2$ , generally taken equal to 1,6  $N/mm^2$  for polyvinyl butyral (PVB). For other interlayer materials the shear modulus value at 25 °C for short time duration load (60 s) shall be declared by the interlayer material manufacturer

$E$  : Young's modulus of the plies, in  $N/mm^2$

$s$  : Shorter side, in m, of rectangular window or sidescuttle.

In case of multiple (more than two plies) laminates the calculation is to be iterated. The iteration is to start from the outer ply (the one directly loaded by water pressure) and end with the inner ply.

**3.3.8 Thickness of laminated window with plies of different materials**

The equivalent thickness  $t_{eq}$ , in mm, of laminates made of  $n$  plies of different materials, of thicknesses  $t_{p,1}, t_{p,2}, \dots, t_{p,n}$  and of Young's modulus  $E_{p,1}, E_{p,2}, \dots, E_{p,n}$  is to comply with the following formula:

$$t_{eq} \geq t$$

where:

$$t_{eq} = \min[t_{eq,j}]$$

$$t_{eq,j} = \sqrt[n]{\frac{\sum_{j=1}^n E_{p,j} t_{p,j}^3}{E_{p,j} t_{p,j}}}$$

$j$  : Ply index, ranging from 1 to  $n$

$t$  : Thickness, in mm, of a monolithic window, calculated according to [3.3.4] for the same material than the ply giving the minimum value of  $t_{eq,j}$ .

**3.3.9 Thickness of double windows**

Double windows are glass windows made of two plies of glass separated by an hermetically sealed spacebar.

The thickness of the ply exposed to the loads defined in [3.3.2] is to be calculated as per monolithic windows according to [3.3.4].

**3.3.10 Thickness of glasses forming screen bulkheads or internal boundaries of deckhouses**

The thickness of glasses forming screen bulkheads on the side of enclosed promenade spaces and that for rectangular windows in the internal boundaries of deckhouses which are protected by such screen bulkheads are considered by the Society on a case by case basis.

The Society may require both limitations on the size of rectangular windows and the use of glasses of increased thickness in way of front bulkheads which are particularly exposed to heavy sea.

**3.4 Deadlight arrangement**

**3.4.1 General**

*Sidescuttles to the following spaces are to be fitted with efficient, hinged inside deadlights:*

- spaces below the freeboard deck
- spaces within the first tier of enclosed superstructures
- first tier deckhouses on the freeboard deck protecting openings leading below or considered buoyant in stability calculations.

*Deadlights are to be capable of being closed and secured watertight if fitted below the freeboard deck and weathertight if fitted above.*

**3.4.2 Watertight deadlights**

*Efficient hinged inside deadlights, so arranged that they can be easily and effectively closed and secured watertight, are to be fitted to all sidescuttles except that, abaft one eighth of the ship's length from the forward perpendicular and above a line drawn parallel to the bulkhead deck at side and having its lowest point at a height of  $(3,7+0,025B)$  m above the deepest subdivision summer load line, the deadlights may be portable in passenger accommodation other than that for steerage passengers, unless the deadlights are required by the International Convention on Load Lines in force to be permanently attached in their proper positions. Such portable deadlights are to be stowed adjacent to the sidescuttles they serve.*

**3.4.3 Openings at the side shell in the second tier**

Sidescuttles and windows at the side shell in the second tier, protecting direct access below or considered buoyant in the stability calculations, are to be provided with efficient, hinged inside deadlights capable of being effectively closed and secured weathertight.

**3.4.4 Openings set inboard in the second tier**

Sidescuttles and windows set inboard from the side shell in the second tier, protecting direct access below to spaces listed in [3.4.1], are to be provided with either efficient, hinged inside deadlights or, where they are accessible, permanently attached external storm covers of approved design and substantial construction capable of being effectively closed and secured weathertight.

Cabin bulkheads and doors in the second tier separating sidescuttles and windows from a direct access leading below may be accepted in place of fitted deadlights or storm covers.

Note 1: Deadlights in accordance with recognised standards are fitted to the inside of windows and sidescuttles, while storm covers of comparable specifications to deadlights are fitted to the outside of windows, where accessible, and may be hinged or portable.

### **3.4.5 Deckhouses on superstructures of less than standard height**

Deckhouses situated on a raised quarterdeck or on a superstructure of less than standard height may be treated as being on the second tier as far as the provision of deadlights is concerned, provided the height of the raised quarterdeck or superstructure is not less than the standard quarterdeck height.

### **3.4.6 Openings protected by a deckhouse**

Where an opening in a superstructure deck or in the top of a deckhouse on the freeboard deck which gives access to a space below the freeboard deck or to a space within an enclosed superstructure is protected by a deckhouse, then it is considered that only those sidescuttles fitted in spaces which give direct access to an open stairway need to be fitted with deadlights.

## **4 Discharges**

### **4.1 Arrangement of discharges**

#### **4.1.1 Inlets and discharges**

*All inlets and discharges in the shell plating are to be fitted with efficient and accessible arrangements for preventing the accidental admission of water into the ship.*

#### **4.1.2 Inboard opening of ash-chute, rubbish-chute**

*The inboard opening of each ash-chute, rubbish-chute, etc. is to be fitted with an efficient cover.*

*If the inboard opening is situated below the bulkhead deck for passenger ships or the freeboard deck for cargo ships, the cover is to be watertight, and in addition an automatic non-return valve is to be fitted in the chute in an easily accessible position above the deepest subdivision summer load line. When the chute is not in use, both the cover and the valve are to be kept closed and secured.*

### **4.2 Arrangement of garbage chutes**

#### **4.2.1 Inboard end above the waterline**

*The inboard end is to be located above the waterline formed by an 8,5° heel, to port or starboard, at a draught corresponding to the assigned summer freeboard, but not less than 1000 mm above the summer load waterline.*

*Where the inboard end of the garbage chute exceeds 0,01L above the summer load waterline, valve control from the freeboard deck is not required, provided the inboard gate valve is always accessible under service conditions.*

#### **4.2.2 Inboard end below the waterline**

*Where the inboard end of a garbage chute is below the freeboard deck of a passenger ship, or the waterline corresponding to the deepest draught after damage in a cargo ship of more than 100 m in length, then:*

- *the inboard end hinged cover/valve is to be watertight*
- *the valve is to be a screw-down non-return valve fitted in an easily accessible position above the deepest subdivision load line*
- *the screw-down non-return valve is to be controlled from a position above the bulkhead deck and provided with open/shut indicators. The valve control is to be clearly marked: "Keep closed when not in use".*

#### **4.2.3 Gate valves**

*For garbage chutes, two gate valves controlled from the working deck of the chute may be accepted instead of a non-return valve with a positive means of closing it from a position above the freeboard deck. In addition, the lower gate valve is to be controlled from a position above the freeboard deck. An interlock system between the two valves is to be arranged.*

*The distance between the two gate valves is to be adequate to allow the smooth operation of the interlock system.*

#### **4.2.4 Hinged cover and discharge flap**

*The upper gate valve, as required in [4.2.3], may be replaced by a hinged weathertight cover at the inboard end of the chute together with a discharge flap which replaces the lower gate valve.*

*The cover and discharge flap are to be arranged with an interlock so that the flap cannot be operated until the hopper cover is closed.*

#### **4.2.5 Marking of valve and hinged cover**

*The gate valve controls and/or hinged cover are to be clearly marked: "Keep closed when not in use".*

### **4.3 Scantlings of garbage chutes**

#### **4.3.1 Material**

The chute is to be constructed of steel. Other equivalent materials are considered by the Society on a case by case basis.

#### **4.3.2 Wall thickness**

The wall thickness of the chute up to and including the cover is to be not less than that obtained, in mm, from Tab 3.

Table 3 : Wall thickness of garbage chutes

External diameter d, in mm	Thickness, in mm
$d \leq 80$	7,0
$80 < d < 180$	$7,0 + 0,03 (d - 80)$
$180 \leq d \leq 220$	$10,0 + 0,063 (d - 180)$
$d > 220$	12,5

## 5 Transducers

### 5.1 General

**5.1.1** Transducers are not to be fitted inside compartments intended for fuel and hydrocarbons. They may only be fitted in adjacent cofferdams.

If transducers are fitted in hazardous areas, they are to be fitted inside a watertight box. In this case, transducers are to be sealed and the connecting cables are to be specially protected.

### 5.2 Protection of transducers in ballast and main compartment

**5.2.1** Transducers may be fitted in compartments intended for ballast (double bottoms, deep tank, peak). In such a case, the instrument and its power cable are to be mechanically protected and the watertightness of the protecting device is to be such that the material and its cable may be considered as protected against external agents.

**5.2.2** Where transducers are not fitted inside a small box or a little separate compartment within a double bottom but directly within a main compartment, it is necessary to provide for inspection of materials of every part which ensures structural and watertight integrity and to test them at works after completion. Besides, the complete set is to be tested under a hydraulic pressure at least equal to 1,5 times the service pressure, the latter being considered as equal to the depth of the ship.

If a transducer is fitted inside a single bottom ship, the tank of the transducer itself is to be considered as ensuring the structural integrity. Special attention is to be paid to welding and testing of the transducer bell.

### 5.3 Fitting of hull boss and transducer receiver

**5.3.1** The hull boss is to be made of steel with the same grade and yield stress as the bottom plates to which it is fitted. Full penetration welding is to be performed with suitable electrodes.

When the transducer receiver, owing to the fitting arrangement, slightly projects beyond the external surface of the shell plates, the precise position of the installation is to be supplied to the Owner to enable him to take the necessary precautions in case of docking.

### 5.4 Fitting of transducer in heavily stressed areas

**5.4.1** Where the transducer is fitted in the midship region or in heavily stressed areas, the openings are to be either elliptical (ratio 2/1, the major axis being parallel to the longitudinal axis of the ship) or truncated ellipse shaped at least for large ships. Moreover, a possible compensation is to be provided on the location of the cut.

## 6 Freeing ports

### 6.1 General provisions

#### 6.1.1 General

*Where bulwarks on the weather portions of freeboard or superstructure decks form wells, ample provision is to be made for rapidly freeing the decks of water and for draining them.*

A well is any area on the deck exposed to the weather, where water may be entrapped. Wells are considered to be deck areas bounded on four sides by deck structures; however, depending on their configuration, deck areas bounded on three or even two sides by deck structures may be deemed wells.

#### 6.1.2 Freeing port areas

The minimum required freeing port areas in bulwarks on the freeboard deck, on each side of the ship, are specified in Tab 4.

#### 6.1.3 Freeing port arrangement

Where a sheer is provided, two thirds of the freeing port area required is to be provided in the half of the well nearer the lowest point of the sheer curve.

Where the exposed freeboard deck or an exposed superstructure deck has little or no sheer, the freeing port area is to be spread along the length of the well.

However, bulwarks may not have substantial openings or accesses near the breaks of superstructures, unless they are effectively detached from the superstructure sides.

**Table 4 : Freeing port area in bulwark located on freeboard deck**

Ship types or ship particulars	Area A of freeing ports, in m <sup>2</sup>	Applicable requirement
Type A	$0,33 \ell_B h_B$	[6.5.2]
Type B-100	$0,33 \ell_B h_B$	[6.5.2]
Type B-60	$0,25 \ell_B h_B$	[6.5.1]
Ships fitted with a trunk included in freeboard calculation and/ or breadth $\geq 0,6 B$	$0,33 \ell_B h_B$	[6.3.1]
Ships fitted with a trunk not included in freeboard calculation and/ or continuous or substantially continuous hatch coamings	$A_2$	[6.3.1]
Ships fitted with non-continuous trunk and/ or hatch coamings	$A_3$	[6.3.2]
Ships fitted with open superstructure	$A_S$ for superstructures	[6.4.2]
	$A_W$ for wells	[6.4.3]
Other ships	$A_1$	[6.2.1]
<b>Note 1:</b>		
$\ell_B$	: Length, in m, of bulwark in a well at one side of the ship	
$h_B$	: Mean height, in m, of bulwark in a well of length $\ell_B$ .	

**6.1.4 Freeing port positioning**

The lower edge of freeing ports is to be as near the deck as practicable.

All the openings in the bulwark are to be protected by rails or bars spaced approximately 230 mm apart.

**6.1.5 Freeing port closures**

If shutters or closures are fitted to freeing ports, ample clearance is to be provided to prevent jamming. Hinges are to have pins or bearings of non-corrodible material. If shutters are fitted with securing appliances, these appliances are to be of approved construction.

In ships operating in areas where icing is likely to occur, no shutters are to be fitted in the freeing ports.

**6.1.6 Gutter bars**

Gutter bars greater than 300 mm in height fitted around the weather decks of tankers, in way of cargo manifolds and cargo piping, are to be treated as bulwarks. The freeing port area is to be calculated in accordance with the applicable requirements of this Section.

**6.2 Freeing port area in a well not adjacent to a trunk or hatchways**

**6.2.1 Freeing port area**

Where the sheer in way of the well is standard or greater than the standard, the freeing port area on each side of the ship for each well is to be not less than that obtained, in m<sup>2</sup>, in Tab 5.

In ships with no sheer, the above area is to be increased by 50%. Where the sheer is less than the standard, the percentage of increase is to be obtained by linear interpolation.

**Table 5 : Freeing port area in a well not adjacent to a trunk or hatchways**

Location	Area A <sub>1</sub> of freeing ports, in m <sup>2</sup>	
	$\ell_B \leq 20$	$\ell_B > 20$
Freeboard deck and raised quarterdecks	$0,7 + 0,035 \ell_B + A_C$	$0,07 \ell_B + A_C$
Superstructure decks	$0,35 + 0,0175 \ell_B + 0,5 A_C$	$0,035 \ell_B + 0,5 A_C$
<b>Note 1:</b>		
$\ell_B$	: Length, in m, of bulwark in the well, to be taken not greater than $0,7 L_{LL}$	
$A_C$	: Area, in m <sup>2</sup> , to be taken, with its sign, equal to:	
	$A_C = \frac{\ell_B}{25}(h_B - 1,2)$ for $h_B > 1,2$	
	$A_C = 0$ for $0,9 \leq h_B \leq 1,2$	
	$A_C = \frac{\ell_B}{25}(h_B - 0,9)$ for $h_B < 0,9$	
$h_B$	: Mean height, in m, of the bulwark in a well of length $\ell_B$ .	

**6.2.2 Minimum freeing port area for a deckhouse having breadth not less than 0,8 B**

Where a flush deck ship is fitted amidships with a deckhouse having breadth not less than 0,8 B and the width of the passageways along the side of the ship less than 1,5 m, the freeing port area is to be calculated for two separate wells, before and abaft the deckhouse. For each of these wells, the freeing port area is to be obtained from Tab 5, where  $\ell_B$  is to be taken equal to the actual length of the well considered.

**6.2.3 Minimum freeing port area for screen bulkhead**

Where a screen bulkhead is fitted across the full breadth of the ship at the fore end of a midship deckhouse, the weather deck is to be considered as divided into two wells, irrespective of the width of the deckhouse, and the freeing port area is to be obtained in accordance with [6.1.2].

**6.3 Freeing port area in a well contiguous to a trunk or hatchways**

**6.3.1 Freeing port area for continuous trunk or continuous hatchway coaming**

The freeing port area in the well contiguous to substantially continuous trunk/hatchway coaming is to be not less than:

- that obtained from Tab 6, where the trunk / hatchway coaming is not included in the freeboard calculation
- 33% of the bulwark area where the trunk / hatchway coaming meets the conditions of the International Convention on Load Lines in force and is included in the freeboard calculation.

**Table 6 : Freeing port area in a well contiguous to a continuous trunk or hatchway**

Breadth $B_H$ , in m, of hatchway or trunk	Area $A_2$ , in $m^2$ , of freeing ports
$B_H \leq 0,4 B$	$0,2 \ell_B h_B \left( \frac{h_s}{2h_w} \right)$
$0,4 B < B_H < 0,75 B$	$\left[ 0,2 - 0,286 \left( \frac{B_H}{B} - 0,4 \right) \right] \ell_B h_B \left( \frac{h_s}{2h_w} \right)$
$B_H \geq 0,75 B$	$0,1 \ell_B h_B \left( \frac{h_s}{2h_w} \right)$

**Note 1:**  
 $\ell_B$  : Length, in m, of bulwark in a well at one side of the ship  
 $h_B$  : Mean height, in m, of bulwark in a well of length  $\ell_B$   
 $h_s$  : Standard superstructure height, in m, defined in [1.2.1]  
 $h_w$  : Distance, in m, of the well deck above the freeboard deck, to be taken not less than 0,5  $h_s$ .

**6.3.2 Freeing area for non-continuous trunk or hatchway coaming**

Where the free flow of water across the deck of the ship is impeded due to the presence of a non-continuous trunk, hatchway coaming or deckhouse in the whole length of the well considered, the freeing port area in the bulwark of this well is to be not less than that obtained, in  $m^2$ , from Tab 7.

**Table 7 : Freeing port area in a well contiguous to a non-continuous trunk or hatchway**

Free flow area $f_p$ , in $m^2$	Freeing port area $A_3$ , in $m^2$
$f_p \leq A_1$	$A_2$
$A_1 < f_p < A_2$	$A_1 + A_2 - f_p$
$f_p \geq A_2$	$A_1$

**Note 1:**  
 $f_p$  : Free flow area on deck, equal to the net area of gaps between hatchways, and between hatchways and superstructures and deckhouses up to the actual height of the bulwark  
 $A_1$  : Area of freeing ports, in  $m^2$ , to be obtained from Tab 5  
 $A_2$  : Area of freeing ports, in  $m^2$ , to be obtained from Tab 6.

## 6.4 Freeing port area in an open space within superstructures

### 6.4.1 General

In ships having superstructures on the freeboard or superstructure decks, which are open at either or both ends to wells formed by bulwarks on the open decks, adequate provision for freeing the open spaces within the superstructures is to be provided.

### 6.4.2 Freeing port area for open superstructures

The freeing port area on each side of the ship for the open superstructure is to be not less than that obtained, in m<sup>2</sup>, from the following formula:

$$A_s = A_1 c_{SH} \left[ 1 - \left( \frac{\ell_W}{\ell_T} \right)^2 \right] \left( \frac{b_0 h_s}{2 \ell_T h_W} \right)$$

where:

- $\ell_T$  : Total well length, in m, to be taken equal to:  $\ell_T = \ell_W + \ell_s$
- $\ell_W$  : Length, in m, of the open deck enclosed by bulwarks
- $\ell_s$  : Length, in m, of the common space within the open superstructures
- $A_1$  : Freeing port area, in m<sup>2</sup>, required for an open well of length  $\ell_T$ , in accordance with Tab 5, where  $A_C$  is to be taken equal to zero
- $c_{SH}$  : Coefficient which accounts for the absence of sheer, if applicable, to be taken equal to:
  - $c_{SH} = 1,0$  in the case of standard sheer or sheer greater than standard sheer
  - $c_{SH} = 1,5$  in the case of no sheer
- $b_0$  : Breadth, in m, of the openings in the end bulkhead of enclosed superstructures
- $h_s, h_W$  : As defined in Tab 6.

### 6.4.3 Freeing port area for open well

The freeing port area on each side of the ship for the open well is to be not less than that obtained, in m<sup>2</sup>, from the following formula:

$$A_w = A_1 c_{SH} \left( \frac{h_s}{2 h_W} \right)$$

- $A_1$  : Freeing port area, in m<sup>2</sup>, required for an open well of length  $\ell_W$ , in accordance with Tab 5
- $\ell_W$  : Defined in [6.4.2].

The resulting freeing port areas for the open superstructure  $A_s$  and for the open well  $A_w$  are to be provided along each side of the open space covered by the open superstructure and each side of the open well, respectively.

## 6.5 Freeing port area in bulwarks of the freeboard deck for ships of types A, B-100 and B-60

### 6.5.1 Freeing arrangement for type B-60

For type B-60 ships, the freeing port area in the lower part of the bulwarks of the freeboard deck is to be not less than 25% of the total area of the bulwarks in the well considered.

The upper edge of the sheer strake is to be kept as low as possible.

### 6.5.2 Freeing arrangement for type A and type B-100 ships with trunks

For type A and type B-100 ships, open rails are to be fitted on the weather parts of the freeboard deck in way of the trunk for at least half the length of these exposed parts.

Alternatively, if a continuous bulwark is fitted, the freeing port area in the lower part of the bulwarks of the freeboard deck is to be not less than 33% of the total area of the bulwarks in the well considered.

## 7 Machinery space openings

### 7.1 Engine room skylights

**7.1.1** Engine room skylights in positions 1 or 2 are to be properly framed, securely attached to the deck and efficiently enclosed by steel casings of suitable strength. Where the casings are not protected by other structures, their strength will be considered by the Society on a case by case basis.

**7.1.2** Skylights, where fitted with openings for light and air, are to have coamings of a height not less than:

- 900 mm, if in position 1
- 760 mm, if in position 2.

## **7.2 Closing devices**

### **7.2.1 Machinery casings**

Openings in machinery space casings in positions 1 or 2 are to be fitted with doors of steel or other equivalent materials, permanently and strongly attached to the bulkhead, and framed, stiffened and fitted so that the whole structure is of equivalent strength to the unpierced bulkhead and weathertight when closed. The doors are to be capable of being operated from both sides and generally to open outwards to give additional protection against wave impact.

Other openings in such casings are to be fitted with equivalent covers, permanently attached in their proper position.

### **7.2.2 Machinery casings on Type A ships**

Machinery casings on Type A ships are to be protected by an enclosed poop or bridge of at least standard height, or by a deckhouse of equal height and equivalent strength.

Machinery casings may, however, be exposed if there are no openings giving direct access from the freeboard deck to the machinery spaces.

However, a weathertight door is permitted in the machinery casing, provided that it leads to a space or passageway which is as strongly constructed as the casing and is separated from the stairway to the engine room by a second weathertight door of steel or other equivalent material.

### **7.2.3 Height of the sill of the door**

The height of the sill of the door is to be not less than:

- 600 mm above the deck if in position 1
- 380 mm above the deck if in position 2
- 230 mm in all other cases.

### **7.2.4 Double doors**

Where casings are not protected by other structures, double doors (i.e. inner and outer doors) are required for ships assigned freeboard less than that based on Table B of regulation 28 of the International Load Line Convention 1966, as amended. An inner sill of 230 mm in conjunction with the outer sill of 600 mm is to be provided.

### **7.2.5 Fiddly openings**

Fiddly openings are to be fitted with strong covers of steel or other equivalent material permanently attached in their proper positions and capable of being secured weathertight.

## **7.3 Coamings**

**7.3.1** Coamings of any fiddly, funnel or machinery space ventilator in an exposed position on the freeboard deck or superstructure deck are to be as high above the deck as is reasonable and practicable.

In general, ventilators necessary to continuously supply the machinery space and, on demand, the emergency generator room are to have coamings whose height is in compliance with [9.1.2], but need not be fitted with weathertight closing appliances.

Where, due to the ship's size and arrangement, this is not practicable, lesser heights for machinery space and emergency generator room ventilator coamings, fitted with weathertight closing appliances in accordance with [9.1.2], may be permitted by the Society in combination with other suitable arrangements to ensure an uninterrupted, adequate supply of ventilation to these spaces.

## **8 Companionway**

### **8.1 General**

#### **8.1.1 Openings in freeboard deck**

Openings in freeboard deck other than hatchways, machinery space openings, manholes and flush scuttles are to be protected by an enclosed superstructure or by a deckhouse or companionway of equivalent strength and weathertightness.

#### **8.1.2 Openings in superstructures**

Openings in an exposed superstructure deck or in the top of a deckhouse on the freeboard deck which give access to a space below the freeboard deck or a space within an enclosed superstructure are to be protected by an efficient deckhouse or companionway.

#### **8.1.3 Openings in superstructures having height less than standard height**

Openings in the top of a deckhouse on a raised quarterdeck or superstructure of less than standard height, having a height equal to or greater than the standard quarterdeck height are to be provided with an acceptable means of closing but need not be protected by an efficient deckhouse or companionway provided the height of the deckhouse is at least the standard height of a superstructure.

## **8.2 Scantlings**

**8.2.1** Companionways on exposed decks protecting openings leading into enclosed spaces are to be of steel and strongly attached to the deck and are to have adequate scantlings.

## **8.3 Closing devices**

### **8.3.1 Doors**

Doorways in deckhouses or companionways leading to or giving access to spaces below the freeboard deck or to enclosed superstructures are to be fitted with weathertight doors. The doors are to be made of steel, to be capable of being operated from both sides and generally to open outwards to give additional protection against wave impact.

Alternatively, if stairways within a deckhouse are enclosed within properly constructed companionways fitted with weathertight doors, the external door need not be watertight.

Where the closing appliances of access openings in superstructures and deckhouses are not weathertight, interior deck openings are to be considered exposed, i.e. situated in the open deck.

### **8.3.2 Height of sills**

*The height above the deck of sills to the doorways in companionways is to be not less than:*

- 600 mm in position 1
- 380 mm in position 2.

Where access is not provided from above, the height of the sills to doorways in a poop bridge or deckhouse on the freeboard deck is to be 600 mm.

Where access is provided to spaces inside a bridge or poop from the deck above as an alternative to access from the freeboard deck, the height of the sills into the bridge or poop is to be at least 380 mm. This also applies to deckhouses on the freeboard deck.

## **9 Ventilators**

### **9.1 Closing appliances**

#### **9.1.1 General**

*Ventilator openings are to be provided with efficient weathertight closing appliances of steel or other equivalent material, designed to offer equivalent strength compared to the adjacent bulkhead or coaming in which they are fitted.*

#### **9.1.2 Closing appliance exemption**

*Ventilators need not be fitted with closing appliances, unless specifically required by the Society, if the coamings extend for more than:*

- 4,5 m above the deck in position 1
- 2,3 m above the deck in position 2.

#### **9.1.3 Closing appliances for ships of not more than 100 m in length**

*In ships of not more than 100 m in length, the closing appliances are to be permanently attached to the ventilator coamings.*

#### **9.1.4 Closing appliances for ships of more than 100 m in length**

*Where, in ships of more than 100 m in length, the closing appliances are not permanently attached, they are to be conveniently stowed near the ventilators to which they are to be fitted.*

#### **9.1.5 Ventilation of machinery spaces and emergency generator room**

In order to satisfactorily ensure, in all weather conditions:

- the continuous ventilation of machinery spaces,
- and, when necessary, the immediate ventilation of the emergency generator room,

the ventilators serving such spaces are to comply with [9.1.2], i.e. their openings are to be so located that they do not require closing appliances.

Note 1: See also Pt C, Ch 4, Sec 2, [2.1] regarding closing appliances for ventilation systems.

#### **9.1.6 Reduced height of ventilator coamings for machinery spaces and emergency generator room**

Where, due to the ship's size and arrangement, the requirements in [9.1.5] are not practicable, lesser heights may be accepted for machinery space and emergency generator room ventilator coamings fitted with weathertight closing appliances in accordance with [9.1.1], [9.1.3] and [9.1.4] in combination with other suitable arrangements, such as separators fitted with drains, to ensure an uninterrupted, adequate supply of ventilation to these spaces.

**9.1.7 Closing arrangements of ventilators led overboard or through enclosed superstructures**

Closing arrangements of ventilators led overboard to the ship side or through enclosed superstructures are considered by the Society on a case by case basis. If such ventilators are led overboard more than 4,5 m above the freeboard deck, closing appliances may be omitted provided that satisfactory baffles and drainage arrangements are fitted.

**9.2 Coamings**

**9.2.1 General**

*Ventilators in positions 1 or 2 to spaces below freeboard decks or decks of enclosed superstructures are to have coamings of steel or other equivalent material, substantially constructed and efficiently connected to the deck.*

*Ventilators passing through superstructures other than enclosed superstructures are to have substantially constructed coamings of steel or other equivalent material at the freeboard deck.*

**9.2.2 Scantlings**

The scantlings of ventilator coamings exposed to the weather are to be not less than those obtained from Tab 8.

*In exposed locations or for the purpose of compliance with buoyancy calculations, the height of coamings may be required to be increased to the satisfaction of the Society.*

**Table 8 : Scantlings of ventilator coamings**

Feature	Scantlings
Height of the coaming, in mm, above the deck	h = 900 in position 1 h = 760 in position 2
Thickness of the coaming, in mm (1)	$t = 5,5 + 0,01 d_v$ with $7,5 \leq t \leq 10,0$
Support	If $h > 900$ mm, the coaming is to be suitably stiffened or supported by stays
(1) Where the height of the ventilator exceeds the height h, the thickness of the coaming may be gradually reduced, above that height, to a minimum of 6,5 mm.	
<b>Note 1:</b> $d_v$ : Internal diameter of the ventilator, in mm.	

**10 Tank cleaning openings**

**10.1 General**

**10.1.1** Ullage plugs, sighting ports and tank cleaning openings may not be arranged in enclosed spaces.

# Section 13 Helicopter Decks and Platforms

## Symbols

$W_H$  : Maximum weight of the helicopter, in t.

## 1 Application

### 1.1 General

**1.1.1** The requirements of this Section apply to areas equipped for the landing and take-off of helicopters with landing gears or landing skids, and located on a deck or on a platform permanently connected to the hull structure.

**1.1.2** Helicopter deck or platform intended for the landing of helicopters having landing devices other than wheels or skids are to be examined by the Society on a case-by-case basis.

## 2 Definition

### 2.1 Landing gear

**2.1.1** A landing gear may consist of a single wheel or a group of wheels.

## 3 General arrangement

### 3.1 Landing area and approach sector

**3.1.1** The main dimensions of the landing area, its location on board, the approach sector for landing and take-off are to comply with the applicable requirements from National or other Authorities.

**3.1.2** The landing area and the approach sector are to be free of obstructions above the level of the helicopter deck or platform.

Note 1: The following items may exceed the height of the landing area, but not more than 100 mm:

- guttering or slightly raised kerb
- lightning equipment
- outboard edge of the safety net
- foam monitors
- those handrails and other items associated with the landing area which are incapable of complete retraction or lowering for helicopter operations.

### 3.2 Sheathing of the landing area

**3.2.1** Within the landing area, a non-skid deck covering is recommended.

Where the helicopter deck or platform is wood sheathed, special attention is to be paid to the fire protection.

### 3.3 Safety net

**3.3.1** It is recommended to provide a safety net at the sides of the helicopter deck or platform.

### 3.4 Drainage system

**3.4.1** Gutterways of adequate height and a drainage system are recommended on the periphery of the helicopter deck or platform.

## 4 Design principle

### 4.1 General

**4.1.1** Local deck strengthening is to be fitted at the connection of diagonals and pillars supporting platform.

## 5 Design loads

### 5.1 Emergency landing load

**5.1.1** The emergency landing force  $F_{EL}$  transmitted through one landing gear or one extremity of skid to the helicopter deck or platform is to be obtained for the static + dynamic design load scenario (design load set DL-1), in kN, from the following formula:

$$F_{EL} = 1,25 g W_H$$

The point of application of the force  $F_{EL}$  is to be taken so as to produce the most severe stresses on the supporting structure.

### 5.2 Garage load

**5.2.1** Where a garage zone is fitted in addition to the landing area, the static and dynamic forces  $F_{W-S}$  and  $F_{W-D}$  transmitted through each landing gear or each landing skid to the helicopter deck or platform are to be obtained for both the static and the static + dynamic design load scenarios (design load sets DL-1 and DL-2), in kN, as specified in Ch 5, Sec 6, [7], where  $M$  is to be taken equal to:

- for helicopter with landing gears:

$M$  is the landing gear load, in t, to be specified by the Designer. If the landing gear load is not known,  $M$  is to be taken equal to:

$$M = \frac{1,25}{n} W_H$$

where  $n$  is the total number of landing gears

- for helicopter with landing skids:  $M = 0,5 W_H$

**5.2.2** When helicopters are parked in an unprotected area, sea pressures on deck, as per Ch 5, Sec 5, [3], are to be considered independently of the loads defined in [5.2.1].

### 5.3 Specific loads for helicopter platforms

**5.3.1** The total force  $F$ , in kN/m<sup>2</sup>, for both the static and the static + dynamic design load scenarios (design load sets DL-1 and DL-2) is to be derived for each dynamic load case and is to be taken as:

- for static design load scenario:  $F = F_S$
- for static + dynamic design load scenario:  $F = F_S + F_W$

where:

$F_S, F_W$  : Still water and inertial forces transmitted to the hull structure, obtained, in kN, from Tab 1.

**Table 1 : Helicopter platforms - Still water and inertial forces**

Ship condition	Design load set	Still water force $F_S$ and inertial force $F_W$ , in kN
Seagoing condition	DL-1	$F_S = (W_H + W_P) g$
		$F_{W,X} = (W_H + W_P) a_x + 1,2 A_{HX}$ in x direction
		$F_{W,Y} = (W_H + W_P) a_y + 1,2 A_{HY}$ in y direction
Harbour condition	DL-2	$F_S = (W_H + W_P) g$ in z direction
<b>Note 1:</b>		
$W_P$ : Structural weight of the helicopter platform, in t, to be evenly distributed, and to be taken not less than the value obtained from the following formula: $W_P = 0,2 A_H$		
$A_H$ : Area, in m <sup>2</sup> , of the entire landing area		
$a_x, a_y, a_z$ : Accelerations, in m/s <sup>2</sup> , determined at the helicopter centre of gravity, and defined in Ch 5, Sec 3, [3]		
$A_{HX}, A_{HY}$ : Vertical areas, in m <sup>2</sup> , of the helicopter platform in x and y directions respectively. Unless otherwise specified, $A_{HX}$ and $A_{HY}$ may be taken equal to $A_H/3$		

## 6 Scantlings

### 6.1 General

**6.1.1** The scantlings of the structure of an helicopter deck or platform are to be obtained according to [6.2], [6.3] and [6.4]. They are to be considered in addition to scantlings obtained from other applicable loads, in particular from sea pressures.

## 6.2 Plating

### 6.2.1 Load model

The following forces  $P_0$ , in kN, are to be considered independently:

- Emergency landing load:  $P_0 = F_{EL}$   
where  $F_{EL}$  is the force corresponding to the emergency landing load, as defined in [5.1]
- Garage load:
  - for static design load scenario:  $P_0 = F_{W-S}$
  - for static + dynamic design load scenario:  $P_0 = F_{W-S} + F_{W-D}$
 where  $F_{W-S}$  and  $F_{W-D}$  are the forces corresponding to the garage load, as defined in [5.2].

### 6.2.2 Net thickness of plating

The net thickness of an helicopter deck or platform subjected to forces defined in [6.2.1] is not to be less than the value obtained according to Ch 7, Sec 4, [3.3], with:

$A_T$  : Tyre or skid print area, in  $m^2$ .

For helicopter with skids in emergency landing case, only the extremity of skid of 0,3 m x 0,01 m is to be considered.

For other cases, where the print area  $A_T$  is not specified by the Designer, the following values are to be taken into account:

- for one tyre: 0,3 m x 0,3 m
- for one skid: 1 m x 0,01 m.

$C_a$  : Coefficient defined in Ch 7, Sec 4, [1.1.1] and taken equal to  $C_{a-max}$  in the particular case of a platform.

### 6.2.3 Helicopter with skids

For helicopters with skids, in the particular case where  $v > \ell$ ,  $v$  being equal to the skid length, the skid print outside of the plate panel is to be disregarded. The load and the print area to be considered are to be reduced accordingly. (see Fig 1).

Figure 1 : Skid print with  $v > \ell$

## 6.3 Ordinary stiffeners

### 6.3.1 Load model

The following forces  $P_0$ , in kN, are to be considered independently:

- Emergency landing load:  $P_0 = F_{EL}$   
where  $F_{EL}$  is the force corresponding to the emergency landing load, as defined in [5.1]
- Garage load:
  - for static design load scenario:  $P_0 = F_{W-S}$
  - for static + dynamic design load scenario:  $P_0 = F_{W-S} + F_{W-D}$
 where  $F_{W-S}$  and  $F_{W-D}$  are the forces corresponding to the garage load, as defined in [5.2].
- Helicopter platform:
  - for static design load scenario:  $F = F_S$
  - for static + dynamic design load scenario:  $F = F_S + F_W$
 where  $F_S$  and  $F_W$  are the forces defined in [5.3].

### 6.3.2 Scantlings

Scantlings of stiffeners induced by loads defined in [6.3.1] are to be calculated according to Ch 7, Sec 5, [1.2] where:

$$w = \frac{\alpha_w K_S P_0 \ell_{bdg}}{6 \chi C_s R_{eH}} 10^3$$

in case of helicopter with wheels, or

$$w = \frac{\alpha_w P_0 \ell_{bdg}}{10 \chi C_s R_{eH}} 10^3$$

in case of helicopter with landing skids.

## **6.4 Primary supporting members**

### **6.4.1 Load model**

The following loads are to be considered independently:

- emergency landing load, as defined in [5.1]
- garage load, as defined in [5.2], if applicable
- for an helicopter platform, specific loads as defined in [5.3].

The most unfavourable case, i.e. where the maximum number of landing gears is located on the same primary supporting members, is to be considered.

### **6.4.2 Checking criteria**

In both cases of helicopter with wheels and helicopter with landing skids, the calculated stress values are to comply with the requirements defined in Ch 7, Sec 6, [5.1.4].

In addition, the hull girder stresses are to be taken equal to 0 in the particular case of an helicopter platform.

Appendix 2	Towing and Mooring Arrangement

# Section 1 Rudders

## Symbols

- $V_{AV}$  : Maximum ahead service speed, in knots, with the ship on summer load waterline; if  $V_{AV}$  is less than 10 knots, the maximum service speed is to be taken not less than the value obtained from the following formula:
- $$V_{MIN} = \frac{V_{AV} + 20}{3}$$
- $V_{AD}$  : Maximum astern speed, in knots, to be taken not less than 0,5  $V_{AV}$
- $A$  : Total area of the rudder blade, in  $m^2$ , bounded by the blade external contour, including the mainpiece and the part forward of the centreline of the rudder pintles, if any
- $k_1$  : Material factor, defined in [1.4.3]
- $k$  : Material factor, defined in Ch 4, Sec 1, [2.2] (see also [1.4.5])
- $C_R$  : Rudder force, in N, acting on the rudder blade, defined in [2.1.2]
- $M_{TR}$  : Rudder torque, in N.m, acting on the rudder blade, defined in [2.1.3] and [2.2.3]
- $M_B$  : Bending moment, in N.m, in the rudder stock, to be calculated according to Ch 12, App 1, [1.4], for each type of rudder listed in Tab 4.

## 1 General

### 1.1 Application

#### 1.1.1 Ordinary profile rudders

The requirements of this Section apply to ordinary profile rudders, without any special arrangement for increasing the rudder force, whose maximum orientation at maximum ship speed is limited to 35° on each side.

In general, an orientation greater than 35° is accepted for manoeuvres or navigation at very low speed.

#### 1.1.2 High efficiency rudders

The requirements of this Section also apply to rudders fitted with flaps to increase rudder efficiency. For these rudder types, an orientation at maximum speed different from 35° may be accepted. In these cases, the rudder forces are to be calculated by the Designer for the most severe combinations between orientation angle and ship speed. These calculations are to be considered by the Society on a case-by-case basis.

The rudder scantlings are to be designed so as to be able to sustain possible failures of the orientation control system, or, alternatively, redundancy of the system itself may be required.

#### 1.1.3 Steering nozzles

The requirements for steering nozzles are given in Article [10].

#### 1.1.4 Special rudder types

Rudders others than those in [1.1.1], [1.1.2] and [1.1.3] are to be considered by the Society on a case-by-case basis.

### 1.2 Gross scantlings

**1.2.1** With reference to Ch 4, Sec 2, [1.1.2], all scantlings and dimensions referred to in this Section are gross, i.e. they include the margins for corrosion.

### 1.3 Arrangements

**1.3.1** Effective means are to be provided for supporting the weight of the rudder without excessive bearing pressure, e.g. by means of a rudder carrier attached to the upper part of the rudder stock. The hull structure in way of the rudder carrier is to be suitably strengthened.

**1.3.2** Suitable arrangements are to be provided to prevent the rudder from lifting.

In addition, structural rudder stops of suitable strength are to be provided, except where the steering gear is provided with its own rudder stopping devices, as detailed in Pt C, Ch 1, Sec 14.

**1.3.3** In rudder trunks which are open to the sea, a seal or stuffing box is to be fitted above the deepest load waterline, to prevent water from entering the steering gear compartment and the lubricant from being washed away from the rudder carrier. If the top of the rudder trunk is below the deepest waterline two separate stuffing boxes are to be provided.

## 1.4 Materials

**1.4.1** Rudder stocks, pintles, coupling bolts, keys and cast parts of rudders are to be made of rolled steel, steel forgings or steel castings according to the applicable requirements in:

- NR216 Materials and Welding, Chapter 3 (steel plate)
- NR216 Materials and Welding, Chapter 5 (steel forgings)
- NR216 Materials and Welding, Chapter 6 (steel castings).

**1.4.2** The material used for rudder stocks, pintles, keys and bolts is to have a specified minimum yield stress not less than 200 N/mm<sup>2</sup>.

**1.4.3** The requirements relevant to the determination of scantlings contained in this Section apply to steels having a specified minimum yield stress equal to 235 N/mm<sup>2</sup>.

Where the material used for rudder stocks, pintles, coupling bolts, keys and cast parts of rudders has a specified minimum yield stress different from 235 N/mm<sup>2</sup>, the scantlings calculated with the formulae contained in the requirements of this Section are to be modified, as indicated, depending on the material factor  $k_1$ , to be obtained from the following formula:

$$k_1 = \left( \frac{235}{R_{eH}} \right)^n$$

where:

- $R_{eH}$  : Specified minimum yield stress, in N/mm<sup>2</sup>, of the specified steel, and not exceeding the lower of 0,7  $R_m$  and 450 N/mm<sup>2</sup>
- $R_m$  : Tensile strength, in N/mm<sup>2</sup>, of the steel used
- $n$  : Coefficient to be taken equal to:
- $n = 0,75$  for  $R_{eH} > 235$  N/mm<sup>2</sup>
  - $n = 1,00$  for  $R_{eH} \leq 235$  N/mm<sup>2</sup>.

**1.4.4** Significant reductions in rudder stock diameter due to the application of steels with specified minimum yield stresses greater than 235 N/mm<sup>2</sup> may be accepted by the Society subject to the results of a check calculation of the rudder stock deformations (refer to [4.2.1]).

**1.4.5** Welded parts of rudders are to be made of approved rolled hull materials. For these members, the material factor  $k$  defined in Ch 4, Sec 1, [2.2] is to be used.

## 2 Force and torque acting on the rudder

### 2.1 Rudder blade without cut-outs

#### 2.1.1 Rudder blade description

A rudder blade without cut-outs may have trapezoidal or rectangular contour.

#### 2.1.2 Rudder force

The rudder force  $C_R$  is to be obtained, in N, from the following formula:  $C_R = 132 n_R A V^2 r_1 r_2 r_3$

where:

- $n_R$  : Navigation coefficient, defined in Tab 1
- $V$  :  $V_{AV}$  or  $V_{AD}$ , depending on the condition under consideration (for high lift profiles see [1.1.2])
- $r_1$  : Shape factor, to be taken equal to:

$$r_1 = \frac{\lambda + 2}{3}$$

- $\lambda$  : Coefficient, to be taken equal to:

$$\lambda = \frac{h^2}{A_T}$$

and not greater than 2

- $h$  : Mean height, in m, of the rudder area to be taken equal to (see Fig 1):

$$h = \frac{z_3 + z_4 - z_2}{2}$$

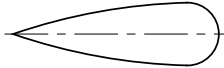

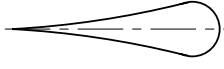

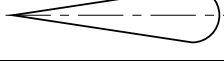

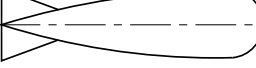

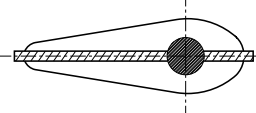

- $A_T$  : Area, in m<sup>2</sup>, to be calculated by adding the rudder blade area  $A$  to the area of the rudder post or rudder horn, if any, up to the height  $h$
- $r_2$  : Coefficient to be obtained from Tab 2

- $r_3$  : Coefficient to be taken equal to:
- $r_3 = 0,8$  for rudders outside the propeller jet (centre rudders on twin screw ships, or similar cases)
  - $r_3 = 1,15$  for rudders behind a fixed propeller nozzle
  - $r_3 = 1,0$  in other cases.

**Table 1 : Navigation coefficient**

Navigation notation	Navigation coefficient $n_R$
<b>unrestricted navigation</b>	1,00
<b>summer zone</b>	0,95
<b>tropical zone</b>	0,85
<b>coastal area</b>	0,85
<b>sheltered area</b>	0,75

**Table 2 : Values of coefficient  $r_2$**

Rudder profile type	$r_2$ for ahead condition	$r_2$ for astern condition
<b>NACA 00 - Goettingen</b> 	1,10	0,80
<b>Hollow</b> 	1,35	0,90
<b>Flat side</b> 	1,10	0,90
<b>High lift</b> 	1,70	1,30
<b>Fish tail</b> 	1,40	0,80
<b>Single plate</b> 	1,00	1,00
<b>Mixed profiles (e.g. HSVA)</b>	1,21	0,90

**2.1.3 Rudder torque**

The rudder torque  $M_{TR}$ , for both ahead and astern conditions, is to be obtained, in N.m, from the following formula:

$$M_{TR} = C_R r$$

where:

$r$  : Lever of the force  $C_R$ , in m, equal to:

$$r = b \left( \alpha - \frac{A_F}{A} \right)$$

and to be taken not less than 0,1 b for the ahead condition

$b$  : Mean breadth, in m, of rudder area to be taken equal to (see Fig 1):

$$b = \frac{x_2 + x_3 - x_1}{2}$$

- $\alpha$  : Coefficient to be taken equal to:
  - $\alpha = 0,33$  for ahead condition
  - $\alpha = 0,66$  for astern condition

$A_F$  : Area, in  $m^2$ , of the rudder blade portion afore the centreline of rudder stock (see Fig 1).

**Figure 1 : Geometry of rudder blade without cut-outs**

**2.2 Rudder blade with cut-outs (semi-spade rudders)**

**2.2.1 Rudder blade description**

A rudder blade with cut-outs may have trapezoidal or rectangular contour, as indicated in Fig 2.

**Figure 2 : Rudder blades with cut-outs**

**2.2.2 Rudder force**

The rudder force  $C_R$ , in N, acting on the blade is to be calculated in accordance with [2.1.2].

**2.2.3 Rudder torque**

The rudder torque  $M_{TR}$ , in N.m, is to be calculated in accordance with the following procedure.

The rudder blade area  $A$  is to be divided into two rectangular or trapezoidal parts having areas  $A_1$  and  $A_2$ , defined in Fig 2, so that:

$$A = A_1 + A_2$$

The rudder forces  $C_{R1}$  and  $C_{R2}$ , acting on each part  $A_1$  and  $A_2$  of the rudder blade, respectively, are to be obtained, in N, from the following formulae:

$$C_{R1} = C_R \frac{A_1}{A}$$

$$C_{R2} = C_R \frac{A_2}{A}$$

The levers  $r_1$  and  $r_2$  of the forces  $C_{R1}$  and  $C_{R2}$ , respectively, are to be obtained, in m, from the following formulae:

$$r_1 = b_1 \left( \alpha - \frac{A_{1F}}{A_1} \right)$$

$$r_2 = b_2 \left( \alpha - \frac{A_{2F}}{A_2} \right)$$

where:

$b_1, b_2$  : Mean breadths of the rudder blade parts having areas  $A_1$  and  $A_2$ , respectively, to be determined according to [2.1.3]

$A_{1F}, A_{2F}$  : Areas, in  $m^2$ , of the rudder blade parts, defined in Fig 3

$\alpha$  : Coefficient to be taken equal to:

- $\alpha = 0,33$  for ahead condition
- $\alpha = 0,66$  for astern condition

For rudder parts located behind a fixed structure such as a rudder horn,  $\alpha$  is to be taken equal to:

- $\alpha = 0,25$  for ahead condition
- $\alpha = 0,55$  for astern condition.

The torques  $M_{TR1}$  and  $M_{TR2}$ , relevant to the rudder blade parts  $A_1$  and  $A_2$  respectively, are to be obtained, in N.m, from the following formulae:

$$M_{TR1} = C_{R1} r_1$$

$$M_{TR2} = C_{R2} r_2$$

The total torque  $M_{TR}$  acting on the rudder stock, for both ahead and astern conditions, is to be obtained, in N.m, from the following formula:

$$M_{TR} = M_{TR1} + M_{TR2}$$

For the ahead condition only,  $M_{TR}$  is to be taken not less than the value obtained, in N.m, from the following formula:

$$M_{TR,MIN} = 0,1 C_R \frac{A_1 b_1 + A_2 b_2}{A}$$

**Figure 3 : Geometry of rudder blade with cut-outs**

### 3 Rudder types and relevant loads acting on the rudder structure

#### 3.1 General

##### 3.1.1 Loads per rudder category - basic assumptions

Depending on the shape of the rudder blade and arrangement of the rudder, twelve types of rudders are considered. Tab 4 summarizes these rudder types.

The force and torque acting on the rudder, defined in [2], may induce in the rudder structure the following loads:

- bending moment and torque in the rudder stock
- support forces at pintle and rudder stock bearings
- bending moment, shear force and torque in the rudder body
- bending moment, shear force and torque in rudder horns and solepieces.

Support forces, bending moments and shear forces are to be obtained according to Ch 12, App 1, [1.4], depending on the rudder type.

##### 3.1.2 Loads for the scantlings and assembling of rudder parts

The loads to be considered for the scantlings of rudder parts and some assembling parts are indicated in Tab 3.

**Table 3 : Scantling of parts, rudder stock couplings and relevant loads**

Item identification	Relevant loads
Rudder stock scantlings	<ul style="list-style-type: none"> <li>• either torque only, or</li> <li>• both, torque and bending moment</li> </ul> See [4]
Rudder stock couplings	<ul style="list-style-type: none"> <li>• either torque only, or</li> <li>• both, torque and bending moment</li> </ul> See [5]
Rudder stock bearings	Horizontal reaction forces, $F_{Air}$ See [6.2]
Pintle bearings	Horizontal reaction forces, $F_{Air}$ See [6.3]
Scantling of pintles	Horizontal reaction forces, $F_{Air}$ See [6.4]
Rudder blade scantlings	Bending moment and shear force See [7]
Rudder horn scantlings	Bending moment, shear force and torque See [8.1] and [8.2]
Solepiece scantlings	Bending moment and shear force See [8.4]

## 4 Rudder stock scantlings

### 4.1 Rudder stock diameter

#### 4.1.1 Basic formulation

The scantling of the rudder stock diameter is based on the Von Mises equivalent stress criterion, written for a state of stress induced by a combined torque,  $M_{TR}$ , and a bending moment,  $M_B$ , acting on the rudder stock. The Von Mises equivalent stress,  $\sigma_E$ , calculated for this state of stress, has to be in compliance with the following formula:  $\sigma_E \leq \sigma_{E,ALL}$

where:

$\sigma_E$  : Equivalent stress, in N/mm<sup>2</sup>, to be obtained from the following formula:

$$\sigma_E = \sqrt{\sigma_B^2 + 3\tau_T^2}$$

$\sigma_B$  : Bending stress, in N/mm<sup>2</sup>, to be obtained from the following formula:

$$\sigma_B = \frac{10,2M_B}{d_s^3} \cdot 10^3$$

$\tau_T$  : Torsional stress, in N/mm<sup>2</sup>, to be obtained from the following formula:

$$\tau_T = \frac{5,1M_{TR}}{d_s^3} \cdot 10^3$$

$d_s$  : Stock diameter, in mm

$\sigma_{E,ALL}$  : Allowable equivalent stress, in N/mm<sup>2</sup>, equal to:  $\sigma_{E,ALL} = 118 / k_1$

For this purpose, the rudder stock diameter is to be not less than the value obtained, in mm, from the following formula:

$$d_{TFi} = 4,2(M_{TR} k_1)^{1/3} \left[ 1 + \frac{4}{3} \left( \frac{M_{Bi}}{M_{TR}} \right)^2 \right]^{1/6}$$

where  $M_{Bi}$  is to be obtained according to Ch 12, App 1, [1.1.1], for each type of rudder listed in Tab 4.

#### 4.1.2 Rule rudder stock diameter

The rudder stock diameter, at the lower part, is to be not less than the value obtained, in mm, from the following formula:

$$d_{TF} = 4,2(M_{TR} k_1)^{1/3} \left[ 1 + \frac{4}{3} \left( \frac{M_B}{M_{TR}} \right)^2 \right]^{1/6}$$

with:

$M_B$  : Maximum absolute value of bending moment  $M_{Bi}$  over the rudder stock length, to be obtained according to Ch 12, App 1, [1.4], for each type of rudder listed in Tab 4.

If not otherwise specified, the notation  $d_1$  used in this Section is equivalent to  $d_{TF}$ .

#### 4.1.3 Rudder stock cross sections with null bending moment

The diameter, in mm, of a rudder stock cross section subjected to torque only is not to be less than the diameter  $d_T$  obtained from [4.1.2], taking  $M_B$  equal to zero:  $d_T = 4,2 (M_{TR} k_1)^{1/3}$

This is equivalent to check that the torsional shear stress  $\tau_T$ , in N/mm<sup>2</sup>, induced by the torque only, is in compliance with the following formula:  $\tau_T \leq \tau_{ALL}$

where:

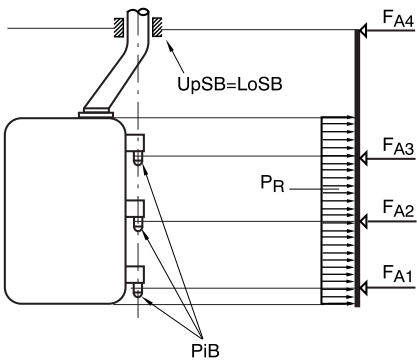

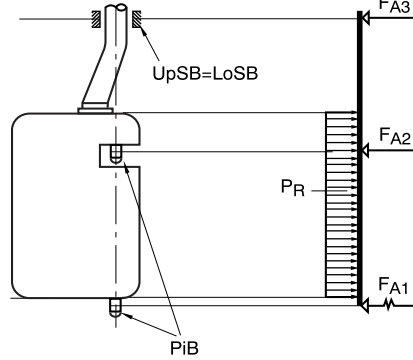

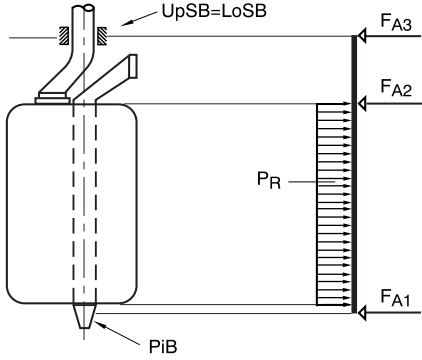

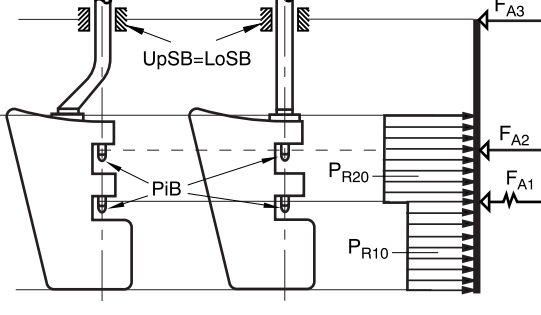

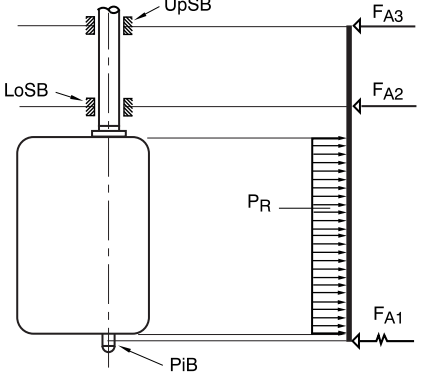

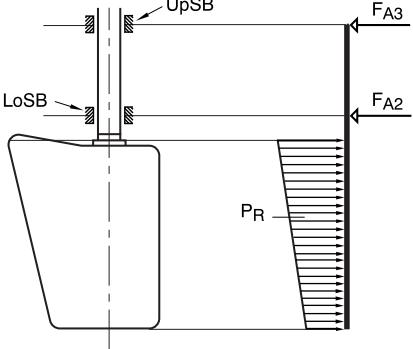

$\tau_{ALL}$  : Allowable torsional shear stress, in N/mm<sup>2</sup>:  $\tau_{ALL} = 68 / k_1$

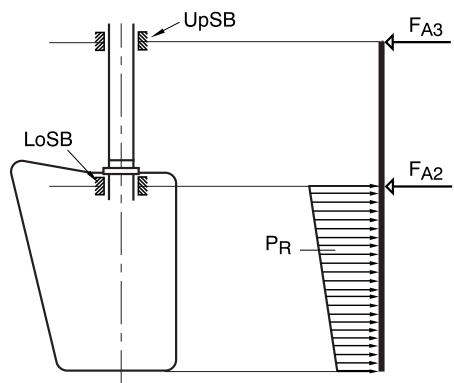

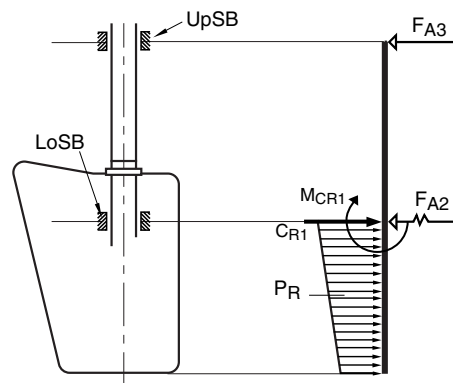

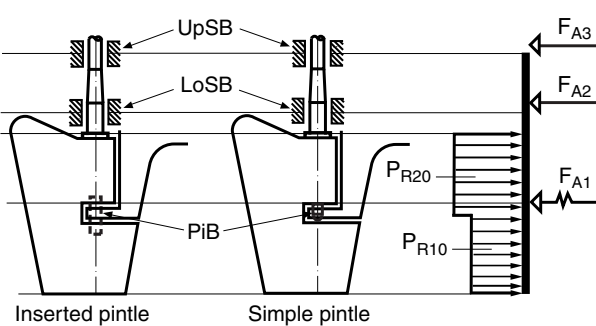

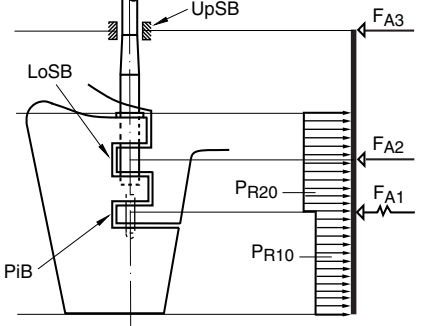

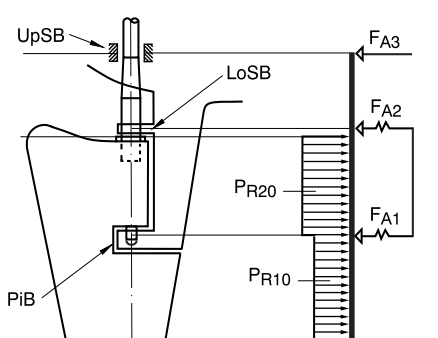

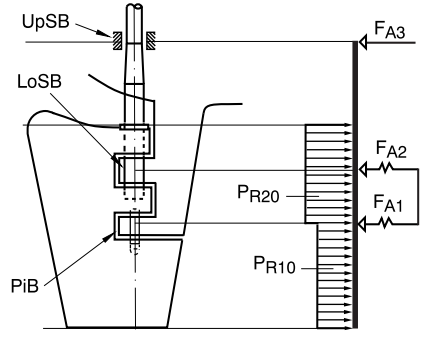

$\tau_T$  : Torsional stress, in N/mm<sup>2</sup>, defined in [4.1.1].

4.1.4 Rule rudder stock diameter in way of the tiller

In general, the diameter of a rudder stock subjected to torque and bending may be gradually tapered above the lower stock bearing so as to reach, from  $d_{TF}$  value, the value of  $d_i$  in way of the quadrant or the tiller.

Table 4 : Types of rudders and load diagram

<p><b>Type 1</b></p>  <p>General description: 4-bearing rudder, including 3 pintle bearings and 1 rudder-stock bearing. See Ch 12, App 1, [1.4.1].</p>	<p><b>Type 2</b></p>  <p>General description: 3-bearing rudder, including 2 pintle bearings and 1 rudder-stock bearing (the lower pintle bearing is represented by 1-elastic support). See Ch 12, App 1, [1.4.2].</p>
<p><b>Type 3</b></p>  <p>General description: 3-bearing rudder, including 2 bearings associated to the simplex rudder shaft and 1 rudder-stock bearing. See Ch 12, App 1, [1.4.3].</p>	<p><b>Type 4</b></p>  <p>General description: 3-bearing semi-spade rudder, including 2 pintle bearings and 1 rudder-stock bearing (the lower pintle bearing is represented by 1-elastic support). See Ch 12, App 1, [1.4.4].</p>
<p><b>Type 5</b></p>  <p>General description: 3-bearing rudder, including 1-elastic pintle bearing and 2 rudder-stock bearings. See Ch 12, App 1, [1.4.5].</p>	<p><b>Type 6a</b></p>  <p>General description: 2-bearing spade rudder, including 2 rudder-stock bearings, both of them located out of the rudder blade area. See Ch 12, App 1, [1.4.6].</p>

<p><b>Type 6b</b></p>  <p>General description: 2-bearing spade rudder, including 2 rudder-stock bearings, the lowest one located inside of the rudder blade area and close to its upper edge. See Ch 12, App 1, [1.4.7].</p>	<p><b>Type 6c</b></p>  <p>General description: 2-bearing spade rudder, including 2 rudder-stock bearings, the lowest one located inside of the rudder blade area. See Ch 12, App 1, [1.4.8].</p>
<p><b>Type 7</b></p>  <p>General description: 3-bearing semi-spade rudder, including 1-elastic pintle bearing and 2 rudder-stock bearings. See Ch 12, App 1, [1.4.9].</p>	<p><b>Type 8</b></p>  <p>General description: 3-bearing semi-spade rudder, including 1-elastic pintle bearing and 2 rudder-stock bearings (with 1 rudder-stock bearing inside of the rudder blade area). See Ch 12, App 1, [1.4.10].</p>
<p><b>Type 9</b></p>  <p>General description: 3-bearing semi-spade rudder, including 1 pintle bearing and 2 rudder-stock bearings (lower pintle and stock bearings represented by 2-conjugate elastic supports). See Ch 12, App 1, [1.4.11].</p>	<p><b>Type 10</b></p>  <p>General description: 3-bearing semi-spade rudder, including 1 pintle bearing and 2 rudder-stock bearings (lower pintle and stock bearings represented by 2-conjugate elastic supports, located inside of the rudder blade area). See Ch 12, App 1, [1.4.12].</p>
<p><b>Note 1:</b> Bending moment and shear forces need to be calculated at any generic horizontal section of the rudder blade, to make possible strength checks prescribed under [7.2].</p> <p><b>Note 2:</b></p> <p>UpSB : Upper rudder-stock bearing          LoSB : Lower rudder-stock bearing          PiB : Position of pintle bearing(s).</p> <p><b>Note 3:</b> Steering nozzle rudders are not included in this table (refer to [10] for more details).</p>	

## **4.2 Deformation criterion**

### **4.2.1 Rudder stock slope in way of bearings**

Large rudder stock deformations are to be avoided in order to avoid excessive edge pressures in way of bearings.

The Society may require an additional check of the rudder stock diameter to make sure that the rudder stock slopes in way of bearings are acceptable, by relating them to bearing lengths (see [6.2.3]) and bearing clearances (see [6.2.4]).

## **4.3 Service notations - Navigation in ice**

### **4.3.1 Service notations**

For specific service notations, increase in rudder stock diameter is required according to the relevant requirements in Part D or Part E.

### **4.3.2 Navigation in ice**

For ships having an additional **ICE CLASS** notation, refer to applicable requirements in Pt F, Ch 8, Sec 2.

## **5 Rudder stock couplings**

### **5.1 Horizontal flange couplings**

#### **5.1.1 General**

In general, the coupling flange and the rudder stock are to be forged from a solid piece. A shoulder radius as large as practicable is to be provided for between the rudder stock and the coupling flange. This radius is to be not less than  $0,15 d_1$ , where  $d_1$  is defined in [4.1.2].

#### **5.1.2 Welding**

Where the rudder stock diameter does not exceed 350 mm, the coupling flange may be welded onto the stock, provided that its thickness is increased by 10% and that the weld extends through the full thickness of the coupling flange and that the assembly obtained is subjected to heat treatment. This heat treatment is not required if the diameter of the rudder stock is less than 75 mm.

Where the coupling flange is welded, the grade of the steel used is to be of weldable quality, with a carbon content not exceeding 0,23% on ladle analysis and a carbon equivalent CEQ not exceeding 0,41. The welding conditions (preparation before welding, choice of electrodes, pre- and post-heating, inspection after welding) are to be defined to the satisfaction of the Society. The throat weld at the top of the flange is to be concave shaped to give a fillet shoulder radius as large as practicable. This radius:

- is to be not less than  $0,15d_1$ , where  $d_1$  is defined in [4.1.2]
- may be obtained by grinding. If disk grinding is carried out, score marks are to be avoided in the direction of the weld
- is to be checked with a template for accuracy. Four profiles at least are to be checked. A report is to be submitted to the Surveyor.

The inspection is to include full non destructive tests at weld location (dye penetrant or magnetic particle test and ultrasonic test).

#### **5.1.3 Bolts**

Horizontal flange couplings are to be connected by fitted bolts having a diameter not less than the value obtained, in mm, from the following formula:

$$d_B = 0,62 \sqrt{\frac{d_1^3 k_{1B}}{n_B e_M k_{1S}}}$$

where:

- $d_1$  : Rudder stock diameter, in mm, defined in [4.1.2]  
 $k_{1S}$  : Material factor  $k_1$  for the steel used for the rudder stock  
 $k_{1B}$  : Material factor  $k_1$  for the steel used for the bolts  
 $e_M$  : Mean distance, in mm, of the bolt axes from the centre of the bolt system  
 $n_B$  : Total number of bolts, which is to be not less than 6.

Non-fitted bolts may be used provided that, in way of the mating plane of the coupling flanges, a key is fitted having a section of  $(0,25d_T \times 0,10d_T)$  mm<sup>2</sup> and keyways in both the coupling flanges, and provided that at least two of the coupling bolts are fitted bolts.

The distance from the bolt axes to the external edge of the coupling flange is to be not less than  $1,2 d_B$ .

**5.1.4 Coupling flange**

The thickness of the coupling flange is to be not less than the value obtained, in mm, from the following formulae, whichever is the greater:

- $t_p = d_B \sqrt{\frac{k_{1F}}{k_{1B}}}$
- $t_p = 0,9 d_B$

where:

- $d_B$  : Bolt diameter, in mm, calculated in accordance with [5.1.3], where the number of bolts  $n_B$  is to be taken not greater than 8
- $k_{1F}$  : Material factor  $k_1$  for the steel used for the flange
- $k_{1B}$  : Material factor  $k_1$  for the steel used for the bolts.

**5.1.5 Locking device**

A suitable locking device is to be provided to prevent the accidental loosening of nuts.

**5.2 Couplings between rudder stocks and tillers****5.2.1 Application**

The requirements of this sub-article apply in addition to those specified in Pt C, Ch 1, Sec 14.

The requirements specified in [5.2.3] and [5.2.4] apply to solid rudder stocks in steel and to tiller bosses, either in steel or in SG iron, with constant external diameter. Solid rudder stocks others than those above will be considered by the Society on a case-by-case basis, provided that the relevant calculations, to be based on the following criteria, are submitted to the Society:

- Young's modulus:
  - $E = 2,06 \cdot 10^5$  N/mm<sup>2</sup> for steel
  - $E = 1,67 \cdot 10^5$  N/mm<sup>2</sup> for SG iron
- Poisson's ratio:
  - $\nu = 0,30$  for steel
  - $\nu = 0,28$  for SG iron
- Frictional coefficient:
  - $\mu = 0,15$  for contact steel/steel
  - $\mu = 0,13$  for contact steel/SG iron
- Torque  $C_T$  transmissible through friction:  $C_T \geq \eta M_{TR}$   
where  $\eta$  is defined in [5.2.3]
- Combined stress in the boss:

$$\sqrt{\sigma_R^2 + \sigma_T^2 - \sigma_R \sigma_T} \leq (0,5 + 0,2 \eta) R_{eH}$$

where:

$\sigma_R, \sigma_T$  : Algebraic values of, respectively, the radial compression stress and the tangent tensile stress, in N/mm<sup>2</sup>, induced by the grip pressure and calculated at the bore surface ( $\sigma_R = p_F$ , where  $p_F$  is the grip pressure in the considered horizontal cross-section of the boss)

- Where the rudder stock is hollow, the following strength criterion is to be complied with, at any point of the rudder stock cross-section:

$$\sqrt{\sigma_R^2 + \sigma_T^2 - \sigma_R \sigma_T + 3\tau^2} \leq 0,7 R_{eH}$$

where:

$\sigma_R, \sigma_T$  : Algebraic values of, respectively, the radial and the tangent compressive stresses, in N/mm<sup>2</sup>, induced by the grip pressure

$\tau$  : Shear stress, in N/mm<sup>2</sup>, induced by the torque  $M_{TR}$ .

**5.2.2 General**

The entrance edge of the tiller bore and that of the rudder stock cone are to be rounded or bevelled.

The right fit of the tapered bearing is to be checked before final fit up, to ascertain that the actual bearing is evenly distributed and at least equal to 80% of the theoretical bearing area; push-up length is measured from the relative positioning of the two parts corresponding to this case.

The required push-up length is to be checked after releasing of hydraulic pressures applied in the hydraulic nut and in the assembly.

**5.2.3 Push-up length of cone couplings with hydraulic arrangements for assembling and disassembling the coupling**

It is to be checked that the push-up length  $\Delta_E$ , in mm, of the rudder stock tapered part into the tiller boss is in compliance with the following formula:

$$\Delta_0 \leq \Delta_E \leq \Delta_1$$

where:

$$\Delta_0 = 6,2 \frac{M_{TR} \eta \gamma}{c d_M t_i \mu_A \beta} 10^{-3}$$

$$\Delta_1 = \frac{2\eta + 5}{1,8} \cdot \frac{\gamma d_0 R_{eH}}{c} 10^{-6}$$

$\eta$  : Coefficient to be taken equal to:

- $\eta = 1$  for keyed connections
- $\eta = 2$  for keyless connections

$c$  : Taper of conical coupling measured on diameter, to be obtained from the following formula:

$$c = (d_U - d_0) / l_c$$

$t_i, l_c, d_U, d_0$ : Geometrical parameters of the coupling, defined in Fig 4

$\beta$  : Coefficient to be taken equal to:

$$\beta = 1 - \left(\frac{d_M}{d_E}\right)^2$$

$d_M$  : Mean diameter, in mm, of the conical bore, to be obtained from the following formula:

$$d_M = d_U - 0,5 c l_c$$

$d_E$  : External boss diameter, in mm

$\mu_A$  : Coefficient to be taken equal to:

$$\mu_A = \sqrt{\mu^2 - 0,25 c^2}$$

$\mu, \gamma$  : Coefficients to be taken equal to:

- for rudder stocks and bosses made of steel:
  - $\mu = 0,15$
  - $\gamma = 1$
- for rudder stocks made of steel and bosses made of SG iron:
  - $\mu = 0,13$
  - $\gamma = 1,24 - 0,1 \beta$

$R_{eH}$  : Defined in [1.4.3].

**Figure 4 : Geometry of cone coupling**

**5.2.4 Boss of cone couplings with hydraulic arrangements for assembling and disassembling the coupling**

The scantlings of the boss are to comply with the following formula:

$$\frac{1,8}{2\eta + 5} \cdot \frac{\Delta_E c}{\gamma d_0} 10^6 \leq R_{eH}$$

where:

- $\Delta_E$  : Push-up length adopted, in mm
- $c, \eta, \gamma$  : Defined in [5.2.3]
- $d_0$  : Defined in Fig 4
- $R_{eH}$  : Defined in [1.4.3].

**5.2.5 Cylindrical couplings by shrink fit**

It is to be checked that the diametral shrinkage allowance  $\delta_E$ , in mm, is in compliance with the following formula:

$$\delta_0 \leq \delta_E \leq \delta_1$$

where:

$$\delta_0 = 6,2 \cdot \frac{M_{TR} \eta \gamma}{d_U t_i \mu \beta_1} 10^{-3}$$

$$\delta_1 = \frac{2\eta + 5}{1,8} \cdot \gamma d_U R_{eH} 10^{-6}$$

- $\eta, \mu, \gamma, c$  : Defined in [5.2.3]
- $d_U$  : Defined in Fig 4
- $\beta_1$  : Coefficient to be taken equal to:

$$\beta_1 = 1 - \left(\frac{d_U}{d_E}\right)^2$$

- $R_{eH}$  : Defined in [1.4.3].

**5.2.6 Keyless couplings through special devices**

The use of special devices for frictional connections, such as expansible rings, may be accepted by the Society on a case-by-case basis provided that the following conditions are complied with:

- evidence that the device is efficient (theoretical calculations and results of experimental tests, references of behaviour during service, etc.) are to be submitted to the Society
- the torque transmissible by friction is to be not less than  $2 M_{TR}$
- design conditions and strength criteria are to comply with [5.2.1]
- instructions provided by the manufacturer are to be complied with, notably concerning the pre-stressing of the tightening screws.

**5.3 Cone couplings between rudder stocks and rudder blades**

**5.3.1 Taper on diameter**

The taper on diameter of the cone couplings is to be in compliance with the following formulae:

- for cone couplings without hydraulic arrangements for assembling and disassembling the coupling:

$$\frac{1}{12} \leq \frac{d_U - d_0}{l_c} \leq \frac{1}{8}$$

- for cone couplings with hydraulic arrangements for assembling and disassembling the coupling (assembling with oil injection and hydraulic nut):

$$\frac{1}{20} \leq \frac{d_U - d_0}{l_c} \leq \frac{1}{12}$$

where:

$d_U, l_c, d_0$  : Geometrical parameters of the coupling, defined in Fig 4.

**5.3.2 Push-up pressure of cone coupling with hydraulic arrangements for assembling and disassembling the coupling**

The push-up pressure, in N/mm<sup>2</sup>, is not to be less than the greater of the two following values:

$$p_{req1} = \frac{2Q_F}{d_M^2 t_i \pi \mu_0} 10^3$$

$$p_{req2} = \frac{6M_{BC}}{t_i^2 d_M} 10^3$$

where:

- $d_M$  : Mean diameter, in mm, of the conical bore defined in [5.2.3]  
 $M_{Bc}$  : Bending moment at mid-height of the cone coupling, in N.m, to be deduced from the calculation of the bending moment in the rudder stock,  $M_B$ , as defined in Ch 12, App 1  
 $Q_F$  : Design yield moment of rudder stock, in N.m, defined in [5.3.6]  
 $t_i$  : Geometrical parameter of the coupling defined in Fig 4  
 $\mu_0$  : Frictional coefficient, taken equal to 0,15.

It has to be demonstrated by the designer that the push-up pressure does not exceed the permissible surface pressure in the cone. The permissible surface pressure, in N/mm<sup>2</sup>, is to be determined by the following formula:

$$p_{perm} = \frac{0,95 R_{eH}(1 - \alpha^2)}{\sqrt{3 + \alpha^4}} - p_b$$

where:

- $p_b$  : Pressure due to rudder bending, to be taken as follows:

$$p_b = \frac{3,5 M_{Bc}}{t_i^2 d_M} 10^3$$

- $R_{eH}$  : Minimum yield stress for the steel used for the gudgeon

$$\alpha = d_M / d_E$$

- $d_E$  : Minimum outer dimension (diameter or width) of the solid part in way of any horizontal cross section.

The outer diameter of the gudgeon is to be not less than 1,25  $d_U$ , with  $d_U$  the rudder stock diameter, in mm, as defined in Fig 4.

### 5.3.3 Push-up length of cone coupling with hydraulic arrangements for assembling and disassembling the coupling

It is to be checked that the push-up length  $\Delta_E$ , in mm, of the rudder stock tapered part into the boss is in compliance with the following formula:

$$\Delta_0 \leq \Delta_E \leq \Delta_1$$

where:

$$\Delta_0 = \frac{p_{req} d_M}{E \left( \frac{1 - \alpha^2}{2} \right) c} + \frac{0,8 R_{tm}}{c}$$

$$\Delta_1 = \frac{p_{perm} d_M}{E \left( \frac{1 - \alpha^2}{2} \right) c} + \frac{0,8 R_{tm}}{c}$$

- $c$  : Taper on conical coupling defined in [5.2.3].  
 $d_M$  : Mean diameter, in mm, of the conical bore defined in [5.2.3]  
 $p_{perm}$  : Permissible surface pressure, in N/mm<sup>2</sup>, calculated in [5.3.2]  
 $p_{req}$  : Push-up pressure, in N/mm<sup>2</sup>, as defined in [5.3.2]  
 $R_{eH}$  : Minimum yield stress for the steel used for the gudgeon  
 $R_{tm}$  : Mean roughness, in mm, taken equal to 0,01  
 $\alpha$  : Ratio defined in [5.3.2].

Note 1: In case of hydraulic pressure connections, the required push-up force  $P_e$ , in N, may be determined by the following formula:

$$P_e = p_{req} d_M \pi t_i \left( \frac{c}{2} + 0,02 \right)$$

### 5.3.4 Lower rudder stock end

The lower rudder stock end is to be fitted with a threaded part having a core diameter,  $d_G$ , in mm, not less than (see Fig 4):

$$d_G = 0,65 d_U$$

where:

- $d_U$  : Rudder stock diameter, in mm, as defined in Fig 4.

This threaded part is to be fitted with an adequate slogging nut efficiently locked in rotation.

The contact length  $t_i$ , in mm, of the rudder stock coupling cone inserted in the massive part (see Fig 4), deduction made of the chamfers and sealing ring grooves (oil grooves may be disregarded), is to be such that:

$$t_i \geq 1,5 d_U \sqrt{k_1}$$

where:

- $k_1$  : Material factor of the massive part.

When the foreseen contact surface ratio between the rudder stock and the massive part is greater than 70%, a lower  $t_i/d_U$  ratio may be accepted, on a case-by-case basis, provided that the contact percentage is proportionally higher, without however being taken less than 1,2.

The dimensions of the slogging nut are recommended to be as follows (see Fig 4):

- outer diameter:  $d_N \geq \text{Max} (1,2 d_0 ; 1,5 d_G)$
- thickness:  $t_N \geq 0,60 d_G$

where:

$d_0$  : As defined in Fig 4.

These dimensions and the core diameter  $d_G$  of the lower rudder stock end are given for guidance only, the determination of the adequate scantlings being left to the Designer.

### 5.3.5 Washer

For cone couplings with hydraulic arrangements for assembling and disassembling the coupling, a washer is to be fitted between the nut and the rudder gudgeon, having a thickness not less than  $0,09 d_G$  and an outer diameter not less than  $1,3 d_0$  or  $1,6 d_G$ , whichever is the greater.

The washer is not needed if the seat-surface of the nut is flat and, at least, identical to the contact surface calculated for a washer with the required diameter.

### 5.3.6 Couplings with key

For cone couplings without hydraulic arrangements for assembling and disassembling the coupling, a key is to be fitted and keyways in both the tapered part and the rudder gudgeon.

The key is to be machined and located on the fore or aft part of the rudder. The key is to be inserted at half-thickness into stock and into the solid part of the rudder.

The key shear area  $a_s$ , in  $\text{cm}^2$ , is to be not less than:

$$a_s = \frac{17,55 Q_F}{d_k R_{eH1}}$$

where:

$Q_F$  : Design yield moment of rudder stock, in N.m, obtained from the following formula:

$$Q_F = 0,02664 \frac{d_1^3}{k_{1S}}$$

Where the actual stock diameter is greater than the calculated diameter  $d_1$ , the actual diameter is to be used, without being taken greater than  $1,145 d_1$ .

$d_1$  : Rudder stock diameter, in mm, taken equal to  $d_T$ , as defined in [4.1.3]

$k_{1S}$  : Material factor  $k_1$  for the steel used for the rudder stock

$d_k$  : Mean diameter of the conical part of the rudder stock at the key, in mm

$R_{eH1}$  : Specified minimum yield stress  $R_{eH}$  for the steel used for key.

The effective surface area  $a_k$ , in  $\text{cm}^2$ , of the key (without rounded edges) between key and rudder stock or cone coupling is not to be less than:

$$a_k = \frac{5 Q_F}{d_k R_{eH2}}$$

where:

$R_{eH2}$  : Specified minimum yield stress  $R_{eH}$  of the key, stock or coupling material, whichever is less.

It is to be proved that 50% of the design yield moment  $Q_F$  is solely transmitted by friction in the cone couplings. This can be done by calculating the required push-up pressure  $p_{req}$  and push-up length  $\Delta_E$  according to [5.3.2] and [5.3.3] for a torsional moment  $Q'_F$  equal to  $0,5 Q_F$ .

In the specific case where the key is considered to transmit the entire rudder torque to the couplings, the scantlings of the key, as well as the push-up force and push-up length, are to be at the discretion of the Society.

### 5.3.7 Instructions

All necessary instructions for hydraulic assembly and disassembly of the nut, including indication of the values of all relevant parameters, are to be available on board.

## 5.4 Vertical flange couplings

**5.4.1** Vertical flange couplings are to be connected by fitted bolts having a diameter, in mm, not less than the value obtained, in mm, from the following formula:

$$d_B = \frac{0,81 d_1}{\sqrt{n_B}} \sqrt{\frac{k_{1B}}{k_{1S}}}$$

where:

- $d_1$  : Rudder stock diameter, in mm, defined in [4.1.2]
- $k_{1S}, k_{1B}$  : Material factors, defined in [5.1.3]
- $n_B$  : Total number of bolts, which is to be not less than 8.

**5.4.2** The first moment of area of the sectional area of bolts about the vertical axis through the centre of the coupling is to be not less than the value obtained, in  $\text{cm}^3$ , from the following formula:

$$M_S = 0,00043 d_1^3$$

where:

- $d_1$  : Rudder stock diameter, in mm, defined in [4.1.2].

**5.4.3** The thickness of the coupling flange, in mm, is to be not less than  $d_B$ , defined in [5.4.1].

**5.4.4** The distance, in mm, from the bolt axes to the external edge of the coupling flange is to be not less than  $1,2 d_B$ , where  $d_B$  is defined in [5.4.1].

**5.4.5** A suitable locking device is to be provided to prevent the accidental loosening of nuts.

## 5.5 Couplings by continuous rudder stock welded to the rudder blade

**5.5.1** When the rudder stock extends through the upper plate of the rudder blade and is welded to it, the thickness of this plate in the vicinity of the rudder stock is to be not less than  $0,20 d_1$ , where  $d_1$  is defined in [4.1.2].

**5.5.2** The welding of the upper plate of the rudder blade with the rudder stock is to be made with a full penetration weld and is to be subjected to non-destructive inspection through dye penetrant or magnetic particle test and ultrasonic test.

The throat weld at the top of the rudder upper plate is to be concave shaped to give a fillet shoulder radius as large as practicable. This radius:

- is to be not less than  $0,15 d_1$ , where  $d_1$  is defined in [4.1.2]
- may be obtained by grinding. If disk grinding is carried out, score marks are to be avoided in the direction of the weld
- is to be checked with a template for accuracy. Four profiles, at least, are to be checked. A report is to be submitted to the Surveyor.

## 5.6 Rudder trunks

**5.6.1** The requirements [5.6.2] to [5.6.8] apply to trunk configurations which are extended below stern frame and arranged in such a way that the trunk is stressed by forces due to rudder action.

**5.6.2** The bending and shear stresses in the rudder trunk, in  $\text{N/mm}^2$ , are to be in compliance with the following formulae:

$$\sigma \leq 80 / k$$

$$\tau \leq 48 / k$$

where  $k$  is not to be taken less than 0,7.

For the calculation of the bending and shear stresses, refer to Ch 12, App 1, [1.8].

**5.6.3** The steel grade used for the rudder trunk is to be of weldable quality, with a carbon content not exceeding 0,23% on ladle analysis or a carbon equivalent CEQ not exceeding 0,41.

**5.6.4** The weld at the connection between the rudder trunk and the shell or the bottom of the skeg is to be full penetration.

The fillet shoulder radius  $r$  is to be as large as practicable and to comply with the following formulae:  $r = 0,1 d_1$

where  $d_1$  is defined in [4.1.2],

without being less than:

$$r = 60 \text{ mm when } \sigma \geq 40 / k \text{ N/mm}^2$$

$$r = 30 \text{ mm when } \sigma < 40 / k \text{ N/mm}^2.$$

The radius may be obtained by grinding. If disk grinding is carried out, score marks are to be avoided in the direction of the weld. The radius is to be checked with a template for accuracy. Four profiles at least are to be checked. A report is to be submitted to the Surveyor.

**5.6.5** In case of type 6c rudders, the trunk tube is to be made with a protrusion at connection with skeg bottom, and scallops in webs are to be avoided at connection between the bottom of the skeg and the trunk or the shell, as shown in Fig 5.

**5.6.6** Before welding is started, a detailed welding procedure specification is to be submitted to the Society covering the weld preparation, welding positions, welding parameters, welding consumables, preheating, post weld heat treatment and inspection procedures. This welding procedure is to be supported by approval tests in accordance with the applicable requirements of NR216 Materials and Welding, Ch 12, Sec 3.

The manufacturer is to maintain records of welding, subsequent heat treatment and inspections traceable to the welds. These records are to be submitted to the Surveyor.

Non destructive tests are to be conducted at least 24 hours after completion of the welding. The welds are to be 100% magnetic particle tested and 100% ultrasonic tested. The welds are to be free from cracks, lack of fusion and incomplete penetration. The non destructive tests reports are to be handed over to the Surveyor.

**5.6.7** Rudder trunks in materials other than steel are to be specially considered by the Society.

**5.6.8** The thickness of the shell or of the bottom plate is to be compatible with the trunk thickness.

**Figure 5 : Typical trunk/skeg connection on type 6c rudders**

## 6 Rudder stock and pintle bearings

### 6.1 Forces on rudder stock and pintle bearings

**6.1.1** Support forces  $F_{Ai}$ , for  $i = 1, 2, 3, 4$ , as described in Tab 4, are to be obtained according to Ch 12, App 1, depending on the rudder type.

### 6.2 Rudder stock bearing

**6.2.1** The mean bearing pressure acting on the rudder stock bearing is to be in compliance with the following formula:

$$p_F \leq p_{F,ALL}$$

where:

$p_F$  : Mean bearing pressure acting on the rudder stock bearings, in  $N/mm^2$ , equal to:

$$p_F = \frac{F_{Ai}}{d_m h_m}$$

$F_{Ai}$  : Support force acting on the rudder stock bearing, in N

$d_m$  : Actual inner diameter, in mm, of the rudder stock bearings (contact diameter)

$h_m$  : Bearing length, in mm (see [6.2.3])

$p_{F,ALL}$  : Allowable bearing pressure, in  $N/mm^2$ , defined in Tab 5.

Values greater than those given in Tab 5 may be accepted by the Society on the basis of specific tests.

**6.2.2** An adequate lubrication of the bearing surface is to be ensured.

**6.2.3** The length/diameter ratio of the bearing surface is not to be greater than 1,2.

Table 5 : Allowable bearing pressure

Bearing material	$p_{F,ALL}$ , in N/mm <sup>2</sup>
Lignum vitae	2,5
White metal, oil lubricated	4,5
Synthetic material with hardness greater than 60 Shore D (1)	5,5 (2)
Steel, bronze and hot-pressed bronze-graphite materials (3)	7,0
(1) Indentation hardness test at 23°C and with 50% moisture to be performed according to a recognised standard. Type of synthetic bearing materials is to be approved by the Society	
(2) Surface pressures exceeding 5,5 N/mm <sup>2</sup> may be accepted in accordance with bearing manufacturer's specification and tests, but in no case more than 10 N/mm <sup>2</sup>	
(3) Stainless and wear-resistant steel in combination with stock liner approved by the Society	

**6.2.4** The manufacturing clearance  $t_0$  on the diameter of metallic supports is to be not less than the value obtained, in mm, from the following formula:

$$t_0 = \frac{d_m}{1000} + 1$$

In the case of non-metallic supports, the clearances are to be carefully evaluated on the basis of the thermal and distortion properties of the materials employed. In any case, for non metallic supports, the clearance on support diameter is to be not less than 1,5 mm unless a smaller clearance is supported by the manufacturer's recommendation and there is documented evidence of satisfactory service history with a reduced clearance.

**6.2.5** Liners and bushes are to be fitted in way of the bearings. Their minimum thickness is to be equal to:

- 8 mm for metallic and synthetic materials
- 22 mm for lignum vitae material.

### 6.3 Pintle bearings

**6.3.1** The mean bearing pressure acting on the gudgeons is to be in compliance with the following formula:  $p_F \leq p_{F,ALL}$

where:

$p_F$  : Mean bearing pressure acting on the gudgeons, in N/mm<sup>2</sup>, equal to:

$$p_F = \frac{F_{Ai}}{d_{AC} h_L}$$

$F_{Ai}$  : Support force acting on the pintle, in N

$d_{AC}$  : Actual diameter, in mm, of the rudder pintles (contact diameter)

$h_L$  : Bearing length, in mm (see [6.3.3])

$p_{F,ALL}$  : Allowable bearing pressure, in N/mm<sup>2</sup>, defined in Tab 5.

Values greater than those given in Tab 5 may be accepted by the Society on the basis of specific tests.

**6.3.2** An adequate lubrication of the bearing surface is to be ensured.

**6.3.3** The length/diameter ratio of the bearing surface is not to be less than 1 and not to be greater than 1,2.

**6.3.4** The manufacturing clearance  $t_0$  on the diameter of metallic supports is to be not less than the value obtained, in mm, from the following formula:

$$t_0 = \frac{d_{AC}}{1000} + 1$$

In the case of non-metallic supports, the clearances are to be carefully evaluated on the basis of the thermal and distortion properties of the materials employed. In any case, for non-metallic supports, the clearance on support diameter is to be not less than 1,5 mm.

**6.3.5** The thickness of any liner or bush, in mm, is to be not less than the greater of:

- $0,01 \sqrt{F_{Ai}}$
- the minimum thickness defined in [6.2.5].

## 6.4 Pintles

**6.4.1** Rudder pintles are to have a diameter not less than the value obtained, in mm, from the following formula:

$$d_A = \frac{0,38V_{AV}}{V_{AV} + 3} \sqrt{F_{Ai}k_1} + f_c$$

where:

$d_A$  : corresponds to  $d_U$  value shown in Fig 4

$F_{Ai}$  : Force, in N, acting on the pintle, as specified in Tab 4

$f_c$  : Coefficient depending on corrosion, whose value may generally be obtained from the following formula:

$$f_c = 30\sqrt{k_1}$$

The Society may accept lower values of  $f_c$ , considering the ship's dimensions and satisfactory service experience of corrosion control systems adopted.

**6.4.2** Provision is to be made for a suitable locking device to prevent the accidental loosening of pintles.

**6.4.3** The pintles are to have a conical coupling with a taper on diameter in accordance with [5.3.1].

The conical coupling is to be secured by a nut. The dimensions of the massive part and slogging nut are to be in accordance with the following formulae:

$$d_E \geq d_M + 0,6 d_A$$

$$t_N \geq 0,60 d_G$$

$$d_N \geq 1,2 d_0 \text{ and, in any case, } d_N \geq 1,5 d_G$$

where:

$d_A$  : Pintle diameter defined in [6.4.1]

$d_E$  : External diameter, in mm, of the massive part of Fig 4, having the thickness  $t_s$

$d_M$  : Mean diameter, in mm, of the conical bore, as defined in [5.2.3]

$t_s, d_G, t_N, d_N, d_0$  : Geometrical parameters of the coupling, defined in Fig 4.

The above minimum dimensions of the locking nut are only given for guidance, the determination of adequate scantlings being left to the Designer.

**6.4.4** The length of the pintle housing in the gudgeon, which corresponds to  $t_i$  in Fig 4, is to be not less than the greater of the values obtained, in mm, from the following formulae:

$$h_L = 0,35\sqrt{F_{Ai}k_1}$$

$$h_L = d_A$$

where:

$F_{Ai}$  : Force, in N, acting on the pintle, as specified in Tab 4.

The thickness of pintle housing in the gudgeon, in mm, is to be not less than  $0,25 d_{Av}$  where  $d_A$  is defined in [6.4.1].

**6.4.5** The required push-up pressure for pintle bearings, in N/mm<sup>2</sup>, is to be determined by the following formula:

$$p_{req} = 0,4 \frac{F_{Ai}d_A}{d_M^2 t_i}$$

where:

$d_M$  : Mean diameter, in mm, of the conical bore defined in [5.2.3]

$t_i$  : Geometrical parameter of the coupling defined in Fig 4.

The push-up length is to be calculated according to [5.3.3] using required push-up pressure and pintle bearing properties.

## 7 Rudder blade scantlings

### 7.1 General

#### 7.1.1 Application

The requirements in [7.1] to [7.6] apply to streamlined rudders and, when applicable, to rudder blades of single plate rudders.

#### 7.1.2 Rudder blade structure

The structure of the rudder blade is to be such that stresses are correctly transmitted to the rudder stock and pintles. To this end, horizontal and vertical web plates are to be provided.

Horizontal and vertical webs acting as main bending girders of the rudder blade are to be suitably reinforced.

**7.1.3 Access openings**

Streamlined rudders, including those filled with pitch, cork or foam, are to be fitted with plug-holes and the necessary devices to allow their mounting and dismounting.

Access openings to the pintles are to be provided. If necessary, the rudder blade plating is to be strengthened in way of these openings.

The corners of openings intended for the dismantling of pintles or stock nuts are to be rounded off with a radius as large as practicable.

Where the access to the rudder stock nut is closed with a welded plate, a full penetration weld is to be provided.

**7.1.4 Connection of the rudder blade to the trailing edge for rudder blade area greater than 6 m<sup>2</sup>**

Where the rudder blade area is greater than 6 m<sup>2</sup>, the connection of the rudder blade plating to the trailing edge is to be made by means of a forged or cast steel fashion piece, a flat or a round bar.

**7.1.5 Rudder horn recess**

Except in way of solid parts in cast steel, the corners of the recess intended for the passage of the rudder horn heel are to be designed with a radius at least equal to 5 times the plate thickness, but in no case smaller than 100 mm.

Welding in side plate is to be avoided in or at the end of these radii.

Edges of side plate and weld adjacent to radii are to be ground smooth.

**7.2 Strength checks**

**7.2.1 Bending stresses**

For the generic horizontal section of the rudder blade it is to be checked that the bending stress  $\sigma$ , in N/mm<sup>2</sup>, induced by the loads defined in [3.1], is in compliance with the following formula:  $\sigma \leq \sigma_{ALL}$

where:

$\sigma_{ALL}$  : Allowable bending stress, in N/mm<sup>2</sup>, specified in Tab 6.

**7.2.2 Shear stresses**

For the generic horizontal section of the rudder blade it is to be checked that the shear stress  $\tau$ , in N/mm<sup>2</sup>, induced by the loads defined in [3.1], is in compliance with the following formula:  $\tau \leq \tau_{ALL}$

where:

$\tau_{ALL}$  : Allowable shear stress, in N/mm<sup>2</sup>, specified in Tab 6.

**7.2.3 Combined bending and shear stresses**

For the generic horizontal section of the rudder blade it is to be checked that the equivalent stress  $\sigma_E$  is in compliance with the following formula:  $\sigma_E \leq \sigma_{E,ALL}$

where:

$\sigma_E$  : Equivalent stress induced by the loads defined in [3.1], to be obtained, in N/mm<sup>2</sup>, from the following formula:

$$\sigma_E = \sqrt{\sigma^2 + 3\tau^2}$$

$\sigma$  : Bending stress, in N/mm<sup>2</sup>

$\tau$  : Shear stress, in N/mm<sup>2</sup>

$\sigma_{E,ALL}$  : Allowable equivalent stress, in N/mm<sup>2</sup>, specified in Tab 6.

**Table 6 : Allowable stresses for rudder blade scantlings**

Type of rudder blade	Allowable bending stress $\sigma_{ALL}$ in N/mm <sup>2</sup>	Allowable shear stress $\tau_{ALL}$ in N/mm <sup>2</sup>	Allowable equivalent stress $\sigma_{E,ALL}$ in N/mm <sup>2</sup>
General	110 / k	50 / k	120 / k
In way of the recess for rudder horn pintle on semi-spade rudders (1)	75	50	100
(1) No benefit is given for high tensile steel in this case.			

### 7.3 Rudder blade plating

#### 7.3.1 Plate thickness

The thickness of each rudder blade plate panel is to be not less than the value obtained, in mm, from the following formula:

$$t_f = 5,5s\beta \sqrt{k\left(T + \frac{C_R 10^{-4}}{A}\right) + 2,5}$$

where:

$\beta$  : Coefficient equal to:

$$\beta = \sqrt{1,1 - 0,5\left(\frac{s}{b_L}\right)^2}$$

to be taken not greater than 1,0 if  $b_L/s > 2,5$

s : Length, in m, of the shorter side of the plate panel

$b_L$  : Length, in m, of the longer side of the plate panel.

#### 7.3.2 Thickness of the top and bottom plates of the rudder blade

The thickness of the top and bottom plates of the rudder blade is to be taken as the maximum of:

- the thickness  $t_f$  defined in [7.3.1], by considering the relevant values of s and  $b_L$ , for both the top and bottom plates
- 1,2 times the thicknesses obtained for the attached side platings around the top and bottom plates, respectively, calculated according to [7.3.1], by considering the relevant values of s and  $b_L$

Where the rudder is connected to the rudder stock with a coupling flange, the thickness of the top plate which is welded in extension of the rudder coupling flange is to be not less than 1,1 times the thickness calculated above.

#### 7.3.3 Web thickness

Web thickness is to be at least 70% of that required for rudder plating and in no case is it to be less than 8 mm, except for the upper and lower horizontal webs. The thickness of each of these webs is to be uniform and not less than that of the web panel having the greatest thickness  $t_f$ , as calculated in [7.3.1]. In any case it is not required that the thickness is increased by more than 20% in respect of normal webs.

When the design of the rudder does not incorporate a mainpiece, this is to be replaced by two vertical webs closely spaced, having thickness not less than that obtained from Tab 7. In rudders having area less than 6 m<sup>2</sup>, one vertical web only may be accepted provided its thickness is at least twice that of normal webs.

#### 7.3.4 Thickness of side plating and vertical web plates welded to solid part or to rudder coupling flange

The thickness, in mm, of the vertical web plates welded to the solid part where the rudder stock is housed, or welded to the rudder coupling flange, as well as the thickness of the rudder side plating under this solid part, or under the rudder coupling flange, is to be not less than the value obtained, in mm, from Tab 7.

#### 7.3.5 Reinforced strake of semi-spade rudders

A reinforced strake is to be provided in the lower pintle zone of semi-spade rudders. Its thickness is to be not less than 1,6  $t_f$ , where  $t_f$  is defined in [7.3.1]. This strake is to be extended forward of the main vertical web plate (see Fig 6).

#### 7.3.6 Main vertical webs of semi-spade rudders

The thickness of the main vertical web plate in the area between the rudder blade upper part and the pintle housing of semi-spade rudders is to be not less than 2,6  $t_f$ , where  $t_f$  is defined in [7.3.1].

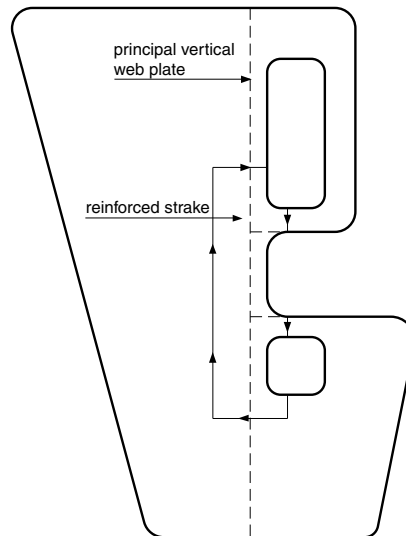

Under the pintle housing the thickness of this web is to be not less than the value obtained from Tab 7.

Where two main vertical webs are fitted, the thicknesses of these webs are to be not less than the values obtained from Tab 7 depending on whether the web is fitted in a rudder blade area without opening or if the web is along the recess cut in the rudder for the passage of the rudder horn heel.

**Table 7 : Thickness of the vertical webs and rudder side plating welded to solid part or to rudder coupling flange**

Type of rudder	Thickness of vertical web plates, in mm		Thickness of rudder plating, in mm	
	Rudder blade without opening	At opening boundary	Rudder blade without opening	Area with opening
Rudder types 1, 2, 3 and 4 (see Tab 4)	$t_f$	1,3 $t_f$	$t_f$	1,2 $t_f$
Rudder type 5 (see Tab 4)	1,2 $t_f$	1,6 $t_f$	1,2 $t_f$	1,4 $t_f$
Rudder types 6, 7, 8, 9 and 10 (see Tab 4)	1,4 $t_f$	2,0 $t_f$	1,3 $t_f$	1,6 $t_f$
<b>Note 1:</b> $t_f$ as defined in [7.3.1].				

Figure 6 : Reinforced strake extension for semi-spade rudders

### 7.3.7 Welding

The welded connections of blade plating to vertical and horizontal webs are to be in compliance with the applicable requirements of NR216 Materials and Welding.

Where the welds of the rudder blade are accessible only from outside of the rudder, slots on a flat bar welded to the webs are to be provided to support the weld root, to be cut on one side of the rudder only.

Slot-welding is to be limited as far as possible. Slot welding is not to be used in areas with large in-plane stresses transverse to the slots or in way of cut-out areas of semi-spade rudders.

When slot welding is applied, the length of the slots is to be at least 75 mm with a breadth of 2 times the rudder plate thickness  $t_F$ , in mm. The distance between ends of slots is not to be greater than 125 mm. The slots are to be fillet welded around the edges and filled with a suitable compound, e.g. epoxy putty. Slots are not to be filled with weld.

### 7.3.8 Rudder nose plate thickness

Rudder nose plates are to have a thickness not less than:

- $1,25 t_F$  without exceeding 22 mm, for  $t_F < 22$  mm
- $t_F$ , for  $t_F \geq 22$  mm

where  $t_F$  is defined in [7.3.1].

The rudder nose plate thickness may be increased on a case by case basis to be considered by the Society.

## 7.4 Connections of rudder blade structure with solid parts in forged or cast steel

### 7.4.1 General

Solid parts in forged or cast steel which ensure the housing of the rudder stock or of the pintle are in general to be connected to the rudder structure by means of two horizontal web plates and two vertical web plates.

### 7.4.2 Minimum section modulus of the connection with the rudder stock housing

The section modulus of the cross-section of the structure of the rudder blade which is connected with the solid part where the rudder stock is housed, which is made by vertical web plates and rudder plating, is to be not less than that obtained, in  $\text{cm}^3$ , from the following formula:

$$w_s = c_s d_i^3 \left( \frac{H_E - H_X}{H_E} \right)^2 \frac{k}{k_1} 10^{-4}$$

where:

$c_s$  : Coefficient, to be taken equal to:

- $c_s = 1,0$  if there is no opening in the rudder plating or if such openings are closed by a full penetration welded plate
- $c_s = 1,5$  if there is an opening in the considered cross-section of the rudder

$d_i$  : Rudder stock diameter, in mm, defined in [4.1.2]

$H_E$  : Vertical distance, in m, between the lower edge of the rudder blade and the upper edge of the solid part

$H_X$  : Vertical distance, in m, between the considered cross-section and the upper edge of the solid part

$k, k_1$  : Material factors, defined in [1.4], for the rudder blade plating and the rudder stock, respectively.

**7.4.3 Calculation of the actual section modulus of the connection with the rudder stock housing**

The actual section modulus of the cross-section of the structure of the rudder blade which is connected with the solid part where the rudder stock is housed is to be calculated with respect to the symmetrical axis of the rudder.

The breadth of the rudder plating to be considered for the calculation of this actual section modulus is to be not greater than that obtained, in m, from the following formula:

$$b = s_v + 2 \frac{H_x}{m}$$

where:

$s_v$  : Spacing, in m, between the two vertical webs (see Fig 7)

$H_x$  : Distance defined in [7.4.2]

$m$  : Coefficient to be taken, in general, equal to 3.

Where openings for access to the rudder stock nut are not closed by a full penetration welded plate according to [7.1.3], they are to be deducted (see Fig 7).

**Figure 7 : Cross-section of the connection between rudder blade structure and rudder stock housing**

**7.4.4 Thickness of horizontal web plates**

The thickness of the horizontal web plates connected to the upper and lower ends of the solid part, as well as that of the rudder blade plating between these webs, is to be not less than the greater of the values obtained, in mm, from the following formulae:

$$t_H = 1,2 t_F$$

$$t_H = 0,045 \frac{d_s^2}{s_H}$$

where:

$t_F$  : Defined in [7.3.1]

$d_s$  : Diameter, in mm, to be taken equal to:

- $d_1$  for the solid part connected to the rudder stock
- $d_A$  for the solid part connected to the pintle

$d_1$  : Rudder stock diameter, in mm, defined in [4.1.2]

$d_A$  : Pintle diameter, in mm, defined in [6.4.1]

$s_H$  : Spacing, in mm, between the two horizontal web plates.

Different thickness may be accepted when justified on the basis of direct calculations submitted to the Society for approval.

**7.4.5 Thickness of side plating and vertical web plates welded to the solid part**

The thickness of the vertical web plates welded to the solid part where the rudder stock is housed as well as the thickness of the rudder side plating under this solid part is to be not less than the values obtained, in mm, from Tab 7.

#### **7.4.6 Solid part protrusions**

The solid parts are to be provided with protrusions. Vertical and horizontal web plates of the rudder are to be butt welded to these protrusions.

These protrusions are not required when the web plate thickness is less than:

- 10 mm for web plates welded to the solid part on which the lower pintle of a semi-spade rudder is housed and for vertical web plates welded to the solid part of the rudder stock coupling of spade rudders
- 20 mm for the other web plates.

### **7.5 Connection of the rudder blade with the rudder stock by means of horizontal flanges**

#### **7.5.1 Minimum section modulus of the connection**

The section modulus of the cross-section of the structure of the rudder blade which is directly connected with the flange, which is made by vertical web plates and rudder blade plating, is to be not less than the value obtained, in  $\text{cm}^3$ , from the following formula:

$$w_s = 1,3 d_1^3 10^{-4}$$

where  $d_1$  is the rudder stock diameter  $d_{TF}$ , in mm, to be calculated in compliance with [4.1.2], taking  $k_1$  equal to 1.

#### **7.5.2 Actual section modulus of the connection**

The section modulus of the cross-section of the structure of the rudder blade which is directly connected with the flange is to be calculated with respect to the symmetrical axis of the rudder.

For the calculation of this actual section modulus, the length of the rudder cross-section equal to the length of the rudder coupling flange is to be considered.

Where the rudder plating is provided with an opening under the rudder coupling flange, the actual section modulus of the rudder blade is to be calculated in compliance with [7.4.3].

#### **7.5.3 Welding of the rudder blade structure to the rudder blade flange**

The welds between the rudder blade structure and the rudder blade flange are to be full penetrated (or of equivalent strength) and are to be 100% inspected by means of non-destructive tests.

Where the full penetration welds of the rudder blade are accessible only from outside of the rudder, a backing flat bar is to be provided to support the weld root.

The external fillet welds between the rudder blade plating and the rudder coupling flange are to be of concave shape and their throat thickness is to be at least equal to 0,5 times the rudder blade thickness.

Moreover, the rudder coupling flange is to be checked before welding by non-destructive inspection for lamination and inclusion detection in order to reduce the risk of lamellar tearing.

#### **7.5.4 Thickness of side plating and vertical web plates welded to the rudder coupling flange**

The thickness of the vertical web plates directly welded to the rudder coupling flange as well as the plating thickness of the rudder blade upper strake in the area of the connection with the rudder coupling flange are to be not less than the values obtained, in mm, from Tab 7.

### **7.6 Single plate rudders**

#### **7.6.1 Mainpiece diameter**

The mainpiece diameter is to be obtained from the formulae in [4.1.2] or [4.1.3].

In any case, the mainpiece diameter is to be not less than the stock diameter.

For spade rudders the lower third may taper down to 0,75 times the stock diameter.

#### **7.6.2 Blade thickness**

The blade thickness is to be not less than the value obtained, in mm, from the following formula:

$$t_B = 1,5sV_{AV}\sqrt{k} + 2,5$$

where:

s : Spacing of stiffening arms, in m, to be taken not greater than 1 m (see Fig 8).

Figure 8 : Single plate rudder

**7.6.3 Arms**

The thickness of the arms is to be not less than the blade thickness.

The section modulus of the generic section is to be not less than the value obtained, in cm<sup>3</sup>, from the following formula:

$$Z_A = 0,5 s C_H^2 V_{AV}^2 k$$

where:

- C<sub>H</sub> : Horizontal distance, in m, from the aft edge of the rudder to the centreline of the rudder stock (see Fig 8)
- s : Defined in [7.6.2].

**8 Rudder horn and solepiece scantlings**

**8.1 General**

**8.1.1** The weight of the rudder is normally supported by a carrier bearing inside the rudder trunk.

In the case of unbalanced rudders having more than one pintle, the weight of the rudder may be supported by a suitable disc fitted in the solepiece gudgeon.

Robust and effective structural rudder stops are to be fitted, except where adequate positive stopping arrangements are provided in the steering gear, in compliance with the applicable requirements of Pt C, Ch 1, Sec 14.

**8.2 Rudder horn**

**8.2.1 General**

When the connection between the rudder horn and the hull structure is designed as a curved transition into the hull plating, special consideration is to be paid to the effectiveness of the rudder horn plate in bending and to the stresses in the transverse web plates.

**8.2.2 Loads**

The following loads acting on the generic section of the rudder horn are to be considered:

- bending moment
- shear force
- torque.

Bending moment, shear forces and torque are to be calculated according to Ch 12, App 1, [1.6], or Ch 12, App 1, [1.7], depending on the relevant type of rudder.

**8.2.3 Shear stress check**

For the generic section of the rudder horn, it is to be checked that:

$$\tau_s \leq \tau_{ALL}$$

where:

$\tau_s$  : Shear stress, in N/mm<sup>2</sup>, to be obtained according to, either Ch 12, App 1, [1.6] or Ch 12, App 1, [1.7]

$\tau_{ALL}$  : Allowable shear stress, in N/mm<sup>2</sup>:

$$\tau_{ALL} = 48 / k_1$$

### 8.2.4 Combined stress strength check

For the generic section of the rudder horn, it is to be checked that:

$$\sigma_E \leq \sigma_{E,ALL}$$

$$\sigma_B \leq \sigma_{B,ALL}$$

where:

$\sigma_E$  : Equivalent stress to be obtained, in N/mm<sup>2</sup>, from the following formula:

$$\sigma_E = \sqrt{\sigma_B^2 + 3(\tau_S^2 + \tau_T^2)}$$

$\sigma_B$  : Bending stress, in N/mm<sup>2</sup>, to be obtained from, either Ch 12, App 1, [1.6] or Ch 12, App 1, [1.7], depending on the rudder type

$\tau_S, \tau_T$  : Shear and torsional stresses, in N/mm<sup>2</sup>, to be obtained according to, either Ch 12, App 1, [1.6] or Ch 12, App 1, [1.7]

$\sigma_{E,ALL}$  : Allowable equivalent stress, in N/mm<sup>2</sup>, equal to:

$$\sigma_{E,ALL} = 120 / k_1$$

$\sigma_{B,ALL}$  : Allowable bending stress, in N/mm<sup>2</sup>, equal to:

$$\sigma_{B,ALL} = 67 / k_1.$$

### 8.2.5 Rudder horn plating

The thickness, in mm, of the rudder horn side plating is not to be less than:

$$t = 2,4\sqrt{Lk}$$

where

L : Rule length as defined in Ch 1, Sec 2, [3.1]

k : Material factor as given in [1.4].

## 8.3 Connection of after peak structures with the rudder horn

### 8.3.1 General

The requirement in Ch 11, Sec 3, [3] apply to the connection between peak structure and rudder horn where the sternframe is of an open type and is fitted with the rudder horn.

## 8.4 Solepieces

### 8.4.1 Strength checks

For the generic section of the solepiece, it is to be checked that:

$$\sigma_B \leq \sigma_{B,ALL}$$

$$\tau \leq \tau_{ALL}$$

where:

$\sigma_B$  : Bending stress, in N/mm<sup>2</sup>, to be obtained according to Ch 12, App 1, [1.5.2]

$\tau$  : Shear stress, in N/mm<sup>2</sup>, to be obtained according to Ch 12, App 1, [1.5.2]

$\sigma_{B,ALL}$  : Allowable bending stress, in N/mm<sup>2</sup>, equal to:

$$\sigma_{B,ALL} = 80 / k_1$$

$\tau_{ALL}$  : Allowable shear stress, in N/mm<sup>2</sup>, equal to:

$$\tau_{ALL} = 48 / k_1.$$

### 8.4.2 Minimum section modulus around the horizontal axis

The section modulus around the horizontal axis Y (see Ch 12, App 1, Fig 11) is to be not less than the value obtained, in cm<sup>3</sup>, from the following formula:

$$W_Y = 0,5 W_Z$$

where:

$W_Z$  : Section modulus, in cm<sup>3</sup>, around the vertical axis Z (see Ch 12, App 1, Fig 11).

## 9 Simplex rudder shaft

### 9.1 Scantlings

#### 9.1.1 Diameter of the rudder shaft

The rudder shaft diameter is to be not less than the value obtained, in mm, from the following formula:

$$d = 17,9 \left( \frac{\alpha A (V_{AV} + 2)^2}{\ell} \right)^{1/3}$$

where:

$\alpha$  : Coefficient equal to:

- $\alpha = b (\ell - b + a)$  if  $a \leq b$
- $\alpha = a (\ell - a + b)$  if  $a > b$

$a, b, \ell$  : Geometrical parameters, in m, defined in Fig 9.

#### 9.1.2 Sectional area of rudder shaft

The overall sectional area of the rudder shaft is to be not less than the greater of the following values:

- 70% of the sectional area for the propeller post defined in Ch 11, Sec 3, [4.2]
- value of the sectional area of the pintle supporting half the rudder blade, whose diameter is to be calculated from the formula in [6.4.1].

If the latter value is the greater, it is to be applied only where the rudder bears on the rudder shaft; in such case, it is recommended that an overthickness or a bush is provided in way of the bearing areas.

#### 9.1.3 Bearings

The bearing length of the rudder shaft is to be not less than  $1,2 d$ , where  $d$  is the shaft diameter defined in [9.1.1].

The mean pressure acting on the bearings is not to exceed the relevant allowable values, defined in Tab 5.

**9.1.4** The manufacturing clearance  $t_0$  on the diameter of metallic supports is to be not less than the value obtained, in mm, from the following formula:

$$t_0 = \frac{d_A}{1000} + 1$$

where:

$d_A$  : Actual inner diameter, in mm, of the rudder shaft bearing (contact diameter).

In the case of non-metallic supports, the clearances are to be carefully evaluated on the basis of the thermal and distortion properties of the materials employed.

In any case, for non-metallic supports, the clearance on support diameter is to be not less than 1,5 mm.

## 9.2 Connections

### 9.2.1 Connection with the hull

The shaft is to be connected with the hull by means of a vertical coupling flange having thickness at least equal to  $d/4$ , where  $d$  is the shaft diameter, obtained from the formula in [9.1.1] (see Fig 9).

The coupling flange is to be secured by means of six fitted bolts. The shank diameter of the bolts is to be not less than the coupling flange thickness defined above.

The distance from the bolt centre lines to the coupling flange edge is to be not less than 1,17 times the bolt diameter defined above.

### 9.2.2 Connection with the solepiece

The rudder shaft is to be connected with the solepiece by means of a cone coupling, having a taper on the radius equal to about 1/10 and housing length not less than 1,1  $d$ , where  $d$  is obtained from the formula in [9.1.1] (See Fig 9).

The mean pressure exerted by the rudder shaft on the bearing is to be not greater than the relevant allowable bearing pressure, defined in Tab 5 assuming a rudder with two pintles.

## 10 Nozzles

### 10.1 General

**10.1.1** The requirements of this Article apply to the scantlings of steering and fixed nozzles for which the power transmitted to the propeller is less than the value obtained, in kW, from the following formula:

$$P = \frac{16900}{d_M}$$

where:

$d_M$  : Inner diameter of the nozzle, in m.

Nozzles for which the power transmitted is greater than the value obtained from the above formula are considered on a case-by-case basis.

**10.1.2** Nozzles normally consist of a double skin cylindrical structure stiffened by ring webs and other longitudinal webs placed perpendicular to the nozzle.

One of the ring webs is to be fitted in way of the axis of rotation of the nozzle.

### 10.1.3

The section modulus  $W_N$ , in  $\text{cm}^3$ , of the nozzle double skin profile (half nozzle cross section) around its neutral axis parallel to the center line, is not to be less than:

$$W_N = nd^2bV_{AV}^2$$

where:

$d$  : Inner diameter of nozzle, in m

$b$  : Length of nozzle, in m

$n$  : Coefficient taken equal to:

- 1,0 for steering nozzles
- 0,7 for fixed nozzles.

**10.1.4** Care is to be taken in the manufacture of the nozzle to ensure the welded connection between plating and webs.

**10.1.5** The internal part of the nozzle is to be adequately protected against corrosion.

### 10.2 Nozzle plating and internal diaphragms

**10.2.1** The thickness of the inner plating of the nozzle is to be not less than the value obtained, in mm, from the following formulae:

$$t_F = (0,085\sqrt{Pd_M} + 9,65)\sqrt{k} \quad \text{for } P \leq \frac{6100}{d_M}$$

$$t_F = (0,085\sqrt{Pd_M} + 11,65)\sqrt{k} \quad \text{for } P > \frac{6100}{d_M}$$

where:

$P, d_M$  : Defined in [10.1.1].

The thickness  $t_f$  is to be extended to a length, across the transverse section containing the propeller blade tips, equal to one fourth of the total nozzle length.

Outside this length, the thickness of the inner plating is to be not less than  $(t_f - 7)$  mm and, in any case, not less than 7 mm.

**10.2.2** The thickness of the outer plating of the nozzle is to be not less than  $(t_f - 9)$  mm, where  $t_f$  is defined in [10.2.1] and, in any case, not less than 7 mm.

**10.2.3** The thicknesses of ring webs and longitudinal webs are to be not less than  $(t_f - 7)$  mm, where  $t_f$  is defined in [10.2.1], and, in any case, not less than 7 mm.

However, the thickness of the ring web, in way of the headbox and pintle support structure, is to be not less than  $t_f$ .

The Society may consider reduced thicknesses where an approved stainless steel is used, in relation to its type.

**10.3 Nozzle stock**

**10.3.1** The diameter of the nozzle stock is to be not less than the value obtained, in mm, from the following formula:

$$d_{NTF} = 6,42 (M_T k_1)^{1/3}$$

where:

$M_T$  : Torque, to be taken as the greater of those obtained, in N.m, from the following formulae:

- $M_{TAV} = 0,3 S_{AV} a$
- $M_{TAD} = S_{AD} b$

$S_{AV}$  : Force, in N, equal to:  $S_{AV} = 150 V_{AV}^2 A_N$

$S_{AD}$  : Force, in N, equal to:  $S_{AD} = 200 V_{AD}^2 A_N$

$A_N$  : Area, in  $m^2$ , equal to:  $A_N = 1,35 A_{1N} + A_{2N}$

$A_{1N}$  : Area, in  $m^2$ , equal to:  $A_{1N} = L_M d_M$

$A_{2N}$  : Area, in  $m^2$ , equal to:  $A_{2N} = L_1 H_1$

$a, b, L_M, d_M, L_1, H_1$  : Geometrical parameters of the nozzle, in m, defined in Fig 10.

The diameter of the nozzle stock may be gradually tapered above the upper stock bearing so as to reach, in way of the tiller or quadrant, the value obtained, in mm, from the following formula:  $d_{NT} = 0,75 d_{NTF}$

**Figure 10 : Geometrical parameters of the nozzle**

**10.4 Pintles**

**10.4.1** The diameter of the pintles is to be not less than the value obtained, in mm, from the following formula:

$$d_A = \left( \frac{0,35 V_{AV}}{V_{AV} + 3} \sqrt{S_{AV} + 30} \right) \sqrt{k_1}$$

where:

$S_{AV}$  : Defined in [10.3.1].

**10.4.2** The length/diameter ratio of the pintle is not to be less than 1 and not to be greater than 1,2.

Smaller values of  $h_A$  may be accepted provided that the pressure on the gudgeon bearing  $p_F$  is in compliance with the following formula:

$$p_F \leq p_{F,ALL}$$

where:

$p_F$  : Mean bearing pressure acting on the gudgeon, to be obtained in N/mm<sup>2</sup>, from the following formula:

$$p_F = \frac{0,6S'}{d'_A h'_A}$$

$S'$  : The greater of the values  $S_{AV}$  and  $S_{AD}$ , in N, defined in [10.3.1]

$d'_A$  : Actual pintle diameter, in mm

$h'_A$  : Actual bearing length of pintle, in mm

$p_{F,ALL}$  : Allowable bearing pressure, in N/mm<sup>2</sup>, defined in Tab 5.

## 10.5 Nozzle coupling

### 10.5.1 Diameter of coupling bolts

The diameter of the coupling bolts is to be not less than the value obtained, in mm, from the following formula:

$$d_B = 0,62 \sqrt{\frac{d_{NTF}^3 k_{1B}}{n_B e_M k_{1S}}}$$

where:

$d_{NTF}$  : Diameter of the nozzle stock, in mm, defined in [10.3.1]

$k_{1S}$  : Material factor  $k_1$  for the steel used for the stock

$k_{1B}$  : Material factor  $k_1$  for the steel used for the bolts

$e_M$  : Mean distance, in mm, from the bolt axes to the longitudinal axis through the coupling centre (i.e. the centre of the bolt system)

$n_B$  : Total number of bolts, which is to be not less than:

- 4 if  $d_{NTF} \leq 75$  mm
- 6 if  $d_{NTF} > 75$  mm.

Non-fitted bolts may be used provided that, in way of the mating plane of the coupling flanges, a key is fitted having a section of  $(0,25d_{NT} \times 0,10d_{NT})$  mm<sup>2</sup>, where  $d_{NT}$  is defined in [10.3.1], and keyways in both the coupling flanges, and provided that at least two of the coupling bolts are fitted bolts.

The distance from the bolt axes to the external edge of the coupling flange is to be not less than  $1,2 d_B$ .

### 10.5.2 Thickness of coupling flange

The thickness of the coupling flange is to be not less than the value obtained, in mm, from the following formula:

$$t_P = d_B \sqrt{\frac{k_{1F}}{k_{1B}}}$$

where:

$d_B$  : Diameter of the coupling bolts, in mm, defined in [10.5.1]

$k_{1B}$  : Material factor  $k_1$  for the steel used for the bolts

$k_{1F}$  : Material factor  $k_1$  for the steel used for the coupling flange.

### 10.5.3 Push-up length of cone couplings with hydraulic arrangements for assembling and disassembling the coupling

It is to be checked that the push-up length  $\Delta_E$  of the nozzle stock tapered part into the boss is in compliance with the following formula:  $\Delta_0 \leq \Delta_E \leq \Delta_1$

where:

$\Delta_0$  : The greater of:

- $6,2 \cdot \frac{M_{TR} \eta \gamma}{c d_M t_i \mu_A \beta}$
- $16 \cdot \frac{M_{TR} \eta \gamma}{c t_i^2 \beta} \cdot \sqrt{\frac{d_{NTF}^2 - d_{NT}^2}{d_{NT}^2}}$

$$\Delta_1 = \frac{2\eta + 5}{1,8} \cdot \frac{\gamma d_0 R_{eH}}{10^6 c (1 + \rho_1)}$$

$$\rho_1 = \frac{80 \sqrt{d_{NTF}^2 - d_{NT}^2}}{R_{eH} d_M t_f^2 \left[ 1 - \left( \frac{d_0}{d_f} \right)^2 \right]}$$

$d_{NTF}, d_{NT}$ : Nozzle stock diameters, in mm, to be obtained from [10.3.1], considering  $k_1 = 1$

$\eta, c, \beta, d_M, d_f, \mu_A, \mu, \gamma$ : Defined in [5.2.3]

$t_f, d_0$  : Defined in Fig 4

$R_{eH}$  : Defined in [1.4.3].

**10.5.4 Locking device**

A suitable locking device is to be provided to prevent the accidental loosening of nuts.

**11 Azimuth propulsion system**

**11.1 General**

**11.1.1 Arrangement**

The azimuth propulsion system is constituted by the following sub-systems (see Fig 11):

- the steering unit
- the bearing
- the hull supports
- the rudder part of the system
- the pod, which contains the electric motor in the case of a podded propulsion system.

**Figure 11 : Azimuth propulsion system**

**11.1.2 Application**

The requirements of this Article apply to the scantlings of the hull supports, the rudder part and the pod.

The steering unit and the bearing are to comply with the requirements in Pt C, Ch 1, Sec 14 and Pt C, Ch 1, Sec 15 respectively.

**11.1.3 Operating conditions**

The maximum angle at which the azimuth propulsion system can be oriented on each side when the ship navigates at its maximum speed is to be specified by the Designer. Such maximum angle is generally to be less than 35° on each side.

In general, orientations greater than this maximum angle may be considered by the Society for azimuth propulsion systems during manoeuvres, provided that the orientation values together with the relevant speed values are submitted to the Society for approval.

## **11.2 Arrangement**

### **11.2.1 Plans to be submitted**

In addition to the plans showing the structural arrangement of the pod and the rudder part of the system, the plans showing the arrangement of the azimuth propulsion system supports are to be submitted to the Society for approval. The scantlings of the supports and the maximum loads which act on the supports are to be specified in these drawings.

### **11.2.2 Locking device**

The azimuth propulsion system is to be mechanically lockable in a fixed position, in order to avoid rotations of the system and propulsion in undesirable directions in the event of damage.

## **11.3 Design loads**

**11.3.1** The lateral pressure to be considered for scantling of plating and ordinary stiffeners of the azimuth propulsion system is to be determined for an orientation of the system equal to the maximum angle at which the azimuth propulsion system can be oriented on each side when the ship navigates at its maximum speed.

The total force which acts on the azimuth propulsion system is to be obtained by integrating the lateral pressure on the external surface of the system.

The calculations of lateral pressure and total force are to be submitted to the Society for information.

## **11.4 Plating**

### **11.4.1 Plating of the rudder part of the azimuth propulsion system**

The thickness of plating of the rudder part of the azimuth propulsion system is to be not less than that obtained, in mm, from the formulae in [7.3.1], in which the term  $C_R/A$  is to be replaced by the lateral pressure calculated according to [11.3].

### **11.4.2 Plating of the pod**

The thickness of plating of the pod is to be not less than that obtained, in mm, from the formulae in Ch 7, Sec 4, where the lateral pressure is to be calculated according to [11.3].

### **11.4.3 Webs**

The thickness of webs of the rudder part of the azimuth propulsion system is to be determined according to [7.3.3], where the lateral pressure is to be calculated according to [11.3].

## **11.5 Ordinary stiffeners**

### **11.5.1 Ordinary stiffeners of the pod**

The scantlings of ordinary stiffeners of the pod are to be not less than those obtained from the formulae in Ch 7, Sec 5, where the lateral pressure is to be calculated according to [11.3].

## **11.6 Primary supporting members**

### **11.6.1 Analysis criteria**

The scantlings of primary supporting members of the azimuth propulsion system are to be obtained by the Designer through direct calculations, to be carried out according to the following requirements:

- the structural model is to include the pod, the rudder part of the azimuth propulsion system, the bearing and the hull supports
- the boundary conditions are to represent the connections of the azimuth propulsion system to the hull structures
- the loads to be applied are those defined in [11.6.2].

The direct calculation analyses (structural model, load and stress calculation, strength checks) carried out by the Designer are to be submitted to the Society for information.

### **11.6.2 Loads**

The following loads are to be considered by the Designer in the direct calculation of the primary supporting members of the azimuth propulsion system:

- gravity loads
- buoyancy
- maximum loads calculated for an orientation of the system equal to the maximum angle at which the azimuth propulsion system can be oriented on each side when the ship navigates at its maximum speed
- maximum loads calculated for the possible orientations of the system greater than the maximum angle at the relevant speed (see [11.1.3])
- maximum loads calculated for the crash stop of the ship obtained through inversion of the propeller rotation
- maximum loads calculated for the crash stop of the ship obtained through a 180° rotation of the pod.

### 11.6.3 Strength check

It is to be checked that the Von Mises equivalent stress  $\sigma_{VM}$  in primary supporting members, calculated, in N/mm<sup>2</sup>, for the load cases defined in [11.6.2], is in compliance with the following criteria:

$$\sigma_{VM} \leq \sigma_{ALL}$$

where:

$\sigma_{ALL}$  : Allowable stress, in N/mm<sup>2</sup>, to be taken equal to 0,55  $R_{eH}$

$R_{eH}$  : Minimum yield stress, in N/mm<sup>2</sup>, of the specified steel.  $R_{eH}$  is not to exceed the lower of 0,7  $R_m$  and 450 N/mm<sup>2</sup>

$R_m$  : Minimum ultimate tensile strength, in N/mm<sup>2</sup>, of the steel used.

When the loads are calculated for crash stop of the ship, the criteria given in [11.6.4] are to be complied with.

When fine mesh finite element analysis is used for the calculation of stresses, the criteria in Ch 8, App 2, [4] is to be applied using the permissible yield utilisation factors for the AC-2 criteria multiplied by  $\sigma_{ALL} / R_{eH}$ .

### 11.6.4 Strength check for crash stop of the ship

When the loads are calculated for crash stop of the ship, the Von Mises equivalent stress  $\sigma_{VM}$  in primary supporting members, calculated, in N/mm<sup>2</sup>, is to be checked with the following criteria:

$$\sigma_{VM} \leq \sigma_{CRASH}$$

where:

$$\sigma_{CRASH} = 1,25 \sigma_{ALL}$$

$\sigma_{ALL}$  : Allowable stress as defined in [11.6.3].

When fine mesh finite element analysis is used for the calculation of stresses, the criteria in Ch 8, App 2, [4] is to be applied using the permissible yield utilisation factors for the AC-2 criteria multiplied by  $\sigma_{CRASH} / R_{eH}$ .

## 11.7 Hull supports of the azimuth propulsion system

### 11.7.1 Analysis criteria

The scantlings of hull supports of the azimuth propulsion system are to be obtained by the Designer through direct calculations, to be carried out in accordance with the requirements in [11.6.1].

### 11.7.2 Loads

The loads to be considered in the direct calculation of the hull supports of the azimuth propulsion system are those specified in [11.6.2].

### 11.7.3 Strength check

It is to be checked that the Von Mises equivalent stress  $\sigma_{VM}$  in hull supports, in N/mm<sup>2</sup>, calculated for the load cases defined in [11.6.2], is in compliance with the following criteria:

$$\sigma_{VM} \leq \sigma_{ALL}$$

where:

$\sigma_{ALL}$  : Allowable stress, in N/mm<sup>2</sup>, equal to:

$$\sigma_{ALL} = 65 / k$$

$k$  : Material factor, defined in Ch 4, Sec 1, [2.2].

When the loads are calculated for crash stop of the ship, the criteria given in [11.7.4] is to be complied with.

Values of  $\sigma_{VM}$  greater than  $\sigma_{ALL}$  may be accepted by the Society on a case-by-case basis, depending on the localisation of  $\sigma_{VM}$  and on the type of direct calculation analysis.

When fine mesh finite element analysis is used for the calculation of stresses, the criteria in Ch 8, App 2, [4] is to be applied using the permissible yield utilisation factors for the AC-2 criteria multiplied by  $\sigma_{ALL} / R_{eH}$ .

### 11.7.4 Strength check for crash stop of the ship

When the loads are calculated for crash stop of the ship, the Von Mises equivalent stress  $\sigma_{VM}$  in primary supporting members, calculated, in N/mm<sup>2</sup>, is to be checked with the following criteria:

$$\sigma_{VM} \leq \sigma_{CRASH}$$

where:

$$\sigma_{CRASH} = 1,25 \sigma_{ALL}$$

$\sigma_{ALL}$  : Allowable stress as defined in [11.7.3].

When fine mesh finite element analysis is used for the calculation of stresses, the criteria in Ch 8, App 2, [4] is to be applied using the permissible yield utilisation factors for the AC-2 criteria multiplied by  $\sigma_{CRASH} / R_{eH}$ .

### 11.7.5 Buckling check

A local buckling check is to be carried out, for plate panels which constitute hull supports of the azimuth propulsion system, according to Ch 9, Sec 1 calculating the stresses in the plate panels according to [11.7.1] and [11.7.2].

## Section 2 Bulwarks and Guard Rails

### 1 General

#### 1.1 Application

1.1.1 Bulwarks or guard rails are to be provided at the boundaries of exposed freeboard and superstructure decks.

#### 1.2 General requirements

##### 1.2.1 Minimum height

Bulwarks or guard rails, are to be of 1,0 m in height as a minimum, measured above sheathing, and are to be constructed as required in [2.2] and [3.2]. Where this height would interfere with the normal operation of the ship, a lesser height may be accepted by the Society on a case-by-case basis.

1.2.2 Where superstructures are connected by trunks, open rails are to be fitted for the whole length of the exposed parts of the freeboard deck.

1.2.3 In type A and B-100 ships, open rails on the weather parts of the freeboard deck for at least half the length of the exposed parts are to be fitted.

Alternatively, freeing ports complying with Ch 11, Sec 12, [6.5.2] are to be fitted.

1.2.4 In ships with bulwarks and trunks of breadth not less than 0,6 B, which are included in the calculation of freeboard, open rails on the weather parts of the freeboard deck in way of the trunk for at least half the length of the exposed parts are to be fitted. Alternatively, freeing ports complying with Ch 11, Sec 12, [6.3.1] are to be fitted.

1.2.5 The freeing port area in the lower part of the bulwarks is to be in compliance with the applicable requirements of Ch 11, Sec 12, [6].

### 2 Bulwarks

#### 2.1 Construction of bulwarks

2.1.1 Bulwark plating is to be stiffened at the upper edge by a suitable rail and supported either by stays or brackets spaced not more than 2,0 m apart.

The free edge of the stay or bracket is to be stiffened.

Bulwarks are to be aligned with the beams located below or are to be connected to them by means of local transverse stiffeners.

As an alternative, the lower end of the stay may be supported by a longitudinal stiffener.

In type A, B-60 and B-100 ships, the spacing forward of 0,07 L from the fore end of brackets and stays is to be not greater than 1,2 m.

2.1.2 Bulwarks are to be arranged to ensure that they do not contribute to hull girder strength.

As a rule, bulwarks are not to be connected either to the upper edge of the sheerstrake plate or to the stringer plate.

Failing this, the detail of the connection will be examined by the Society on a case-by-case basis.

2.1.3 Bulwark plating and stays are to be adequately strengthened in way of eye plates used for shrouds or other tackles used for cargo gear operation, as well as in way of hawser holes or fairleads provided for mooring or towing.

2.1.4 Openings in bulwarks are to be arranged so that the protection of the crew is to be at least equivalent to that provided by the horizontal courses in [3.2.3].

For this purpose, vertical rails or bars spaced approximately 230 mm apart may be accepted in lieu of rails or bars arranged horizontally.

Cut-outs in bulwarks for gangways or other openings are to be kept clear of superstructures discontinuities.

Where bulwarks are cut completely, the scantlings of stays or brackets are to be increased with respect to those given in [2.2].

2.1.5 In the case of ships intended for the carriage of timber deck cargoes, the specific provisions of the freeboard regulations are to be complied with.

## **2.2 Scantlings**

### **2.2.1 Thickness**

The thickness of bulwarks on the freeboard deck not exceeding 1100 mm in height is to be not less than:

- 5,5 mm for  $L \leq 30$  m
- 6,0 mm for  $30 \text{ m} < L \leq 120$  m
- 6,5 mm for  $L > 120$  m.

Where the height of the bulwark is equal to or greater than 1800 mm, its thickness is to be equal to that calculated for the side of a superstructure situated in the same location as the bulwark, as obtained from Ch 11, Sec 5, [2.1.1], without being taken less than the minimum thicknesses specified above.

For bulwarks between 1100 mm and 1800 mm in height, their thickness is to be calculated by linear interpolation.

### **2.2.2 Stays**

The gross section modulus of stays in way of the lower part of the bulwark is to be not less than the value  $Z_{\text{stay-gr}}$  in  $\text{cm}^3$ , obtained from the following formula:

$$Z_{\text{stay-gr}} = 40 s_{\text{stay}} (1 + 0,01 L) h_{\text{blwk}}^2$$

where:

- $s_{\text{stay}}$  : Spacing of the stays, in m
- $L$  : Length of ship, in m, to be assumed not greater than 100 m
- $h_{\text{blwk}}$  : Height of bulwark from the top of the deck plating to the top of the rail, in m.

The Society may accept scantlings determined by direct calculations as an alternative to the above value of  $Z_{\text{stay-gr}}$ .

The actual section of the connection between stays and deck structures is to be taken into account when calculating the above section modulus.

To this end, the bulb or face plate of the stay may be taken into account only where welded to the deck; in this case the beam located below is to be connected by double continuous welding.

For stays with strengthening members not connected to the deck, the calculation of the required minimum section modulus is considered by the Society on a case-by-case basis.

At the ends of the ship, where the bulwark is connected to the sheerstrake, an attached plating having width not exceeding 600 mm may also be included in the calculation of the actual section modulus of stays.

**2.2.3** At the ends of partial superstructures and for the distance over which their side plating is tapered into the bulwark, the latter is to have the same thickness as the side plating; where openings are cut in the bulwark at these positions, adequate compensation is to be provided either by increasing the thickness of the plating or by other suitable means.

**2.2.4** Bulwarks located in the bow flare area as defined in Ch 11, Sec 1, [3.3] are to be reinforced according to Ch 11, Sec 1, [3], considering the stays as cantilever primary supporting members.

## **3 Guard rails**

### **3.1 General**

**3.1.1** Where guard rails are provided, the upper edge of sheerstrake is to be kept as low as possible.

**3.1.2** Where superstructures are connected by trunks, open rails are to be fitted along the whole length of the exposed parts of the freeboard deck.

**3.1.3** Guard rails fitted on superstructure and freeboard decks shall have at least three courses. In other locations, guard rails with at least two courses shall be fitted.

### **3.2 Construction of guard rails**

**3.2.1** Stanchions of guard rails are to comply with the following requirements:

- a) fixed, removable or hinged stanchions are to be fitted approximately 1,5 m apart
- b) at least every third stanchion is to be supported by a bracket or stay (other alternatives may be accepted under the requirements of [3.2.2])
- c) removable or hinged stanchions are to be capable of being locked in the upright position
- d) in the case of ships with rounded gunwales or sheerstrake, the stanchions are to be placed on the flat part of the deck
- e) in the case of ships with welded sheerstrake, the stanchions are not to be attached to the sheerstrake, an upstand or a continuous gutter bar.

**3.2.2** In lieu of at least every third stanchion supported by a stay, three other alternatives may be accepted:

- at least every third stanchion is of increased breadth:  $k b_s = 2,9 b_s$
- at least every second stanchion is of increased breadth:  $k b_s = 2,4 b_s$
- every stanchion is of increased breadth:  $k b_s = 1,9 b_s$

where:

$b_s$  : breadth of normal stanchion according to the design standard

Flat steel stanchions of increased breadth (see Fig 1) are to be aligned with member below deck. A minimum flat bar 100 x 12 is to be welded to deck by double continuous fillet welds with leg size of minimum 7 mm or as specified by the design standard.

The stanchions with increased breadth need not be aligned with under deck structure for deck plating exceeding 20 mm. This minimum plate thickness may be achieved by doubling plates.

**3.2.3** The size of openings, below the lowest course of rails and the deck or upstand, is to be a maximum of 230 mm. The distance between other courses is not to be greater than 380 mm.

**3.2.4** Wire ropes may be accepted, in lieu of guard rails, only in special circumstances and then only in limited lengths. In such cases, they are to be made taut by means of turnbuckles.

**3.2.5** Chains may be accepted, in lieu of guard rails, only where they are fitted between two fixed stanchions and/or bulwarks. If the opening is wide, the chains are to be fitted with vertical courses to prevent the horizontal courses from spreading apart.

**Figure 1 : Guard rail stanchion of increased breadth**

## Section 3 Propeller shaft brackets

### Symbols

$F_C$  : Force, in kN, taken equal to:

$$F_C = \left(\frac{2\pi N}{60}\right)^2 R_p P$$

$P$  : Mass of a propeller blade, in t

$N$  : Number of revolutions per minute of the propeller

$R_p$  : Distance, in m, of the centre of gravity of a blade in relation to the rotation axis of the propeller

$\sigma_{ALL}$  : Allowable stress, in N/mm<sup>2</sup>:

$$\sigma_{ALL} = 70 / k$$

$k$  : Material factor, as defined in Ch 4, Sec 1, [2.2]

$w_A$  : Section modulus, in cm<sup>3</sup>, of the arm at the level of the connection to the hull with respect to a transversal axis

$w_B$  : Section modulus, in cm<sup>3</sup>, of the arm at the level of the connection to the hull with respect to a longitudinal axis

$A$  : Sectional area, in cm<sup>2</sup>, of the arm

$A_S$  : Shear sectional area, in cm<sup>2</sup>, of the arm

$d_p$  : Propeller shaft diameter, in mm, measured inside the liner, if any.

## 1 Propeller shaft brackets

### 1.1 General

1.1.1 Propeller shafting is either enclosed in bossing or independent of the main hull and supported by shaft brackets.

### 1.2 Double arm propeller shaft brackets

#### 1.2.1 General

This type of propeller shaft bracket consists of two arms arranged, as far as practicable, at right angles and converging in the propeller shaft bossing.

Exceptions to this will be considered by the Society on a case by case basis.

#### 1.2.2 Scantlings of arms

The moment in the arm, in kN.m, is to be obtained from the following formula:

$$M = \frac{F_C}{\sin \alpha} \left( \frac{L}{\ell} d_1 \cos \beta + L - \ell \right)$$

where:

$\alpha$  : Angle between the two arms

$\beta$  : Angle defined in Fig 1

$d_1$  : Distance, in m, defined in Fig 1

$L, \ell$  : Lengths, in m, defined in Fig 2.

It is to be checked that the bending stress  $\sigma_F$ , the compressive stress  $\sigma_N$  and the shear stress  $\tau$  are in compliance with the following formula:

$$\sqrt{(\sigma_F + \sigma_N)^2 + 3\tau^2} \leq \sigma_{ALL}$$

where:

$$\sigma_F = \frac{M}{w_A} 10^3$$

$$\sigma_N = 10F_C \frac{L \sin \beta}{A \ell \sin \alpha}$$

$$\tau = 10F_C \frac{L \cos \beta}{A_S \ell \sin \alpha}$$

Figure 1 : Angle  $\beta$  and length  $d_1$

Figure 2 : Lengths  $L$  and  $\ell$

**1.2.3 Scantlings of propeller shaft bossing**

The length of the propeller shaft bossing is to be not less than the length of the aft sterntube bearing bushes (see Pt C, Ch 1, Sec 7, [2.4]).

The thickness of the propeller shaft bossing is to be not less than  $0,33 d_p$ .

**1.2.4 Bracket arm attachments**

In way of bracket arms attachments, the thickness of deep floors or girders is to be suitably increased. Moreover, the shell plating is to be increased in thickness and suitably stiffened.

The securing of the arms to the hull structure is to prevent any displacement of the brackets with respect to the hull.

**1.3 Single arm propeller shaft brackets**

**1.3.1 General**

This type of propeller shaft bracket consists of one arm and may be used only on ships less than 65 m in length.

**1.3.2 Scantlings of arms**

The moment in case of a single arm, in kN.m, is to be obtained from the following formula:

$$M = d_2 0,75 F_c \frac{L}{\ell}$$

where:

$d_2$  : Length of the arm, in m, measured between the propeller shaft axis and the hull

$L, \ell$  : Lengths, in m, defined in Fig 2.

It is to be checked that the bending stress  $\sigma_f$  and the shear stress  $\tau$  are in compliance with the following formula:

$$\sqrt{\sigma_f^2 + 3\tau^2} \leq \sigma_{ALL}$$

where:

$$\sigma_f = \frac{M}{w_B} 10^3$$

$$\tau = 10 F_c \frac{L}{A_S \ell}$$

**1.3.3 Scantlings of propeller shaft bossing**

The length of the propeller shaft bossing is to be not less than the length of the aft sterntube bearing bushes (see Pt C, Ch 1, Sec 7, [2.4]).

The thickness of the propeller shaft bossing is to be not less than  $0,33 d_p$ .

**1.3.4 Bracket arm attachments**

In way of bracket arms attachments, the thickness of deep floors or girders is to be suitably increased. Moreover, the shell plating is to be increased in thickness and suitably stiffened.

The securing of the arm to the hull structure is to prevent any displacement of the bracket with respect to the hull.

**1.4 Bossed propeller shaft brackets**

**1.4.1 General**

Where bossed propeller shaft brackets are fitted, their scantlings are to be considered by the Society on a case by case basis.

**1.4.2 Scantling of the boss**

The length of the boss is to be not less than the length of the aft sterntube bearing bushes (see Pt C, Ch 1, Sec 7, [2.4]).

The thickness of the boss, in mm, is to be not less than  $0,33 d_p$ .

The aft end of the bossing is to be adequately supported.

**1.4.3 Scantling of the end supports**

The scantlings of end supports are to be specially considered. Supports are to be adequately designed to transmit the loads to the main structure.

End supports are to be connected to at least two deep floors of increased thickness or connected to each other within the ship.

**1.4.4 Stiffening of the boss plating**

Stiffening of the boss plating is to be specially considered. At the aft end, transverse diaphragms are to be fitted at every frame and connected to floors of increased scantlings.

At the fore end, web frames spaced not more than four frames apart are to be fitted.

# Section 4 Equipment

## Symbols

- EN : Equipment Number defined in [1.2]
- $R_{eH}$  : Minimum yield stress, in N/mm<sup>2</sup>, of the material, defined in Ch 1, Sec 3, Tab 2
- $R_m$  : Tensile strength, in N/mm<sup>2</sup>, of the material, defined in Ch 1, Sec 3, Tab 2
- $\sigma_{ALL}$  : Allowable stress, in N/mm<sup>2</sup>, used for the yielding check in [3.9.7], [3.10.7], [3.11.2] and [3.11.3], to be taken as the lesser of:
- $\sigma_{ALL} = 0,67 R_{eH}$
  - $\sigma_{ALL} = 0,40 R_m$

## 1 General

### 1.1 Application

**1.1.1** The requirements of the present Article and Article [2] apply to temporary mooring of a ship within a harbour or sheltered area when the ship is awaiting a berth, the tide, etc.

Therefore, the equipment complying with these requirements:

- is not intended for holding a ship off fully exposed coasts in rough weather or for stopping a ship which is moving or drifting.
- is intended for holding a ship in good holding ground, where the conditions are such as to avoid dragging of the anchor. In poor holding ground the holding power of the anchors is significantly reduced.

**1.1.2** The required anchoring equipment in [1.2] is given considering the following environmental conditions:

- maximum current speed of 5 knots (2,5 m/s)
- maximum wind speed of 50 knots (25 m/s)
- no waves
- minimum scope of chain cable of 6, the scope being the ratio between length of chain paid out and water depth.

**1.1.3** As guidance for the limitations of the anchoring equipment used in semi-sheltered anchorages, the required anchoring equipment as defined in [1.2] can also be considered applicable for ships with the length  $L_E$  as defined in [1.2.2] greater than 135 m to the following environmental conditions including waves:

- maximum current speed of 3 knots (1,54 m/s)
- maximum wind speed of 21 knots (11 m/s)
- waves with maximum significant height of 2 m
- minimum scope of chain cable of 6, the scope being the ratio between length of chain paid out and water depth.

**1.1.4** For ships intended to anchor in deep and unsheltered water and assigned with the additional class notation **UNSHelterED ANCHORING** refer to additional applicable requirements in Pt F, Ch 11, Sec 4.

**1.1.5** It is assumed that under normal circumstances a ship uses only one bow anchor and chain cable at a time.

### 1.2 Equipment number

#### 1.2.1 General

All ships are to be provided with equipment in anchors and chain cables, to be obtained from Tab 1, based on their Equipment Number EN.

For ships having the navigation notation **coastal area** or **sheltered area**, the equipment in anchors and chain cables may be reduced. The reduction consists of entering in Tab 1 one line higher for ships having the navigation notation **coastal area** and two lines higher for ships having the navigation notation **sheltered area**, based on their Equipment Number EN.

Table 1 : Equipment

Equipment number EN A ≤ EN < B		Stockless bower anchors		Stud link chain cables for bower anchors			
		Number of anchors	Mass per anchor, in kg	Total length in m	Diameter, in mm		
A	B				Q1	Q2	Q3
50	70	2	180	220,0	14,0	12,5	
70	90	2	240	220,0	16,0	14,0	
90	110	2	300	247,5	17,5	16,0	
110	130	2	360	247,5	19,0	17,5	
130	150	2	420	275,0	20,5	17,5	
150	175	2	480	275,0	22,0	19,0	
175	205	2	570	302,5	24,0	20,5	
205	240	2	660	302,5	26,0	22,0	20,5
240	280	2	780	330,0	28,0	24,0	22,0
280	320	2	900	357,5	30,0	26,0	24,0
320	360	2	1020	357,5	32,0	28,0	24,0
360	400	2	1140	385,0	34,0	30,0	26,0

**1.2.2 Equipment Number formulae**

The Equipment Number EN is to be obtained from the following formula:

$$EN = \Delta^{2/3} + 2 (h B + S_{fun}) + 0,1 A$$

where:

A : Side projected area, in m<sup>2</sup>, of the hull, superstructures houses and funnels above the summer load waterline which are within the length L<sub>E</sub> and also have a breadth greater than B/4.

In case a single funnel is fitted on the ship, the side projected area is considered in A when A<sub>FS</sub> is greater than zero. In this case, the side projected area of the funnel should be calculated between the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the effective height h<sub>F</sub>.

In case several funnels are fitted on the ship, the total side projected area of the funnels is to be considered in the side projected area A when A<sub>FS</sub> is greater than zero.

In case of several funnels, the shielding effect of funnels in transverse direction may be considered in the total side projected area, i.e., when the side projected areas of two or more funnels fully or partially overlap, the overlapped area needs only to be counted once.

A<sub>FS</sub> : In case a single funnel is fitted on the ship, front projected area of the funnel, in m<sup>2</sup>, calculated between the upper deck at centreline, or notional deck line where there is local discontinuity in the upper deck, and the effective height h<sub>F</sub>. A<sub>FS</sub> is taken equal to zero if the funnel breadth is less than or equal to B/4 at all elevations along the funnel height.

In case several funnels are fitted on the ship, sum of the front projected area of each funnel, in m<sup>2</sup>, calculated between the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the effective height h<sub>F</sub>. A<sub>FS</sub> is to be taken equal to zero if the sum of each funnel breadth is less or equal to B/4 at all elevations along the funnels height.

a : Vertical distance at hull side, in m, from the Summer Load waterline amidships to the upper deck.

$h$  : Effective height, in m, from the summer load waterline to the top of the uppermost house, to be obtained in accordance with the following formula:

$$h = a + \sum h_n$$

When calculating  $h$ , sheer and trim are to be disregarded.

$h_F$  : In case a single funnel is fitted on the ship, effective height of the funnel, in m, measured from the upper deck at centreline, or notional deck line where there is local discontinuity in the upper deck, to the top of the funnel. The top of the funnel may be taken at the level where the funnel breadth reaches  $B/4$ .

In case several funnels are fitted on the ship, effective height of the funnel, in m, measured from the upper deck, or notional deck line where there is local discontinuity in the upper deck, to the top of the highest funnel. The top of the highest funnel may be taken at the level where the sum of each funnel breadth reaches  $B/4$ .

$h_n$  : Height, in m, at the centreline of tier “n” of superstructures or deckhouses having a breadth greater than  $B/4$ . Where a house having a breadth greater than  $B/4$  is above a house with a breadth of  $B/4$  or less, the upper house is to be included and the lower ignored.

For the lowest tier,  $h_i$  is to be measured at centreline from the upper deck or from a notional deck line where there is local discontinuity in the upper deck, see Fig 1.

$L_E$  : Equipment length, in m, equal to  $L$  without being taken neither less than 96% nor greater than 97% of the total length of the summer load waterline.

$S_{fun}$  : Effective front projected area of the funnel, in  $m^2$ , defined as:

$$S_{fun} = A_{FS} - S_{shield}$$

$S_{shield}$  : The section of front projected area  $A_{FS}$ , in  $m^2$ , which is shielded by all deck houses having breadth greater than  $B/4$ .

If there are more than one shielded section, the individual shielded sections i.e  $S_{shield1}$ ,  $S_{shield2}$ , etc., as shown in Fig 2 are to be added together.

To determine  $S_{shield}$ , the deckhouse breadth is assumed  $B$  for all deck houses having breadth greater than  $B/4$  as shown for  $S_{shield1}$ ,  $S_{shield2}$  in Fig 2.

$\Delta$  : Moulded displacement of the ship, in t, to the summer load waterline.

Fixed screens, fixed picture windows or bulwarks 1,5 m or more in height are to be regarded as parts of houses when determining  $h$  and  $A$ . In particular, the hatched area shown in Fig 3 is to be included. In case of non butt-jointed picture windows, only the efficient closed areas are to be included.

The height of hatch coamings and that of any deck cargo, such as containers, may be disregarded when determining  $h$  and  $A$ .

**1.2.3 Specific cases**

For ships of special design or ships engaged in special services or on special voyages, the Society may consider equipment other than that in Tab 1 on a case-by-case basis.

The Society may accept ships high equipment number ( $EN \geq 16000$ ). The determination of the equipment will be considered on a case-by-case basis.

However, the design of such equipment is to comply with the present Section and the requirements in NR216 Materials and Welding, Chapter 10."

**Figure 1 : Effective height h**

Figure 2 : Shielded sections

Figure 3 : Effective area of bulwarks or fixed screen to be included in the Equipment Number

## 2 Anchoring equipment

### 2.1 Anchors

#### 2.1.1 General

The anchors are to be of an approved type and satisfy the testing conditions laid down in NR216 Rules for Materials and Welding. The scantlings of anchors are to be in compliance with [2.1.2] to [2.1.7].

In general, stockless anchors are to be adopted.

Anchors are to be constructed and tested in compliance with approved plans.

#### 2.1.2 Ordinary anchors

The required mass for each bower anchor is to be obtained from Tab 1.

The individual mass of a main anchor may differ by  $\pm 7\%$  from the mass required for each anchor, provided that the total mass of anchors is not less than the total mass required in Tab 1.

The mass of the head of an ordinary stockless anchor, including pins and accessories, is to be not less than 60% of the total mass of the anchor.

Where a stock anchor is provided, the mass of the anchor, excluding the stock, is to be not less than 80% of the mass required in Tab 1 for a stockless anchor. The mass of the stock is to be not less than 25% of the mass of the anchor without the stock but including the connecting shackle.

#### 2.1.3 High and very high holding power anchors

High holding power (HHP) and very high holding power (VHHP) anchors, i.e. anchors for which a holding power higher than that of ordinary anchors has been proved according to NR216 Materials and Welding, Ch 10, Sec 1, do not require prior adjustment or special placement on the sea bottom.

Where HHP or VHHP anchors are used as bower anchors, the mass of each anchor is to be not less than 75% or 50%, respectively, of that required for ordinary stockless bower anchors in Tab 1.

The mass of VHHP anchors is to be, in general, less than or equal to 1500 kg.

### **2.1.4 Installation of chain cables and anchors on board**

The bower anchors are to be connected to their own chain cables and positioned on board ready for use.

To hold the anchor tight in against the hull or the anchor pocket, respectively, it is recommended to fit anchor lashings, e.g., a 'devil's claw'.

Anchor lashings should be designed to resist a load at least corresponding to twice the anchor mass plus 10 m of cable without exceeding 40% of the yield strength of the material.

### **2.1.5 Tests for high holding power anchors approval**

For approval of a HHP anchor, comparative full scale tests are to be performed to show that the holding power of the HHP anchor is at least twice the holding power of an ordinary stockless anchor of the same mass.

For approval as HHP anchors of a whole range of mass, such tests are to be carried out on anchors whose sizes are, as far as possible, representative of the full range of masses proposed. In this case, at least two anchors of different sizes are to be tested. The mass of the maximum size to be approved is to be not greater than 10 times the maximum size tested. The mass of the smallest is to be not less than 0,1 times the minimum size tested.

### **2.1.6 Tests for very high holding power anchors approval**

For approval of a VHHP anchor, comparative full scale tests are to be performed to show that the holding power of the VHHP anchor is to be at least four times the holding power of an ordinary stockless anchor of the same mass or at least twice the holding power of a previously approved HHP anchor of the same mass.

For approval as VHHP anchors of a whole range of mass, such tests are to be carried out on anchors whose sizes are, as far as possible, representative of the full range of masses proposed. In this case, at least three anchors of different sizes are to be tested, indicative of the bottom, middle and top of the mass range.

### **2.1.7 Specification for tests on high holding power and very high holding power anchors**

Full scale tests are to be performed on various types of sea bottom: soft mud or silt, sand or gravel and hard clay or similar compounded material.

Tests are generally to be carried out from a tug. Shore based tests may be accepted by the Society on a case-by-case basis.

The holding power test load is to be less than or equal to the proof load of the anchor, specified in NR216 Materials and Welding, Ch 10, Sec 1.

For each series of sizes, the two anchors selected for testing (ordinary stockless and HHP anchors for testing HHP anchors, ordinary stockless and VHHP anchors or, when ordinary stockless anchors are not available, HHP and VHHP anchors for testing VHHP anchors) are to have the same mass.

The length of chain cable connected to each anchor, having a diameter appropriate to its mass, is to be such that the pull on the shank remains horizontal. For this purpose a value of the ratio between the length of the chain cable paid out and the water depth equal to 10 is considered normal. A lower value of this ratio may be accepted by the Society on a case-by-case basis, without being less than 6.

Three tests are to be carried out for each anchor and type of sea bottom.

The pull is to be measured by dynamometer; measurements based on the RPM/bollard pull curve of tug may, however, be accepted instead of dynamometer readings.

Note is to be taken where possible of the stability of the anchor and its ease of breaking out.

## **2.2 Chain cables for bower anchors**

### **2.2.1 Material**

The anchor chain cables are classified as grade Q1, Q2 or Q3 depending on the type of steel used and its manufacture.

The characteristics of the steel used and the method of manufacture of chain cables are to be approved by the Society for each manufacturer. The material from which chain cables are manufactured and the completed chain cables themselves are to be tested in accordance with the applicable requirements of:

- NR216 Materials and Welding, Ch 10, Sec 2
- NR216 Materials and Welding, Ch 10, Sec 3.

Chain cables made of grade Q1 may not be used with high holding power and very high holding power anchors.

### **2.2.2 Scantlings of stud link chain cables**

The mass and geometry of stud link chain cables, including the links, are to be in compliance with the requirements in NR216 Materials and Welding, Ch 10, Sec 2.

The diameter of stud link chain cables is to be not less than the value in Tab 1.

### **2.2.3 Studless link chain cables**

For ships with EN less than 90, studless short link chain cables may be accepted by the Society as an alternative to stud link chain cables, provided that the equivalence in strength is based on proof load, defined in NR216 Materials and Welding, Ch 10, Sec 3, and that the steel grade of the studless chain is equivalent to the steel grade of the stud chains it replaces, as defined in [2.2.1].

**2.2.4 Anchor chain cable arrangement**

Anchor chain cables are to be made by lengths of 27,5 m each, joined together by Dee or lugless shackles.

The total length of chain cable, required in Tab 1, is to be divided in approximately equal parts between the two anchors ready for use.

Where different arrangements are provided, they are considered by the Society on a case-by-case basis.

**2.3 Attachment pieces**

**2.3.1 General**

Where the lengths of chain cable are joined to each other by means of shackles of the ordinary Dee type, the anchor may be attached directly to the end link of the first length of chain cable by a Dee type end shackle.

A detachable open link in two parts riveted together may be used in lieu of the ordinary Dee type end shackle; in such case the open end link with increased diameter, defined in [2.3.2], is to be omitted.

Where the various lengths of chain cable are joined by means of lugless shackles and therefore no special end and increased diameter links are provided, the anchor may be attached to the first length of chain cable by a special pear-shaped lugless end shackle or by fitting an attachment piece.

**2.3.2 Scantlings**

The diameters of the attachment pieces, in mm, are to be not less than the values indicated in Tab 2.

Attachment pieces may incorporate the following items between the increased diameter stud link and the open end link:

- swivel, having diameter = 1,2 d
- increased stud link, having diameter = 1,1 d.

Where different compositions are provided, they will be considered by the Society on a case-by-case basis.

**Table 2 : Diameters of attachment pieces**

Attachment piece	Diameter, in mm
End shackle	1,4 d
Open end link	1,2 d
Increased stud link	1,1 d
Common stud link	d
Lugless shackle	d
<b>Note 1:</b> d : Diameter, in mm, of the common link.	

**2.3.3 Material**

Attachment pieces, joining shackles and end shackles are to be of such material and design as to provide strength equivalent to that of the attached chain cable, and are to be tested in accordance with the applicable requirements of NR216 Materials and Welding, Chapter 10.

**2.4 Hawse pipes**

**2.4.1** Hawse pipes are to be of substantial construction. Their position and slope are to be arranged so as to facilitate housing and dropping of the anchors and avoid damage to the hull during these operations. The parts on which the chains bear are to be rounded to a suitable radius.

**2.4.2** All mooring units and accessories, such as tumbler, riding and trip stoppers are to be securely fastened, to the Surveyor's satisfaction.

**2.5 Windlass**

**2.5.1 General**

Considering the windlass brake capacity defined in [2.5.2], the anchor windlass is to comply with the applicable requirements given in NR626 Anchor Windlass and Chain Stopper.

**2.5.2 Brake capacity**

Based on mooring line arrangements with brakes engaged and cable lifter disengaged, the capacity HL (Holding Load), in kN, of the windlass brake is to be sufficient to withstand the following design loads without any permanent deformation of the stressed parts and without brake slip:

- 0,8 times the breaking load BL of the chain, if not combined with a chain stopper
- 0,45 times the breaking load BL of the chain, if combined with a chain stopper.

## 2.6 Chain stopper

**2.6.1** A chain stopper is generally to be fitted between the windlass and the hawse pipe in order to relieve the windlass of the pull of the chain cable when the ship is at anchor. The chain stopper is to comply with applicable requirements given in the Rule Note NR626 Anchor Windlass.

The chain stopper is to comply with the applicable requirements given in NR626 Anchor Windlass and Chain Stopper.

**2.6.2** Where the windlass is at a distance from the hawse pipes and no chain stoppers are fitted, suitable arrangements are to be provided to lead the chain cables to the windlass.

## 2.7 Chain locker

**2.7.1** The capacity of the chain locker is to be adequate to stow all chain cable equipment and provide an easy direct lead to the windlass.

**2.7.2** Where two chains are used, the chain lockers are to be divided into two compartments, each capable of housing the full length of one line.

**2.7.3** The inboard ends of chain cables are to be secured to suitably reinforced attachments in the structure by means of end shackles, whether or not associated with attachment pieces.

Generally, such attachments are to be able to withstand a force not less than 15% of the breaking load of the chain cable.

In an emergency, the attachments are to be easily released from outside the chain locker.

**2.7.4** The chain locker boundaries and access openings are to be watertight. Provisions are to be made to minimise the probability of the chain locker being flooded in bad weather. Adequate drainage facilities for the chain locker are to be provided.

**2.7.5** Spurling pipes and chain lockers are to be watertight up to the weather deck.

Bulkheads between separate chain lockers (see Fig 4, Arrangement 1) or which form a common boundary of chain lockers (see Fig 4, Arrangement 2), need not however be watertight.

**2.7.6** Where means of access is provided, it is to be closed by a substantial cover and secured by closely spaced bolts.

**2.7.7** Where a means of access to spurling pipes or cable lockers is located below the weather deck, the access cover and its securing arrangements are to be in accordance with recognized standards or equivalent for watertight manhole covers. Butterfly nuts and/or hinged bolts are prohibited as the securing mechanism for the access cover.

**2.7.8** Spurling pipes through which anchor cables are led are to be provided with permanently attached closing appliances, to minimize water ingress.

Examples of arrangements for permanently attached closing appliances are such as steel plates with cut-outs to accommodate chain links or canvas hoods with a lashing arrangement that maintains the cover in the secured position.

## 3 Emergency towing arrangement

### 3.1 Definitions

#### 3.1.1 Deadweight

*Deadweight is the difference, in t, between the displacement of a ship in water of a specific gravity of 1,025 t/m<sup>3</sup> at the summer load line corresponding to the assigned summer freeboard and the lightweight of the ship.*

### 3.2 Application

**3.2.1** The requirements of this Article apply to equipment arrangement for towing ships out of danger in emergencies such as complete mechanical breakdowns, loss of power or loss of steering capability.

The concerned ships are:

- the ships as defined in [3.2.2]
- all ships when the additional class notation **ETA** is assigned.

**3.2.2** An emergency towing arrangement is to be fitted at both ends on board of ships of 20000 t deadweight and above with one of the following service notations:

- **combination carrier ESP**
- **oil tanker ESP**
- **FLS tanker**
- **chemical tanker ESP**
- **liquefied gas carrier.**

**3.3 Documentation**

**3.3.1 Documentation for approval**

In addition to the documents in Ch 1, Sec 4, the following documentation is to be submitted to the Society for approval:

- general layout of the bow and stern towing arrangements and associated equipment
- operation manual for the bow and stern towing arrangements
- construction drawings of the bow and stern strongpoints (towing brackets or chain cable stoppers) and fairleads (towing chocks), together with material specifications and relevant calculations
- drawings of the local ship structures supporting the loads applied by strongpoints, fairleads and roller pedestals.

**3.3.2 Documentation for information**

The following documentation is to be submitted to the Society for information (see Ch 1, Sec 4):

- specifications of chafing gears, towing pennants, pick-up gears and roller fairleads
- height, in m, of the lightest seagoing ballast freeboard measured at stern towing fairlead
- deadweight, in t, of the ship at summer load line.

**3.4 General**

**3.4.1 Scope**

*The emergency towing arrangements are to be so designed as to facilitate salvage and emergency towing operations on the concerned ship, primarily to reduce the risk of pollution.*

**3.4.2 Main characteristics**

*The emergency towing arrangements are, at all times, to be capable of rapid deployment in the absence of main power on the ship to be towed and easy connection to the towing ship.*

To demonstrate such rapid and easy deployment, the emergency towing arrangements are to comply with the requirements in [3.12].

**3.4.3 Typical layout**

*Fig 5 shows an emergency towing arrangement which may be used as reference.*

**3.4.4 List of major components**

*The major components of the towing arrangements, their position on board and the requirements of this Article which they are to comply with are defined in Tab 3.*

**3.4.5 Inspection and maintenance**

*All the emergency towing arrangement components are to be inspected by ship personnel at regular intervals and maintained in good working order.*

**Table 3 : Major components of the emergency towing arrangement**

Towing component	Non pre-rigged	Pre-rigged	Reference of applicable requirements
Towing pennant	Optional	Required	[3.7]
Fairlead	Required	Required	[3.9]
Strongpoint (inboard end fastening of the towing gear)	Required	Required	[3.10]
Pick-up gear	Optional	Required	No requirement
Pedestal roller fairlead	Required	Depending on design	No requirement

Towing component	Forward	Afterward	Reference of applicable requirements
Chafing gear	Required	Depending on design	[3.8]

Figure 5 : Typical emergency towing arrangement

### 3.5 Emergency towing arrangement approval

#### 3.5.1 General

Emergency towing arrangements of ships are to comply with the following requirements:

- they are to comply with the requirements of this item
- they are to be type approved according to the requirements in [3.13]
- Certificates of inspection of materials and equipment are to be provided according to [3.13.2]
- fitting on board of the emergency towing arrangements is to be witnessed by a Surveyor of the Society and a relevant Certificate is to be issued
- demonstration of the rapid deployment according to the criteria in [3.12] is to be effected for each ship and this is to be reported in the above Certificate.

#### 3.5.2 Alternative to testing the rapid deployment for each ship

At the request of the Owner, the testing of the rapid deployment for each ship according to [3.5.1] may be waived provided that:

- the design of emergency towing arrangements of the considered ship is identical to the type approved arrangements and this is confirmed by the on board inspection required in [3.5.1]
- the strongpoints (chain stoppers, towing brackets or equivalent fittings) are type approved (prototype tested).

In this case, an exemption certificate is to be issued.

In general, such dispensation may be granted to subsequent ships of a series of identical new buildings fitted with identical arrangements.

### 3.6 Safe working load (SWL) of towing pennants, chafing gears, fairleads and strongpoints

#### 3.6.1 Safe working load

The safe working load (defined as one half of the ultimate strength) of towing pennants, chafing gear, fairleads and strongpoints is to be not less than that obtained, in kN, from Tab 4.

The strength of towing pennants, chafing gear, fairleads and strongpoints is to be sufficient for all pulling angles of the towline, i.e. up to 90° from the ship's centreline to port and starboard and 30° vertical downwards.

The safe working load of other components is to be sufficient to withstand the load to which such components may be subjected during the towing operation.

Table 4 : Safe working load

Ship deadweight DWT, in t	Safe working load, in kN
20000 ≤ DWT < 50000	1000
DWT ≥ 50000	2000

### 3.7 Towing pennant

#### 3.7.1 Material

The towing pennant may be made of steel wire rope or synthetic fibre rope, which is to comply with the applicable requirements in NR216 Materials and Welding, Ch 10, Sec 5.

#### 3.7.2 Length of towing pennant

The length  $\ell_p$  of the towing pennant is to be not less than that obtained, in m, from the following formula:

$$\ell_p = 2H + 50$$

where:

$H$  : Lightest seagoing ballast freeboard measured, in m, at the fairlead.

#### 3.7.3 Minimum breaking strength of towing pennants when separate chafing gear is used

Where a separate chafing gear is used, the minimum breaking strength  $MBS_p$  of towing pennants, including their terminations, is to be not less than that obtained from the following formula:

$$MBS_p = 2 \text{ SWL}$$

where:

SWL : Safe working load of the towing pennants, defined in [2.6.1].

#### 3.7.4 Minimum breaking strength of towing pennants when no separate chafing gear is used

Where no separate chafing gear is used (i.e. where the towing pennant may chafe against the fairlead during towing operation), the minimum breaking strength of the towing pennants  $MBS_{PC}$  is to be not less than that obtained, in kN, from the following formula:

$$MBS_{PC} = \phi MBS_p$$

where:

$MBS_p$  : Minimum breaking strength, in kN, defined in [3.7.3]

$\phi$  : Coefficient to be taken equal to:

$$\phi = \frac{2\sqrt{\rho}}{2\sqrt{\rho} - 1}$$

$\phi$  may be taken equal to 1,0 if tests carried out under a test load equal to twice the safe working load defined in [3.6.1] demonstrate that the strength of the towing pennants is satisfactory

$\rho$  : Bending ratio (ratio between the minimum bearing surface diameter of the fairlead and the towing pennant diameter), to be taken not less than 7.

#### 3.7.5 Towing pennant termination

For towing connection, the towing pennant is to have a hard eye-formed termination allowing connection to a standard shackle.

Socketed or ferrule-secured eye terminations of the towing pennant are to be type tested in order to demonstrate that their minimum breaking strength is not less than twice the safe working load defined in [3.6.1].

### 3.8 Chafing gear

#### 3.8.1 General

Different solutions for the design of chafing gear may be used.

If a chafing chain is to be used, it is to have the characteristics defined in the following requirements.

#### 3.8.2 Type

Chafing chains are to be stud link chains.

#### 3.8.3 Material

In general, grade Q3 chain cables and associated accessories complying with the applicable requirements in:

- NR216 Materials and Welding, Ch 10, Sec 2
- NR216 Materials and Welding, Ch 10, Sec 3

are to be used.

#### 3.8.4 Chafing chain length

The chafing chain is to be long enough to ensure that the towing pennant, or the towline, remains outside the fairlead during the towing operation. A chain extending from the strongpoint to a point at least 3 m beyond the fairlead complies with this requirement.

#### 3.8.5 Minimum breaking strength

The minimum breaking strength of the stud link chafing chain and the associated links is to be not less than twice the safe working load defined in [3.6.1].

**3.8.6 Diameter of the common links**

The diameter of the common links of stud link chain cables is to be not less than:

- 52 mm for a safe working load, defined in [3.6.1], equal to 1000 kN
- 76 mm for a safe working load, defined in [3.6.1], equal to 2000 kN.

**3.8.7 Chafing chain ends**

One end of the chafing chain is to be suitable for connection to the strongpoint. Where a chain stopper is used, the inboard end of the chafing chain is to be efficiently secured in order to prevent any inadvertent loss of the chafing chain when operating the stopping device. Where the chafing chain is connected to a towing bracket, the corresponding chain end may be constructed as shown in Fig 6, but the inner dimension of the pear link may be taken as 5,30 d (instead of 5,75 d).

The other end of the chafing chain is to be fitted with a standard pear-shaped open link allowing connection to a standard bow shackle. A typical arrangement of this chain end is shown in Fig 6. Arrangements different than that shown in Fig 6 are considered by the Society on a case-by-case basis.

**3.8.8 Storing**

The chafing chain is to be stored and stowed in such a way that it can be rapidly connected to the strongpoint.

**Figure 6 : Typical outboard chafing chain end**

**3.9 Fairleads**

**3.9.1 General**

Fairleads are normally to be of a closed type (such as Panama chocks).

Fairleads are to have an opening large enough to pass the largest portion of the chafing gear, towing pennant or towline. The corners of the opening are to be suitably rounded.

Where the fairleads are designed to pass chafing chains, the openings are to be not less than 600mm in width and 450mm in height.

**3.9.2 Material**

Fairleads are to be made of fabricated steel plates or other ductile materials such as weldable forged or cast steel complying with the applicable requirements of:

- NR216 Materials and Welding, Chapter 3 (steel plate)
- NR216 Materials and Welding, Chapter 5 (steel forgings)
- NR216 Materials and Welding, Chapter 6 (steel castings).

**3.9.3 Operating condition**

The fairleads are to give adequate support for the towing pennant during towing operation, which means bending 90° to port and starboard side and 30° vertical downwards.

**3.9.4 Positioning**

The fairleads are to be located so as to facilitate towing from either side of the bow or stern and minimise the stress on the towing system.

The fairleads are to be located as close as possible to the deck and, in any case, in such a position that the chafing chain is approximately parallel to the deck when it is under strain between the strongpoint and the fairlead.

Furthermore, the bow and stern fairleads are normally to be located on the ship's centreline. Where it is practically impossible to fit the towing fairleads exactly on the ship's centreline, it may be acceptable to have them slightly shifted from the centreline.

### **3.9.5 Bending ratio**

The bending ratio (ratio between the towing pennant bearing surface diameter and the towing pennant diameter) is to be not less than 7.

### **3.9.6 Fairlead lips**

The lips of the fairlead are to be suitably faired in order to prevent the chafing chain from fouling on the lower lip when deployed or during towing.

### **3.9.7 Yielding check**

The equivalent Von Mises stress  $\sigma_E$ , in N/mm<sup>2</sup>, induced in the fairlead by a load equal to the safe working load defined in [3.6.1], is to comply with the following formula:

$$\sigma_E \leq \sigma_{ALL}$$

Areas subjected to stress concentrations are considered by the Society on a case-by-case basis.

Where the fairleads are analysed through standard mesh finite element models, the allowable stress may be taken as 1,1  $\sigma_{ALL}$ .

### **3.9.8 Alternative to the yielding check**

The above yielding check may be waived provided that fairleads are tested with a test load equal to twice the safe working load defined in [3.6.1] and this test is witnessed by a Surveyor of the Society. In this case, the Designer is responsible for ensuring that the fairlead scantlings are sufficient to withstand such a test load.

Unless otherwise agreed by the Society, components subjected to this test load are considered as prototype items and are to be discarded.

## **3.10 Strongpoint**

### **3.10.1 General**

The strongpoint (inboard end fastening of the towing gear) is to be a chain cable stopper or a towing bracket or other fitting of equivalent strength and ease of connection. The strongpoint can be designed integral with the fairlead.

The strongpoint is to be type approved according to [3.13] and is to be clearly marked with its SWL.

### **3.10.2 Materials**

The strongpoint is to be made of fabricated steel or other ductile materials such as forged or cast steel complying with the applicable requirements of:

- NR216 Materials and Welding, Chapter 3 (steel plate)
- NR216 Materials and Welding, Chapter 5 (steel forgings)
- NR216 Materials and Welding, Chapter 6 (steel castings).

Use of spheroidal graphite cast iron (SG iron) may be accepted for the main framing of the strongpoint provided that:

- the part concerned is not intended to be a component part of a welded assembly
- the SG iron is of ferritic structure with an elongation not less than 12%
- the yield stress at 0,2% is measured and certified
- the internal structure of the component is inspected by suitable non-destructive means.

The material used for the stopping device (pawl or hinged bar) of chain stoppers and for the connecting pin of towing brackets is to have mechanical properties not less than those of grade Q3 chain cables, defined in NR216 Materials and Welding, Chapter 10.

### **3.10.3 Typical strongpoint arrangement**

Typical arrangements of chain stoppers and towing brackets are shown in Fig 7, which may be used as reference.

Chain stoppers may be of the hinged bar type or pawl (tongue) type or of other equivalent design.

### **3.10.4 Position and operating condition**

The operating conditions and the positions of the strongpoints are to comply with those defined in [3.9.3] and [3.9.4], respectively, for the fairleads.

### **3.10.5 Stopping device**

The stopping device (chain engaging pawl or bar) is to be arranged, when in closed position, to prevent the chain stopper from working in the open position, in order to avoid chain cable release and allow it to pay out.

Stopping devices are to be easy and safe to operate and, in the open position, are to be properly secured.

### **3.10.6 Connecting pin of the towing bracket**

The scantlings of the connecting pin of the towing bracket are to be not less than those of a pin of a grade Q3 end shackle, as shown in Fig 7, provided that clearance between the two side lugs of the bracket does not exceed 2,0d, where d is the chain diameter specified in [3.8.6] (see also Fig 6).

**3.10.7 Yielding check**

The equivalent Von Mises stress  $\sigma_{E}$ , in N/mm<sup>2</sup>, induced in the strongpoint by a load equal to the safe working load defined in [3.6.1], is to comply with the following formula:

$$\sigma_E \leq \sigma_{ALL}$$

Areas subjected to stress concentrations are considered by the Society on a case-by-case basis.

Where the strongpoints are analysed through standard mesh finite element models, the allowable stress may be taken as 1,1  $\sigma_{ALL}$ .

**3.10.8 Alternative to the yielding check**

The above yielding check may be waived provided that strongpoints are tested with a test load equal to twice the safe working load defined in [3.6.1] and this test is witnessed by a Surveyor. In this case, the Designer is responsible for ensuring that the fairlead scantlings are sufficient to withstand such a test load.

Unless otherwise agreed by the Society, components subjected to this test load are considered as prototype items and are to be discarded.

**3.10.9 Bolted connection**

Where a chain stopper or a towing bracket is bolted to a seating welded to the deck, the bolts are to be relieved from shear force by means of efficient thrust chocks capable of withstanding a horizontal force equal to 1,3 times the safe working load defined in [3.6.1] within the allowable stress defined in [3.10.7].

The steel quality of bolts is to be not less than grade 8.8 as defined by ISO standard No. 898/1.

Bolts are to be pre-stressed in compliance with appropriate standards and their tightening is to be suitably checked.

**Figure 7 : Typical strongpoint arrangement**

### **3.11 Hull structures in way of fairleads or strongpoints**

#### **3.11.1 Materials and welding**

The materials used for the reinforcement of the hull structure in way of the fairleads or the strongpoints are to comply with the applicable requirements of NR216 Materials and Welding.

Main welds of the strongpoints with the hull structure are to be 100% inspected by adequate non-destructive tests.

#### **3.11.2 Yielding check of bulwark and stays**

The equivalent Von Mises stress  $\sigma_E$ , in N/mm<sup>2</sup>, induced in the bulwark plating and stays in way of the fairleads by a load equal to the safe working load defined in [3.6.1], for the operating condition of the fairleads defined in [3.9.3], is to comply with the following formula:

$$\sigma_E \leq \sigma_{ALL}$$

#### **3.11.3 Yielding check of deck structures**

The equivalent Von Mises stress  $\sigma_E$ , in N/mm<sup>2</sup>, induced in the deck structures in way of chain stoppers or towing brackets, including deck seatings and deck connections, by a horizontal load equal to 1,3 times the safe working load defined in [3.6.1], is to comply with the following formula:

$$\sigma_E \leq \sigma_{ALL}$$

#### **3.11.4 Minimum gross thickness of deck plating**

The gross thickness of the deck is to be not less than:

- 12 mm for a safe working load, defined in [3.6.1], equal to 1000 kN
- 15 mm for a safe working load, defined in [3.6.1], equal to 2000 kN.

### **3.12 Rapid deployment of towing arrangement**

#### **3.12.1 General**

*To facilitate approval of towing arrangements and to ensure rapid deployment, emergency towing arrangements are to comply with the requirements of this item.*

#### **3.12.2 Marking**

*All components, including control devices, of the emergency towing arrangements are to be clearly marked to facilitate safe and effective use even in darkness and poor visibility.*

#### **3.12.3 Aft arrangement**

*The aft emergency towing arrangement is to be pre-rigged and be capable of being deployed in a controlled manner in harbour conditions in not more than 15 minutes.*

*The pick-up gear for the aft towing pennant is to be designed at least for manual operation by one person taking into account the absence of power and the potential for adverse environmental conditions that may prevail during such emergency towing operations.*

*The pick-up gear is to be protected against the weather and other adverse conditions that may prevail.*

#### **3.12.4 Forward**

*The forward emergency towing arrangement is to be capable of being deployed in harbour conditions in not more than 1 hour.*

*The forward emergency towing arrangement is to be designed at least with a means of securing a tow line to the chafing gear using a suitably positioned pedestal roller to facilitate connection of the towing pennant.*

*Forward emergency towing arrangements which comply with the requirements for aft emergency towing arrangements may be accepted.*

### **3.13 Type approval**

#### **3.13.1 Type approval procedure**

Emergency towing arrangements are to be type approved according to the following procedure:

- the arrangement design is to comply with the requirements of this Section
- each component of the towing arrangement is to be tested and its manufacturing is to be witnessed and certified by a Surveyor according to [3.13.2]
- prototype tests are to be carried out in compliance with [3.13.3].

#### **3.13.2 Inspection and certification**

The materials and equipment are to be inspected and certified as specified in Tab 5.

**3.13.3 Prototype tests**

Prototype tests are to be witnessed by a Surveyor and are to include the following:

- demonstration of the rapid deployment according to the criteria in [3.12]
- load test of the strongpoints (chain stoppers, towing brackets or equivalent fittings) under a proof load equal to 1,3 times the safe working load defined in [3.6.1].

A comprehensive test report duly endorsed by the Surveyor is to be submitted to the Society for review.

**Table 5 : Material and equipment certification status**

Component	Material		Equipment	
	Certificate	Reference of applicable requirements	Certificate	Reference of applicable requirements
Towing pennant	Not applicable	[3.7.1]	COI (1)	[3.7]
Chafing chain and associated accessories	COI (2)	[3.8.3]	COI (1)	[3.8]

**4 Towing and mooring arrangement**

**4.1 General**

**4.1.1 Condition of classification**

The towing and mooring arrangement as defined in Ch 12, App 2, [1] and the towing and mooring lines as defined in Ch 12, App 2, [2] are given as a guidance but are not required as a condition of classification.

**4.2 Shipboard fittings and supporting hull structures associated with towing and mooring**

**4.2.1 Definitions**

- “Normal towing” means towing operations necessary for manoeuvring in ports and sheltered waters associated with the normal operations of the ship.
- “Escort towing” means towing operations required in specific estuaries, in particular, for laden oil tankers or LNG carriers. Its main purpose is to control the ship in case of failures of the propulsion or steering system.
- “Other towing” means towing operations necessary for towing the ship by another ship or a tug, e.g. such as to assist the ship in case of emergency, for ships not assigned with the additional class notation **ETA**.
- “Emergency towing” means towing operations to assist the ship in case of emergency, for ships assigned with the additional class notation **ETA**.
- “Canal transit towing” means towing operations for ships transiting canals, e.g. the Panama Canal.
- “Shipboard fittings” means the components limited to the following: bollards and bits, fairleads, stand rollers, chocks used for mooring and similar components used for normal, escort and other towing operations. Other components such as capstans, winches, etc. are not covered by the present sub-article. Any weld or bolt or equivalent device connecting the shipboard fitting to the supporting structure is part of the shipboard fitting and if selected from an recognised standard subject to that standard.

- “Supporting hull structure” means the part of the ship structure on/in which the shipboard fitting is placed and which is directly submitted to the forces exerted on the shipboard fitting. The supporting hull structure of capstans, winches, etc. used for mooring and for normal, escort and other towing operations is also subject to the present sub-article.
- The “nominal capacity condition” is defined as the theoretical condition where the maximum possible deck cargoes are included in the ship arrangement in their respective positions. For ships carrying containers, the nominal capacity condition represents the theoretical condition where the maximum possible number of containers is included in the ship arrangement in their respective positions.
- “Ship Design Minimum Breaking Load” ( $MBL_{SD}$ ) means the minimum breaking load of new, dry mooring lines or tow line for which shipboard fittings and supporting hull structures are designed in order to meet mooring restraint requirements or the towing requirements of other towing service.
- “Line Design Break Force” (LDBF) means the minimum force that a new, dry, spliced, mooring line will break at. This is for all synthetic cordage materials.  
LDBF is to be neither less than 100% nor greater than 105% of the  $MBL_{SD}$ .

**4.2.2 Application**

Requirements under the present sub-article apply to:

- conventional ships, i.e. displacement-type ships of 500 GT and above, excluding special purpose ships as defined in the IMO resolution MSC.266(84)
- shipboard fittings used for mooring and for normal, escort and other towing operations
- supporting hull structure under shipboard fittings used for mooring and for normal, escort and other towing operations
- supporting hull structure under winches and capstans used for mooring operations.

Requirements under the present sub-article do not apply for following towing operations:

- emergency towing: refer to Article [3]
- canal transit towing: reference is to be made to local canal transit requirements.

**4.2.3 Arrangement**

The strength of shipboard fittings used for mooring and for normal, escort and other towing operations at bow, sides and stern, and of their supporting hull structures are to comply with the present sub-article.

The strength of supporting hull structures of winches and capstans used for mooring are to comply with the present sub-article as well.

Shipboard fittings, winches and capstans are to be located on stiffeners and/or girders, which are part of the deck construction so as to facilitate efficient distribution of the towing and mooring loads.

The reinforced members beneath shipboard fittings are to be effectively arranged for any variation of direction (horizontally and vertically) of the mooring and towing forces acting upon the shipboard fittings, see Fig 8 for a sample arrangement. Proper alignment of fitting and supporting hull structure is to be ensured.

Other arrangements may be accepted (for chocks in bulwarks, etc.) provided the strength is confirmed adequate for the intended service.

**Figure 8 : Reinforced members beneath shipboard fittings**

**4.2.4 Selection of shipboard fittings**

Shipboard fittings may be selected from a recognised standard accepted by the Society (ISO standard for example) and at least based on the following loads:

- Normal towing operations: the intended maximum towing load (e.g. static bollard pull) as indicated on the towing and mooring arrangements plan
- Escort or other towing operations: the  $MBL_{SD}$  of the tow line according to Ch 12, App 2
- For fittings intended to be used for, both, normal and escort or other towing operations, the greater of the loads according to a) and b)
- Mooring operations: the  $MBL_{SD}$  of the mooring line according to Ch 12, App 2.

Towing bits (double bollards) may be chosen for the towing line attached with eye splice if the recognised standard distinguishes between different methods to attach the line, i.e. figure-of-eight or eye splice attachment, see Fig 9.

Mooring bitts (double bollards) are to be chosen for the mooring line attached in figure-of-eight fashion if the recognised standard distinguishes between different methods to attach the line, i.e. figure-of-eight or eye splice attachment, see Fig 10.

When the shipboard fitting is not selected from an accepted standard:

- The design load used to assess its strength and its attachment to the ship is to be in accordance with [4.2.5].
- Towing bitts (double bollards) are required to resist the loads caused by the towing line attached with eye splice
- Mooring bitts (double bollards) are required to resist the loads caused by the mooring line attached in figure-of-eight fashion.
- At the discretion of the Society, load tests may be accepted as alternative to strength assessment by calculations.

Note 1: With the line attached to a mooring bitt in the usual way (figure-of-eight fashion), either of the two posts of the mooring bitt can be subjected to a force twice as large as that acting on the mooring line.

**Figure 9 : Attachment point of the towing line on bollard and bitts**

**Figure 10 : Attachment point of the mooring line on bollard and bitts**

**4.2.5 Design load**

The design load is to be applied to fittings in all directions that may occur by taking into account the arrangement shown on the mooring and towing arrangements plan. Where the mooring or towing line takes a turn at a fitting the total design load applied to the fitting is equal to the resultant of the design loads acting on the line, see Fig 11.

However, in no case does the design load applied to the fitting need to be greater than twice the design load on the line.

The acting point of the force on shipboard fittings is to be taken at the attachment point of the mooring or towing line or at a change in its direction. For bollards and bitts the attachment point of the line is to be taken not less than 4/5 of the tube height above the base, see Fig 9 and Fig 10.

However, if fins are fitted to the bollard tubes to keep the mooring line as low as possible, the attachment point of the mooring line may be taken at the location of the fins, see b) in Fig 10.

The design load to be applied to supporting hull structures and to shipboard fittings not selected from a recognised standard, in kN, is to be taken equal to:

- a) Normal towing operations:  
1,25 times the greater of the intended maximum towing load (e.g. static bollard pull) and the safe towing load TOW requested by the applicant, see [4.2.8]
- b) Escort or other towing operations:  
the greater of the ship design minimum breaking load according to Ch 12, App 2 and 1,25 times the safe towing load TOW requested by the applicant, see [4.2.8]
- c) For fittings intended to be used for, both, normal and escort or other towing operations:  
the greater of the design loads according to a) and b).
- d) Mooring operations:  
1,15 times the greater of the  $MBL_{SD}$  of the mooring line according to Ch 12, App 2 and the SWL of the shipboard fitting requested by the applicant, see [4.2.9].

The design load to be applied to supporting hull structure of winches and capstans used for mooring operations, in kN, is to be taken equal to:

- Supporting hull structure of winches:  
1,25 times the intended maximum brake holding load, see notes below.
- Supporting hull structure of capstans:  
1,25 times the maximum hauling-in force.

Note 1: The maximum brake holding load of winches used for mooring operations is to be assumed not less than 80% of the  $MBL_{SD}$  of the mooring line according to Ch 12, App 2, [2].

Note 2: The  $MBL_{SD}$  of tow and mooring lines taken in Ch 12, App 2, Tab 1 are to be based on an Equipment Number calculated according to [1.2.2] with a side projected area A including deck cargoes as given by the ship nominal capacity condition defined in [4.2.1].

Note 3: The increase of the LDBF of tow and mooring lines for synthetic ropes as required in Ch 12, App 2, [2.5] needs not to be taken into account for the loads applied to shipboard fittings and supporting hull structure.

Note 4: For fittings intended to be used for both towing and mooring operations, the corresponding design loads are to be considered independently.

**Figure 11 : Design load on fitting**

**4.2.6 Allowable stresses**

Allowable stresses under the design load conditions as specified in [4.2.5] are as follows:

- a) For strength assessment by means of beam theory or grillage analysis:
  - normal stress:  $1,0 R_{eH}$
  - shear stress:  $0,6 R_{eH}$
- b) For strength assessment by means of finite element analysis:
  - Von Mises stress:  $1,0 R_{eH}$

Note 1: Normal stress is to be considered as the sum of bending stress and axial stress, with the corresponding shearing stress acting perpendicular to the normal stress. No stress concentration factors are to be taken into account.

Note 2: For strength assessment by means of finite element analysis the mesh is to be fine enough to represent the geometry as realistically as possible. The aspect ratios of elements are not to exceed 3. Girders are to be modelled using shell or plane stress elements. Symmetric girder flanges may be modelled by beam or truss elements. The element height of girder webs is not to exceed one-third of the web height. In way of small openings in girder webs the web thickness is to be reduced to a mean thickness over the web height. Large openings are to be modelled. Stiffeners may be modelled by using shell, plane stress, or beam elements. The mesh size of stiffeners is to be fine enough to obtain proper bending stress. If flat bars are modelled using shell or plane stress elements, dummy rod elements are to be modelled at the free edge of the flat bars and the stresses of the dummy elements are to be evaluated. Stresses are to be read from the centre of the individual element. For shell elements the stresses are to be evaluated at the mid plane of the element.

**4.2.7 Corrosion additions**

The scantlings obtained by applying the allowable stresses as specified in [4.2.6] are net scantlings excluding any addition for corrosion.

The total corrosion addition  $t_c$  is not to be less than the following values:

- for the supporting hull structure, according to Ch 4, Sec 3 for the surrounding structure (e.g. deck structures, bulwark structures).
- for pedestals and foundations on deck which are not part of a fitting according to a recognised standard, 2.0 mm.
- for shipboard fittings not selected from a recognised standard, 2.0 mm.

Note 1: In addition to the corrosion addition  $t_c$  given above, a wear allowance  $t_w$  not less than 1.0 mm is to be included for shipboard fittings not selected from an recognised standard. This wear allowance is to be added to surfaces which are intended to regularly contact the line.

#### **4.2.8 Safe Towing Load (TOW)**

The safe towing load (TOW) is the safe load limit of shipboard fittings used for towing purpose.

Unless a greater TOW is requested by the applicant, the TOW is not to exceed:

- a) Normal towing operations: the intended maximum towing load (e.g. static bollard pull)
- b) Escort or other towing operations: 80% of the  $MBL_{SD}$  according to Ch 12, App 2
- c) For fittings intended to be used for, both, normal and escort or other towing operations: the greater of the design loads according to a) and b).

TOW, in t, of each shipboard fitting is to be marked (by weld bead or equivalent) on the deck fittings used for towing.

For fittings intended to be used for, both, towing and mooring, SWL, in t, according to [4.2.9] is to be marked in addition to TOW.

Note 1: The above requirements on TOW apply for the use with no more than one line. If not otherwise chosen, for towing bits (double bollards) TOW is the load limit for a towing line attached with eye-splice.

#### **4.2.9 Safe Working Load (SWL)**

The safe working load (SWL) is the safe load limit of shipboard fittings used for mooring purpose.

Unless a greater SWL is requested by the applicant, the SWL is not to exceed the  $MBL_{SD}$  as given in Ch 12, App 2, Tab 1.

SWL, in t, of each shipboard fitting is to be marked (by weld bead or equivalent) on the deck fittings used for mooring.

For fittings intended to be used for, both, mooring and towing, TOW, in t, according to [4.2.8] is to be marked in addition to SWL.

Note 1: The above requirements on SWL apply for the use with no more than one mooring line.

#### **4.2.10 Towing and mooring arrangements plan**

A plan showing the towing and mooring arrangement is to be submitted to the Society for information. This plan is to define the method of using the towing and mooring lines and is to include the following information for each shipboard fitting:

- a) Location on the ship
- b) Fitting type
- c) SWL/TOW
- d) Purpose (mooring, harbour towing, escort towing, other towing)
- e) Manner of applying towing and mooring lines including limiting fleet angle i.e. angle of change in direction of a line at the fitting.

Item c) with respect to items d) and e), is subject to approval by the Society.

Furthermore, following information is to be clearly indicated on the plan:

- the arrangement of mooring lines showing the number of lines
- the  $MBL_{SD}$  of each mooring line
- the length of each mooring line
- restrictions or limitations on the type (including material and construction), stiffness and diameter of mooring lines which are compatible with the mooring equipments and fittings
- the acceptable environmental conditions as given in Ch 12, App 2, [2.7.3] for the  $MBL_{SD}$  of mooring lines for ships with Equipment Number EN > 2000:
  - 30 second mean wind speed from any direction ( $v_w$  or  $v_w^*$  according to Ch 12, App 2, [2.7.3])
  - maximum current speed acting on bow or stern ( $\pm 10^\circ$ )

Note 1: The SWL and TOW for the intended use for each shipboard fitting is to be noted in the towing and mooring arrangements plan available on board for the guidance of the Master. It is to be noted that TOW is the load limit for towing purpose and SWL that for mooring purpose. If not otherwise chosen, for towing bits it is to be noted that TOW is the load limit for a towing line attached with eye-splice.

Note 2: The information as listed above is to be incorporated into the pilot card in order to provide the pilot proper information on harbour, escort and other towing operations.

# Appendix 1      Criteria for Direct Calculation of Rudder Loads

## Symbols

- $l_{10}, l_{20}, l_{30}, l_{40}$  : Lengths, in m, of the individual girders of the rudder system
- $l_{50}$  : Length, in m, of the solepiece
- $l_{TRU}$  : Length, in m, of the trunk
- $J_{10}, J_{20}, J_{30}, J_{40}$  : Moments of inertia about the x axis, in  $\text{cm}^4$ , of the individual girders of the rudder system having lengths  $l_{10}, l_{20}, l_{30}, l_{40}$ . For rudders supported by a solepiece only,  $J_{20}$  indicates the moment of inertia of the pintle in the sole piece
- $J_{50}$  : Moment of inertia about the z axis, in  $\text{cm}^4$ , of the solepiece
- $J_{TRU}$  : Moment of inertia about the x axis, in  $\text{cm}^4$ , of the trunk
- $C_R$  : Rudder force, in N, acting on the rudder blade, defined in Ch 12, Sec 1, [2.1.1]
- $C_{R1}, C_{R2}$  : Rudder forces, in N, defined in Ch 12, Sec 1, [2.2.3]
- $E$  : Young's modulus, in  $\text{N/m}^2$ :  $E = 2,06 \cdot 10^{11} \text{ N/m}^2$
- $G$  : Shear elasticity modulus, in  $\text{N/m}^2$ :  $G = 7,85 \cdot 10^{10} \text{ N/m}^2$ .

## 1 Criteria for direct calculation of the loads acting on the rudder structure

### 1.1 General

#### 1.1.1 Application

The requirements of this Appendix apply to all types of rudders listed under Ch 12, Sec 1, Tab 4.

The requirements of this Appendix provide the criteria for calculating the following forces and moments:

- bending moment  $M_{Bi}$  in the rudder stock (defined as the maximum of absolute values of bending moment  $M_{Bi}$  over the rudder stock length)
- support forces  $F_{Ai}$
- bending moment  $M_R$  and shear force  $Q_R$  in the rudder body.

#### 1.1.2 Calculation of forces and moments

The forces and moments in [1.1.1] are to be calculated according to [1.4], for each type of rudder.

They are to be used for the stress analysis required in:

- Ch 12, Sec 1, [4], for the rudder stock
- Ch 12, Sec 1, [6], for the rudder stock and the pintle bearings
- Ch 12, Sec 1, [7] for the rudder blade
- Ch 12, Sec 1, [8] for the rudder horn and the solepiece.

### 1.2 Required data

#### 1.2.1 Forces per unit length

The forces per unit length are to be calculated, in  $\text{N/m}$ , for each type of rudder, according to requirements given under [1.4].

#### 1.2.2 Support stiffness properties

Three general cases are considered:

- all supports are completely rigid. This is assumed for the rudder types 1 and 3.
- Combination of one elastic support with several rigid supports.  
The elastic support is represented by a spring, with its constant calculated in  $\text{N/m}$ , according to [1.3.1] and [1.3.2]:
  - $Z_C$  for rudders with solepiece (rudder type 2 as in Fig 1, and rudder type 5 as in Fig 3)
  - $Z_P$  for semi-spade rudders with one elastic support provided by a rudder horn (rudder type 4 as in Fig 2, rudder type 7 as in Fig 7, and rudder type 8 as in Fig 8)
  - $Z_{TRU}$  for spade rudders with rudder trunk (rudder type 6c, as shown in Fig 6).
- Combination of 2-conjugate elastic supports and one rigid support (rudder type 9 as in Fig 9, and rudder type 10 as in Fig 10).  
The 2-conjugate elastic supports are defined by using two additional equations, according to [1.3.3].

### 1.3 Calculation of support stiffness properties

#### 1.3.1 Sole piece

The spring constant  $Z_C$  for the support in the solepiece (see Fig 11) is to be obtained, in N/m, from the following formula:

$$Z_C = \frac{3EJ_{50}}{\ell_{50}^3} \cdot 10^{-8}$$

#### 1.3.2 Rudder horn with 1-elastic support

The spring constant  $Z_P$  for the support in the rudder horn (see Fig 12 and Fig 13) is to be obtained, in N/m, from the following formula:

$$Z_P = \frac{1}{f_B + f_T}$$

where:

$f_B$  : Unit displacement of rudder horn due to a unit force of 1 N acting in the centroid of the rudder horn, to be obtained, in m/N, from the following formula:

$$f_B = 1,3 \frac{d^3}{3EJ_N} \cdot 10^8$$

$f_T$  : Unit displacement due to torsion, in m/N, to be obtained, in case of a rudder horn with a hollow cross section, from the following formula:

$$f_T = \frac{de^2}{4GF_T^2} \sum_i \frac{u_i}{t_i}$$

with:

$d$  : Height, in m, of the rudder horn as defined in Fig 12 and Fig 13. This value is measured downwards from the upper rudder horn end, at the point of curvature transition, till the mid-line of the lower rudder horn pintle

$J_N$  : Moment of inertia of rudder horn about the x axis, in  $\text{cm}^4$

$e$  : Rudder-horn torsion lever, in m, as defined in Fig 12 and Fig 13 (value taken at  $z = d/2$ )

$F_T$  : Mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn, in  $\text{m}^2$

$u_i$  : Length, in mm, of the individual plates forming the mean horn sectional area

$t_i$  : Thickness of the individual plates mentioned above, in mm.

#### 1.3.3 Rudder horn with 2-conjugate elastic supports

The 2-conjugate elastic supports are defined by the following equations:

- at the lower rudder horn bearing:  $y_1 = -K_{12} F_{A2} - K_{22} F_{A1}$
- at the upper rudder horn bearing:  $y_2 = -K_{11} F_{A2} - K_{12} F_{A1}$

where:

$y_1, y_2$  : Horizontal displacements, in m, at the lower and upper rudder horn bearings, respectively

$F_{A1}, F_{A2}$  : Horizontal support forces, in N, at the lower and upper rudder horn bearings, respectively

$K_{11}, K_{22}, K_{12}$ : Rudder horn compliance constants obtained, in m/N, from the following formulae:

$$K_{11} = 1,3 \cdot \left[ \frac{\lambda^3}{3EJ_{1h}} + \frac{e^2 \cdot \lambda}{GJ_{th}} \right]$$

$$K_{12} = 1,3 \cdot \left[ \frac{\lambda^3}{3EJ_{1h}} + \frac{\lambda^2 \cdot (d-\lambda)}{2EJ_{1h}} \right] + \frac{e^2 \cdot \lambda}{GJ_{th}}$$

$$K_{22} = 1,3 \cdot \left[ \frac{\lambda^3}{3EJ_{1h}} + \frac{\lambda^2 \cdot (d-\lambda)}{EJ_{1h}} + \frac{\lambda \cdot (d-\lambda)^2}{EJ_{1h}} + \frac{(d-\lambda)^3}{3EJ_{2h}} \right] + \frac{e^2 \cdot d}{GJ_{th}}$$

where:

$d$  : Height of the rudder horn, in m, defined in Fig 14 and Fig 15. This value is measured downwards from the upper rudder horn end, at the point of curvature transition, till the mid-line of the lower rudder horn pintle

$\lambda$  : Length, in m, as defined in Fig 14 and Fig 15. This length is measured downwards from the upper rudder horn end, at the point of curvature transition, till the mid-line of the upper rudder horn bearing. For  $\lambda = 0$ , the above formulae converge to those given in [1.3.2], in case of a rudder horn with a hollow cross-section

$e$  : Rudder-horn torsion lever, in m, as defined in Fig 14 and Fig 15 (value taken at  $z = d/2$ )

$J_{1h}$  : Moment of inertia of rudder horn about the x axis, in  $\text{m}^4$ , for the region above the upper rudder horn bearing. Note that  $J_{1h}$  is an average value over the length  $\lambda$  (see Fig 15)

$J_{2h}$  : Moment of inertia of rudder horn about the x axis, in  $\text{m}^4$ , for the region between the upper and lower rudder horn bearings. Note that  $J_{2h}$  is an average value over the length  $d - \lambda$  (see Fig 15)

$J_{th}$  : Torsional stiffness factor of the rudder horn, in  $\text{m}^4$ .

For any thin wall closed section:

$$J_{th} = \frac{4F_T^2}{\sum_i \frac{u_i}{t_i}}$$

$F_T$  : Mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn, in m<sup>2</sup>

$u_i$  : Length, in mm, of the individual plates forming the mean horn sectional area

$t_i$  : Thickness, in mm, of the individual plates mentioned above

Note that the  $J_{th}$  value is taken as an average value, valid over the rudder horn height.

**1.3.4 Rudder trunk**

The spring constant  $Z_{TRU}$  for the support in the trunk (lower rudder stock bearing as shown in Fig 16) is to be obtained, in N/m, from the following formula:

$$Z_{TRU} = \frac{3EJ_{TRU}}{\ell_{TRU}^3} \cdot 10^{-8}$$

**1.4 Calculation of the main structure of the rudder system**

**1.4.1 Rudder type 1**

The force per unit length  $p_R$  acting on the rudder body is to be obtained, in N/m, from the following formula:

$$p_R = \frac{C_R}{\ell}$$

with:

$\ell$  : Height of the rudder blade, in m.

The rudder structure is to be calculated according to approximate formulae given here below:

- maximum bending moment in the rudder stock, in N·m:  $M_B = 0$
- support forces, in N:
  - $F_{A1} = F_{A2} = F_{A3} = C_R / 3$
  - $F_{A4} = 0$
- bending moment in the rudder blade of streamlined rudders, in N·m:  $M_R = C_R \ell / 24$

**1.4.2 Rudder type 2**

The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 1.

The force per unit length  $p_R$  acting on the rudder body is to be obtained, in N/m, from the following formula:

$$p_R = \frac{C_R}{\ell}$$

with:

$\ell$  : Height of the rudder blade, in m, as follows:

$$\ell = \ell_{10} + \ell_{30}$$

The spring constant  $Z_c$  is to be calculated according to [1.3.1].

**Figure 1 : Rudder type 2**

**1.4.3 Rudder type 3**

The force per unit length  $p_R$  acting on the rudder body is to be obtained, in N/m, from the following formula:

$$p_R = \frac{C_R}{l}$$

with:

$l$  : Height of the rudder blade, in m.

The rudder structure is to be calculated according to approximate formulae given here below:

- maximum bending moment in the rudder stock, in N·m:  $M_B = 0$
- support forces, in N:

$$F_{A1} = F_{A2} = C_R/2$$

$$F_{A3} = 0$$

**1.4.4 Rudder type 4**

The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 2.

The forces per unit length  $p_{R10}$  and  $p_{R20}$  acting on the rudder body are to be obtained, in N/m, from the following formulae:

$$p_{R10} = \frac{C_{R2}}{l_{10}}$$

$$p_{R20} = \frac{C_{R1}}{l}$$

with:

$$l = l_{20} + l_{30}$$

The spring constant  $Z_p$  is to be calculated according to [1.3.2].

**Figure 2 : Rudder type 4**

**1.4.5 Rudder type 5**

The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 3.

The force per unit length  $p_R$  acting on the rudder body is to be obtained, in N/m, from the following formula:

$$p_R = \frac{C_R}{l}$$

with:

$l$  : Height of the rudder blade, in m.

The spring constant  $Z_c$  is to be calculated according to [1.3.1].

Figure 3 : Rudder type 5

1.4.6 Rudder type 6a

The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 4. The force per unit length  $p_R$  acting on the rudder body is to be obtained, in N/m, from the following formula:

$$p_{Rz} = p_{R10} + \left( \frac{p_{R20} - p_{R10}}{l_{10}} \right) \cdot z$$

where:

- $z$  : Position of rudder blade section, in m, taken over  $l_{10}$  length
- $p_{Rz}$  : Force per unit length, in N/m, obtained at the  $z$  position
- $p_{R10}$  : Force per unit length, in N/m, obtained for  $z$  equal to zero
- $p_{R20}$  : Force per unit length, in N/m, obtained for  $z$  equal to  $l_{10}$ .

For this type of rudder, the results of calculations performed according to diagrams shown in Fig 4 may also be obtained from the following formulae:

- maximum bending moment in the rudder stock, in N·m:

$$M_B = C_R \left( l_{20} + \frac{l_{10}(2C_1 + C_2)}{3(C_1 + C_2)} \right)$$

where  $C_1$  and  $C_2$  are the lengths, in m, defined in Fig 4

- support forces, in N:

$$F_{A3} = \frac{M_B}{l_{30}}$$

$$F_{A2} = C_R + F_{A3}$$

- maximum shear force in the rudder body, in N:  $Q_R = C_R$ .

Figure 4 : Rudder type 6a

**1.4.7 Rudder type 6b**

This type of rudder is regarding spade rudders with rudder trunks continued into the rudder blade, through a quite short length, in such way the centre of gravity of the rudder blade is located below the lower rudder stock bearing. The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 5.

The force per unit length  $p_R$  acting on the lower part of the rudder body is to be obtained, in N/m, from the following formula:

$$p_{Rz} = p_{R10} + \left( \frac{p_{R20} - p_{R10}}{\ell_{10}} \right) \cdot z$$

where:

- $z$  : Position of rudder blade section, in m, taken over  $\ell_{10}$  length
- $p_{Rz}$  : Force per unit length, in N/m, obtained at the  $z$  position
- $p_{R10}$  : Force per unit length, in N/m, obtained for  $z$  equal to zero
- $p_{R20}$  : Force per unit length, in N/m, obtained for  $z$  equal to  $\ell_{10}$ .

The values of  $p_{R10}$  and  $p_{R20}$  are obtained from the following two equations:

$$p_{R10} = \frac{2C_R(2\ell_{10} - 3\ell_{CG})}{\ell_{10}^2}$$

$$p_{R20} = \frac{2C_R(3\ell_{CG} - \ell_{10})}{\ell_{10}^2}$$

where:

- $C_R$  : Force, in N, acting on the total rudder blade area  $A$ , to be calculated in accordance with Ch 12, Sec 1, [2.1.2]
- $A$  : Total rudder blade area, in  $m^2$
- $\ell_{CG}$  : Vertical position, in m, of the centre of gravity of the total rudder blade area  $A$ , to be taken from the bottom of the rudder blade.

The bending moments  $M_R$  and  $M_B$ , in N·m, for the scantling of both the rudder blade and the lower rudder stock diameter, respectively, are identical and shall be taken as follows:

$$M_R = M_B = C_R \cdot (\ell_{10} - \ell_{CG})$$

The reaction forces  $F_{A2}$  and  $F_{A3}$ , in N, may be determined as follows:

$$F_{A3} = M_B / \ell_{20}$$

$$F_{A2} = -(C_R + F_{A3})$$

**Figure 5 : Rudder type 6b**

**1.4.8 Rudder type 6c**

This type of rudder provides a more general solution for the scantling of spade rudders with rudder trunks continued into the rudder blade. There is no limitation on the location of the centre of gravity of the total rudder blade area, which may be located either below the lower rudder stock bearing or slightly above it. The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 6.

The force per unit length  $p_R$  acting on the lower part of the rudder body is to be obtained, in N/m, from the following formula:

$$p_{Rz} = p_{R10} + \left( \frac{p_{R20} - p_{R10}}{\ell_{10}} \right) \cdot z$$

where:

- $z$  : Position of rudder blade section, in m, taken over  $\ell_{10}$  length

- $p_{Rz}$  : Force per unit length, in N/m, obtained at the z position
- $p_{R10}$  : Force per unit length, in N/m, obtained for z equal to zero
- $p_{R20}$  : Force per unit length, in N/m, obtained for z equal to  $l_{10}$ .

The values of  $p_{R10}$  and  $p_{R20}$  are obtained from the following two equations:

$$p_{R10} = \frac{2C_{R2}(2l_{10} - 3l_{CG2})}{l_{10}^2}$$

$$p_{R20} = \frac{2C_{R2}(3l_{CG2} - l_{10})}{l_{10}^2}$$

where:

- $C_{R2}$  : Force, in N, acting on the rudder blade area  $A_2$ , to be calculated in accordance with Ch 12, Sec 1, [2.2.3]
- $A_2$  : Rudder blade area, in  $m^2$ , located below the lower rudder stock bearing
- $l_{CG2}$  : Vertical position, in m, of the centre of gravity of the rudder blade area  $A_2$ , to be taken from the bottom of the rudder blade.

The bending moment  $M_R$ , in N·m, for the scantling of the rudder blade, shall be taken as the greatest of the following values:

- $M_{C_{R2}} = C_{R2} \cdot (l_{10} - l_{CG2})$
- $M_{C_{R1}} = C_{R1} \cdot (l_{CG1} - l_{10})$

where:

- $M_{C_{R2}}$  : Bending moment, in N·m, induced by the rudder force  $C_{R2}$  ( $M_{C_{R2}}$  is assumed to be of a negative sign)
- $M_{C_{R1}}$  : Bending moment, in N·m, induced by the rudder force  $C_{R1}$  ( $M_{C_{R1}}$  is assumed to be of a positive sign)
- $C_{R1}$  : Force, in N, acting on the rudder blade area  $A_1$ , to be calculated in accordance with Ch 12, Sec 1, [2.2.3]
- $A_1$  : Rudder blade area, in  $m^2$ , located above the lower rudder stock bearing
- $l_{CG1}$  : Vertical position, in m, of the centre of gravity of the rudder blade area  $A_1$ , to be taken from the bottom of the rudder blade.

The bending moment  $M_B$ , in N·m, for the scantling of the lower rudder stock diameter, is given by the algebraic sum of  $M_{C_{R2}}$  and  $M_{C_{R1}}$ , as follows:  $M_B = M_{C_{R2}} + M_{C_{R1}}$

The reaction forces  $F_{A2}$  and  $F_{A3}$ , in N, may be determined as follows:

$$F_{A3} = M_B / (l_{20} + l_{30})$$

$$F_{A2} = -(C_{R1} + C_{R2} + F_{A3})$$

**Figure 6 : Rudder type 6c**

**1.4.9 Rudder type 7**

The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 7.

The forces per unit length  $p_{R10}$  and  $p_{R20}$  acting on the rudder body are to be obtained, in N/m, from the following formulae:

$$p_{R10} = \frac{C_{R2}}{l_{10}}$$

$$p_{R20} = \frac{C_{R1}}{l}$$

where:

- $l$  : Value equal to:  $l = l_{20}$

The spring constant  $Z_p$  is to be calculated according to [1.3.2].

Figure 7 : Rudder type 7

1.4.10 Rudder type 8

The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 8.

The forces per unit length  $p_{R10}$  and  $p_{R20}$  acting on the rudder body are to be obtained, in N/m, from the following formulae:

$$p_{R10} = \frac{C_{R2}}{l_{10}}$$

$$p_{R20} = \frac{C_{R1}}{l}$$

with:

$$l = l_{20} + l_{30}$$

The spring constant  $Z_p$  is to be calculated according to [1.3.2].

Figure 8 : Rudder type 8

1.4.11 Rudder type 9

The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 9.

The forces per unit length  $p_{R10}$  and  $p_{R20}$  acting on the rudder body are to be obtained, in N/m, from the following formulae:

$$p_{R10} = \frac{C_{R2}}{l_{10}}$$

$$p_{R20} = \frac{C_{R1}}{l}$$

with:

$$l = l_{20}$$

The stiffness properties of the 2-conjugate elastic supports are to be calculated according to [1.3.3].

Figure 9 : Rudder type 9

Figure 10 : Rudder type 10

1.4.12 Rudder type 10

The rudder structure is to be calculated according to load, shear force and bending moment diagrams shown in Fig 10.

The forces per unit length  $p_{R10}$  and  $p_{R20}$  acting on the rudder body are to be obtained, in N/m, from the following formulae:

$$p_{R10} = \frac{C_{R2}}{l_{10}}$$

$$p_{R20} = \frac{C_{R1}}{l}$$

with:

$$l = l_{20} + l_{30}$$

The stiffness properties of the 2-conjugate elastic supports are to be calculated according to [1.3.3].

1.5 Calculation of the solepiece

1.5.1 Bending moment

The bending moment acting on the generic section of the solepiece is to be obtained, in N·m, from the following formula:

$$M_S = F_{A1} \times x$$

where:

$F_{A1}$  : Supporting force, in N, in the pintle bearing, to be determined according to [1.4], for the relevant type of rudder

$x$  : Distance, in m, defined in Fig 11.

**1.5.2 Stress calculations**

For the generic section of the solepiece within the length  $\ell_{50}$ , defined in Fig 11, the following stresses are to be calculated:

$\sigma_B$  : Bending stress to be obtained, in N/mm<sup>2</sup>, from the following formula:

$$\sigma_B = \frac{M_S}{W_Z}$$

$\tau$  : Shear stress to be obtained, in N/mm<sup>2</sup>, from the following formula:

$$\tau = \frac{F_{A1}}{A_S}$$

$M_S$  : Bending moment, in N·m, at the section considered, as defined in [1.5.1]

$F_{A1}$  : Force, in N, defined in [1.5.1]

$W_Z$  : Section modulus, in cm<sup>3</sup>, around the vertical axis Z (see Fig 11)

$A_S$  : Shear sectional area, in mm<sup>2</sup>, in a plane perpendicular to the X axis of the solepiece.

**Figure 11 : Solepiece geometry**

**1.6 Rudder horn calculation (case of 1-elastic support)**

**1.6.1 Bending moment**

The bending moment acting on the generic section of the rudder horn is to be obtained, in N·m, from the following formula:

$$M_H = F_{A1} z$$

where:

$F_{A1}$  : Support force at the rudder horn lower-pintle, in N, to be obtained according to [1.4], for the relevant type of rudder

$z$  : Distance, in m, defined in Fig 13, to be taken less than the distance  $d$ , in m, defined in the same figure.

**1.6.2 Shear force**

The shear force  $Q_H$  acting on the generic section of the rudder horn is to be obtained, in N, from the following formula:

$$Q_H = F_{A1}$$

where:

$F_{A1}$  : Force, in N, defined in [1.6.1].

**1.6.3 Torque**

The torque acting on the generic section of the rudder horn is to be obtained, in N·m, from the following formula:

$$M_T = F_{A1} e_{(z)}$$

where:

$F_{A1}$  : Force, in N, defined in [1.6.1]

$e_{(z)}$  : Torsion lever, in m, defined in Fig 13.

**1.6.4 Stress calculations**

For the generic section of the rudder horn within the length  $d$ , defined in Fig 13, the following stresses are to be calculated:

$\sigma_B$  : Bending stress to be obtained, in N/mm<sup>2</sup>, from the following formula:

$$\sigma_B = \frac{M_H}{W_X}$$

$M_H$  : Bending moment at the section considered, in N·m, defined in [1.6.1]

$W_X$  : Section modulus, in cm<sup>3</sup>, around the horizontal axis X (see Fig 13)

$\tau_s$  : Shear stress to be obtained, in N/mm<sup>2</sup>, from the following formula:

$$\tau_s = \frac{F_{A1}}{A_H}$$

$F_{A1}$  : Force, in N, defined in [1.6.1]

$A_H$  : Effective shear sectional area of the rudder horn, in mm<sup>2</sup>, in y-direction

$\tau_T$  : Torsional stress to be obtained for hollow rudder horn, in N/mm<sup>2</sup>, from the following formula:

$$\tau_T = \frac{M_T 10^{-3}}{2F_T t_H}$$

For solid rudder horn,  $\tau_T$  is to be considered by the Society on a case-by-case basis

$M_T$  : Torque, in N·m, defined in [1.6.3]

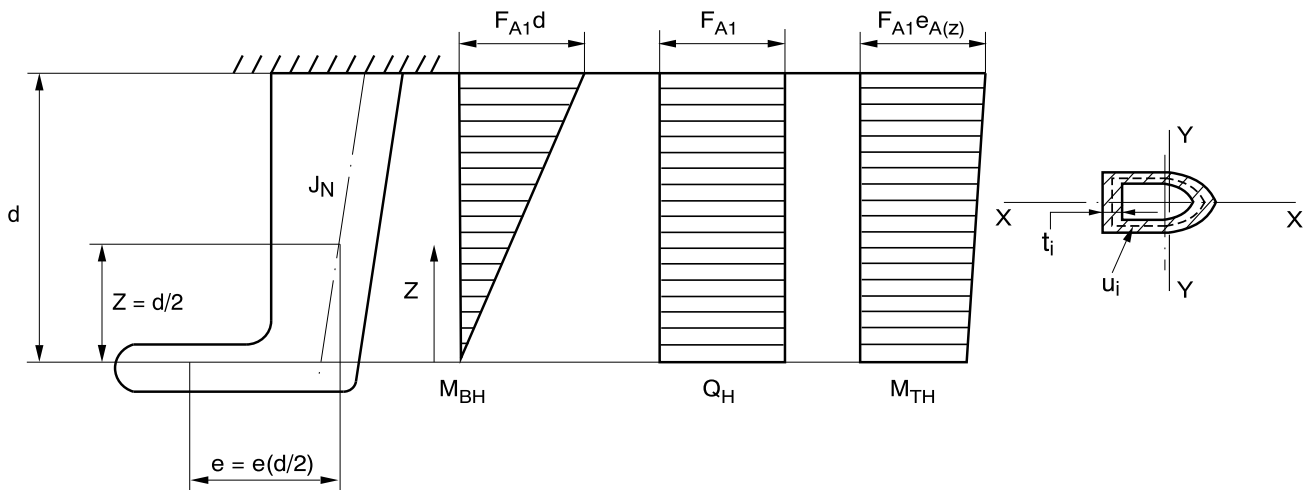

$F_T$  : Mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn, in m<sup>2</sup>

$t_H$  : Plate thickness of rudder horn, in mm. For a given cross section of the rudder horn, the maximum value of  $\tau_T$ , is obtained at the minimum value of  $t_H$ .

**Figure 12 : Rudder and rudder horn geometries (1-elastic support)**

**Figure 13 : Rudder horn geometry (1-elastic support)**

## 1.7 Rudder horn calculation (case of 2-conjugate elastic supports)

### 1.7.1 Bending moment

The bending moment acting on the generic section of the rudder horn is to be obtained, in N·m, from the following formulae:

- between the lower and upper supports provided by the rudder horn:  $M_H = F_{A1} z$
- above the rudder horn upper-support:  $M_H = F_{A1} z + F_{A2} (z - d_{iu})$

where:

- $F_{A1}$  : Support force at the rudder horn lower-support, in N, to be obtained according to [1.4], for the relevant type of rudder  
 $F_{A2}$  : Support force at the rudder horn upper-support, in N, to be obtained according to [1.4], for the relevant type of rudder  
 $z$  : Distance, in m, defined in Fig 15, to be taken less than the distance  $d$ , in m, defined in the same figure  
 $d_{lu}$  : Distance, in m, between the rudder-horn lower and upper bearings (according to Fig 14,  $d_{lu} = d - \lambda$ ).

**1.7.2 Shear force**

The shear force  $Q_H$  acting on the generic section of the rudder horn is to be obtained, in N, from the following formulae:

- between the lower and upper rudder horn bearings:  $Q_H = F_{A1}$
- above the rudder horn upper-bearing:  $Q_H = F_{A1} + F_{A2}$

where:

- $F_{A1}, F_{A2}$  : Support forces, in N, defined in [1.7.1].

**1.7.3 Torque**

The torque acting on the generic section of the rudder horn is to be obtained, in N·m, from the following formulae:

- between the lower and upper rudder horn bearings:  $M_T = F_{A1} e_{(z)}$
- above the rudder horn upper-bearing:  $M_T = F_{A1} e_{(z)} + F_{A2} e_{(z)}$

where:

- $F_{A1}, F_{A2}$  : Support forces, in N, defined in [1.7.1]  
 $e_{(z)}$  : Torsion lever, in m, defined in Fig 15.

**1.7.4 Shear stress calculation**

- a) For a generic section of the rudder horn, located between its lower and upper bearings, the following stresses are to be calculated:

- $\tau_s$  : Shear stress, in N/mm<sup>2</sup>, to be obtained from the following formula:

$$\tau_s = \frac{F_{A1}}{A_H}$$

- $\tau_T$  : Torsional stress, in N/mm<sup>2</sup>, to be obtained for hollow rudder horn from the following formula:

$$\tau_T = \frac{M_T 10^{-3}}{2 F_T t_H}$$

For solid rudder horn,  $\tau_T$  is to be considered by the Society on a case-by-case basis

- b) For a generic section of the rudder horn, located in the region above its upper bearing, the following stresses are to be calculated:

- $\tau_s$  : Shear stress, in N/mm<sup>2</sup>, to be obtained from the following formula:

$$\tau_s = \frac{F_{A1} + F_{A2}}{A_H}$$

- $\tau_T$  : Torsional stress, in N/mm<sup>2</sup>, to be obtained for hollow rudder horn from the following formula:

$$\tau_T = \frac{M_T 10^{-3}}{2 F_T t_H}$$

For solid rudder horn,  $\tau_T$  is to be considered by the Society on a case-by-case basis

where:

- $F_{A1}, F_{A2}$  : Support forces, in N, defined in [1.7.1]  
 $A_H$  : Effective shear sectional area of the rudder horn, in mm<sup>2</sup>, in y-direction  
 $M_T$  : Torque, in N·m, defined in [1.7.3]  
 $F_T$  : Mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn, in m<sup>2</sup>  
 $t_H$  : Plate thickness of rudder horn, in mm. For a given cross section of the rudder horn, the maximum value of  $\tau_T$ , is obtained at the minimum value of  $t_H$ .

**1.7.5 Bending stress calculation**

For the generic section of the rudder horn within the length  $d$ , defined in Fig 15, the following stresses are to be calculated:

- $\sigma_B$  : Bending stress, in N/mm<sup>2</sup>, to be obtained from the following formula:

$$\sigma_B = \frac{M_H}{W_X}$$

- $M_H$  : Bending moment at the section considered, in N·m, defined in [1.7.1]  
 $W_X$  : Section modulus, in cm<sup>3</sup>, around the horizontal axis X (see Fig 15).

Figure 14 : Rudder and rudder horn geometries (2-conjugate elastic supports)

Figure 15 : Rudder horn geometry (2-conjugate elastic supports)

## 1.8 Calculation of the rudder trunk

### 1.8.1 Bending moment

The bending moment acting on the generic section of the trunk is to be obtained, in N·m, from the following formula:

$$M_{TRU} = F_{A2} z$$

where:

- $F_{A2}$  : Support force, in N, at the lower rudder stock bearing, as defined in [1.4]
- $z$  : Distance, in m, defined in Fig 16.

### 1.8.2 Stress calculations

For the generic section of the trunk within the length  $l_{TRU}$ , defined in Fig 16, the following stresses are to be calculated:

- $\sigma_B$  : Bending stress to be obtained, in N/mm<sup>2</sup>, from the following formula:

$$\sigma_B = \frac{M_{TRU}}{W_{TRU}}$$

- $\tau$  : Shear stress to be obtained, in N/mm<sup>2</sup>, from the following formula:

$$\tau = \frac{F_{A2}}{A_{TRU}}$$

- $M_{TRU}$  : Bending moment, in N·m, at the section considered, as defined in [1.8.1]
- $F_{A2}$  : Support force, in N, at the lower rudder stock bearing, as defined in [1.4]
- $W_{TRU}$  : Section modulus, in cm<sup>3</sup>, around the horizontal axis X (see Fig 16)

$A_{TRU}$  : Shear sectional area, in mm<sup>2</sup>, in a plane perpendicular to the Z axis of the trunk.

The length  $l_{TRU}$  is the distance in m, taken between the mid-line of the lower rudder stock bearing and the “top line” of the trunk. This “top line” is defined either where the trunk is clamped into the shell or at the bottom of the skeg, as shown in the diagram Fig 16.

**Figure 16 : Rudder trunk geometry**

## Appendix 2 Towing and Mooring Arrangement

### 1 General

#### 1.1 Application

**1.1.1** The towing and mooring arrangement as defined in the present article and the towing and mooring lines as defined in Article [2] are given as a guidance but are not required as a condition of classification.

#### 1.2 Definition

**1.2.1** For symbols and definitions not defined in this Section, refer to Ch 12, Sec 4.

#### 1.3 Mooring arrangement

**1.3.1** Attention is to be given to the arrangement of the equipment for towing and mooring operations in order to prevent interference of mooring and towing lines as far as practicable. It is beneficial to provide dedicated towing arrangements separate from the mooring equipment.

**1.3.2** Mooring lines in the same service (e.g. breast lines as defined in [2.7.1]) are to be of the same characteristic in terms of strength and elasticity.

**1.3.3** As far as possible, sufficient number of mooring winches are to be fitted to allow for all mooring lines to be belayed on winches. This allows for an efficient distribution of the load to all mooring lines in the same service and for the mooring lines to shed load before they break. If the mooring arrangement is designed such that mooring lines are partly to be belayed on bits or bollards, it should be considered that these lines may not be as effective as the mooring lines belayed on winches.

**1.3.4** Mooring lines are to have as straight a lead as is practicable from the mooring drum to the fairlead.

**1.3.5** At points of change in direction sufficiently large radii of the contact surface of a rope on a fitting are to be provided to minimize the wear experienced by mooring lines and as recommended by the rope manufacturer for the rope type intended to be used.

#### 1.4 Towing arrangement

**1.4.1** As far as possible, towing lines is to be led through a closed chock. The use of open fairleads with rollers or closed roller fairleads is to be avoided.

**1.4.2** For towing purpose it is recommended to provide at least one chock close to centreline of the ship forward and aft. It is also beneficial to provide additional chocks on port and starboard side at the transom and at the bow.

**1.4.3** Towing lines are to have a straight lead from the towing bitt or bollard to the chock.

**1.4.4** For the purpose of towing, bits or bollards serving a chock are to be located slightly offset and in a distance of at least 2 m away from the chock, see Fig 1.

**1.4.5** Warping drums are to be preferably positioned not more than 20 m away from the chock, measured along the path of the line.

**Figure 1 : Bitts or bollards serving a chock for towing purpose**

## 2 Tow lines and mooring lines

### 2.1 General

**2.1.1** The equipment in tow line and mooring lines (length,  $MBL_{SD}$  and number of lines) is obtained from Tab 1 and Tab 2 based on an Equipment Number EN calculated according to Ch 12, Sec 4, [1.2.2] with a side projected area A including deck cargoes at ship nominal capacity, as defined in Ch 12, Sec 4, [4.2.1].

**2.1.2** For mooring lines for ships with  $EN > 2000$ , length, breaking load and number of lines are defined in [2.7].

**2.1.3** The breaking load given in Tab 1, Tab 2 or in [2.7.4] is used to determine the maximum design load applied to shipboard fittings as defined in Ch 12, Sec 4, [4.2.5].

**2.1.4** The tow lines having the characteristics defined in Tab 1, Tab 2 and [2.7] are intended as those belonging to the ship to be towed by a tug or another ship under normal towing conditions (calm water / harbour).

**2.1.5** The Designer is to verify the adequacy of towing lines based on assessments carried out for the individual towing arrangement.

**2.1.6** The designer is to verify the adequacy of mooring lines based on assessments carried out for the individual mooring arrangement, expected shore-side mooring facilities and design environmental conditions for the berth.

### 2.2 Materials

**2.2.1** Tow lines and mooring lines may be of wire or synthetic fibre or a mixture of wire and fibre.

**2.2.2** The breaking loads defined in Tab 1, Tab 2 and [2.7.4] refer to steel wires.

**2.2.3** As a guidance, all requirements about manufacturing, sampling and testing for steel wires and fibre ropes are available in NR216 Materials and Welding, Ch 10, Sec 5.

**Table 1 : Tow line and mooring lines for  $EN \leq 2000$**

Equipment number EN $A < EN \leq B$		Tow line		Mooring lines		
A	B	Minimum length, in m	$MBL_{SD}$ , in kN (1)	N (2)	Length of each line, in m	$MBL_{SD}$ , in kN (1)

13400	14600	300	1471
14600	16000	300	1471

(1) Refer to Ch 12, Sec 4, [4.2.1]

### 2.3 Steel wires

2.3.1 Steel wires are to be made of flexible galvanised steel and are to be of types defined in Tab 3.

2.3.2 Where the wire is wound on the winch drum, steel wires to be used with mooring winches may be constructed with an independent metal core instead of a fibre core. In general such wires are to have not less than 186 threads in addition to the metallic core.

**Table 3 : Steel wire composition**

Breaking load $B_L$ , in kN	Steel wire components		
	Number of threads	Range of ultimate tensile strength of threads, in N/mm <sup>2</sup>	Composition of wire
$B_L < 216$	72	1420 – 1570	6 strands with 7-fibre core
$216 < B_L < 490$	144	1570 – 1770	6 strands with 7-fibre core
$B_L > 490$	216 or 222	1770 – 1960	6 strands with 1-fibre core

### 2.4 Length of mooring lines

2.4.1 The length of individual mooring lines may be reduced by up to 7% of the length defined in Tab 1 and [2.7.5] provided that the total length of mooring lines is greater than that obtained by adding the lengths of the individual lines defined in Tab 1 and [2.7.5].

2.4.2 For ships with the service notation **supply**, the length of mooring lines may be reduced. The reduced length  $\ell$  is to be not less than that obtained, in m, from the following formula:

$$\ell = L + 20$$

### 2.5 Synthetic fibre ropes

2.5.1 Where synthetic fibre ropes are adopted, their size is to be determined taking into account the type of material used and the manufacturing characteristics of the rope, as well as the different properties of such ropes.

2.5.2 It is recommended to use lines with reduced risk of recoil (snap-back) to mitigate the risk of injuries or fatalities in the case of breaking mooring lines.

2.5.3 The line design break force of synthetic fibre ropes LDBF, as defined in Ch 12, Sec 4, [4.2.1], is to be not less than that obtained, in kN, from the following formula:

$$LDBF = K B_{L0}$$

where:

$B_{L0}$  :  $MBL_{SD}$ , in kN, for the line, defined in Tab 1, Tab 2 and [2.7.4]

K : Coefficient to be taken equal to:

- for polyamide lines:  $K = 1,2$
- for lines made in other synthetic material:  $K = 1,1$

2.5.4 Fibre rope diameters are to be not less than 20 mm.

2.5.5 For mooring lines made of nylon, the LDBF is to be verified under wet and spliced conditions when breaking tests are performed according to NR216, Ch 10, Sec 6, [1.3.4].

### 2.6 Additional mooring lines

2.6.1 For ships having the ration  $A/EN > 0,9$ , additional mooring lines are defined in Tab 4, in addition to the number of mooring lines defined in Tab 1.

**Table 4 : Additional mooring lines**

A / EN	Number of additional mooring lines
$0,9 < A / EN \leq 1,1$	1
$1,1 < A / EN \leq 1,2$	2
$1,2 < A / EN$	3

**Note 1:** A and EN are defined in Ch 12, Sec 4, [1.2.2].

## 2.7 Mooring lines for ships with EN > 2000

### 2.7.1 Definitions

The following is defined with respect to the purpose of mooring lines, see also Fig 2:

- breast line: mooring line that is deployed perpendicular to the ship, restraining the ship in the off-berth direction.
- spring line: mooring line that is deployed almost parallel to the ship, restraining the ship in fore or aft direction.
- head/Stern line: mooring line that is oriented between longitudinal and transverse direction, restraining the ship in the off-berth and in fore or aft direction. The amount of restraint in fore or aft and off-berth direction depends on the line angle relative to these directions.

Figure 2 : Breast, spring and head/stern mooring lines

### 2.7.2 Side projected area $A_1$

The strength of mooring lines and the number of head, stern, and breast lines for ships with an Equipment Number EN > 2000 are based on the side-projected area  $A_1$ .

Side projected area  $A_1$  is to be calculated similar to the side-projected area  $A$  according to Ch 12, Sec 4, [1.2.2] but considering the following conditions:

- the ballast draft is to be considered for the calculation of the side projected area  $A_1$ . For ship types having small variation in the draft, like e.g. passenger and RO/RO ships, the side projected area  $A_1$  may be calculated using the summer load waterline.
- deck cargoes at ship nominal capacity condition as defined in Ch 12, Sec 4, [4.2.1] are to be included for the determination of side-projected area  $A_1$ . For the condition with cargo on deck, the summer load waterline may be considered.

Note 1: Wind shielding of the pier can be considered for the calculation of the side-projected area  $A_1$  unless the ship is intended to be regularly moored to jetty type piers. A height of the pier surface of 3 m over waterline may be assumed, i.e. the lower part of the side-projected area with a height of 3 m above the waterline for the considered loading condition may be disregarded for the calculation of the side-projected area  $A_1$ .

Note 2: Deck cargoes may not need to be considered if ballast draft condition generates a larger side-projected area  $A_1$  than the full load condition with cargoes on deck. The larger of both side-projected areas is to be chosen as side-projected area  $A_1$ .

### 2.7.3 Environmental conditions

The mooring lines are based on a maximum current speed of 2 knots (1,0 m/s) and the following maximum wind speed  $v_w$ , in m/s:

- for ships with one of the service notations **passenger ship**, **ro-ro passenger ship** or **ro-ro cargo ship**:
  - with  $2000 \text{ m}^2 < A_1 \leq 4000 \text{ m}^2$ :  
 $v_w = 25,0 - 0,002 (A_1 - 2000)$
  - with  $A_1 > 4000 \text{ m}^2$ :  
 $v_w = 21,0$
- for other ships:  
 $v_w = 25,0$

The wind speed is considered representative of a 30 second mean speed from any direction and at a height of 10 m above the ground. The current speed is considered representative of the maximum current speed acting on bow or stern ( $\pm 10^\circ$ ) and at a depth of one-half of the mean draft. Furthermore, it is considered that ships are moored to solid piers that provide shielding against cross current.

Additional loads caused by, e.g., higher wind or current speeds, cross currents, additional wave loads, or reduced shielding from non-solid piers may need to be particularly considered. Furthermore, it should be observed that unbeneficial mooring layouts can considerably increase the loads on single mooring lines.

### 2.7.4 Ship design minimum breaking load

The ship design minimum breaking load  $MBL_{SD}$ , in kN, of the mooring lines is to be taken as:

$$MBL_{SD} = 0,1 A_1 + 350$$

The ship design minimum breaking load  $MBL_{SD}$  may be limited to 1275 kN (130 t).

However, in this case the moorings are to be considered as not sufficient for environmental conditions given in [2.7.3].

For these ships, the acceptable wind speed  $v_w^*$ , in m/s, can be estimated as follows:

$$v_w^* = v_w \sqrt{\frac{MBL_{SD}^*}{MBL_{SD}}}$$

where  $v_w$  as defined in [2.7.3],  $MBL_{SD}$  as defined above and  $MBL_{SD}^*$  the ship design minimum breaking load of the mooring lines intended to be supplied.

However, the ship design minimum breaking load is not to be taken less than corresponding to an acceptable wind speed of 21 m/s:

$$MBL_{SD}^* \geq \left(\frac{21}{v_w}\right)^2 MBL_{SD}$$

If lines are intended to be supplied for an acceptable wind speed  $v_w^*$  higher than  $v_w$  as defined in [2.7.3], the ship design minimum breaking load  $MBL_{SD}^*$  is to be taken as:

$$MLB_{SD}^* = \left(\frac{v_w^*}{v_w}\right)^2 MBL_{SD}$$

### 2.7.5 Length of mooring lines

For ships with  $EN > 2000$ , the length of mooring lines may be taken as 200 m.

### 2.7.6 Head, stern and breast lines

The total number of head, stern and breast lines is to be taken as:

- for ships with one of the service notations **oil tanker**, **oil tanker ESP**, **chemical tanker ESP**, **bulk carrier**, **bulk carrier ESP**, **self-unloading bulk carrier ESP**, **ore carrier ESP** or **combination carrier ESP**:

$$n = 8,3 \cdot 10^{-4} A_1 + 4$$

- for other ships:

$$n = 8,3 \cdot 10^{-4} A_1 + 6$$

This number  $n$  is to be rounded to the nearest whole number and may be increased or decreased in conjunction with an adjustment to the strength of the lines. The adjusted ship design minimum breaking load  $MBL_{SD}^{**}$ , should be taken as:

- for increased number of lines:

$$MBL_{SD}^{**} = 1,2 \cdot MBL_{SD} \cdot \frac{n}{n^{**}} \leq MBL_{SD}$$

- for reduced number of lines:

$$MBL_{SD}^{**} = MBL_{SD} \cdot \frac{n}{n^{**}}$$

where  $MBL_{SD}$  is  $MBL_{SD}$  or  $MBL_{SD}^*$  specified in [2.7.4],  $n^{**}$  is the increased or decreased total number of head, stern and breast lines and  $n$  the number of lines for the considered ship type as calculated by the above formulas without rounding.

Vice versa, the ship design minimum breaking load of head, stern and breast lines may be increased or decreased in conjunction with an adjustment to the number of lines.

### 2.7.7 Spring lines

The total number of spring lines is to be taken not less than:

- for ship with  $EN < 5000$ : two lines
- for ships with  $EN \geq 5000$ : four lines.

The ship design minimum breaking load of spring lines is to be the same as that of the head, stern and breast lines. If the number of head, stern and breast lines is increased in conjunction with an adjustment to the ship design minimum breaking load of the lines, the number of spring lines should be taken as follows, but rounded up to the nearest even number:

$$n_s^* = \frac{MBL_{SD}}{MBL_{SD}^{**}} \cdot n_s$$

where  $MBL_{SD}$  is  $MBL_{SD}$  or  $MBL_{SD}^*$  specified in [2.7.4],  $n_s$  is the number of spring lines as given above and  $n_s^*$  is the increased number of spring lines.

Section 6	Testing
Appendix 1	Welding Details
Appendix 2	Reference Sheets for Special Structural Details

# Section 1 Construction and Fabrication

## 1 General

### 1.1 Workmanship

**1.1.1** All workmanship is to be of standard marine quality and acceptable to the Surveyor. Welding is to be in accordance with the requirements of Ch 13, Sec 2. Any defect is to be rectified to the satisfaction of the Surveyor before the material is covered with paint, cement or any other composition.

### 1.2 Fabrication standard

**1.2.1** Structural fabrication is to be carried out in accordance with IACS Recommendation No. 47 or with a recognised fabrication standard which has been accepted by the Society prior to the commencement of fabrication/construction.

**1.2.2** The fabrication standard to be used during fabrication/construction is to be made available to the attending representative of the Society prior to the commencement of the fabrication/construction.

**1.2.3** The fabrication standard is to include information, to establish the range and the tolerance limits, for the items specified as follows:

- a) Cut edges:  
The slope of the cut edge and the roughness of the cut edges.
- b) Flanged stiffeners and brackets and built-up sections:  
The breadth of flange and depth of web, angle between flange and web, and straightness in plane of flange or at the top of face plate.
- c) Pillars:  
The straightness between decks and cylindrical structure diameter.
- d) Brackets and flat bar stiffeners:  
The distortion at the free edge line of tripping brackets and flat bar stiffeners.
- e) Sub-assembly stiffeners:  
Details of sniped end of face plates and webs.
- f) Plate assembly:  
For flat and curved blocks, the dimensions (length and breadth), distortion and squareness, and the deviation of interior members from the plate.
- g) Cubic assembly:  
In addition to the criteria for plate assembly, twisting deviation between upper and lower plates, for flat and curved cubic blocks.
- h) Special assembly:  
The distance between upper and lower gudgeons, distance between aft edge of propeller boss and aft peak bulkhead, twist of stern frame assembly, breadth and length of top plate of main engine bed. Where boring out of the propeller boss and stern frame, skeg or solepiece are to be carried out after completing the major part of the welding of the aft part of the ship. Where block boring is used, the shaft alignment is to be carried out using a method and sequence submitted to and recognised by the Society. The fit-up and alignment of the rudder, pintles and axles are to be carried out after completing the major parts of the welding of the aft part of the ship. The contacts between the conical surfaces of pintles, rudder stocks and rudder axles are to be checked before the final mounting.
- i) Butt joints in plating:  
Alignment of butt joint in plating.
- j) Cruciform joints:  
Alignment measured on the median line and measured on the heel line of cruciform joints.
- k) Alignment of interior members:  
Alignments of flange of T profiles, alignment of panel stiffeners, gaps in T joints and lap joints, and distance between scallop and cut-outs for continuous stiffeners in assembly and in erection joints.
- l) Keel and bottom sighting:  
Deflections for whole length of the ship, and for the distance between two adjacent bulkheads, cocking-up of fore body and of aft body, and rise of floor amidships.

m) Dimensions:

Length between perpendiculars, moulded breadth and depth at midship, and length between aft edge of propeller boss and main engine.

n) Fairness of plating between frames:

Deflections between frames of shell, tank top, bulkhead, upper deck, superstructure deck, deckhouse deck and wall plating.

o) Fairness of plating in way of frames:

Deflections of shell, tank top, bulkhead, strength deck plating and other structures measured in way of frames.

## 2 Cut-outs, plate edges

### 2.1 General

**2.1.1** The free edges (cut surfaces) of cut-outs, hatch corners, etc are to be properly prepared and are to be free from notches. As a general rule, cutting draglines, etc are to be smoothly ground. All edges are to be broken or in cases of highly stressed parts, be rounded off.

Free edges on flame or machine cut plates or flanges are not to be sharp cornered and are to be finished off as specified above. This also applies to cutting drag lines, etc, in particular to the upper edge of sheer strake and analogously to weld joints, changes in sectional areas or similar discontinuities.

**2.1.2** Corners in hatch opening are to be machine cut.

## 3 Cold forming

### 3.1 Special structural members

**3.1.1** For highly stressed components of the hull girder where notch toughness is of particular concern (e.g. items required to be Class III in Ch 4, Sec 1, Tab 3, such as radius gunwales (bent sheer plates) and bilge strakes), the inside bending radius, in cold formed plating, is not to be less than 10 times the as-built plate thickness for carbon-manganese steels (see Ch 4, Sec 1). The allowable inside bending radius may be reduced provided the requirements stated in [3.3] are complied with.

### 3.2 Corrugated bulkheads and hopper knuckles

**3.2.1** For corrugated bulkheads and hopper knuckles, the inside bending radius  $R$ , as defined in Ch 4, Sec 5, Fig 27, in cold formed plating, is not to be less than 4.5 times the as-built plate thickness for carbon-manganese steels (see Ch 4, Sec 1). The allowable inside bending radius may be reduced provided the requirements stated in [3.3] are complied with.

### 3.3 Low bending radius

**3.3.1** When the inside bending radius is reduced below the limits defined [3.1], supporting data is to be provided. The bending radius is in no case to be less than 2 times the as-built plate thickness. As a minimum, the following additional requirements are to be complied with:

a) For all bent plates:

- 100% visual inspection of the bent area is to be carried out
- random checks by magnetic particle testing are to be carried out.

b) In addition to item a), for bent plates at boundaries to tanks or ballast holds:

- the steel is to be of grade D/DH or higher
- the material is impact tested in the strain-aged condition and satisfies the requirements stated herein. The deformation is to be equal to the maximum deformation to be applied during production, calculated by the formula  $t_{as-built} / (2r_{bdg} + t_{as-built})$ , where  $t_{as-built}$  is the as-built thickness of the plate material and  $r_{bdg}$  is the bending radius. One sample is to be plastically strained at the calculated deformation or 5%, whichever is greater and then artificially aged at 250°C for one hour then subject to Charpy V-notch testing. The average impact energy after strain ageing is to meet the impact requirements specified for the grade of steel used.

## 4 Hot forming

### 4.1 Temperature requirements

**4.1.1** Steel is not to be formed between the upper and lower critical temperatures. If the forming temperature exceeds 650°C for as-rolled, controlled rolled, thermo-mechanical controlled rolled or normalised steels, or is not at least 30°C lower than the tempering temperature for quenched and tempered steels, mechanical tests are to be made to assure that these temperatures have not adversely affected both the tensile and impact properties of the steel. Where curve forming or fairing, by line or spot heating, is carried out in accordance with [4.2.1], these mechanical tests are not required.

**4.1.2** After further heating, other than specified in [4.1.1], of thermo-mechanically controlled steels (TMCP plates) for forming and stress relieving, it is to be demonstrated that the mechanical properties meet the requirements specified by a procedure test using representative material.

## **4.2 Line or spot heating**

**4.2.1** Curve forming or fairing, by linear or spot heating, is to be carried out using approved procedures in order to ensure that the properties of the material are not adversely affected. Heating temperature on the surface is to be controlled so as not to exceed the maximum allowable limit applicable to the plate grade.

## **5 Modifications and repairs during construction**

### **5.1 General**

**5.1.1** Deviations in the joint preparation and other specified requirements, in excess of the permitted tolerances and found during construction, are to be repaired as agreed with the Society on a case by case basis.

### **5.2 Gap and weld deformations**

**5.2.1** Welding by building up of gaps exceeding the required values and repairs of weld deformations may be accepted by the Society upon special examination.

### **5.3 Defects**

**5.3.1** Defects and imperfections on the materials and welded connections found during construction are to be evaluated for possible acceptance on the basis of the applicable requirements of the Society.

Where the limits of acceptance are exceeded, the defective material and welds are to be discarded or repaired, as deemed appropriate by the Surveyor on a case by case basis.

When any serious or systematic defect is detected either in the welded connections or in the base material, the manufacturer is required to promptly inform the Surveyor and submit the repair proposal.

The Surveyor may require destructive or non-destructive examinations to be carried out for initial identification of the defects found and, in the event that repairs are undertaken, for verification of their satisfactory completion.

### **5.4 Repairs on structures already welded**

**5.4.1** In the case of repairs involving the replacement of material already welded on the hull, the procedures to be adopted are to be agreed with the Society on a case by case basis.

## Section 2 Fabrication by Welding

### 1 General

#### 1.1 Application

**1.1.1** The requirements of this Section apply for the preparation, execution and inspection of welded connections in hull structures.

They are to be complemented by the criteria given in Ch 13, App 1, to which reference is made. These criteria being given as recommendations, minor departures may be accepted by the Society, on a case by case basis.

The general requirements relevant to fabrication by welding and qualification of welding procedures are given in NR216 Materials and Welding, Chapter 12.

**1.1.2** Weld connections are to be executed according to the approved plans. A detail not specifically represented in the plans is, if any, to comply with the applicable requirements.

**1.1.3** It is understood that welding of the various types of steel is to be carried out by means of welding procedures approved for the purpose, even though an explicit indication to this effect may not appear on the approved plans.

**1.1.4** The quality standard adopted by the shipyard is to be submitted to the Society and applies to all constructions unless otherwise specified on a case by case basis.

#### 1.2 Base material

**1.2.1** The requirements of this Section apply for the welding of hull structural steels or aluminium alloys of the types considered in NR216 Materials and Welding or other types accepted as equivalent by the Society.

**1.2.2** The service temperature is intended to be the ambient temperature, unless otherwise stated.

#### 1.3 Documentation to be submitted

**1.3.1** The structural plans to be submitted for approval, according to Ch 1, Sec 4, are to contain the necessary data relevant to the fabrication by welding of the structures and items represented as far as class is concerned.

For important structures, the main sequences of prefabrication, assembly and welding and non-destructive examination planned are also to be represented in the plans.

Plans relevant to the special details specified in Ch 13, Sec 5 are to be submitted.

**1.3.2** A plan showing the location of the various steel types is to be submitted at least for outer shell, deck and bulkhead structures.

#### 1.4 Personnel and equipment

##### 1.4.1 Welders and welding operators

Welders for manual welding and for semi-automatic welding processes are to be properly trained and are to be certified by the Society, as required in the individual applications, unless otherwise agreed.

Welders are to be certified according to the procedures given in Rule Note NR476 Approval Testing of Welders.

The certification is to be in due course of validity.

Personnel manning the automatic welding machines are to be competent and sufficiently trained.

##### 1.4.2 Automatic welding operators

Personnel manning automatic welding machines and equipment are to be competent and sufficiently trained.

##### 1.4.3 Organisation

The internal organisation of the shipyard is to be such as to ensure compliance with the requirements in [1.4.1] and [1.4.2] and to provide for assistance and inspection of welding personnel, as necessary, by means of a suitable number of competent supervisors.

##### 1.4.4 Non-destructive testing operators

Requirements for NDT personnel are given in Ch 13, Sec 4, [3].

**1.4.5 Technical equipment and facilities**

The welding equipment is to be appropriate to the adopted welding procedures, of adequate output power and such as to provide for stability of the arc in the different welding positions.

In particular, the welding equipment for special welding procedures is to be provided with adequate and duly calibrated measuring instruments, enabling easy and accurate reading, and adequate devices for easy regulation and regular feed.

Manual electrodes, wires and fluxes are to be stored in suitable locations so as to ensure their preservation in proper condition. Especially, where consumables with hydrogen-controlled grade are to be used, proper precautions are to be taken to ensure that manufacturer’s instructions are followed to obtain (drying) and maintain (storage, maximum time exposed, re-backing, ...) hydrogen-controlled grade.

**2 Welding**

**2.1 General**

**2.1.1** All welding is to be carried out by approved welders, in accordance with approved welding procedures, using approved welding consumables, in compliance with NR216 Materials and welding.

**2.2 Welding consumables and procedures**

**2.2.1 Approval of welding consumables and procedures**

Welding consumables and welding procedures adopted are to be approved by the Society.

The requirements for the approval of welding consumables are given in NR216 Materials and Welding, Chapter 11.

The requirements for the approval of welding procedures are given in NR216 Materials and Welding, Chapter 12.

**2.2.2 Consumables**

For welding of hull structural steels, the minimum consumable grades to be adopted, as defined in NR216 Materials and welding, are specified in Tab 1 depending on the steel grade.

Consumables used for manual or semi-automatic welding (covered electrodes, flux-cored and flux-coated wires) of higher strength hull structural steels are to be at least of hydrogen-controlled grade H15 (H). Where the carbon equivalent  $C_{eq}$  is not more than 0,41% and the thickness is below 30 mm, any type of approved higher strength consumables may be used at the discretion of the Society.

Especially, welding consumables with hydrogen-controlled grade H15 (H) and H10 (HH) shall be used for welding hull steel forgings and castings of respectively ordinary strength level and higher strength level.

Where quality control systems are in place which ensure that the grade of welding consumable used is higher than the minimum required for the particular strength steel being welded, the welding consumables that are used may have a weld deposit material yield strength that is greater than  $R_{eH\_weld}$  specified in Ch 13, Sec 3 and the size of the weld may be determined based on the yield strength of the higher grade welding consumable.

**Table 1 : Consumable grades**

Steel grade	Consumable minimum grade	
	Butt welding, partial and full T penetration welding	Fillet welding
A	1	1
B - D	2	
E	3	
AH32 - AH36 - DH32 - DH36	2Y	2Y
EH32 - EH36 - EH36CAS	3Y	
FH32 - FH36 - FH36CAS	4Y	
AH40	2Y40	2Y40
DH40 - EH40 - EH40CAS	3Y40	
FH40 - FH40CAS	4Y40	
EH47 - EH47CAS	3Y47	3Y47

**Note 1:** Welding consumables approved for welding higher strength steels (Y) may be used in lieu of those approved for welding normal strength steels having the same or a lower grade; welding consumables approved in grade Y40 may be used in lieu of those approved in grade Y having the same or a lower grade.

**Note 2:** In the case of welded connections between two hull structural steels of different grades, as regards strength or notch toughness, welding consumables appropriate to one or the other steel are to be adopted.

## 2.3 Welding operations

### 2.3.1 Weather protection

Adequate protection from the weather is to be provided to parts being welded; in any event, such parts are to be dry.

In welding procedures using bare, cored or coated wires with gas shielding, the welding is to be carried out in weather protected conditions, so as to ensure that the gas outflow from the nozzle is not disturbed by winds and draughts.

### 2.3.2 Butt connection edge preparation

The edge preparation is to be of the required geometry and correctly performed. In particular, if edge preparation is carried out by flame, it is to be free from cracks or other detrimental notches.

### 2.3.3 Surface condition

The surfaces to be welded are to be free from rust, moisture and other substances, such as mill scale, slag caused by oxygen cutting, grease or paint, which may produce defects in the welds.

Effective means of cleaning are to be adopted particularly in connections with special welding procedures; flame or mechanical cleaning may be required.

The presence of a shop primer may be accepted, provided it has been approved by the Society.

Shop primers are to be approved by the Society for a specific type and thickness according to NR216 Materials and Welding, Ch 13, Sec 1.

### 2.3.4 Assembling and gap

The setting appliances and system to be used for positioning are to ensure adequate tightening adjustment and an appropriate gap of the parts to be welded, while allowing maximum freedom for shrinkage to prevent cracks or other defects due to excessive restraint.

The gap between the edges is to comply with the required tolerances or, when not specified, it is to be in accordance with normal good practice.

Completed welded joints are to be to the satisfaction of the attending Surveyor. Edge preparations and root gaps are to be in accordance with the approved welding procedure. The gap between the members being joined should not exceed the maximum values given in IACS Recommendation No. 47 or as specified in recognised fabrication standard approved by the Society. Where the gap between members being joined exceeds the specified values, corrective measures are to be taken in accordance with an approved welding procedure specification.

### 2.3.5 Gap in fillet weld tee connections

In fillet weld tee connections, a gap  $g$ , as shown in Fig 1, not greater than 2 mm may be accepted without increasing the throat thickness calculated according to Ch 13, Sec 3, [3.2.7] or Ch 4, Sec 5, [5.2.8], as applicable.

In the case of a gap greater than 2 mm, the above throat thickness is to be increased accordingly as specified in Ch 13, Sec 5 for some special connections of various ship types.

In any event, the gap  $g$  may not exceed 4 mm.

### 2.3.6 Plate misalignment in butt connections

The misalignment  $m$ , measured as shown in Fig 2, between plates with the same as-built thickness  $t_{as-built}$  is to be less than  $0,15 t_{as-built}$  without being greater than 3 mm.

### 2.3.7 Misalignment in cruciform connections

The misalignment  $m$  in cruciform connections, measured on the median lines as shown in Fig 3, is to be less than:

- $t_{as-built}/2$ , in general, where  $t_{as-built}$  is the thickness of the thinner abutting plate
- the values specified in Ch 13, Sec 5 for some special connections of various ship types.

The Society may require lower misalignment to be adopted for cruciform connections subjected to high stresses.

Figure 1 : Gap in fillet weld tee connections

Figure 2 : Plate misalignment in butt connections

Figure 3 : Misalignment in cruciform connections

### 2.3.8 Assembling of aluminium alloy parts

When welding aluminium alloy parts, particular care is to be taken so as to:

- reduce as far as possible restraint from welding shrinkage, by adopting assembling and tack welding procedures suitable for this purpose
- keep possible deformations within the allowable limits.

### 2.3.9 Preheating and interpass temperatures

Suitable preheating, to be maintained during welding, and slow cooling may be required by the Society on a case by case basis.

### 2.3.10 Welding sequences

Consideration is to be given to the assembly sequence and the effect of the overall shrinkage of plate panels, assemblies, etc, resulting from the welding processes employed. Welding is to proceed systematically, with each welded joint being completed in correct sequence, without undue interruption. When practicable, welding is to commence at the centre of a joint and proceed outwards, or at the centre of assembly and progress outwards towards the perimeter so that each part has freedom to move in one or more directions.

Welding sequences and direction of welding are to be determined so as to minimise deformations and prevent defects in the welded connection.

All main connections are generally to be completed before the ship is afloat.

Departures from the above provision may be accepted by the Society on a case by case basis, taking into account any detailed information on the size and position of welds and the stresses of the zones concerned, both during ship launching and with the ship afloat.

Moreover, during the welding operation afloat, loading conditions are to be adjusted in order to have an acceptable level of longitudinal stress.

Note 1: As a general guidance, the level of longitudinal stress during the welding operation is to be below 50 MPa in the concerned area; however, lower limits may be requested by the surveyor depending on the specificities of the ship and/or welding.

In general, butt joints are to be welded from both sides. Before welding is carried out on the second side, unsound metal is to be removed at the root by a suitable method. Butt welding from one side will only be permitted for specific applications with an approved welding procedure specification.

### **2.3.11 Interpass cleaning**

After each run, the slag is to be removed by means of a chipping hammer and a metal brush; the same precaution is to be taken when an interrupted weld is resumed or two welds are to be connected.

### **2.3.12 Stress relieving**

It is recommended and in some cases it may be required that special structures subject to high stresses, having complex shapes and involving welding of elements of considerable thickness (such as rudder spades and stern frames), are prefabricated in parts of adequate size and stress-relieved in the furnace, before final assembly, at a temperature within the range  $550^{\circ}\text{C} \div 620^{\circ}\text{C}$ , as appropriate for the type of steel.

### **2.3.13 Arrangements at junctions of welds**

Welds are to be made flush in way of the faying surface where stiffening members, attached by continuous fillet welds, cross the completely finished butt or seam welds. Similarly, butt welds in webs of stiffening members are to be completed and made flush with the stiffening member before the fillet weld is made. The ends of the flush portion are to run out smoothly without notches or sudden changes of section. Where these conditions can not be complied with, a scallop is to be arranged in the web of the stiffening member. Scallops are to be of the size, and in a position, that a satisfactory return weld can be made.

## **2.4 Crossing of structural elements**

**2.4.1** In the case of T crossing of structural elements (one element continuous, the other physically interrupted at the crossing) when it is essential to achieve structural continuity through the continuous element (continuity obtained by means of the welded connections at the crossing), particular care is to be devoted to obtaining the correspondence of the interrupted elements on both sides of the continuous element. Suitable systems for checking such correspondence are to be adopted.

## **2.5 Hatch coaming**

### **2.5.1 Application**

This sub-article applies to welding of plates having a minimum specified yield stress  $R_{eH}$  equal to 460 N/mm<sup>2</sup> and a thickness equal to or greater than 50 mm but not greater than 100 mm, used for longitudinal structural members in the upper deck region (such as hatch side coaming, hatch coaming top and attached longitudinal stiffeners).

Specific procedures are to be submitted to the Society for plates having a thickness greater than 100 mm.

Special care is to be paid to the final welding so that harmful defects do not remain.

### **2.5.2 Short bead**

Short bead length for tack and repairs of welds by welding is not to be less than 50 mm. In the case where the cold cracking susceptibility index  $P_{cmv}$ , as defined in NR216 Materials and Welding, is less than or equal to 0,19, short bead length of 25 mm may be considered by the Society on a case-by-case basis.

### **2.5.3 Preheating**

Preheating is to be at least 50°C when air temperature is 5°C and under. In the case where the cold cracking susceptibility index  $P_{cmv}$ , as defined in NR216 Materials and Welding, is less than or equal to 0,19, air temperature of 0°C and under may be considered by the Society on a case-by-case basis.

## **3 Inspections and checks**

### **3.1 General**

**3.1.1** Materials, workmanship, structures and welded connections are to be subjected, at the beginning of the work, during construction and after completion, to inspections by the Shipbuilder suitable to check compliance with the applicable requirements, approved plans and standards.

**3.1.2** The Shipbuilder is to make available to the Surveyor a list of the manual welders and welding operators and their respective qualifications.

The Shipbuilder's internal organisation is responsible for ensuring that welders and operators are not employed under improper conditions or beyond the limits of their respective valid qualifications and that welding procedures are adopted within the approved limits and under the appropriate operating conditions.

**3.1.3** The Shipbuilder is responsible for ensuring that the operating conditions, welding procedures and work schedule are in accordance with the applicable requirements, approved plans and recognised good welding practice.

**3.1.4** The Shipbuilder is responsible for ensuring that non-destructive testing are planned, carried out and reported in accordance with Ch 13, Sec 4.

## **3.2 Hatch coaming**

### **3.2.1 Application**

This sub-article applies to ships with hatch side coaming plate thickness  $t$  such that:

- $85 \text{ mm} \leq t \leq 100 \text{ mm}$  for steel with  $R_{eH} = 355 \text{ N/mm}^2$
- $50 \text{ mm} \leq t \leq 100 \text{ mm}$  for steel with  $R_{eH} = 390 \text{ N/mm}^2$  or  $R_{eH} = 460 \text{ N/mm}^2$ .

Special consideration is to be given to hatch side coaming plate thickness greater than 100 mm.

### **3.2.2 Ultrasonic testing**

Ultrasonic testing is to be performed on all block-to-block butt welds of upper longitudinal members along central part over their full lengths.

Upper longitudinal members are defined as follows:

- uppermost strakes of inner hull and longitudinal bulkheads
- sheerstrake
- main deck
- coaming side plate
- coaming top plate

and all their attached longitudinal stiffeners.

# Section 3 Design of Weld Joints

## Symbols

$A_{\text{weld}}$  : Effective fillet weld area, in  $\text{cm}^2$ , weld throat multiplied by weld length

$d$  : Length of the welded connection in mm

$f$  : Root face, in mm

$f_{\text{yd}}$  : Coefficient not to be taken less than:

$$f_{\text{yd}} = \left(\frac{1}{k}\right)^{0,50} \left(\frac{235}{R_{\text{eH\_weld}}}\right)^{0,75}$$

nor less than 0,71

$k$  : Material factor of the abutting member

$l_{\text{dep}}$  : Total length of deposit of weld metal, in mm

$l_{\text{leg}}$  : Leg length of continuous, lapped or intermittent fillet weld, in mm

$p$  : Distance between successive fillet welds, in mm

$R_{\text{eH\_weld}}$  : Minimum yield stress of weld deposit, in  $\text{N/mm}^2$

$R_{\text{eH\_weld}}$  : Specified minimum yield stress for the weld deposit, in  $\text{N/mm}^2$ , not to be less than:

- 305  $\text{N/mm}^2$  for welding of normal strength steel with  $R_{\text{eH}} = 235 \text{ N/mm}^2$
- 375  $\text{N/mm}^2$  for welding of higher strength steel with  $R_{\text{eH}}$  from 265 to 355  $\text{N/mm}^2$
- 400  $\text{N/mm}^2$  for welding of higher strength steel with  $R_{\text{eH}} = 390 \text{ N/mm}^2$
- 460  $\text{N/mm}^2$  for welding of higher strength steel with  $R_{\text{eH}} = 460 \text{ N/mm}^2$ .

$t_{\text{throat}}$  : Throat thickness of fillet weld in mm, as defined in [3.2.7]

$t_{\text{gap}}$  : Allowance for fillet weld gap, is to be taken equal to 2,0 mm

$t_{\text{as-built}}$  : As-built thickness of the plating abutting on another plating, in mm

$w_{\text{F}}$  : Weld factor

## 1 General

### 1.1 Application

#### 1.1.1 General

For the various structural details typical of welded construction in shipbuilding and not dealt with in this Section, the rules of good practice, recognised standards and past experience are to apply as agreed by the Society.

#### 1.1.2 Weld type, size and materials

The requirements of this Section apply to the design of welded connections in hull structures and are based on the following considerations:

- joint type
- criticality of the joint
- magnitude, type and direction of the stress in the joint
- material properties of the parent and weld material
- weld gap size.

**1.1.3** The requirements given in this Section are considered minimum for electric-arc welding in hull construction, but alternative methods, arrangements and details will be specially considered for approval.

**1.1.4** Plans and/or specifications showing weld sizes and weld details are to be submitted for approval.

#### 1.1.5 Minimum leg length

Whether the welds are continuous or intermittent, the leg length thickness of the fillet welds is not to be less than:

- 4,0 mm, for plating as built thickness of less than 6 mm
- 5,0 mm, otherwise.

## 1.2 Arrangement

### 1.2.1 Plate orientation

The plates of the shell and strength deck are generally to be arranged with their length in the fore-aft direction. Possible exceptions to the above will be considered by the Society on a case-by-case basis; tests as deemed necessary (for example, transverse impact tests) may be required by the Society.

### 1.2.2 Overall arrangement

Particular consideration is to be given to the overall arrangement and structural details of highly stressed parts of the hull.

### 1.2.3 Prefabrication sequences

Prefabrication sequences are to be arranged so as to facilitate positioning and assembling as far as possible.

The amount of welding to be performed on board is to be limited to a minimum and restricted to easily accessible connections.

### 1.2.4 Distance between welds

In general, the distance between two adjacent butts in the same strake of shell or deck plating is to be greater than two frame spaces.

## 2 Butt joint

### 2.1 General

**2.1.1** In general, butt connections of plating are to be full penetration, welded on both sides except where special procedures or specific techniques, considered equivalent by the Society, are adopted.

Connections different from the above may be accepted by the Society on a case by case basis; in such cases, the relevant detail and workmanship specifications are to be approved.

### 2.1.2 Welding of plates with different thicknesses

In the case of welding of plates with difference in as-built thickness greater than 4 mm on one side, the thicker plate is normally to be tapered. The taper length is to be not less than 3 times the difference in as-built thickness on the considered side (see Fig 1).

Figure 1 : Taper length

### 2.1.3 Edge preparation, root gap

Typical edge preparations and gaps are indicated in Ch 13, App 1, [1.2].

The acceptable root gap is to be in accordance with the adopted welding procedure and relevant bevel preparation.

### 2.1.4 Butt welding on permanent backing

Butt welding on permanent backing, i.e. butt welding assembly of two plates backed by the flange or the face plate of a stiffener, may be accepted where back welding is not feasible or in specific cases deemed acceptable by the Society.

The type of bevel and the gap between the members to be assembled are to be such as to ensure a proper penetration of the weld on its backing and an adequate connection to the stiffener as required.

### 2.1.5 Section, bulbs and flat bars

When lengths of longitudinals of the shell plating and strength deck within 0,6 L amidships, or elements in general subject to high stresses, are to be connected together by butt joints, these are to be full penetration. Other solutions may be adopted if deemed acceptable by the Society on a case by case basis.

The work is to be done in accordance with an approved procedure; in particular, this requirement applies to work done on board or in conditions of difficult access to the welded connection. Special measures may be required by the Society.

Welding of bulbs without a doubler is to be performed by welders specifically certified by the Society for such type of welding.

### 3 Tee or cross joint

#### 3.1 Application

**3.1.1** The connection of primary supporting members, stiffener webs to plating as well as the plating abutting on another plating, are to be made by fillet or penetration welding, as shown in Fig 2.

**3.1.2** Where the connection is highly stressed or otherwise considered critical, a partial or full penetration weld is to be achieved by bevelling the edge of the abutting plate.

**Figure 2 : Tee or cross joints**

$t_{as-built}$  : As-built thickness of the member being attached, in mm  
 $\theta$  : Connecting angle, in deg.

#### 3.2 Fillet welding

##### 3.2.1 General

Ordinary fillet welding may be adopted for tee connections of the various simple and composite structural elements, where they are subjected to low tensile stress or where they are not critical for fatigue.

Where this is not the case, partial or full tee penetration welding according to [3.3] is to be adopted.

**3.2.2** The required weld sizes are to be rounded to the nearest half millimetre.

##### 3.2.3 Fillet welding types

Fillet welding may be of the following types:

- continuous fillet welding, where the weld is constituted by a continuous fillet on each side of the abutting plate (see [3.2.4])
- intermittent fillet welding, which may be subdivided (see [3.2.5]) into:
  - chain welding
  - scallop welding
  - staggered welding.

##### 3.2.4 Continuous fillet welding

Continuous fillet welding is to be adopted in general:

- for watertight connections
- for connections of brackets, lugs and scallops
- at the ends of connections for a length of at least 75mm
- where intermittent welding is not allowed, according to [3.2.5]
- for connections of stiffeners subject to wheeled loads.

Continuous fillet welding may also be adopted in lieu of intermittent welding wherever deemed suitable, and it is recommended where the spacing  $p$ , calculated according to [3.2.5], is low.

##### 3.2.5 Intermittent welding

Where continuous welding is not required, intermittent welding may be applied.

Where beams, stiffeners, frames, etc. are intermittently welded and pass through slotted girders, shelves or stringers, there is to be a pair of matched intermittent welds (double continuous welds having the length of an intermittent fillet weld) on each side of every intersection. In addition, the beams, stiffeners and frames are to be efficiently attached to the girders, shelves and stringers.

Where intermittent welding or one side continuous welding is permitted, double continuous welds are to be applied for one-tenth of their shear span at each end, in accordance with [3.2.6] and [3.2.7].

One side continuous welding may be accepted instead of chain and staggered intermittent welding for connections of stiffeners in the dry spaces of deckhouses and superstructures, where not affected by sea pressure, tank pressure or concentrated loads.

The size for one side continuous weld is to be of fillet required by [3.2.6] for intermittent welding, where  $f_3$  factor is to be taken as 2,0.

The spacing  $p$  and the length  $d$ , in mm, of an intermittent weld, shown in:

- Fig 3, for chain welding
- Fig 4, for scallop welding
- Fig 5, for staggered welding

are to be such that:

$$\frac{p}{d} \leq \varphi$$

where the coefficient  $\varphi$  is defined in Tab 1 and Tab 3 for the different types of intermittent welding, depending on the type and location of the connection.

In general, staggered welding is not allowed for connections subjected to high alternate stresses.

In addition, the following limitations are to be complied with:

- chain welding (see Fig 3):
  - $d \geq 75$  mm
  - $p - d \leq 200$  mm
- scallop welding (see Fig 4):
  - $d \geq 75$  mm
  - $p - d \leq 150$  mm
  - $v \leq 0,25 b$  without being greater than 75 mm
- staggered welding (see Fig 5):
  - $d \geq 75$  mm
  - $p - 2d \leq 300$  mm
  - $p \leq 2d$  for connections subjected to high alternate stresses.

**Figure 3 : Intermittent chain welding**

**Figure 4 : Intermittent scallop welding**

**Figure 5 : Intermittent staggered welding**

### 3.2.6 Leg length

The leg length  $l_{leg}$ , in mm, of continuous, lapped or intermittent fillet welds is not to be taken less than the greater of the following values:

$$l_{leg} = f_1 f_2 t_{as-built}$$

$$l_{leg} = f_{yd} w_F f_2 f_3 t_{as-built} + t_{gap}$$

nor less than the minimum values given in [1.1.5],

where:

- $f_1$  : Coefficient depending on the welding type:
  - $f_1 = 0,30$  for double continuous welding
  - $f_1 = 0,38$  for intermittent welding
- $f_2$  : Coefficient depending on the edge preparation:
  - $f_2 = 1,0$  for welds without bevelling
  - $f_2 = 0,7$  for welds with one/both side bevelling and  $f = t_{as-built} / 3$  (see Ch 13, App 1)
- $w_F$  : Weld factor, defined in Tab 1 for various hull structural connections and Tab 2; for connections of primary supporting members belonging to single skin structures and not mentioned in Tab 1 or Tab 2,  $w_F$  is defined in Tab 3; for some connections of specific ship types, the values of  $w_F$  specified in Part D or Part E for these ship types are to be used in lieu of the corresponding values in Tab 1, Tab 2 or Tab 3
- $f_3$  : Correction factor for the type of weld:
  - $f_3 = 1,0$  for double continuous weld
  - $f_3 = p / d$  for intermittent welding

Leg length for intermittent welding is not to exceed the greater of 6,5 mm or 0,62  $t_{as-built}$ .

### 3.2.7 Throat size

The throat size, in mm, as shown in Fig 6, is not to be less than:

$$t_{throat} = \frac{l_{leg}}{\sqrt{2}}$$

In the case of automatic or semi-automatic deep penetration weld, the throat thickness (the minimum values included) may be reduced according to [3.2.13].

The throat thickness may be required by the Society to be increased, depending on the results of structural analyses.

Figure 6 : Weld scantlings definitions

### 3.2.8 Longitudinal stiffeners

Welding of longitudinal stiffeners to plating is to be double continuous at the ends of the longitudinal stiffeners over 15% of their shear span as defined in Ch 4, Sec 6, [1.1.3].

In way of primary supporting members, the length of the double continuous weld is to be equal to the depth of the longitudinal or the end bracket, whichever is greater.

Where the as-built web thickness of the abutting longitudinal stiffener is greater than 15 mm and exceeds the thickness of the attached plating, the welding is to be double continuous and the leg length of the weld is not to be less than the greatest of the following values:

- a)  $0,30 t_{as-built}$ , where  $t_{as-built}$  is the as-built thickness of the attached plating without being taken greater than 30 mm
- b)  $0,27 t_{as-built} + 1$ , where  $t_{as-built}$  is the as-built thickness of the abutting member. The leg size resulting of this formula need not be taken greater than 8,0 mm
- c) the minimum leg length given in [1.1.5].

**Table 1 : Weld factors  $w_F$  and coefficient  $\phi$  for the various hull structural connections**

(1) In connections for which  $w_F \geq 0,50$ , continuous fillet welding is to be adopted  
(2) For coefficient  $\phi$ , see [3.2.5]. In connections for which no  $\phi$  value is specified for a certain type of intermittent welding, such type is not permitted and continuous welding is to be adopted  
(3) CH = chain welding, SC = scallop welding, ST = staggered welding  
(4) The web at the end of intermittently welded girders or stiffeners is to be continuously welded to the plating or the flange plate, as applicable, over a distance  $d$  at least equal to the depth  $h$  of the girder or stiffeners, with  $300 \text{ mm} \geq d \geq 75 \text{ mm}$ . Where end brackets are fitted, ends means the area extended in way of brackets and at least 50 mm beyond the bracket toes  
(5) For connections not mentioned, the requirements for the central part apply  
(6)  $A$  is the face plate sectional area of the side girders, in  $\text{cm}^2$   
(7)  $w_F = 0,43$  for hatch coaming other than in cargo holds  
(8) Continuous welding

**Table 2 : Weld factors  $w_F$  for miscellaneous fittings and equipment**

Item		Connection to	$w_F$
Hatch cover	Primary supporting members	at ends (10% of span) of PSM	0,48
		elsewhere	0,24
	Stiffeners	at ends	0,38
		elsewhere	0,20
Mast, derrick post, crane pedestal, etc.		deck / underdeck reinforced structure	0,43
Deck machinery seat		deck	0,24
Mooring equipment seat		deck	0,43
Ring for access hole type cover		anywhere	0,43
Stiffening of side shell doors and weathertight doors		anywhere	0,24
Frames of shell and weathertight doors		anywhere	0,43
Coaming of ventilator and air pipe		deck	0,43
Ventilators, etc., fittings		anywhere	0,24

Cleats and fittings		hatch coaming and hatch cover	0,24 (1)

(1) Minimum value of the weld factor. Where  $t_{as-built} > 11,5\text{mm}$ ,  $l_{leg}$  need not exceed  $0,62 t_{as-built}$ . Penetration welding may be required depending on the design.

**Table 3 : Welding factors  $w_F$  and coefficient  $\phi$  for connections of primary supporting members**

Primary supporting member	Connection		$w_F$ (1)	$\phi$ (2) (3)			$p_1$ , in mm (see [3.2.9]) (3)
	of	to		CH	SC	ST	
General (4)	web, where $A < 65 \text{ cm}^2$	plating	at ends	0,48			
			elsewhere	0,38	3,0	3,0	CH/SC 210
		face plate	at ends	0,28			
			elsewhere	0,24	3,0	3,0	CH/SC 210
	web, where $A \geq 65 \text{ cm}^2$	plating	at ends	0,48			
			elsewhere	0,38			
		face plate	at ends	0,50			
			elsewhere	0,38	1,8	1,8	CH/SC 130
end brackets	face plate	0,38					
In tanks, where $A < 65 \text{ cm}^2$ (5)	web	plating	at ends	0,48			
			elsewhere	0,38	2,2	2,2	CH/SC 160
		face plate	at ends	0,28			
			elsewhere	0,24	3,0	3,0	CH/SC 210
	end brackets	face plate	0,48				
In tanks, where $A \geq 65 \text{ cm}^2$	web	plating	at ends	0,48			
			elsewhere	0,38			
		face plate	0,38				
	end brackets	face plate	0,48				

(1) In connections for which  $w_F \geq 0,50$  continuous fillet welding is to be adopted.  
(2) For coefficient  $\phi$ , see [3.2.5]. In connections for which no  $\phi$  value is specified for a certain type of intermittent welding, such type is not permitted.  
(3) CH = chain welding, SC = scallop welding, ST = staggered welding.  
(4) For cantilever deck beams, continuous welding is to be adopted.  
(5) For primary supporting members in tanks intended for the carriage of ballast or fresh water, continuous welding is to be adopted.  
**Note 1:** A is the face plate sectional area of the primary supporting member, in  $\text{cm}^2$ .  
**Note 2:** Ends of primary supporting members means the area extended 15% of the shear span from the span ends. Where end brackets are fitted, ends means the area extended in way of brackets and at least 100 mm beyond the bracket toes.

**3.2.9 Weld dimensions in a specific case**

Where intermittent fillet welding is adopted with:

- length  $d = 75 \text{ mm}$
- throat thickness  $t_{throat}$  specified in Tab 4 depending on the thickness  $t_{as-built}$

the weld spacing may be taken equal to the value  $p_1$  defined in Tab 1. The values of  $p_1$  in Tab 1 may be used when:

$8 \leq t_{as-built} \leq 16 \text{ mm}$ .

For thickness  $t_{as-built}$  less than 8 mm, the values of  $p_1$  may be increased, with respect to those in Tab 1, by:

- 10 mm for chain or scallop welding
- 20 mm for staggered welding,

without exceeding the limits in [3.2.5].

For thickness  $t_{as-built}$  greater than 16 mm, the values of  $p_1$  are to be reduced, with respect to those in Tab 1, by:

- 10 mm for chain or scallop welding
- 20 mm for staggered welding.

Table 4 : Required throat thickness

$t_{as-built}$ in mm	$t_{throat}$ in mm	$t_{as-built}$ in mm	$t_{throat}$ in mm
6	3,0	17	7,0
8	3,5	18	7,0
9	4,0	19	7,5
10	4,5	20	7,5
11	5,0	21	8,5
12	5,5	22	8,5
13	6,0	23	9,0
14	6,0	24	9,0
15	6,5	25	10,0
16	6,5	26	10,0

3.2.10 Throat thickness of welds between cut-outs

The throat thickness of the welds between the cut-outs in primary supporting member webs for the passage of ordinary stiffeners is to be not less than the value obtained, in mm, from the following formula:

$$t_{TC} = t_{throat} \frac{\epsilon}{\lambda}$$

where:

- $t_{throat}$  : Throat thickness defined in [3.2.7]
- $\epsilon, \lambda$  : Dimensions, in mm, to be taken as shown in:
  - Fig 7 for continuous welding
  - Fig 8 for intermittent scallop welding.

Figure 7 : Continuous fillet welding between cut-outs

Figure 8 : Intermittent scallop fillet welding between cut-outs

**3.2.11 Shear area of primary supporting member end connections**

Welding of the end connections of primary supporting members is to be such that the weld area is to be equivalent to the gross cross-sectional area of the member. The weld leg length  $l_{leg}$ , in mm, is to be taken as:

$$l_{leg} = 1,41 f_{yd} \frac{h_w t_{gr-req}}{l_{dep}}$$

where:

$h_w$  : Web height of primary supporting members, in mm

$t_{gr-req}$  : Required gross thickness, in mm, of the web in way of the end connection, including 10% of shear span, based on the highest average usage factor for yield from cargo hold FE analysis or the shear area requirement for PSM outside central part

$l_{dep}$  : Total length of deposit of weld metal, in mm, taken as (see Fig 9):

$$l_{dep} = 2 l_{weld}$$

$l_{weld}$  : Length of the welded connection in mm, as shown in Fig 9

The size of weld is not to be less than the value calculated in accordance with [3.2.6].

**3.2.12 Longitudinal continuity provided by brackets**

Where the longitudinal continuity of a member contributing to the longitudinal strength of the ship is provided by brackets, the weld area  $A_{weld}$  is not to be less than the gross cross-sectional area of the member. The weld area  $A_{weld}$ , in  $cm^2$ , is to be determined by the following formula:

$$A_{weld} = \frac{f_{yd} t_{throat} l_{dep}}{100}$$

**Figure 9 : Shear area of primary supporting member**

Note: The length  $l_{weld}$  is the length of the welded connection. The total length of the weld deposit  $l_{dep}$  if welded with double continuous fillet welds is twice the length of the welded connection  $l_{weld}$ .

**3.2.13 Reduced weld size of deep penetration fillet welding**

Where an approved automatic deep penetration procedure is used and where the gap between the assembled members can be controlled to be not more than 1 mm, the weld factors given in Tab 2 may be reduced by 15%, without leading to leg size reduction of more than 1,5 mm. Reductions of up to 20%, without leading to leg size reduction of more than 1,5 mm, will be accepted provided that the shipyard is able to demonstrate that the following requirements are consistently met:

- a) The welding is performed in accordance with welding procedure tests covering both minimum and maximum root gaps.
- b) The weld penetration at the root is at least equivalent to the granted leg size reduction.
- c) An established quality control system is in place.

The same reduction applies also for semi-automatic procedures where the welding is carried out in the downhand position.

### **3.2.14 Reduced weld size justification**

Where any of the methods for reduction of the weld size are adopted, the specific requirements allowing the reduction are to be indicated on the drawings. The drawings are to document the weld design and dimensioning requirements for the reduced weld length and the required weld leg length given by [3.2.6] without the leg length reduction. Also, notes are to be added to the drawings to describe the difference in the two leg lengths and the requirements for their application.

## **3.3 Partial or full penetration welds**

### **3.3.1 Partial or full penetration welding**

In areas with high tensile stresses or areas considered critical, full or partial penetration welds are to be used.

Partial or full tee penetration welding is required, in any event, where indicated for the connections specified in Part D or Part E depending on the ship type. Further requirements are specified in Ch 13, Sec 5.

Examples of partial or full penetration welds with typical edge preparation are given in Ch 13, App 1.

### **3.3.2 One side partial penetration weld**

For partial penetration welds with one side bevelling the fillet weld at the opposite side of the bevel is to satisfy the requirements given in [3.2].

### **3.3.3 Extent of full or partial penetration welding**

The extent of full or partial penetration welding in each particular location listed in [3.3.5] and [3.3.6] is to be approved by the Society. However, the minimum extent of full/partial penetration welding from the reference point (i.e. intersection point of structural members, end of bracket toe, etc.) is not to be taken less than 300 mm, unless otherwise specially stated.

### **3.3.4 Lamellar tearing**

Precautions are to be taken in order to avoid lamellar tears, which may be associated with:

- cold cracking when performing tee connections between plates of considerable thickness or high restraint
- large fillet welding and full penetration welding on higher strength steels.

### **3.3.5 Locations required for full penetration welding**

Full penetration welds are to be used in the following locations and elsewhere as required by these rules:

- a) floors to hopper/inner bottom plating in way of radiused hopper knuckle
- b) radiused hatch coaming plate at corners to deck
- c) connection of vertical corrugated bulkhead to the lower hopper plate and to the inner bottom plate within the cargo hold region, when the vertical corrugated bulkhead is arranged without a lower stool
- d) connection of structural elements in the double bottom in line with corrugated bulkhead flanges to the inner bottom plate, when the vertical corrugated bulkhead is arranged without a lower stool
- e) connection of vertical corrugated bulkhead to the lower hopper plate, and connection of structural elements in the lower hopper area in line with corrugated bulkhead flanges to the lower hopper plate, where connections are clear of lower stools
- f) connection of vertical corrugated bulkhead to top plating of lower stool.
- g) corrugated bulkhead lower stool side plating to lower stool top plate.
- h) corrugated bulkhead lower stool side plating to inner bottom
- i) connection of structural elements in double bottom to the inner bottom plate in holds intended for the carriage of liquid at sea with a distance of 300 mm from the side plating of the lower stool
- j) edge reinforcement or pipe penetration both to strength deck, sheer strake and bottom plating within 0,6 L amidships, when the dimensions of the opening exceeds 300 mm
- k) abutting plate panels with as-built thickness less than or equal to 12 mm, forming outer shell boundaries below the scantling draught, including but not limited to: sea chests, rudder trunks, and portions of transom. For as-built thickness greater than 12 mm, partial penetration in accordance with [3.3.1]
- l) crane pedestals and associated bracketing and support structure
- m) for toe connections of longitudinal hatch coaming end bracket to the deck plating, full penetration weld for a distance of  $0,15 H_c$  from toe of side coaming termination bracket is required, where  $H_c$  is the hatch coaming height
- n) rudder horns and shaft brackets to shell structure
- o) thick flanges of long transverse web frames to side web frames. Thick flanges of long longitudinal girder to bulkhead web frames
- p) brackets connecting face plates of cross decks and deck girders
- q) cross deck structures to transverse web frames (recommendation).

**3.3.6 Locations required for partial penetration welding**

Partial penetration welding as defined in [3.3.1], is to be used in the following locations:

- a) Connection of hopper sloping plate to longitudinal bulkhead (inner hull) or horizontal girder in double side space.
- b) End connection of longitudinal/transverse bulkhead primary supporting member, including buttress structure, to the double bottom and both end connections of backing bracket, where it is fitted
- c) Corrugated bulkhead lower stool supporting floors to inner bottom
- d) Corrugated bulkhead gusset and shedder plates
- e) Lower 15% of the length of built-up corrugation of vertical corrugated bulkheads
- f) structural elements in double bottom below bulkhead primary supporting members and stool plates, except in way of [3.3.5] item i)
- g) Lower hopper plate to inner bottom
- h) horizontal stringers on bulkheads in way of their bracket toe and the heel.

**3.3.7 Fine mesh finite element analysis**

High stress area means an area where fine mesh finite element analysis is to be carried out and the fine mesh yield utilisation factor in elements adjacent to the weld is more than 90% of the fine mesh permissible utilisation factor, as defined in Ch 8, App 2, [4.1.3]

In high stress area, at least partial penetration welds as defined in [3.3.1] are to be used. The minimum extent of full or partial penetration welding in that case is to be the greater of the following:

- 150 mm in either direction from the element with the highest yield utilisation factor
- the extent covering all elements that exceed the above mentioned yield utilisation factor criteria.

**4 Other types of joints**

**4.1 Lapped joints**

**4.1.1 General**

Lap joint welds may be adopted in very specific cases subject to the approval of the Society. Lap joint welds may be adopted for the following:

- peripheral connections of doubler plates
- internal structural elements subject to very low stress.

Elsewhere, lap-joint welding may be allowed by the Society on a case by case basis, if deemed necessary under specific conditions.

Continuous welding is generally to be adopted.

**4.1.2 Dimensions**

The dimensions of the lap-joint are to be specified and are considered on a case by case basis. Typical details are given in Ch 13, App 1, [1.4].

**4.1.3 Gap**

The surfaces of lap-joints are to be in sufficiently close contact.

**4.1.4 Overlaps for lugs**

The overlaps for lugs and collars in way of cut-outs for the passage of stiffeners through webs and bulkhead plating are not to be less than three times the thickness of the lug and not be greater than 50 mm.

**4.1.5 Lapped end connections**

Lapped end connections are to have continuous welds on each edge with leg length  $l_{leg}$ , in mm, as shown on Fig 10 such that the sum of the two leg lengths is not less than 1,5 times the as-built thickness of the thinner plate.

**Figure 10 : Fillet weld in lapped joint**

#### **4.1.6 Overlapped seams**

Overlapped seams are to have continuous welds on both edges, of the sizes required by [3.2.6] for the boundaries of tank/hold or watertight bulkheads. Seams for plates with as-built thickness of 12,5 mm or less, which are clear of tanks/holds, may have one edge with intermittent welds in accordance with [3.2.6] for watertight bulkhead boundaries.

### **4.2 Slot welds**

#### **4.2.1 General**

Slot welds may be adopted in very specific cases subject to the approval of the Society. However, slot welds of doublers on the outer shell and strength deck are not permitted within 0,6 L amidships.

#### **4.2.2 Dimensions**

Slot welds are to be of appropriate shape (in general oval) and dimensions, depending on the plate thickness, and may not be completely filled by the weld.

Typical dimensions of the slot weld and the throat thickness of the fillet weld are given in Ch 13, App 1, [1.4].

The distance between two consecutive slot welds is to be not greater than a value which is defined on a case by case basis taking into account:

- the transverse spacing between adjacent slot weld lines
- the stresses acting in the connected plates
- the structural arrangement below the connected plates.

#### **4.2.3 Closing plates**

For the connection of plating to internal webs, where access for welding is not practicable, the closing plating may be attached by slot welds to face plates fitted to the webs.

Slots are to be well-rounded and have a minimum slot length  $\ell$  of 90 mm and a minimum width  $G$  of twice the as-built plate thickness. Slots cut in plating are to have smooth, clean and square edges and are in general to be spaced a distance  $L$  not greater than 140 mm. Slots are not to be filled with welding.

### **4.3 Stud and lifting lug welds**

**4.3.1** Where permanent or temporary studs or lifting lugs are to be attached by welding to main structural parts in areas subject to high stress, the proposed locations are to be submitted for approval.

### **4.4 Plug welding**

**4.4.1** Plug welding may be adopted only when accepted by the Society on a case by case basis, according to specifically defined criteria. Typical details are given in Ch 13, App 1, [1.4].

## **5 Specific weld connections**

### **5.1 Bilge keels**

**5.1.1** The ground bar is to be connected to the shell with a continuous fillet weld, and the bilge keel to the ground bar with a continuous fillet weld in accordance with Tab 5.

**5.1.2** Butt welds, in the bilge keel and ground bar, are to be well clear of each other and of butts in the shell plating as shown in Fig 11. In general, shell butts are to be flush in way of the ground bar and ground bar butts are to be flush in way of the bilge keel. Direct connection between ground bar butt welds and shell plating is not permitted. This may be obtained by use of removable backing.

**5.1.3** At the ends of the ground bar, the leg length is to be increased as given in Tab 5, without exceeding the as-built thickness of the ground bar as shown in Fig 11. The welded transition at the ends of the ground bar to the plating connection should be formed with the weld flank angle of 45° or less.

**5.1.4** In general, scallops and cut-outs are not to be used. Crack arresting holes are to be drilled in the bilge keel butt welds as close as practicable to the ground bar. The diameter of the hole is to be greater than the width  $W$  of the butt weld and is to be a minimum of 25 mm. Where the butt weld has been subject to non-destructive examination, the crack arresting hole may be omitted.

**Table 5 : Connections of bilge keels**

Structural items being joined	Leg length of weld, in mm	
	At ends (1)	Elsewhere
Ground bar to the shell	0,62 t <sub>1as-built</sub>	0,48 t <sub>1as-built</sub>
Bilge keel web to ground bar	0,48 t <sub>2as-built</sub>	0,30 t <sub>2as-built</sub>

t<sub>1as-built</sub> : As-built thickness of ground bar, in mm  
t<sub>2as-built</sub> : As-built thickness of web of bilge keel, in mm.  
(1) Zone "b" in Ch 4, Sec 5, Fig 25 and Ch 4, Sec 5, Fig 26 for definition of "ends"

**Figure 11 : Bilge keel**

**5.2 End connections of pillars**

**5.2.1** The end connections of pillars are to have an effective fillet weld area, in cm<sup>2</sup>, (weld throat multiplied by weld length) not less than:

$$A_{weld} = f_3 \left( \frac{235}{R_{eH\_weld}} \right)^{0,75} F$$

where:

- F : Design load, for the structure under consideration, in kN
- f<sub>3</sub> : Coefficient equal to:
  - 0,05 when pillar is in compression only
  - 0,14 when pillar is in tension.

When A<sub>weld</sub> cannot practically be achieved by fillet welding for pillars in tension, full penetration welding is to be adopted.

**5.3 Abutting plates with small angles**

**5.3.1** Where angle θ between the abutting plate and the connected plate is less than 75° as shown in Fig 12, the size of fillet welds l<sub>θ</sub>, in mm, for the side of larger angle is to be increased in accordance with:

$$l_{\theta} = \frac{l_{leg}}{\sqrt{2} \sin \frac{\theta}{2}}$$

where:

- l<sub>leg</sub> : Leg length of fillet weld, in mm, as defined in [3.2.6]
- θ : Connecting angle, in deg, as shown in Fig 12.

**5.3.2** Connections of main strength members where  $\theta$  is less than  $45^\circ$ , see Fig 12, may be applied only in dry spaces and voids.

**Figure 12 : Connecting angle**

**5.4 Struts connecting ordinary stiffeners**

**5.4.1** In case of a strut connected by lap joint to the ordinary stiffener, the throat thickness of the weld is to be obtained, in mm, from the following formula:

$$t_{throat} = \frac{\eta F}{n l_w \tau} 10^3$$

where:

- F : Maximum force transmitted by the strut, in kN
- $\eta$  : Safety factor, to be taken equal to 2
- n : Number of welds in way of the strut axis
- $l_w$  : Length of the weld in way of the strut axis, in mm
- $\tau$  : Permissible shear stress, to be taken equal to 100 N/mm<sup>2</sup>.

**5.5 Connection between propeller post and propeller shaft bossing**

**5.5.1** Fabricated propeller posts are to be welded with full penetration welding to the propeller shaft bossing.

**5.6 Bar stem connections**

**5.6.1** The bar stem is to be welded to the bar keel generally with butt welding. The shell plating is also to be welded directly to the bar stem with butt welding.

**5.7 Deck subjected to wheeled loads**

**5.7.1** Double continuous fillet welding is to be adopted for the connections of ordinary stiffeners with deck plating.

# Section 4 Non-Destructive Testing

## 1 General

### 1.1 Scope

**1.1.1** This Section gives requirements on the methods and quality levels that are to be adopted for the non-destructive testing (NDT) of ship hull structure steel welds during new building.

**1.1.2** For the purpose of this Section, the hull structure is defined as follows:

- a) hull envelope including all internal and external structures
- b) superstructures, deckhouses and casings
- c) welded foundations, e.g. main engine seatings
- d) hatch coamings, bulwarks
- e) all penetrations fitted and welded into bulkheads, decks and shell
- f) the fittings of all connections to decks, bulkheads and shell, such as air pipes and ship side valves – all ILLC 1966, as amended, items
- g) welded attachments to shell, decks and primary members, e.g. crane
- h) pedestals, bitts and bollards, but only as regards their interaction on the hull structure.

**1.1.3** The quality levels given in this Section refer to production quality and not to fitness for-purpose of the welds examined.

**1.1.4** The NDT is normally to be performed by the Shipbuilder or its subcontractors in accordance with the requirements of this Section. The Surveyor may require witnessing of the testing.

**1.1.5** It is the Shipbuilder's responsibility to assure that testing specifications and procedures are adhered to during the construction and the reports are made available to the Society on the findings made by the NDT.

**1.1.6** In case of non-destructive testing carried out by an independent company from the manufacturer or shipyard, such company has to comply with the requirements set out in NR669 "Recognition of non-destructive testing suppliers".

**1.1.7** The extent of testing and the number of checkpoints are to be agreed between the Shipbuilder and the Society. For criticality of structure reference is to be made to Ch 4, Sec 1, Tab 3, Ch 4, Sec 1, Tab 8, Ch 4, Sec 1, Tab 10 and, as applicable, NR606 Common Structural Rules for Bulk Carriers and Oil Tankers.

**1.1.8** This Section covers conventional NDT methods. As far as advanced non-destructive testing (ANDT) methods are concerned, reference is made to NR216 Materials and Welding, Chapter 14. ANDT methods are typically phased array ultrasonic testing (PAUT), time of flight diffraction (TOFD), digital radiography (RT-D), radiosopic testing (RT-S), and computed radiography (RT-CR).

#### 1.1.9 Terms and definitions

The following terms and definitions apply:

- NDT : Non-Destructive Testing: the development and application of technical methods to examine materials or components in ways that do not impair their future usefulness and serviceability, in order to measure geometrical characteristics and to detect, locate, measure and evaluate flaws. NDT is also known as non-destructive examination (NDE), non-destructive inspection (NDI) and non-destructive evaluation (NDE).
- RT : Radiographic Testing
- UT : Ultrasonic Testing
- MT : Magnetic Particle Testing
- PT : Dye or Liquid Penetrant Testing
- PWHT : Post Weld Heat Treatment
- VT : Visual Testing.

## 2 Application

### 2.1 Base metals

**2.1.1** This Section applies to fusion welds made in normal and higher strength hull structural steels, extra high strength steels for welded structure, connection welds with hull steel forgings and castings in accordance with NR216 Materials and Welding. Base metal other than the above may be considered by the Society.

### 2.2 Welding processes

**2.2.1** This Section applies to fusion welds made using manual metal arc welding (shielded metal arc welding, 111), gas-shielded metal arc welding (gas metal arc welding, including flux cored arc welding, 13x), gas-shielded arc welding with non-consumable tungsten electrode (gas tungsten arc welding, 14x), submerged arc welding (12x), electro-slag welding (72x) and electro-gas welding processes (73).

Note 1: Terms and numbers according to ISO 4063:2009 ("x" indicates that relevant subgroups are included).

This Section may also be applied to welding processes other than the above at the discretion of the Society.

### 2.3 Weld joints

**2.3.1** This Section applies to butt welds with full penetration, tee, corner and cruciform joints with or without full penetration, and fillet welds.

### 2.4 Timing of NDT

**2.4.1** NDT is to be conducted after welds have cooled to ambient temperature and after post weld heat treatment where applicable.

**2.4.2** For high strength steels for welded structure with specified minimum yield stress in the range of 420 N/mm<sup>2</sup> to 690 N/mm<sup>2</sup>, NDT is not to be carried out before 48 hours after completion of welding. For steel with specified minimum yield greater than 690 N/mm<sup>2</sup>, NDT is not to be carried out before 72 hours after completion of welding. Regardless of yield strength, consideration is to be given to requiring a delayed inspection where evidence of delayed cracking has been observed in production welds.

At the discretion of the Surveyor, a longer interval and/or additional random inspection at a later period may be required, (for example in case of high thickness welds).

At the discretion of the Surveyor, the 72 hour interval may be reduced to 48 hours for RT or UT inspection, provided there is no indication of delayed cracking, and a complete visual and random MT or PT inspection to the satisfaction of the Surveyor is conducted 72 hours after welds have been completed and cooled to ambient temperature.

Where PWHT is carried out the requirement for testing after a delay period may be relaxed, at the discretion of the Surveyor.

### 2.5 Applicable methods for testing of weld joints

**2.5.1** The methods mentioned in this Section for detection of surface imperfections are VT, PT and MT. The methods mentioned for detection of internal imperfections are UT and RT.

**2.5.2** Applicable methods for testing of the different types of weld joints are given in Tab 1.

**Table 1 : Applicable methods for testing of weld joints**

Weld joints	Parent material thickness	Applicable test methods
Butt welds with full penetration	thickness < 8mm <b>(1)</b>	VT, PT, MT, RT
	thickness ≥ 8mm	VT, PT, MT, UT, RT
Tee joints, corner joints and cruciform joints with full penetration	thickness < 8mm <b>(1)</b>	VT, PT, MT, RT <b>(3)</b>
	thickness ≥ 8mm	VT, PT, MT, UT, RT <b>(3)</b>
Tee joints, corner joints and cruciform joints without full penetration and fillet welds	All	VT, PT, MT, UT <b>(2)</b> , RT <b>(3)</b>
<b>(1)</b> In cases of thickness below 8mm the Society may consider application of an appropriate advanced UT method <b>(2)</b> UT may be used to check the extent of penetration in tee, corner and cruciform joints. This requirement is to be agreed with the Society <b>(3)</b> RT may be applied however there will be limitations		

### **3 Qualification of personnel involved in NDT**

#### **3.1 General**

**3.1.1** The Shipbuilder or its subcontractors is responsible for the qualification and preferably 3rd party certification of its supervisors and operators to a recognised certification scheme based on ISO 9712:2012.

Personnel qualification to an employer based qualification scheme as e.g. SNT-TC-1A, 2016 or ANSI/ASNT CP-189, 2016 may be accepted if the Shipbuilder or its subcontractors written practice is reviewed and found acceptable by the Society. The Shipbuilder or its subcontractors written practice is to, as a minimum, except for the impartiality requirements of a certification body and/or authorised body, comply with ISO 9712:2012.

The supervisors and operators certificates and competence are to comprise all industrial sectors and techniques being applied by the Shipbuilder or its subcontractors.

Level 3 personnel is to be certified by an accredited certification body.

**3.1.2** The Shipbuilder or its subcontractors are to have a supervisor or supervisors, responsible for the appropriate execution of NDT operations and for the professional standard of the operators and their equipment, including the professional administration of the working procedures. The Shipbuilder or its subcontractors are to employ, on a full-time basis, at least one supervisor independently certified to Level 3 in the method(s) concerned as per the requirements of [3.1.1]. It is not permissible to appoint Level 3 personnel; they must be certified by an accredited certification body. It is recognised that a Shipbuilder or its subcontractors may not directly employ a Level 3 in all the stated methods practiced. In such cases, it is permissible to employ an external, independently certified, Level 3 in those methods not held by the full-time Level 3(s) of the Shipbuilder or its subcontractors.

The supervisor is to be directly involved in review and acceptance of NDT procedures, NDT reports, calibration of NDT equipment and tools. The supervisor is to, on behalf of the Shipbuilder or its subcontractors, re-evaluate the qualification of the operators annually.

**3.1.3** The operator carrying out the NDT and interpreting indications, is to be, as a minimum, qualified and certified to Level 2 in the NDT method(s) concerned and as described in [3.1.1].

However, operators only undertaking the gathering of data using any NDT method and not performing data interpretation or data analysis may be qualified and certified as appropriate, at level 1.

The operator is to have adequate knowledge of materials, welding, structures or components, NDT equipment and limitations that are sufficient to apply the relevant NDT method for each application appropriately.

**3.1.4** In case of non-destructive testing carried out by an independent company from the manufacturer or shipyard, qualification of operators is to comply with the requirements set out in NR669 Recognition of non-destructive testing suppliers.

### **4 Surface condition**

#### **4.1 General**

**4.1.1** Areas to be examined are to be free from scale, slag, loose rust, weld spatter, oil, grease, dirt or paint that might affect the sensitivity of the testing method.

Preparation and cleaning of welds for subsequent NDT are to be in accordance with the accepted NDT procedures, and are to be to the satisfaction of the Surveyor. Surface conditions that prevent proper interpretation may be cause for rejection of the weld area of interest.

### **5 General plan of testing**

#### **5.1 NDT method selection**

**5.1.1** The extent of testing and the associated quality levels are to be planned by the Shipbuilder according to the ship design, ship type and welding processes used. For new construction survey, reference is to be made to the NDT requirements of Pt A, Ch 3, Sec 7 and applicable parts of NR540 Kick-Off Meeting Templates for Newbuilding.

**5.1.2** For each construction, the Shipbuilder is to submit a plan for review by the Society, specifying the areas to be examined, the extent of testing and the quality levels, with reference to the NDT procedures to be used. Particular attention is to be paid to inspecting welds in highly stressed areas and welds in primary and special category structural members indicated in Ch 4, Sec 1. The NDT procedure(s) are to meet the requirement stated in Article [6]. The plan is only to be released to the personnel in charge of the NDT and its supervision.

**5.1.3** In selecting checkpoints, emphasis is to be given to the following inspection locations:

- welds in high stressed areas
- fatigue sensitive areas
- other important structural elements
- welds which are inaccessible or very difficult to inspect in service
- field erected welds
- suspected problem areas.

Block construction welds performed in the yards, or at subcontracted yards/facilities, are to be considered in selecting checkpoints.

If an unacceptable level of indications is found the NDT extent is to be increased.

**5.1.4** The NDT requirements given in Ch 13, Sec 6 are to be taken into consideration in the NDT plan.

**5.1.5** The identification system is to identify the exact locations of the lengths of weld examined.

**5.1.6** All welds over their full length are to be subject to VT by personnel designated by the Shipbuilder, who may be exempted from the qualification requirements defined in [3].

**5.1.7** As far as practicable, PT or MT are to be used when investigating the outer surface of welds, checking the intermediate weld passes and back-gouged joints prior to subsequent passes deposition. MT is to be performed in ferromagnetic materials welds unless otherwise agreed with the Society. Surface inspection of important tee or corner joints, using an approved MT or PT method, is to be conducted to the satisfaction of the Surveyor.

**5.1.8** Welded connections of large cast or forged components (e.g. stern frame, stern boss, rudder parts, shaft brackets...) are to be tested over their full length using MT (MT is the preferred method) or PT, (PT is to be applied for non-ferrous metals) and at agreed locations using RT or UT.

**5.1.9** As given in Tab 1, UT or RT or a combination of UT and RT may be used for testing of butt welds with full penetration of 8 mm or greater. Methods to be used are to be agreed with the Society. The method used is to be suited for the detection of particular types and orientations of discontinuities. RT and UT are used for detection of internal discontinuities, and in essence they supplement and complement each other. RT is generally most effective in detecting volumetric discontinuities (e.g. porosity and slag) whilst UT is more effective for detecting planar discontinuities (e.g. laminations, lack of fusion and cracks).

**5.1.10** In general start/stop points in welds made using automatic (mechanized) welding processes are to be examined using RT or UT, except for internal members where the extent of testing is to be agreed with the attending Surveyor. Panel butt welds made using automatic welding at pre-manufacturing stage are to be tested at random by RT or UT.

**5.1.11** Where the Surveyor becomes aware that an NDT location has been repaired without a record of the original defect, the shipyard is to carry out additional examinations on adjacent areas to the repaired area to the satisfaction of the attending Surveyor.

## **6 Testing**

### **6.1 General**

**6.1.1** The testing method, equipment and conditions are to comply with recognized National or International standards, or other documents to the satisfaction of the Society.

**6.1.2** Sufficient details are to be given in a written procedure for each NDT technique submitted to the Society for acceptance.

**6.1.3** The testing volume is to be the zone which include the weld and parent material for at least 10mm each side of the weld, or the width of the heat affected zone (HAZ), whichever is greater. In all cases inspection is to cover the whole testing volume.

**6.1.4** Provision is to be made for the Surveyor to verify the inspection, reports and records (e.g. radiographs) on request.

### **6.2 Visual testing (VT)**

**6.2.1** The personnel in charge of VT is to confirm that the surface condition is acceptable prior to carrying out the inspection. VT is to be carried out in accordance with standards agreed between the Shipbuilder and the Society.

### **6.3 Liquid penetrant testing (PT)**

**6.3.1** PT is to be carried out in accordance to ISO 3452-1:2013 or a recognized standard accepted by the Society.

**6.3.2** The extent of PT is to be in accordance to the plans agreed with the attending Surveyor and to the satisfaction of the Surveyor.

**6.3.3** The surface to be examined is to be clean and free from scale, oil, grease, dirt or paint so there are not contaminants and entrapped material that may impede penetration of the inspection media.

**6.3.4** The temperature of parts examined is to be typically between 5°C and 50°C. Outside this temperature range special low/high temperature penetrant and reference comparator blocks are to be used.

## **6.4 Magnetic particle testing (MT)**

**6.4.1** MT is to be carried out in accordance to ISO 17638:2016 or a recognized standard accepted by the Society.

**6.4.2** The extent of MT is to be in accordance to the plans agreed with the attending Surveyor and to the satisfaction of the Surveyor.

**6.4.3** The surface to be examined is to be free from scale, weld spatter, oil, grease, dirt or paint and is to be clean and dry. In general, the inside and outside of the welds to be inspected need to be sufficiently free from irregularities that may mask or interfere with interpretation.

## **6.5 Radiographic testing (RT)**

**6.5.1** RT is to be carried out in accordance to ISO 17636-1:2013 or a recognized standard accepted by the Society.

**6.5.2** The minimum inspected weld length for each checkpoint is to be specified in the approved NDT plan (see [5.1.2]). For hull welds the minimum length inspected by RT is typically 300 mm.

The extent of RT is to be in accordance to the approved plans and the requirements of this paragraph, to the satisfaction of the Surveyor.

The number of checkpoints is to be increased if the proportion of non-conforming indications is abnormally high.

**6.5.3** The inside and outside surfaces of the welds to be radiographed are to be sufficiently free from irregularities that may mask or interfere with interpretation. Surface conditions that prevent proper interpretation of radiographs may be cause for rejection of the weld area of interest.

**6.5.4** RT is to be carried out on the welded butts of shell plating, strength deck plating as well as of members contributing to the longitudinal strength.

RT may also be required for the joints of members subject to heavy stresses.

**6.5.5** The requirements given in [6.5.6] and Article [6] are to be considered as general rules. Reduction of the number of RT checkpoints may be accepted by the Society when consistent satisfactory quality is justified by the Shipbuilder. In such case, the extent of NDT is to remain equivalent to that given in [6.5.6] and Article [6].

**6.5.6** In the midship area, RT checkpoints are to be selected at the joining of panels.

Each RT checkpoint is to be located at a crossing of butt joints.

In a given ship cross-section bounded by the panels, one RT checkpoint is to be selected for each butt of sheerstrake, stringer, bilge and keel plate. In addition, the following RT checkpoints are to be selected:

- bottom plating: two RT checkpoints
- deck plating: two RT checkpoints
- side shell plating: two RT checkpoints at each side.

For ships where  $B + D \leq 15$  m, only one RT checkpoint is to be selected for each of the above items.

This requirement remains applicable where panel butts are shifted or where some strakes are built independently from the panels. It is recommended to select most of these RT checkpoints at the crossing of butt and panel seams.

Still in the midship area, RT checkpoints are to be selected, at random, for the following main structural members:

- butts of continuous longitudinal bulkheads
- butts of longitudinal stiffeners, deck and bottom girders contributing to the overall strength
- assembly joints of insert plates at the corners of the openings.

Additionally, RT checkpoints are to be selected, at random, for the butt welds of the bilge keel and of intermediate flat.

**6.5.7** Apart from the midship area, RT checkpoints are to be selected at random by the Shipbuilder in agreement with the Surveyor for the major location points. It is further recommended:

- to select a number of RT checkpoints for the very thick parts and those comprising restrained joint, such as sternframes, shaft brackets, stabiliser recesses, masts
- to check the full length or to increase the number of RT checkpoints for the first joint of a series of identical joints. This recommendation is applicable not only to the assembly joints of prefabricated members completed on the slip, but also to joints completed in the workshop to prepare such prefabricated members.

**6.5.8** Consideration may be given for reduction of inspection frequency for automated welds where quality assurance techniques indicate consistent satisfactory quality.

**6.6 Ultrasonic testing (UT)**

**6.6.1** UT is to be carried out according to procedure based on ISO 17640:2018 (testing procedure), ISO 23279:2017 (characterization) and ISO 11666:2018 (acceptance levels) or recognized standards accepted by the Society.

**6.6.2** The minimum inspected weld length for each checkpoint is to be specified in the approved NDT plan (see [5.1.2]). The extent of UT is to be in accordance to the approved plans and to the satisfaction of the Surveyor.

A checkpoint is to consist of the entire weld length or a length agreed with the Society.

**7 Acceptance Levels (criteria)**

**7.1 General**

**7.1.1** This Article details the acceptance levels (criteria) followed for the assessment of the NDT results. Techniques include but are not limited to: VT, MT, PT, RT and UT.

**7.1.2** As far as necessary, testing techniques are to be combined to facilitate the assessment of indications against the acceptance criteria.

**7.1.3** The assessment of indications not covered by this Article is to be made in accordance with a standard agreed with the Society. Alternative acceptance criteria can be agreed with the Society, provided equivalency is established.

The general accepted methods for testing of welds are provided in Tab 2 and Tab 3 for surface and embedded discontinuities respectively (Refer to ISO 17635:2016).

**Table 2 : Method for detection of surface discontinuities (All type of welds including fillet welds)**

Materials	Testing method
Ferritic steel	VT
	VT, MT
	VT, PT

**Table 3 : NDT for detection of embedded discontinuities (for butt and T joints with full penetration)**

Materials and type of joint	Nominal thickness (t) of the parent material to be welded (mm)		
	t < 8	8 ≤ t ≤ 40	t > 40
Ferritic butt-joints	RT or UT (1)	RT or UT	UT or RT (2)
Ferritic T-joints	UT (1) or RT (2)	UT or RT (2)	UT or RT (2)
(1) Below 8mm the Society may consider application of an appropriate advanced UT method.			
(2) RT may be applied however there will be limitations.			

**7.2 Quality Levels**

**7.2.1** Testing requirements follow the designation of a particular quality level of imperfections in fusion-welded joints in accordance with ISO 5817:2014. Three quality levels (B, C and D) are specified.

In general Quality level C is to be applied for hull structure.

Quality level B corresponds to the highest requirement on the finished weld, and may be applied on critical welds.

This standard applies to steel materials with thickness above 0,5 mm.

Note 1: ISO 5817:2014 Table 1 provides the requirements on the limits of imperfections for each quality level. ISO 5817:2014 Annex A also provides examples for the determination of percentage of imperfections (number of pores in surface percent).

All levels (B, C and D) refer to production quality and not to the fitness for purpose (ability of product, process or service to serve a defined purpose under specific conditions). The correlation between the quality levels defined in ISO 5817:2014, testing levels/ techniques and acceptance levels (for each NDT technique) will serve to define the purpose under specific conditions. The acceptance level required for examination shall be agreed with the Society. This will determine the quality level required in accordance with the non-destructive technique selected. Refer to Tab 4 to Tab 9.

**7.3 Testing Levels**

**7.3.1** The testing coverage and thus the probability of detection increases from testing level A to testing level C. The testing level is to be agreed with the Society. Testing level D is intended for special applications, this can only be used when defined by the Shipbuilder specification.

Note 1: ISO 17640:2018 Annex A tables A.1 to A.7 provide guidance on the selection of testing levels for all type of joints in relation to the thickness of parent material and inspection requirements.

**7.3.2** The testing technique used for the assessment of indications is also to be specified.

**7.4 Acceptance Levels**

**7.4.1** The acceptance levels are specified for each testing technique used for performing the inspection. The criteria applied is to comply with each standard identified in Tab 4 to Tab 9 (or any recognized acceptable standard agreed with the Society).

**7.4.2** Probability of detection (POD) indicates the probability that a testing technique will detect a given flaw.

**7.5 Visual testing (VT)**

**7.5.1** The acceptance levels and required quality levels for VT are provided in IACS Recommendation 47, “Shipbuilding and Repair Quality Standard” and Tab 4.

**7.6 Penetrant testing (PT)**

**7.6.1** The acceptance levels and required quality levels for PT are provided in Tab 5.

**7.7 Magnetic Particle testing (MT)**

**7.7.1** The acceptance levels and required quality levels for MT is provided in Tab 6.

**7.8 Radiographic testing (RT)**

**7.8.1** The acceptance levels and required quality levels for RT are provided in Tab 7.

Reference radiographs for the assessment of weld imperfections are to be provided in accordance to ISO 5817:2014 or acceptable recognized standard agreed with the Society.

**Table 4 : Visual testing**

Quality levels (ISO 5817:2014 applies) (1)	Testing techniques/ levels (ISO 17637:2016 applies) (1)	Acceptance levels (2)
B	Level not specified	B
C		C
D		D
(1) Or any recognized standard agreed with the Society and demonstrated to be acceptable		
(2) The acceptance levels for VT are the same to the quality levels requirements of ISO 5817:2014		

**Table 5 : Penetrant testing**

Quality levels (ISO 5817:2014 applies) (1)	Testing techniques/ levels (ISO 3452-1:2013 applies) (1)	Acceptance levels (ISO 23277:2015 applies) (1)
B	Level not specified	2X
C		2X
D		3X
(1) Or any recognized standard agreed with the Society and demonstrated to be acceptable		

**Table 6 : Magnetic Particle Testing**

Quality levels (ISO 5817:2014 applies) (1)	Testing techniques/ levels (ISO 17638:2016 applies) (1)	Acceptance levels (ISO 23278:2015 applies) (1)
B	Level not specified	2X
C		2X
D		3X
(1) Or any recognized standard agreed with the Society and demonstrated to be acceptable		

**Table 7 : Radiographic Testing**

Quality levels (ISO 5817:2014 applies) (1)	Testing techniques/ levels (ISO 17636-1:2013 applies) (1)	Acceptance levels (ISO 10675-1:2016 applies) (1)
B	B (class)	1
C	B (2) (class)	2
D	at least A (class)	3
(1) Or any recognized standard agreed with the Society and demonstrated to be acceptable (2) For circumferential weld testing, the minimum number of exposures may correspond to the requirements of ISO 17636-1:2013, class A		

**7.9 Ultrasonic testing (UT)**

**7.9.1** The acceptance levels and required quality levels for UT are provided in Tab 8 and Tab 9.

**7.9.2** UT Acceptance Levels apply to the examination of full penetration ferritic steel welds, with thickness from 8 mm to 100 mm. The nominal frequency of probes used is to be between 2MHz and 5MHz. Examination procedures for other type of welds, material, thicknesses above 100 mm and examination conditions are to be submitted to the consideration of the Society.

**7.9.3** The acceptance levels for UT of welds are to be defined in accordance to ISO 11666:2018 requirements or any recognized acceptable standard agreed with the Society. The standard specifies acceptance level 2 and 3 for full penetration welded joints in ferritic steels, corresponding to quality levels B and C (Refer to table 8).

**Table 8 : Ultrasonic Testing**

Quality levels (ISO 5817:2014 applies) (1) (2)	Testing techniques/ levels (ISO 17640:2018 applies) (1) (2)	Acceptance levels (ISO 11666:2018 applies) (1) (2)
B	at least B	2
C	at least A	3
D	at least A	3 (3)
(1) Or any recognized standard agreed with the Society and demonstrated to be acceptable (2) When characterization of indications is required, ISO 23279:2017 is to be applied (3) UT is not recommended but can be defined in a specification with same requirement as Quality Level C		

**Table 9 : Recommended Testing and Quality Levels (ISO 17640)**

Testing level (1) (2) (3) (ISO 17640:2018 applies)	Quality level (ISO 5817:2014 applies)
A	C, D
B	B
C	By agreement
D	Special application
(1) POD increases from testing level A to C as testing coverage increases (2) Testing Level D for special application is to be agreed with the Society (3) Specific requirements for testing levels A to C, are provided for various types of joints in ISO 17460:2018 Annex A	

**7.9.4** Sensitivity settings and levels. The sensitivity levels are set by the following techniques:

- Technique 1: based on 3 mm diameter side-drilled holes
- Technique 2: based on distance gain size (DGS) curves for flat bottom holes (diskshaped reflectors)
- Technique 3: using a distance-amplitude-corrected (DAC) curve of a rectangular notch of 1 mm depth and 1 mm width
- Technique 4: using the tandem technique with reference to a 6 mm diameter flatbottom hole (disk shaped reflector)

The evaluation levels (reference, evaluative, recording and acceptance) are specified in ISO 11666:2018 Annex A.

**8 Reporting**

**8.1 General**

**8.1.1** Reports of NDT required are to be prepared by the Shipbuilder and are to be made available to the Society.

**8.1.2** Reports of NDT are to include the following generic items:

- date of testing
- hull number, location and length of weld inspected
- names, qualification level and signature of personnel that have performed the testing
- identification of the component examined
- identification of the welds examined
- steel grade, type of joint, thickness of parent material, welding process
- acceptance criteria
- testing standards used
- testing equipment and arrangement used
- any test limitations, viewing conditions and temperature
- results of testing with reference to acceptance criteria, location and size of reportable indications
- statement of acceptance / non-acceptance, evaluation date, name and signature of evaluator
- number of repairs if specific area repaired more than twice.

**8.1.3** In addition to generic items, reports of PT are to include the following specific items:

- type of penetrant, cleaner and developer used
- penetration time and development time.

**8.1.4** In addition to generic items, reports of MT are to include the following specific items:

- type of magnetization
- magnetic field strength
- detection media
- viewing conditions
- demagnetization, if required.

**8.1.5** In addition to generic items, reports of RT are to include the following specific items:

- type and size of radiation source (width of radiation source), X-ray voltage
- type of film/designation and number of film in each film holder/cassette
- number of radiographs (exposures)
- type of intensifying screens
- exposure technique, time of exposure and source-to-film distance as per below:
- distance from radiation source to weld
- distance from source side of the weld to radiographic film
- angle of radiation beam through the weld (from normal)
- sensitivity, type and position of IQI (source side or film side)
- density
- geometric un-sharpness
- specific acceptance class criteria for RT.

Examinations used for acceptance or rejection of welds are to be recorded in an acceptable medium. A written record providing following information: identification and description of welds, procedures and equipment used, location within recorded medium and results are to be included. The control of documentation unprocessed original images and digitally processes images is to be to the satisfaction of the Surveyor.

**8.1.6** In addition to generic items, reports of UT are to include the following specific items:

- type and identification of ultrasonic equipment used (instrument maker, model, series number), probes (instrument maker, serial number), transducer type (angle, serial number and frequency) and type of couplant (brand)
- sensitivity levels calibrated and applied for each probe
- transfer loss correction applied Type of reference blocks
- signal response used for defect detection
- reflections interpreted as failing to meet acceptance criteria.

The method for review and evaluation of UT reports is required for adequate quality control and is to be to the satisfaction of the Surveyor.

**8.1.7** The shipyard is to keep the inspection records specified in [8.1.2] to [8.1.6] for at least for 5 years.

## **9 Unacceptable indications and repairs**

### **9.1 General**

**9.1.1** Unacceptable indications are to be eliminated and repaired where necessary. The repair welds are to be examined on their full length using appropriate NDT method at the discretion of the Surveyor.

**9.1.2** When unacceptable indications are found, additional areas of the same weld length are to be examined unless it is agreed with the Surveyor and fabricator that the indication is isolated without any doubt. In case of automatic welded joints, additional NDT are to be extended to all areas of the same weld length.

All radiographs exhibiting non-conforming indications are to be brought to the attention of the Surveyor. Such welds are to be repaired and inspected as required by the Surveyor. When non-conforming indications are observed at the end of a radiograph, additional RT is generally required to determine their extent. As an alternative, the extent of non-conforming welds may be ascertained by excavation, when approved by the Surveyor.

**9.1.3** The extent of testing may be extended at the Surveyor's discretion when repeated non-acceptable discontinuities are found, specially for butts of sheerstrake, stringer plate, bilge strake or keel plate.

**9.1.4** The inspection records specified in Article [8] are to include the records of repaired welds.

**9.1.5** The Shipbuilder is to take appropriate actions to monitor and improve the quality of welds to the required level. The repair rate is to be recorded by the shipyard and any necessary corrective actions are to be identified in the builder's Quality Assurance system.

# Section 5 Special Structural Details

## 1 General

### 1.1 Application

**1.1.1** Special structural details are those characterised by complex geometry, possibly associated with high or alternate stresses.

**1.1.2** For special structural details, specific requirements are to be fulfilled during:

- design
- construction
- selection of materials
- welding
- survey.

The purpose of these requirements is specified in [1.2] to [1.6].

**1.1.3** Special structural details are those listed in Article [2] together with the specific requirements which are to be fulfilled. Other structural details may be considered by the Society as special details, when deemed necessary on the basis of the criteria in [1.1.1]. The criteria to be fulfilled in such cases are defined by the Society on a case by case basis.

**1.1.4** As regards matters not explicitly specified in Article [2], the Rule requirements are to be complied with in any event; in particular:

- Part B, Chapter 4 for design principles and structural arrangements
- Part B, Chapter 7, for structural scantling
- Part B, Chapter 13 for construction and welding requirements
- the applicable requirements of Part D, Part E and Part F.

### 1.2 Design requirements

#### 1.2.1 General requirements

Design requirements specify:

- the local geometry, dimensions and scantlings of the structural elements which constitute the detail
- any local strengthening
- the cases where a fatigue check is to be carried out according to Part B, Chapter 10.

#### 1.2.2 Fatigue check requirements

Where a fatigue check is to be carried out, the design requirements specify (see Ch 10, Sec 1, [2]):

- the locations (hot spots) where the stresses are to be calculated and the fatigue check performed
- the direction in which the normal stresses are to be calculated

### 1.3 Constructional requirements

**1.3.1** Constructional requirements specify the allowable misalignment and tolerances, depending on the detail arrangement and any local strengthening.

### 1.4 Material requirements

**1.4.1** Material requirements specify the material quality to be used for specific elements which constitute the detail, depending on their manufacturing procedure, the type of stresses they are subjected to, and the importance of the detail with respect to the ship operation and overall safety.

In addition, these requirements specify where material inspections are to be carried out.

### 1.5 Welding requirements

**1.5.1** Welding requirements specify where partial or full T penetration welding (see Ch 13, Sec 3, [3.3]) or any particular welding type or sequence is to be adopted. In addition, these requirements specify when welding procedures are to be approved.

Since weld shape and undercuts are influencing factors on fatigue behaviour, fillet welds are to be elongated in the direction of the highest stresses and care is to be taken to avoid undercuts, in particular at the hot spots.

## **1.6 Survey requirements**

**1.6.1** Survey requirements specify where non-destructive examinations of welds are to be carried out and, where this is the case, which type is to be adopted.

## **2 List and characteristics of special structural details**

### **2.1 General**

**2.1.1** This Article specifies the requirements which are to be fulfilled for the different ship types and related special structural details:

- a description of the hull areas where the details are located (see Tab 1)
- the structural detail description
- the requirements for the fine mesh yielding analysis
- the requirements for the fatigue check
- a reference to a table in Ch 13, App 2 where a sketch of the detail is shown together with the specific requirements which are to be fulfilled.

### **2.2 All types of ships with longitudinally framed sides**

**2.2.1** The special structural details relevant to all types of longitudinally framed ships, including those mentioned in [2.3] to [2.7], are listed and described in Tab 2.

### **2.3 Ships carrying liquid cargo in bulk, except liquefied gas carriers**

**2.3.1** The special structural details for various hull areas relevant to ships with the service notation **oil tanker ESP**, **chemical tanker ESP**, **FLS tanker**, **asphalt carrier** or **tanker** are listed and described in Tab 3.

When the structural arrangement in a certain area is such that the details considered in Tab 3 can not comply with corresponding requirements, specific requirements are defined by the Society on a case by case basis, depending on the arrangement adopted.

### **2.4 Liquefied gas carriers**

**2.4.1** The special structural details for various hull areas relevant to ships with the service notation **liquefied gas carrier** are listed and described in:

- Tab 4 for structural details common to all liquefied gas carriers
- Tab 5 for additional structural details for type A gas carriers and type B gas carriers fitted with independent tanks, primarily constructed of plane surfaces
- Tab 6 for additional structural details for type B gas carriers fitted with independent tanks, primarily constructed of bodies of revolution
- Tab 7 and Pt D, Ch 9, Sec 4, [11.7.7] for additional structural details for membrane type gas carriers.

When the structural arrangement in a certain area is such that the details considered in the above specified tables can not comply with corresponding requirements, specific requirements are defined by the Society on a case by case basis, depending on the arrangement adopted.

### **2.5 Container ships**

**2.5.1** The special structural details for various hull areas relevant to ships with the service notation **container ship** are listed and described in Tab 8.

When the structural arrangement in a certain area is such that the details considered in Tab 8 can not comply with corresponding requirements, specific requirements are defined by the Society on a case by case basis, depending on the arrangement adopted.

### **2.6 Bulk, ore and combination carriers**

**2.6.1** The special structural details for various hull areas relevant to ships with the service notation **bulk carrier** or **bulk carrier ESP**, **self-unloading bulk carrier ESP**, **ore carrier ESP** and **combination carrier ESP** are listed and described in Tab 9.

When the structural arrangement in a certain area is such that the details considered in Tab 9 can not comply with corresponding requirements, specific requirements are defined by the Society on a case by case basis, depending on the arrangement adopted.

2.7 Ro-ro ships

2.7.1 The special structural details for various hull areas relevant to ships with the service notation **ro-ro cargo ship**, **ro-ro passenger ship** or **PCTC** are listed and described in Tab 10.

When the structural arrangement in a certain area is such that the details considered in Tab 10 can not comply with corresponding requirements, specific requirements are defined by the Society on a case by case basis, depending on the arrangement adopted.

2.8 Passenger ships

2.8.1 The special structural details for various hull areas relevant to ships with the service notation **passenger ship** are listed and described in Tab 11.

When the structural arrangement in a certain area is such that the details considered in Tab 11 can not comply with corresponding requirements, specific requirements are defined by the Society on a case by case basis, depending on the arrangement adopted.

Table 1 : List of special structural detail areas

Area ref. No.	Area description	Ship type						
		All ships (1)	Ships carrying liquid cargo in bulk (2)	Liquefied gas carriers	Container ships	Bulk, ore and combination carriers	Ro-ro ships	Passenger ships
		see [2.2]	see [2.3]	see [2.4]	see [2.5]	see [2.6]	see [2.7]	see [2.7]

# Section 6 Testing

## 1 Testing procedures of watertight compartments

### 1.1 Application

**1.1.1** These test procedures are to confirm the watertightness of tanks, watertight boundaries and the structural adequacy of tanks forming a part of the watertight subdivisions of ships. These procedures may also be applied to verify the weathertightness of structures and shipboard outfitting.

The tightness of all tanks and watertight boundaries of ships during new construction and ships relevant to major conversions or major repairs is to be confirmed by these test procedures prior to the delivery of the ships.

Note 1: Watertight subdivision means the transverse and longitudinal subdivisions of the ship required to satisfy the subdivision requirements of SOLAS Chapter II-1.

Note 2: Major repair means a repair affecting structural integrity.

**1.1.2** Testing procedures of watertight compartments for SOLAS Ships are to be carried out in accordance with requirements [1.4.1] to [1.9.1], unless:

- a) the shipyard provides documentary evidence of the shipowner's agreement to a request to the Flag Administration for an exemption from the application of SOLAS Chapter II-1, Regulation 11, or for an equivalency agreeing that the content of [1.10] is equivalent to SOLAS Chapter II-1, Regulation 11; and
- b) the above-mentioned exemption/equivalency has been granted by the responsible Flag Administration.

**1.1.3** All gravity tanks and other boundaries required to be watertight or weathertight are to be tested in accordance with these procedures and proven tight and structurally adequate as follows:

- gravity tanks for their tightness and structural adequacy
- watertight boundaries other than tank boundaries for their watertightness
- weathertight boundaries for their weathertightness.

Note 1: Gravity tank means a tank that is subject to vapour pressure not greater than 70 kPa.

**1.1.4** Testing of structures not listed in Tab 2 or Tab 3 is to be specially considered by the Society.

### 1.2 General

**1.2.1** Tests are to be carried out in the presence of a Surveyor at a stage sufficiently close to the completion of work, with all the hatches, doors, windows, etc., installed and all the penetrations including pipe connections fitted, and before any ceiling and cement work is applied over the joints. Specific test requirements are given in [1.6] and Tab 2. For the timing of the application of coating and the provision of safe access to joints, see [1.7], [1.8] and Tab 4.

### 1.3 Definitions

#### 1.3.1 Structural test

A structural test is a test to verify the structural adequacy of tank construction. This may be a hydrostatic test or, where the situation warrants, a hydropneumatic test.

Each type of structural test is defined in Tab 1.

#### 1.3.2 Leak test

A leak test is a test to verify the tightness of a boundary. Unless a specific test is indicated, this may be a hydrostatic/hydropneumatic test or an air test. A hose test may be considered to be an acceptable form of leak test for certain boundaries, as indicated by footnote (3) of Tab 2.

Each type of leak test is defined in Tab 1.

#### 1.3.3 Top of overflow

Top of any overflow system which is used to prevent overfilling of a tank. Such system can be an overflow pipe, airpipe, intermediate tank. For gravity tanks (i.e. sewage, grey water and similar tanks, not filled with pumps) the top of the overflow is to be taken as the highest point of the filling line.

Where a tank is fitted with multiple means of preventing overfilling, the decision on which overflow system is to be used to determine the test head is to be based on the highest point to which the liquid may rise in service.

Note 1: Gauging devices are not considered equivalent to an overflow system with the exception of fuel oil overflow tanks not intended to hold fuel which have been fitted with a level alarm.

**1.4 Structural test procedures**

**1.4.1 Type and time of test**

Where a structural test is specified in Tab 1 and Tab 3, a hydrostatic test in accordance with [1.6.1] is acceptable. Where practical limitations (strength of building berth, light density of liquid, etc.) prevent the performance of a hydrostatic test, a hydropneumatic test in accordance with [1.6.2] may be accepted instead.

A hydrostatic or hydropneumatic test for the confirmation of structural adequacy may be carried out while the ship is afloat, provided the results of a leak test are confirmed to be satisfactory before the ship is set afloat.

Alternative equivalent tank testing procedures may be considered for tanks which are constructed from composite materials such as glass reinforced plastic (GRP) and fibre reinforced plastic (FRP) based on the recommendations of the composite manufacturer.

**Table 1 : Types of test**

Test types	Procedure
Hydrostatic test (leak and structural)	The space to be tested is filled with a liquid to a specified head
Hydropneumatic test (leak and structural)	Combination of a hydrostatic test and an air test, the space to be tested being partially filled with liquid and pressurized with air
Hose test (leak)	Tightness check of the joint to be tested by means of a jet of water, the joint being visible from the opposite side
Air test (leak)	Tightness check by means of an air pressure differential and a leak-indicating solution. It includes tank air tests and joint air tests, such as compressed air fillet weld tests and vacuum box tests
Compressed air fillet weld test (leak)	Air test of fillet welded tee joints, by means of a leak indicating solution applied on fillet welds
Vacuum box test (leak)	A box over a joint with a leak indicating solution applied on the welds. A vacuum is created inside the box to detect any leaks
Ultrasonic test (leak)	Tightness check of the sealing of closing devices such as hatch covers, by means of ultrasonic detection techniques
Penetration test (leak)	Check, by means of low surface tension liquids (i.e. dye penetrant test), that no visual dye penetrant indications of potential continuous leakages exist in the boundaries of a compartment

**1.4.2 Testing schedule for new construction and major structural conversion or repair**

- a) tanks which are intended to hold liquids, and which form part of the watertight subdivision of the ship, shall be tested for tightness and structural strength as indicated in Tab 2 and Tab 3
- b) tank boundaries are to be tested from at least one side. The tanks for the structural test are to be selected so that all the representative structural members are tested for the expected tension and compression
- c) watertight boundaries of spaces other than tanks may be exempted from the structural test, provided that the boundary watertightness of the exempted spaces is verified by leak tests and inspections. The tank structural test is to be carried out and the requirements from item a) to item b) are to be applied for ballast holds, chain lockers, and for a representative cargo hold in case of cargo holds intended for in-port ballasting
- d) tanks which do not form part of the watertight subdivision of the ship, may be exempted from structural testing provided that the boundary watertightness of the exempted spaces is verified by leak tests and inspections.

**1.5 Leak test procedures**

**1.5.1** For the leak tests specified in Tab 2, tank air tests, compressed air fillet weld tests and vacuum box tests, in accordance respectively with [1.6.3], [1.6.5] and [1.6.6], or their combinations, are acceptable. Hydrostatic or hydropneumatic tests may be also accepted as leak tests, provided [1.7], [1.8] and [1.9] are complied with. Hose tests, in accordance with [1.6.3], are also acceptable for items 14 to 17 referred to in Tab 2, taking footnote (3) into account.

**1.5.2** Air tests of joints may be carried out at the block stage, provided that all work on the block that may affect the tightness of a joint is completed before the test. The application of the leak test for each type of welded joint is specified in Tab 4. See also [1.7.1] for the application of final coatings, [1.8] for the safe access to joints, and Tab 4 for the summary.

**Table 2 : Test requirements for tanks and boundaries**

No.	Tank or boundaries to be tested	Test type	Test head or pressure	Remarks
1	Double bottom tanks (4)	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• top of the overflow (9)</li> <li>• 2,4 m above top of tank (2)</li> <li>• bulkhead deck</li> </ul>	
2	Double bottom voids (5)	leak	See [1.6.4] to [1.6.6], as applicable	Including pump room double bottom and bunker tank protection double hull required by MARPOL Annex I
3	Double side tanks	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• top of the overflow (9)</li> <li>• 2,4 m above top of tank (2)</li> <li>• bulkhead deck</li> </ul>	
4	Double side voids	leak	See [1.6.4] to [1.6.6], as applicable	
5	Deep tanks other than those listed elsewhere in this Table	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• top of the overflow (9)</li> <li>• 2,4 m above top of tank (2)</li> </ul>	
6	Cargo oil tanks	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• top of the overflow (9)</li> <li>• 2,4 m above top of tank (2)</li> <li>• top of tank plus the design vapour pressure (2)</li> </ul>	
7	Ballast holds of bulk carriers	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• top of the overflow</li> <li>• top of cargo hatch coaming</li> </ul>	
8	Peak tanks	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• top of the overflow (9)</li> <li>• 2,4 m above top of tank (2)</li> </ul>	After peak to be tested after installation of stern tube
9	a) Fore peak spaces with equipment	leak	See [1.6.3] to [1.6.6], as applicable	
	b) Fore peak voids	leak	See [1.6.3] to [1.6.6], as applicable	
	c) Aft peak spaces with equipment	leak	See [1.6.3] to [1.6.6], as applicable	
	d) Aft peak voids	leak	See [1.6.4] to [1.6.6], as applicable	After peak to be tested after installation of stern tube
10	Cofferdams	leak	See [1.6.4] to [1.6.6], as applicable	
11	a) Watertight bulkheads	leak (8)	See [1.6.3] to [1.6.6], as applicable (7)	
	b) Superstructure end bulkheads	leak	See [1.6.3] to [1.6.6], as applicable	
12	Watertight doors below freeboard or bulkhead deck	leak (6) (7)	See [1.6.3] to [1.6.6], as applicable	
13	Double plate rudder blades	leak	See [1.6.4] to [1.6.6], as applicable	
14	Shaft tunnels clear of deep tanks	leak (3)	See [1.6.3] to [1.6.6], as applicable	
15	Shell doors	leak (3)	See [1.6.3] to [1.6.6], as applicable	
16	Weather-tight hatch covers and closing appliances	leak (3) (7)	See [1.6.3] to [1.6.6], as applicable	Hatch covers closed by tarpaulins and battens excluded
17	Watertight hatch covers and closing appliances	leak and structural	Damage equilibrium waterline (10) (11)	
18	Dual purpose tank/dry cargo hatch covers	leak (3) (7)	See [1.6.3] to [1.6.6], as applicable	In addition to the structural test in item 6 or item 7
19	Chain lockers	leak and structural	Head of water up to top of chain pipe	
20	L.O. sump tanks and other similar tanks/spaces under main engines	leak (12)	See [1.6.3] to [1.6.6], as applicable	
21	Ballast ducts	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• ballast pump maximum pressure</li> <li>• setting of any pressure relief valve</li> </ul>	

No.	Tank or boundaries to be tested	Test type	Test head or pressure	Remarks
22	Fuel oil tanks	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• top of the overflow (9)</li> <li>• 2,4 m above top of tank (2)</li> <li>• top of tank plus the design vapour pressure (2)</li> <li>• bulkhead deck</li> </ul>	
23	Fuel oil overflow tanks not intended to hold fuel	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• top of the overflow (9)</li> <li>• 2,4 m above top of tank (2)</li> <li>• bulkhead deck</li> </ul>	
<p>(1) See [1.4.2]</p> <p>(2) The top of a tank is the deck forming the top of the tank, excluding any hatchways.</p> <p>(3) Hose test may be also considered as a medium of the leak test. See [1.3.2].</p> <p>(4) Including the tanks arranged in accordance with the provisions of Ch 2, Sec 2, [3.1.4].</p> <p>(5) Including the duct keels and dry compartments arranged in accordance with the provisions of SOLAS, Regulations II-1/11.2 and II-1/9.4 respectively, and/or the oil fuel tank protection and pump room bottom protection arranged in accordance with the provisions of MARPOL Annex I, Chapter 3, Part A, Regulation 12A and Chapter 4, Part A, Regulation 22, respectively.</p> <p>(6) Where watertightness of watertight doors has not been confirmed by a prototype test, a hydrostatic test (filling of the watertight spaces with water) is to be carried out. See SOLAS Regulation II-1/16.2 and MSC.1/Circ.1572/Rev.1.</p> <p>(7) As an alternative to the hose test, other testing methods listed in [1.6.7] to [1.6.9] may be acceptable, subject to adequacy of such testing methods being verified. See SOLAS Regulation II-1/11.1. For watertight bulkheads (item 11 a)), alternatives to the hose test may be used only where the hose test is not practicable.</p> <p>(8) A structural test (see [1.4.2]) is also to be carried out for a representative cargo hold in case of cargo holds intended for in-port ballasting. The filling level required for the structural test of such cargo holds is to be the maximum loading that will occur in-port, as indicated in the loading manual.</p> <p>(9) See [1.3.3]</p> <p>(10) For cargo ships not covered by damage stability requirements, watertight hatches are to be tested by water pressure to a head of water measured from the lower edge of the opening to one metre above the freeboard deck. (see SOLAS II-1 Part B-2 Reg 16)</p> <p>(11) A prototype pressure test of each type and size of hatch may be carried out instead of individual hatches tests.</p> <p>(12) Where L.O. sump tanks and other similar spaces under main engines intended to hold liquid form part of the watertight subdivision of the ship, they are to be tested as per the requirements of Item 5, Deep tanks other than those listed elsewhere in this table.</p>				

**Table 3 : Additional test requirements for special service ships/tanks**

Item	Type of ship/tank	Structure to be tested	Type of test	Test head or pressure	Remarks
1	Liquefied gas carriers	Integral tanks	leak and structural	See Pt D, Ch 9, Sec 4	
		Hull structure supporting membrane or semi-membrane tanks	See Pt D, Ch 9, Sec 4	See Pt D, Ch 9, Sec 4	
		Independent tanks type A	See Pt D, Ch 9, Sec 4	See Pt D, Ch 9, Sec 4	
		Independent tanks type B			
		Independent tanks type C			
2	Edible liquid tanks	Independent tanks	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• top of the overflow (2)</li> <li>• 0,9 m above top of tank (3)</li> </ul>	
3	Chemical carriers	Integral or independent cargo tanks	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• 2,4 m above top of tank (3)</li> <li>• top of tank plus the design vapour pressure (3)</li> </ul>	Where a cargo tank is designed for the carriage of cargoes with specific gravities greater than 1,0 (see [1.6.1])
4	Chemical fuel tanks	Integral or independent tanks	leak and structural (1)	The greater of: <ul style="list-style-type: none"> <li>• 2,4 m above top of tank (3)</li> <li>• top of tank plus the design vapour pressure (3)</li> </ul>	Where a cargo tank is designed for the carriage of cargoes with specific gravities greater than 1,0 (see [1.6.1])
<p>(1) See [1.4.2]</p> <p>(2) See [1.3.3]</p> <p>(3) Top of tank is deck forming the top of the tank excluding any hatchways</p>					

**Table 4 : Application of leak test, coating, and provision of safe access for the different types of welded joints**

Type of welded joints		Leak test	Coating (1)		Safe access (2)	
			Before leak test	After leak test but before structural test	Leak test	Structural test
Butt	Automatic	not required	allowed (3)	not applicable	not required	not required
	Manual or semi-automatic (4)	required	not allowed	allowed	required	not required
Fillet	Boundary including penetrations	required	not allowed	allowed	required	not required

(1) Coating refers to internal (tank/hold) coating, where applied, and external (shell/deck) painting. It does not refer to shop primer.  
 (2) Temporary means of access for verification of the leak test.  
 (3) The condition applies provided that the welds have been visually inspected with care, to the satisfaction of the Surveyor.  
 (4) Flux Core Arc Welding (FCAW) semi-automatic butt welds need not be tested, provided careful visual inspections show continuous and uniform weld profile shape, free from repairs, and the results of NDT show no significant defects.

## 1.6 Test methods

### 1.6.1 Hydrostatic test

Unless another liquid is approved, hydrostatic tests are to consist in filling the space with fresh water or sea water, whichever is appropriate for testing, to the level specified in Tab 2 or Tab 3. See also [1.9].

In case where a tank is intended for cargoes having a density higher than the density of the liquid used for the test, the testing pressure height is to be adjusted to simulate the actual loading as far as practicable. The test pressure is not to exceed the maximum design internal pressure at the top of tank.

All the external surfaces of the tested space are to be examined for structural distortion, bulging and buckling, any other related damage, and leaks.

### 1.6.2 Hydropneumatic test

Hydropneumatic tests, where approved, are to be such that the test condition, in conjunction with the approved liquid level and supplemental air pressure, simulates the actual loading as far as practicable. The requirements and recommendations in [1.6.4] for tank air tests apply also to hydropneumatic tests. See also [1.9].

All the external surfaces of the tested space are to be examined for structural distortion, bulging and buckling, any other related damage, and leaks.

### 1.6.3 Hose test

Hose tests are to be carried out with the pressure in the hose nozzle maintained at least at  $2 \cdot 10^5$  Pa during the test. The nozzle is to have a minimum inside diameter of 12 mm and to be at a perpendicular distance from the joint not exceeding 1,5 m. The water jet is to impinge upon the weld.

Where a hose test is not practical because of possible damage to machinery, electrical equipment insulation, or outfitting items, it may be replaced by a careful visual examination of the welded connections, supported where necessary by means such as a dye penetrant test or an ultrasonic leak test, or equivalent.

### 1.6.4 Tank air test

All boundary welds, erection joints and penetrations including pipe connections are to be examined in accordance with approved procedures and under a stabilized pressure differential above atmospheric pressure not less than  $0,15 \cdot 10^5$  Pa, with a leak-indicating solution (such as soapy water/detergent or a proprietary solution) applied.

A U-tube having a height sufficient to hold a head of water corresponding to the required test pressure is to be arranged. The cross-sectional area of the U-tube is not to be less than that of the pipe supplying air to the tank. Arrangements involving the use of two calibrated pressure gauges to verify the required test pressure may be accepted taking into account the provisions in F5.1 and F7.4 of IACS Recommendation 140, "Recommendation for Safe Precautions during Survey and Testing of Pressurized Systems".

A double inspection of the tested welds is to be carried out. The first inspection is to be made immediately upon application of the leak indication solution; the second one is to be made approximately four or five minutes after, in order to detect those smaller leaks which may take time to appear.

### 1.6.5 Compressed air fillet weld test

In this air test, compressed air is injected from one end of a fillet welded joint, and the pressure verified at the other end of the joint by a pressure gauge. Pressure gauges are to be arranged so that an air pressure of at least  $0,15 \cdot 10^5$  Pa can be verified at each end of any passage within the portion being tested.

Note 1: Where a leak test is required for fabrication involving partial penetration welds, a compressed air test is also to be carried out in the same manner as to fillet weld where the root face is large, i.e. 6-8 mm.

### **1.6.6 Vacuum box test**

A box (vacuum testing box) with air connections, gauges and an inspection window is placed over the joint with a leak-indicating solution applied to the weld cap vicinity. The air within the box is removed by an ejector to create a vacuum of  $0,20 \cdot 10^5$  to  $0,26 \cdot 10^5$  Pa inside the box.

### **1.6.7 Ultrasonic test**

An ultrasonic echo transmitter is to be arranged on the inside of a compartment, and a receiver on the outside. The watertight/ weathertight boundaries of the compartment are scanned with the receiver, in order to detect an ultrasonic leak indication. Any leakage in the sealing of the compartment is indicated at a location where sound is detectable by the receiver.

### **1.6.8 Penetration test**

For the test of butt welds or other weld joints, a low surface tension liquid is applied on one side of a compartment boundary or a structural arrangement. If no liquid is detected on the opposite sides of the boundaries after the expiration of a defined period of time, this indicates tightness of the boundaries. In certain cases, a developer solution may be painted or sprayed on the other side of the weld to aid leak detection.

### **1.6.9 Other test**

Other methods of testing may be considered by the Society upon submission of full particulars prior to the commencement of the tests.

## **1.7 Application of coating**

### **1.7.1 Final coating**

For butt joints welded by means of an automatic process, the final coating may be applied at any time before completion of a leak test of the spaces bounded by the joints, provided that the welds have been visually inspected with care, to the satisfaction of the Surveyor.

The Surveyors reserve the right to require a leak test prior to the application of a final coating over automatic erection butt welds.

For all the other joints, the final coating is to be applied after the completion of the joint leak test. See also Tab 4.

### **1.7.2 Temporary coating**

Any temporary coating which may conceal defects or leaks is to be applied at the same time as for a final coating (see [1.7.1]). This requirement does not apply to shop primers.

## **1.8 Safe access to joints**

**1.8.1** For leak tests, a safe access to all joints under examination is to be provided. See also Tab 4.

## **1.9 Hydrostatic or hydropneumatic tightness test**

**1.9.1** In cases where the hydrostatic or hydropneumatic tests are applied instead of a specific leak test, the examined boundaries are to be dew-free, otherwise small leaks are not visible.

## **1.10 SOLAS Exempt / Equivalent Ships**

**1.10.1** Testing procedures are to be carried out in accordance with the requirements [1.4.1] to [1.9.1] in association with the following alternative procedures for [1.4.2]

**1.10.2** The tank boundaries are to be tested from at least one side. The tanks for structural test are to be selected so that all representative structural members are tested for the expected tension and compression.

**1.10.3** Structural tests are to be carried out for at least one tank of a group of tanks having structural similarity (i.e. same design conditions, alike structural configurations with only minor localised differences determined to be acceptable by the attending Surveyor) on each vessel provided all other tanks are tested for leaks by an air test. The acceptance of leak testing using an air test instead of a structural test does not apply to cargo space boundaries adjacent to other compartments in tankers and combination carriers or to the boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships.

**1.10.4** Additional tanks may require structural testing if found necessary after the structural testing of the first tank.

**1.10.5** For tanks which are less than  $2 \text{ m}^3$  in volume, structural testing may be replaced by leak testing.

**1.10.6** Where the structural adequacy of the tanks and spaces of a vessel were verified by the structural testing required by either requirements [1.4] to [1.9] or [1.10.3], subsequent vessels in the series (i.e. sister ships built from the same plans at the same shipyard) may be exempted from structural testing of tanks, provided that:

- a) water-tightness of boundaries of all tanks and spaces is verified by leak tests and thorough inspections are carried out.
- b) structural testing is carried out for at least one tank or space of each type among all tanks/spaces of each sister vessel.
- c) additional tanks and spaces may require structural testing if found necessary after the structural testing of the first tank or if deemed necessary by the attending Surveyor.

For cargo space boundaries adjacent to other compartments in tankers and combination carriers or boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships, structural tests are to be carried out for at least one tank of a group of tanks having structural similarity (i.e. same design conditions, alike structural configurations with only minor localised differences determined to be acceptable by the attending Surveyor) on each vessel provided all other tanks are tested for leaks by an air test.

**1.10.7** Sister ships built (i.e. keel laid) two years or more after the delivery of the last ship of the series, may be tested in accordance with [1.10.6] at the discretion of the Society, provided that:

- a) general workmanship has been maintained (i.e. there has been no discontinuity of shipbuilding or significant changes in the construction methodology or technology at the yard, shipyard personnel are appropriately qualified and demonstrate an adequate level of workmanship as determined by the Society); and
- b) an NDT plan is implemented and evaluated by the Society for the tanks not subject to structural tests. Shipbuilding quality standards for the hull structure during new construction are to be reviewed and agreed during the kick-off meeting. The work is to be carried out in accordance with the Rules and under survey of the Society.

## **1.11 Non-SOLAS Ships**

**1.11.1** Testing procedures are to be carried out in accordance with the requirements [1.4.1] to [1.9.1] in association with the following alternative procedures for [1.4.2].

**1.11.2** The tank boundaries are to be tested from at least one side. The tanks for structural test are to be selected so that all representative structural members are tested for the expected tension and compression.

**1.11.3** The requirements given in Tab 2 to structurally test tanks to 2,4 metres above the top of the tank do not apply. Instead, the minimum test pressure for structural testing is to be taken as  $0,3D + 0,76$  metres above the top of the tank where the top of the tank is the deck forming the top of the tank, excluding any hatchways and D is the depth of the ship. The minimum test pressure need not be taken greater than 2,4 metres above the top of the tank.

**1.11.4** Structural tests are to be carried out for at least one tank of a group of tanks having structural similarity (i.e. same design conditions, alike structural configurations with only minor localised differences determined to be acceptable by the attending Surveyor) on each vessel provided all other tanks are tested for leaks by an air test. The acceptance of leak testing using an air test instead of a structural test does not apply to cargo space boundaries adjacent to other compartments in tankers and combination carriers or to the boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships.

**1.11.5** Additional tanks may require structural testing if found necessary after the structural testing of the first tank.

**1.11.6** For tanks which are less than 2 m<sup>3</sup> in volume, structural testing may be replaced by leak testing.

**1.11.7** Where the structural adequacy of the tanks of a vessel were verified by the structural testing required by either Tab 2 or [1.11.4], subsequent vessels in the series (i.e. sister ships built from the same plans at the same shipyard) may be exempted from structural testing of tanks, provided that:

- a) water-tightness of boundaries of all tanks and spaces are verified by leak tests and thorough inspections are carried out.
- b) structural testing is carried out for at least one tank or space among all tanks/spaces of each sister vessel.
- c) additional tanks and spaces may require structural testing if found necessary after the structural testing of the first tank or if deemed necessary by the attending Surveyor.

For cargo space boundaries adjacent to other compartments in tankers and combination carriers or boundaries of tanks for segregated cargoes or pollutant cargoes in other types of ships, structural tests are to be carried out for at least one tank of a group of tanks having structural similarity (i.e. same design conditions, alike structural configurations with only minor localised differences determined to be acceptable by the attending Surveyor) on each vessel provided all other tanks are tested for leaks by an air test.

**1.11.8** Sister ships built (i.e. keel laid) two years or more after the delivery of the last ship of the series, may be tested in accordance with [1.11.7] at the discretion of the Society, provided that:

- a) general workmanship has been maintained (i.e. there has been no discontinuity of shipbuilding or significant changes in the construction methodology or technology at the yard, shipyard personnel are appropriately qualified and demonstrate an adequate level of workmanship as determined by the Society); and
- b) an NDT plan is implemented and evaluated by the Society for the tanks not subject to structural tests. Shipbuilding quality standards for the hull structure during new construction are to be reviewed and agreed during the kick-off meeting. The work is to be carried out in accordance with the Rules and under survey of the Society.

## **2 Miscellaneous**

### **2.1 Watertight decks, trunks, etc.**

**2.1.1** *After completion, a hose or flooding test is to be applied to watertight decks and a hose test to watertight trunks, tunnels and ventilators.*

### **2.2 Steering nozzles**

**2.2.1** Upon completion of manufacture, the nozzle is to be subjected to a leak test.

# Appendix 1 Welding Details

## Symbols

f : Root face, in mm.

## 1 Contents

### 1.1 General

1.1.1 Types and edge plate preparation of the manual welds carried out on the various parts of the hull are dealt with in this Appendix.

Other types and tolerances may be used after special examination of the Society.

1.1.2 The method used to prepare the parts to be welded is left to the discretion of each shipyard, according to its own technology and experience. It is approved at the same time as the approval of the welding procedures referred to in Ch 13, Sec 2, [2.2.1].

### 1.2 Butt welding edge preparation

1.2.1 Typical butt weld plate edge preparation for manual welding is specified in Tab 1 and Tab 2.

**Table 1 : Typical butt weld plate edge preparation (manual welding) - See Note 1**

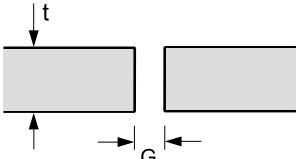

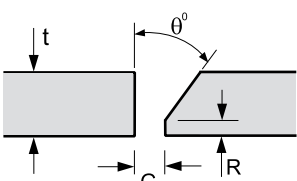

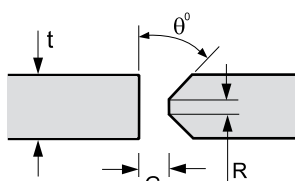

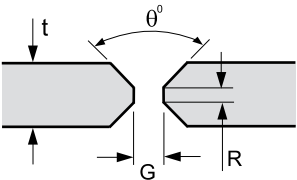

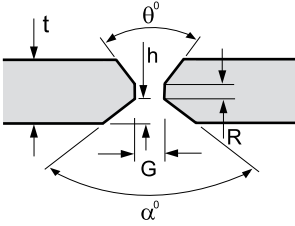

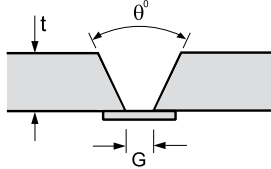

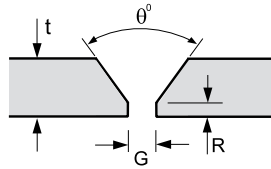

Detail	Dimensions	Detail	Dimensions
<p><b>Square butt</b></p> 	$t \leq 5 \text{ mm}$ $G = 3 \text{ mm}$		
<p><b>Single bevel butt</b></p> 	$t > 5 \text{ mm}$ $G \leq 3 \text{ mm}$ $R \leq 3 \text{ mm}$ $50^\circ \leq \theta \leq 70^\circ$	<p><b>Double bevel butt</b></p> 	$t > 19 \text{ mm}$ $G \leq 3 \text{ mm}$ $R \leq 3 \text{ mm}$ $50^\circ \leq \theta \leq 70^\circ$
<p><b>Double vee butt, uniform bevels</b></p> 	$G \leq 3 \text{ mm}$ $R \leq 3 \text{ mm}$ $50^\circ \leq \theta \leq 70^\circ$	<p><b>Double vee butt, non-uniform bevels</b></p> 	$G \leq 3 \text{ mm}$ $R \leq 3 \text{ mm}$ $6 \leq h \leq t/3 \text{ mm}$ $\theta = 50^\circ$ $\alpha = 90^\circ$
<p><b>Note 1:</b> Different plate edge preparation may be accepted by the Society on the basis of an appropriate welding procedure specification.</p>			

Table 2 : Typical butt weld plate edge preparation (manual welding) - See Note 1

Detail	Dimensions	Detail	Dimensions
<p>Single vee butt, one side welding with backing strip (temporary or permanent)</p> 	$3 \leq G \leq 9 \text{ mm}$ $30^\circ \leq \theta \leq 45^\circ$	<p>Single vee butt</p> 	$G \leq 3 \text{ mm}$ $50^\circ \leq \theta \leq 70^\circ$ $R \leq 3 \text{ mm}$
<p><b>Note 1:</b> Different plate edge preparation may be accepted by the Society on the basis of an appropriate welding procedure specification.</p>			

### 1.3 Partial of full penetration edge preparation

1.3.1 Typical edge preparations for partial or full penetration welding are indicated in:

- for partial penetration welds: Fig 1, in which  $f$ , in mm, is to be taken between 3 mm and  $t_{as-built}/3$ , and  $\alpha$  between  $40^\circ$  and  $60^\circ$

Figure 1 : Partial penetration weld

- for full penetration welds: Fig 2, in which  $f$ , in mm, is to be taken between 0 and 3 mm, and  $\alpha$  between  $40^\circ$  and  $60^\circ$

Back gouging is generally required for full penetration welds.

In case of full penetration welding, the root face is to be removed, e.g. by gouging before welding of the back side.

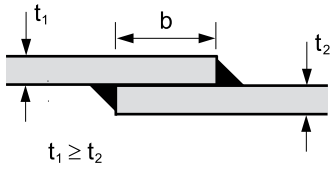

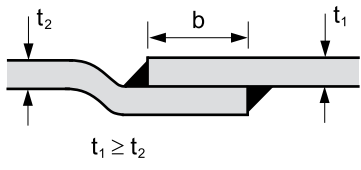

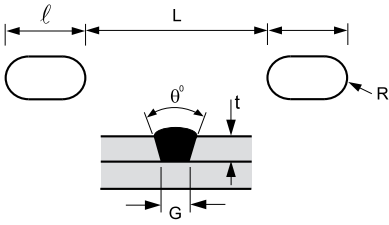

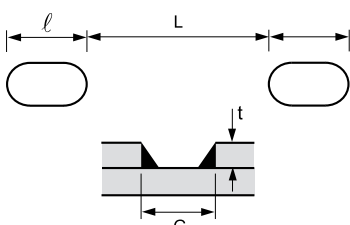

Figure 2 : Full penetration weld

### 1.4 Lap-joint, slot and plug welding

1.4.1 Welding details of lap-joint, slot and plug welds are specified in Tab 3.

Table 3 : Typical lap joint, plug and slot welding (manual welding)

<p><b>Fillet weld in lap joint</b></p>  <p><math>t_1 \geq t_2</math></p> <p><math>b = 2 t_2 + 25 \text{ mm}</math></p> <p>Remark: location of lap joint to be approved by the Society</p>	<p><b>Fillet weld in joggled lap joint</b></p>  <p><math>t_1 \geq t_2</math></p> <p><math>b \geq 2 t_2 + 25 \text{ mm}</math></p> <p>Remark: location of lap joint to be approved by the Society</p>
<p><b>Plug welding</b></p>  <ul style="list-style-type: none"> <li><math>t \leq 12 \text{ mm}</math></li> <li><math>l = 60 \text{ mm}</math></li> <li><math>R = 6 \text{ mm}</math></li> <li><math>40^\circ \leq \theta \leq 50^\circ</math></li> <li><math>G = 12 \text{ mm}</math></li> <li><math>L &gt; 2 l</math></li> </ul> <ul style="list-style-type: none"> <li><math>12 \text{ mm} &lt; t \leq 25 \text{ mm}</math></li> <li><math>l = 80 \text{ mm}</math></li> <li><math>R = 0,5 t \text{ mm}</math></li> <li><math>\theta = 30^\circ</math></li> <li><math>G = t \text{ mm}</math></li> <li><math>L &gt; 2 l</math></li> </ul>	<p><b>Slot welding</b></p>  <ul style="list-style-type: none"> <li><math>t_{\text{as-built}} \leq 12 \text{ mm}</math></li> <li><math>G = 20 \text{ mm}</math></li> <li><math>l = 80 \text{ mm}</math></li> <li><math>2 l \leq L \leq 3 l, \text{ max } 250 \text{ mm}</math></li> </ul> <ul style="list-style-type: none"> <li><math>t &gt; 12 \text{ mm}</math></li> <li><math>G = 2 t</math></li> <li><math>l = 100 \text{ mm}</math></li> <li><math>2 l \leq L \leq 3 l, \text{ max } 250 \text{ mm}</math></li> </ul>

# Appendix 2 Reference Sheets for Special Structural Details

## 1 Contents

### 1.1 General

1.1.1 This Appendix includes the reference sheets for special structural details, as referred to in Ch 13, Sec 5.

**Table 1 : ALL LONGITUDINALLY FRAMED SIDE SHIPS**

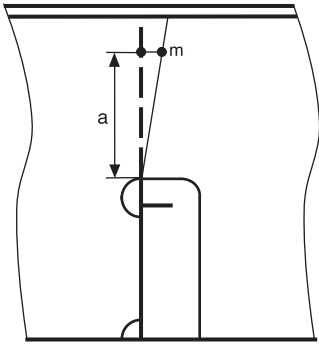

AREA 1: Side between $0,7T_{BAL}$ and $1,15T$ from the baseline	Connection of side longitudinal ordinary stiffeners with transverse primary supporting members - No collar plate	Sheet 1.1

## Chapter 4 Fire Protection, Detection and Extinction

### Section 1 General

1	Application	601
1.1	General	
1.2	National regulations	
1.3	Applicable requirements depending on ship type	
1.4	Documentation to be submitted	
1.5	Type approved products	
2	Definitions	603
2.1	A class divisions	
2.2	Accommodation spaces	
2.3	Atriums	
2.4	B class divisions	
2.5	Bulkhead decks	
2.6	C class divisions	
2.7	Cabin balconies	
2.8	Cargo ship	
2.9	Cargo spaces	
2.10	Central control station	
2.11	Chemical tankers	
2.12	Closed ro-ro spaces	
2.13	Closed vehicle spaces	
2.14	Combination carriers	
2.15	Continuous B class ceilings or linings	
2.16	Continuously manned central control stations	
2.17	Control stations	
2.18	Dangerous goods	
2.19	Deadweight	
2.20	Fire damper	
2.21	Fire Test Procedures Code	
2.22	Gas carriers	
2.23	Helicopter facility	
2.24	Helicopter landing area	
2.25	Helideck	
2.26	Lightweight	
2.27	Low flame-spread	
2.28	Machinery spaces	
2.29	Machinery spaces of category A	
2.30	Main vertical zones	
2.31	Non-combustible material	
2.32	Non-sparking fan	
2.33	Oil fuel unit	
2.34	Open ro-ro spaces	
2.35	Open vehicle spaces	
2.36	Passenger ship	
2.37	Public spaces	
2.38	Rooms containing furniture and furnishings of restricted fire risk	
2.39	Ro-ro passenger ship	

# Table of Content

2.40	Ro-ro spaces
2.41	Safety centre
2.42	Sauna
2.43	Semi-enclosed space
2.44	Service spaces
2.45	Smoke damper
2.46	Special category spaces
2.47	Standard fire test
2.48	Steel or other equivalent material
2.49	Tanker
2.50	Vehicle carrier
2.51	Vehicle spaces
2.52	Weather decks
2.53	Winching area

## Section 2 Prevention of Fire

<b>1</b>	<b>Probability of ignition</b>	<b>611</b>
1.1	Arrangements for fuel oil, lubrication oil and other flammable oils	
1.2	Arrangements for gaseous fuel for domestic purposes	
1.3	Miscellaneous items of ignition sources and ignitability	
<b>2</b>	<b>Fire growth potential</b>	<b>611</b>
2.1	Control of air supply and flammable liquid to the space	
2.2	Fire protection materials	
<b>3</b>	<b>Smoke generation potential and toxicity</b>	<b>614</b>
3.1	Paints, varnishes and other finishes	
3.2	Primary deck coverings	

## Section 3 Suppression of Fire: Detection and Alarm

<b>1</b>	<b>General</b>	<b>615</b>
1.1	Passenger ships	
1.2	Minimum number of detectors	
<b>2</b>	<b>Initial and periodical tests</b>	<b>615</b>
2.1	General	
<b>3</b>	<b>Protection of machinery spaces</b>	<b>615</b>
3.1	Installation	
3.2	Design	
3.3	Protection of spaces containing a ballast water management system	
<b>4</b>	<b>Protection of accommodation and service spaces and control stations</b>	<b>616</b>
4.1	Application	
4.2	Smoke detectors in accommodation spaces	
4.3	Requirements for passenger ships carrying more than 36 passengers	
4.4	Requirements for passenger ships carrying not more than 36 passengers	
4.5	Protection of atriums	
4.6	Protection of cabin balconies on passenger ships	
4.7	Cargo ships	
<b>5</b>	<b>Protection of cargo spaces</b>	<b>617</b>
5.1	Application and general requirements	
<b>6</b>	<b>Manually operated call points</b>	<b>617</b>
6.1	General requirements	
<b>7</b>	<b>Inspection hatches</b>	<b>617</b>
7.1	Application	
7.2	Inspection hatches

	8.2	Control panel	
	8.3	Passenger ships carrying more than 36 passengers	
	8.4	Special alarm	
<b>Section 4</b>	<b>Suppression of Fire: Control of Smoke Spread</b>		
	1	General	619
	1.1	Application	
	2	Protection of control stations outside machinery spaces	619
	2.1	General	
	3	Release of smoke from machinery spaces	619
	3.1	Release of smoke	
	3.2	Controls	
	4	Draught stops	619
	4.1		
	5	Smoke extraction systems	619
	5.1	Atriums	
<b>Section 5</b>	<b>Suppression of Fire: Containment of Fire</b>		
	1	Thermal and structural boundaries	620
	1.1	Application	
	1.2	Thermal and structural subdivision	
	1.3	Passenger ships	
	1.4	Cargo ships except tankers	
	1.5	Tankers	
	2	Penetrations in fire-resisting divisions and prevention of heat transmission	635
	2.1	Penetrations in A class divisions	
	2.2	Penetrations in B class divisions	
	2.3	Pipes penetrating A or B class divisions	
	2.4	Prevention of heat transmission	
	3	Protection of openings in fire-resisting divisions	635
	3.1	Application	
	3.2	Openings in bulkheads and decks	
	3.3	Doors in fire-resisting divisions	
	4	Protection of openings in machinery space boundaries	637
	4.1	Application	
	4.2	Protection of openings in machinery space boundaries	
	5	Protection of cargo space boundaries	638
	5.1	Application	
	5.2	Passenger ships carrying more than 36 passengers	
	5.3	Indicators	
	6	Ventilation systems	638
	6.1	Application	
	6.2	General	
	6.3	Arrangement of ducts	
	6.4	Details of fire dampers and duct penetrations	
	6.5	Ventilation systems for passenger ships carrying more than 36 passengers	
	6.6	Exhaust ducts from galley ranges	
	6.7	Ventilation rooms serving machinery spaces of category A containing internal combustion machinery	
	6.8	Ventilation systems for laundries in passenger ships carrying more than 36 passengers

Appendix 7	Exhaust Gas Back Pressure Analysis

# Section 1 General Requirements

## 1 General

### 1.1 Application

**1.1.1** Part C, Chapter 1 applies to the design, construction, installation, tests and trials of main propulsion and essential auxiliary machinery systems and associated equipment, boilers and pressure vessels, piping systems, and steering and manoeuvring systems installed on board classed ships, as indicated in each Section of this Chapter and as far as class is concerned only. For computerized machinery systems, requirements contained in Part C, Chapter 3 shall be referred to.

### 1.2 Additional requirements

**1.2.1** Additional requirements for machinery are given in:

- Part D and Part E for the assignment of the service notations
- Part F, for the assignment of additional class notations.

### 1.3 Documentation to be submitted

**1.3.1** Before the actual construction is commenced, the Manufacturer, Designer or Shipbuilder is to submit to the Society the documents (plans, diagrams, specifications and calculations) requested in the relevant Sections of this Chapter.

### 1.4 Definitions

#### 1.4.1 Continuity of service

The Shipyard is to give special consideration to the reliability of single essential propulsion components. This *may require a separate source of propulsion power sufficient to give the ship a navigable speed, especially in the case of unconventional arrangements.*

#### 1.4.2 Dead ship condition

Dead ship condition is the condition under which the whole propulsion system, including the main power supply, is not in operation and auxiliary means for bringing the main propulsion machinery into operation and for the restoration of the main power supply, such as compressed air and starting current from batteries, are not available, but assuming that means are available to start the emergency generator at all times.

## 2 Design and construction

### 2.1 General

**2.1.1** *The machinery, boilers and other pressure vessels, associated piping systems and fittings are to be of a design and construction adequate for the service for which they are intended and shall be so installed and protected as to reduce to a minimum any danger to persons on board, due regard being paid to moving parts, hot surfaces and other hazards.*

*The design is to have regard to materials used in construction, the purpose for which the equipment is intended, the working conditions to which it will be subjected and the environmental conditions on board.*

### 2.2 Materials, welding and testing

#### 2.2.1 General

Materials, welding and testing procedures are to be in accordance with the requirements of NR216 Materials and Welding, and those given in the other Sections of this Chapter. In addition, for machinery components fabricated by welding the requirements given in [2.2.2] apply.

#### 2.2.2 Welded machinery components

Welding processes and welders are to be approved by the Society in accordance with NR216 Materials and Welding, Chapter 12 and NR476 Approval testing of welders.

References to welding procedures adopted are to be clearly indicated on the plans submitted for approval.

Joints transmitting loads are to be either:

- full penetration butt-joints welded on both sides, except when an equivalent procedure is approved
- full penetration T- or cruciform joints.

For joints between plates having a difference in thickness greater than 3 mm, a taper having a length of not less than 4 times the difference in thickness is required. Depending on the type of stress to which the joint is subjected, a taper equal to three times the difference in thickness may be accepted.

T-joints on scalloped edges are not permitted.

Lap-joints and T-joints subjected to tensile stresses are to have a throat size of fillet welds equal to 0,7 times the thickness of the thinner plate on both sides.

In the case of welded structures including cast pieces, the latter are to be cast with appropriate extensions to permit connection, through butt-welded joints, to the surrounding structures, and to allow any radiographic and ultrasonic examinations to be easily carried out.

Where required, preheating and stress relieving treatments are to be performed according to the welding procedure specification.

**2.2.3 Non-destructive testing suppliers**

In case of non-destructive testing carried out by an independent company from the manufacturer or shipyard, such company has to comply with the requirements set out in NR669 Recognition of non-destructive testing suppliers.

**2.3 Vibrations**

**2.3.1** Shipyards and manufacturers are to give *special consideration to the design, construction and installation of propulsion machinery systems and auxiliary machinery so that any mode of their vibrations shall not cause undue stresses in this machinery in the normal operating ranges.*

**2.4 Operation in inclined position**

**2.4.1** *Main propulsion machinery and all auxiliary machinery essential to the propulsion and the safety of the ship are, as fitted in the ship, be designed to operate when the ship is upright and when inclined at any angle of list either way and trim by bow or stern as stated in Tab 1.*

*The Society may permit deviations from angles given in Tab 1, taking into consideration the type, size and service conditions of the ship.*

Machinery with a horizontal rotation axis is generally to be fitted on board with such axis arranged alongships. If this is not possible, the Manufacturer is to be informed at the time the machinery is ordered.

**Table 1 : Inclination of ship**

Installations, components	Angle of inclination (degrees) (1) (4)			
	Athwartship		Fore and aft	
	static	dynamic	static	dynamic
Main and auxiliary machinery	15	22,5	5	7,5
Safety equipment, e.g. emergency power installations, emergency fire pumps and their devices Switch gear, electrical and electronic appliances (3) and remote control systems	22,5 (2)	22,5 (2)	10	10
(1) Athwartship and fore-and-aft inclinations may occur simultaneously. (2) In ships for the carriage of liquefied gases and of chemicals the emergency power supply must also remain operable with the ship flooded to a final athwartship inclination up to a maximum of 30°. (3) No undesired switching operations or operational changes are to occur (4) Where the length of the ship exceeds 100m, the fore-and-aft static angle of inclination may be taken as 500/L degrees, where L is the length of the ship, in metres, as defined in Pt B, Ch 1, Sec 3, [2.1.1]				

**2.5 Ambient conditions**

**2.5.1** Machinery and systems covered by the Rules are to be designed to operate properly under the ambient conditions specified in Tab 2, unless otherwise specified in each Section of this Chapter.

**2.6 Power of machinery**

**2.6.1** Unless otherwise stated in each Section of this Chapter, where scantlings of components are based on power, the values to be used are determined as follows:

- for main propulsion machinery, the power/rotational speed for which classification is requested
- for auxiliary machinery, the power/rotational speed which is available in service.

Table 2 : Ambient conditions

AIR TEMPERATURE	
Location, arrangement	Temperature range, in °C
In enclosed spaces	between 0 and +45 (2)
On machinery components, boilers In spaces subject to higher or lower temperatures	According to specific local conditions
On exposed decks	between -25 and +45 (1)

WATER TEMPERATURE	
Coolant	Temperature, in °C
Sea water or, if applicable, sea water at charge air coolant inlet	up to +32
(1) Electronic appliances are to be designed for an air temperature up to 55°C (for electronic appliances see also Part C, Chapter 2).	
(2) Different temperatures may be accepted by the Society in the case of ships intended for restricted service.	

## 2.7 Astern power

**2.7.1** Sufficient power for going astern is to be provided to secure proper control of the ship in all normal circumstances.

In order to maintain sufficient manoeuvrability and secure control of the ship in all normal circumstances, the main propulsion machinery is to be capable of reversing the direction of thrust so as to bring the ship to rest from the maximum service speed. The main propulsion machinery is to be capable of maintaining in free route astern at least 70% of the ahead revolutions.

Where steam turbines are used for main propulsion, they are to be capable of maintaining in free route astern at least 70% of the ahead revolutions for a period of at least 15 minutes.

For main propulsion systems with reversing gears, controllable pitch propellers or electrical propeller drive, running astern is not to lead to an overload of propulsion machinery.

During the sea trials, the ability of the main propulsion machinery to reverse the direction of thrust of the propeller is to be demonstrated and recorded (see also Ch 1, Sec 18).

## 2.8 Safety devices

**2.8.1** Where risk from overspeeding of machinery exists, means are to be provided to ensure that the safe speed is not exceeded.

**2.8.2** Where main or auxiliary machinery including pressure vessels or any parts of such machinery are subject to internal pressure and may be subject to dangerous overpressure, means shall be provided, where practicable, to protect against such excessive pressure.

**2.8.3** Main turbine propulsion machinery and, where applicable, main internal combustion propulsion machinery and auxiliary machinery shall be provided with automatic shut-off arrangements in the case of failures, such as lubricating oil supply failure, which could lead rapidly to complete breakdown, serious damage or explosion.

The Society may permit provisions for overriding automatic shut-off devices.

See also the specific requirements given in the other Sections of this Chapter.

## 2.9 Fuels

**2.9.1** Fuel oils employed for engines and boilers are, in general, to have a flashpoint (determined using the closed cup test) of not less than 60°C, except as otherwise permitted in items a) to c) below.

a) Fuel oils having a flashpoint of less than 60°C but not less than 43°C may be accepted:

- in emergency generators;
- for feeding the emergency fire pump's engines and the auxiliary machines which are not located in the machinery spaces of category A; or
- for ships assigned with a restricted navigation notation which are not intended to comply with IMO SOLAS Convention, and provided that:
  - Special precautions are taken to the Society's satisfaction including a demonstration that the temperature of spaces where fuel oil is stored or employed will remain at least 10°C below the fuel oil flashpoint at all times; and
  - This arrangement is also acceptable to the Flag Authority.

b) For installations specially approved for use of natural gas or other low-flashpoint fuel as fuel for boilers or propulsion engines, in the scope of the additional service features **LNGfuel**, **CNGfuel**, **LPGfuel** or, as relevant, other additional service features defined in Pt A, Ch 1, Sec 2, [4.16.4] and subject to the corresponding requirements.

**2.9.2** Machineries and piping systems for the usage of fuel oil having a flashpoint less than 60°C shall also comply with the following:

- a) For oil fuel having a flashpoint of less than 60°C but not less than 43°C, oil tanks except those arranged in double bottom compartments shall be located outside of machinery spaces of category A
- b) For oil fuel having a flashpoint of less than 43°C, where permitted, oil tanks are to be located outside machinery spaces and the arrangements adopted have to be specially approved by the Society
- c) Provisions for the measurement of oil temperature should be provided on the suction pipe of oil fuel pump
- d) Stop valves and/or cocks are to be provided to the inlet side and outlet side of the oil fuel strainers
- e) Pipe joints of welded construction or of circular cone type or spherical type union joint are to be applied as much as possible.

### **3 Arrangement and installation on board**

#### **3.1 General**

**3.1.1** Provision shall be made to facilitate cleaning, inspection and maintenance of main propulsion and auxiliary machinery, including boilers and pressure vessels.

Easy access to the various parts of the propulsion machinery is to be provided by means of metallic ladders and gratings fitted with strong and safe handrails.

Spaces containing main and auxiliary machinery are to be provided with adequate lighting and ventilation.

#### **3.2 Floor plating and gratings**

**3.2.1** The floor plating and gratings in machinery spaces are to be metallic, divided into easily removable panels.

**3.2.2** The floor plating of normal passageways in machinery spaces of category A shall be made of steel.

#### **3.3 Bolting down**

**3.3.1** Bedplates of machinery are to be securely fixed to the supporting structures by means of foundation bolts which are to be distributed as evenly as practicable and of a sufficient number and size so as to ensure proper fitting.

Where the bedplates bear directly on the inner bottom plating, the bolts are to be fitted with suitable gaskets so as to ensure a tight fit and are to be arranged with their heads within the double bottom.

Continuous contact between bedplates and foundations along the bolting line is to be achieved by means of chocks of suitable thickness, carefully arranged to ensure a complete contact.

The same requirements apply to thrust block and shaft line bearing foundations.

Particular care is to be taken to obtain levelling and general alignment between the propulsion engines and their shafting (see Ch 1, Sec 7).

**3.3.2** Chocking resins are to be type approved.

**3.3.3** Where stays are provided for fixing the upper part of engines to the ship's structure in order, for example, to reduce the amplitude of engine vibrations, such stays are to be so designed as to prevent damage to these engines further to deformation of the shell plating in way of the said stays. The stays are to be connected to the hull in such a way as to avoid abnormal local loads on the structure of the ship.

#### **3.4 Safety devices on moving parts**

**3.4.1** Suitable protective devices on access restrictions are to be provided in way of moving parts (flywheels, couplings, etc.) in order to avoid accidental contact of personnel with moving parts.

#### **3.5 Gauges**

**3.5.1** All gauges are to be grouped, as far as possible, near each manoeuvring position; in any event, they are to be clearly visible.

#### **3.6 Ventilation in machinery spaces**

**3.6.1** Machinery spaces of Category A shall be adequately ventilated so as to ensure that when machinery or boilers therein are operating at full power in all weather conditions including heavy weather, an adequate supply of air is maintained to the spaces for the safety and comfort of personnel and the operation of the machinery. Any other machinery space shall be adequately ventilated appropriate for the purpose of that machinery space.

The ventilation of machinery spaces is to be supplied through suitably protected openings arranged in such a way that they can be used in all weather conditions, taking into account Reg. 17(3) and Reg. 19 of the 1966 Load Line Convention as amended by the Protocol of 1988.

Special attention is to be paid both to air delivery and extraction and to air distribution in the various spaces. The quantity and distribution of air are to be such as to satisfy machinery requirements for developing maximum continuous power.

The ventilation is to be so arranged as to prevent any accumulation of flammable gases or vapours.

### **3.7 Hot surfaces and fire protection**

**3.7.1** Surfaces, having temperature exceeding 60°C, with which the crew are likely to come into contact during operation are to be suitably protected or insulated.

Surfaces of machinery with temperatures above 220°C, e.g. steam, thermal oil and exhaust gas lines, silencers, exhaust gas boilers and turbochargers, are to be effectively insulated with non-combustible material or equivalently protected to prevent the ignition of combustible materials coming into contact with them. Where the insulation used for this purpose is oil absorbent or may permit the penetration of oil, the insulation is to be encased in steel sheathing or equivalent material.

Fire protection, detection and extinction is to comply with the requirements of Part C, Chapter 4.

#### **3.7.2 Specific requirements on fire protection related to engine, turbine and gearbox installations**

Materials other than steel may be assessed in relation to the risk of fire associated with the component and its installation when engines, turbines and gearboxes are considered.

The use of materials other than steel is considered acceptable for the following applications:

- internal pipes which cannot cause any release of flammable fluid onto the machinery or into the machinery space in case of failure (this does not cover double sheeted pipes), or
- components that are only subject to liquid spray on the inside when the machinery is running, such as machinery covers, rocker box covers, camshaft end covers, inspection plates and sump tanks. It is a condition that the pressure inside these components and all the elements contained therein is less than 0,18 N/mm<sup>2</sup> and that wet sumps have a volume not exceeding 100 litres, or
- components attached to machinery which satisfy fire test criteria according to standard ISO 19921:2005 / 19922:2005 or other standards acceptable to the Society and which retain mechanical properties adequate for the intended installation.

**3.7.3** Incinerators (except those exclusively intended to burn oil residue), as well as thermal fluid heaters, are to be located in rooms other than the following spaces:

- propulsion plant and auxiliary spaces
- steering gear room
- rooms containing electric generating sets (including the emergency generating set) or containing the main or the emergency switchboard
- rooms containing hydraulic equipment
- engine control room
- engineers' and electricians' workshops.

**3.7.4** As far as practicable, the hydraulic power units are not to be located in machinery spaces containing the boilers, main engine, its auxiliaries or other sources of ignition. Unless otherwise specified, the hydraulic systems are to comply with the provision of Ch 1, Sec 10, [14].

### **3.8 Machinery remote control, alarms and safety systems**

**3.8.1** For remote control systems of main propulsion machinery and essential auxiliary machinery and relevant alarms and safety systems, the requirements of Part C, Chapter 3 apply.

## **4 Tests and trials**

### **4.1 Works tests**

**4.1.1** Equipment and its components are subjected to works tests which are detailed in the relevant Sections of this Chapter. The Surveyor is to be informed in advance of these tests.

Where such tests cannot be performed in the workshop, the Society may allow them to be carried out on board, provided this is not judged to be in contrast either with the general characteristics of the machinery being tested or with particular features of the shipboard installation. In such cases, the Surveyor is to be informed in advance and the tests are to be carried out in accordance with the provisions of NR216 Materials and Welding, relative to incomplete tests.

*All boilers, all parts of machinery, all steam, hydraulic, pneumatic and other systems and their associated fittings which are under internal pressure shall be subjected to appropriate tests including a pressure test before being put into service for the first time as detailed in the other Sections of this Chapter.*

### **4.2 Trials on board**

**4.2.1** Trials on board of machinery are detailed in Ch 1, Sec 18.

# Section 2 Diesel Engines

## 1 General

### 1.1 Application

**1.1.1** Diesel engines listed below are to be designed, constructed, installed, tested and certified in accordance with the requirements of this Section, under the supervision and to the satisfaction of the Society's Surveyors:

- a) main propulsion engines
- b) engines driving electric generators, including emergency generators
- c) engines driving other auxiliaries essential for safety and navigation and cargo pumps in tankers, when they develop a power of 110 kW and over.

All other engines are to be designed and constructed according to sound marine practice, with the equipment required in [2.3.4], and delivered with the relevant works' certificate (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.3]).

Engines intended for propulsion of lifeboats and compression ignition engines intended for propulsion of rescue boats are to comply with the relevant Rule requirements.

Additional requirements for control and safety systems for dual fuel engines are given in Ch 1, App 2.

In addition to the requirements of this Section, those given in Ch 1, Sec 1 apply.

### 1.2 Documentation flow for diesel engine

#### 1.2.1 Document flow for obtaining a type approval certificate

- For the initial engine type, the engine designer prepares the documentation in accordance with requirements in Tab 1 and Tab 2 and forwards to the Society according to the agreed procedure for review.

In addition, the documents and drawing listed in Ch 1, App 2, Tab 1 are to be submitted for approval of DF engines

- Upon review and approval of the submitted documentation (evidence of approval), it is returned to the engine designer.
- The engine designer arranges for a Surveyor to attend an engine type test and upon satisfactory testing the Society issues a type approval certificate.

#### 1.2.2 Document flow for engine certificate

- a) The engine type must have a type approval certificate. For the first engine of a type, the type approval process and the engine certification process (ECP) may be performed simultaneously.
- b) Engines to be installed in specific applications may require the engine designer/licensor to modify the design or performance requirements. The modified drawings are forwarded by the engine designer to the engine builder/licensee to develop production documentation for use in the engine manufacture in accordance with Tab 3.
- c) The engine builder/licensee develops a comparison list of the production documentation to the documentation listed in Tab 1 and Tab 2.

If there are differences in the technical content on the licensee's production drawings/documents compared to the corresponding licensor's drawings, the licensee must obtain agreement to such differences from the licensor.

If the designer acceptance is not confirmed, the engine is to be regarded as a different engine type and is to be subjected to the complete type approval process by the licensee.

- d) The engine builder/licensee submits the comparison list and the production documentation to the Society according to the agreed procedure for review/approval.
- e) The Society returns documentation to the engine builder/licensee with confirmation that the design has been approved. This documentation is intended to be used by the engine builder/licensee and their subcontractors and attending Surveyors. As the attending Surveyors may request the engine builder/licensee or their subcontractors to provide the actual documents indicated in the list, the documents are necessary to be prepared and available for the Surveyors.
- f) The attending Surveyors, at the engine builder/licensee/subcontractors, will issue product certificates as necessary for components manufactured upon satisfactory inspections and tests.
- g) The engine builder/licensee assembles the engine, tests the engine with a Surveyor present. An engine certificate is issued by the Surveyor upon satisfactory completion of assembly and tests.

#### 1.2.3 Approval of diesel engine components

Components of engine designer's design which are covered by the type approval certificate of the relevant engine type are regarded as approved whether manufactured by the engine manufacturer or sub-supplied. For components of subcontractor's design, necessary approvals are to be obtained by the relevant suppliers (e.g. exhaust gas turbochargers, charge air coolers, etc.).

**Table 1 : Document to be submitted for information, as applicable**

No.	Item
1	Engine particulars (e.g. Data sheet with general engine information, Project Guide, Marine Installation Manual)
2	Engine cross section
3	Engine longitudinal section
4	Bedplate and crankcase of cast design
5	Thrust bearing assembly <b>(1)</b>
6	Frame/frame box/gearbox of cast design <b>(2)</b>
7	Tie rod
8	Connecting rod
9	Connecting rod, assembly <b>(3)</b>
10	Crosshead, assembly <b>(3)</b>
11	Piston rod, assembly <b>(3)</b>
12	Piston, assembly <b>(3)</b>
13	Cylinder jacket/ block of cast design <b>(2)</b>
14	Cylinder cover, assembly <b>(3)</b>
15	Cylinder liner
16	Counterweights (if not integral with crankshaft), including fastening
17	Camshaft drive, assembly <b>(3)</b>
18	Flywheel
19	Fuel oil injection pump
20	Shielding and insulation of exhaust pipes and other parts of high temperature which may be impinged as a result of a fuel system failure, assembly
21	For electronically controlled engines, construction and arrangement of:
22	• Control valves
23	• High-pressure pumps
24	• Drive for high pressure pumps
24	Operation and service manuals <b>(4)</b>
25	FMEA (for engine control system) <b>(5)</b>
26	Production specifications for castings and welding (sequence)
27	Evidence of quality control system for engine design and in service maintenance
28	Quality requirements for engine production
29	Type approval certification for environmental tests, control components <b>(6)</b>
<p><b>(1)</b> If integral with engine and not integrated in the bedplate.  <b>(2)</b> Only for one cylinder or one cylinder configuration.  <b>(3)</b> Including identification (e.g. drawing number) of components.  <b>(4)</b> Operation and service manuals are to contain maintenance requirements (servicing and repair) including details of any special tools and gauges that are to be used with their fitting/settings together with any test requirements on completion of maintenance.  <b>(5)</b> Where engines rely on hydraulic, pneumatic or electronic control of fuel injection and/or valves, a failure mode and effects analysis (FMEA) is to be submitted to demonstrate that failure of the control system will not result in the operation of the engine being degraded beyond acceptable performance criteria for the engine.  <b>(6)</b> Tests are to demonstrate the ability of the control, protection and safety equipment to function as intended under the specified testing conditions (see Ch 3, Sec 6, [2]).</p>	

**Table 2 : Documentation to be submitted for approval, as applicable**

No	Item
1	Bedplate and crankcase of welded design, with welding details and welding instructions <b>(1) (2)</b>
2	Thrust bearing bedplate of welded design, with welding details and welding instructions <b>(1)</b>
3	Bedplate/oil sump welding drawings <b>(1)</b>
4	Frame/framebox/gearbox of welded design, with welding details and instructions <b>(1) (2)</b>
5	Engine frames, welding drawings <b>(1) (2)</b>

See [1.2.2], item b).</p>	

### **1.3 Definitions**

#### **1.3.1 Engine type**

In general, the type of an engine is defined by the following characteristics:

- the cylinder diameter
- the piston stroke
- the method of injection (direct or indirect injection)
- the kind of fuel (liquid, gaseous or dual-fuel)
- the working cycle (4-stroke, 2-stroke)
- the gas exchange (naturally aspirated or supercharged)
- the maximum continuous power per cylinder at the corresponding speed and/or brake mean effective pressure corresponding to the above-mentioned maximum continuous power
- the method of pressure charging (pulsating system or constant pressure system)
- the charging air cooling system (with or without intercooler, number of stages, etc.)
- cylinder arrangement (in-line or V-type).

#### **1.3.2 Engine power**

The maximum continuous power is the maximum power at ambient reference conditions (see [1.3.3]) which the engine is capable of delivering continuously, at nominal maximum speed, in the period of time between two consecutive overhauls.

Power, speed and the period of time between two consecutive overhauls are to be stated by the Manufacturer and agreed by the Society.

The rated power is the maximum power at ambient reference conditions (see [1.3.3]) which the engine is capable of delivering as set after works trials (fuel stop power) at the maximum speed allowed by the governor.

The rated power for engines driving electric generators is the nominal power, taken at the net of overload, at ambient reference conditions (see [1.3.3]), which the engine is capable of delivering as set after the works trials (see [4.3]).

#### **1.3.3 Ambient reference conditions**

The power of engines as per [1.1.1], items a), b) and c) is to be referred to the following conditions:

- barometric pressure = 0,1 MPa
- relative humidity = 60%
- ambient air temperature = 45°C
- sea water temperature (and temperature at inlet of sea water cooled charge air cooler) = 32°C.

In the case of ships assigned with a navigation notation other than unrestricted navigation, different temperatures may be accepted by the Society.

The engine Manufacturer is not expected to provide the above ambient conditions at a test bed. The rating is to be adjusted according to a recognised standard accepted by the Society.

#### **1.3.4 Same type of engines**

Two diesel engines are considered to be of the same type when they do not substantially differ in design and construction characteristics, such as those listed in the engine type definition as per [1.3.1], it being taken for granted that the documentation concerning the essential engine components listed in Tab 1, Tab 2 and Tab 3, and associated materials employed has been submitted, examined and, where necessary, approved by the Society.

#### **1.3.5 Substantive modifications or major modifications or major changes**

Design modifications, which lead to alterations in the stress levels, operational behaviour, fatigue life or an effect on other components or characteristics of importance such as emissions.

**1.3.6 Low-Speed Engines** means diesel engines having a rated speed of less than 300 rpm.

Medium-Speed Engines means diesel engines having a rated speed of 300 rpm and above, but less than 1400 rpm.

High-Speed Engines means diesel engines having a rated speed of 1400 rpm and above.

## 2 Design and construction

### 2.1 Materials and welding

#### 2.1.1 Crankshaft materials

In general, crankshafts are to be of forged steel having a tensile strength not less than 400 N/mm<sup>2</sup> and not greater than 1000 N/mm<sup>2</sup>.

The use of forged steels of higher tensile strength is subject to special consideration by the Society in each case.

The Society, at its discretion and subject to special conditions (such as restrictions in ship navigation), may accept crankshafts made of cast carbon steel, cast alloyed steel of appropriate quality and manufactured by a suitable procedure having a tensile strength as follows:

- a) between 400 N/mm<sup>2</sup> and 560 /mm<sup>2</sup> for cast carbon steel
- b) between 400 N/mm<sup>2</sup> and 700 N/mm<sup>2</sup> for cast alloyed steel.

The Society, at its discretion and subject to special conditions (such as restrictions in ship navigation), may also accept crankshafts made of cast iron for engines of a nominal power not exceeding 110 kW with a significative in-service behaviour either in marine or industry. The cast iron is to be of "SG" type (spheroidal graphite) of appropriate quality and manufactured by a suitable procedure.

#### 2.1.2 Welded frames and foundations

Steels used in the fabrication of welded frames and bedplates are to comply with the requirements of NR216 Materials and Welding.

Welding is to be in accordance with the requirements of Ch 1, Sec 1, [2.2].

### 2.2 Crankshaft

#### 2.2.1 Check of the scantling

The check of crankshaft strength is to be carried out in accordance with Ch 1, App 1.

### 2.3 Crankcase

#### 2.3.1 Strength

Crankcase construction and crankcase doors are to be of sufficient strength to withstand anticipated crankcase pressures that may arise during a crankcase explosion taking into account the installation of explosion relief valves required by [2.3.4]. Crankcase doors are to be fastened sufficiently securely for them not be readily displaced by a crankcase explosion.

#### 2.3.2 Ventilation and drainage

Ventilation of crankcase, and any arrangement which could produce a flow of external air within the crankcase, is in principle not permitted.

Vent pipes, where provided, are to be as small as practicable. If provision is made for the forced extraction of gases from the crankcase (e.g. for detection of explosive mixtures), the vacuum in the crankcase is not to exceed:

2,5 10<sup>-4</sup> MPa

To avoid interconnection between crankcases and the possible spread of fire following an explosion, crankcase ventilation pipes and oil drain pipes for each engine are to be independent of any other engine.

#### 2.3.3 Warning notice

A warning notice is to be fitted, preferably on a crankcase door on each side of the engine, or alternatively on the control stand.

This warning notice is to specify that whenever overheating is suspected in the crankcase, the crankcase doors or sight holes are not to be opened until a reasonable time has elapsed after stopping the engine, sufficient to permit adequate cooling of the crankcase.

#### 2.3.4 Crankcase explosion relief valves

- a) Diesel engines of a cylinder diameter of 200 mm and above or a crankcase gross volume of 0,6 m<sup>3</sup> and above are to be provided with crankcase explosion relief valves in accordance with the following requirements.
- b) Engines having a cylinder bore not exceeding 250 mm, are to have at least one valve near each end, but over eight crankthrows, an additional valve is to be fitted near the middle of the engine. Engines having a cylinder bore exceeding 250 mm, but not exceeding 300 mm, are to have at least one valve in way of each alternate crankthrow, with a minimum of two valves. Engines having a cylinder bore exceeding 300 mm are to have at least one valve in way of each main crankthrow.
- c) Additional relief valves are to be fitted on separate spaces of the crankcase, such as gear or chain cases for camshaft or similar drives, when the gross volume of such spaces is 0,6 m<sup>3</sup> or above. Scavenge spaces in open connection to the cylinders are to be fitted with explosion relief valves.

- d) The free area of each relief valve is not to be less than 45 cm<sup>2</sup>.
- e) The combined free area of the valves fitted on an engine is not to be less than 115 cm<sup>2</sup> per cubic metre of the crankcase gross volume. (See Note 1).
- f) Crankcase explosion relief valves are to be provided with lightweight spring-loaded valve discs or other quick-acting and self closing devices to relieve a crankcase of pressure in the event of an internal explosion and to prevent any inrush of air thereafter.
- g) The valve discs in crankcase explosion relief valves are to be made of ductile material capable of withstanding the shock of contact with stoppers at the full open position.
- h) Crankcase explosion relief valves are to be designed and constructed to open quickly and to be fully open at a pressure not greater than 0,02 MPa.
- i) Crankcase explosion relief valves are to be provided with a flame arrester that permits flow for crankcase pressure relief and prevents passage of flame following a crankcase explosion.
- j) Crankcase explosion relief valves are to be type tested in a configuration that represents the installation arrangements that will be used on an engine.

The purpose of type testing crankcase explosion valves is:

- to verify the effectiveness of the flame arrester
- to verify that the valve closes after an explosion
- to verify that the valve is gas/air tight after an explosion
- to establish the level of overpressure protection provided by the valve.

Where crankcase relief valves are provided with arrangements for shielding emissions from the valve following an explosion, the valve is to be type tested to demonstrate that the shielding does not adversely affect the operational effectiveness of the valve.

Type testing procedure is to comply with Ch 1, App 4.

- k) Crankcase explosion relief valves are to be provided with a copy of the manufacturer's installation and maintenance manual that is pertinent to the size and type of valve being supplied for installation on a particular engine.

The manual is to contain the following information:

- description of valve with details of function and design limits
- copy of type test certification
- installation instructions
- maintenance in service instructions to include testing and renewal of any sealing arrangements
- actions required after a crankcase explosion.

- l) A copy of the installation and maintenance manual required in i) above is to be provided on board the unit.

- m) Valves are to be provided with suitable markings that include the following information:

- name and address of manufacturer
- designation and size
- month/year of manufacture
- approved installation orientation.

Note 1: The total volume of the stationary parts within the crankcase may be discounted in estimating the crankcase gross volume (rotating and reciprocating components are to be included in the gross volume).

### **2.3.5 Oil mist detection**

- a) Oil mist detection arrangements (or engine bearing temperature monitors or equivalent devices) are required:
  - for alarm and slow down purposes for low speed diesel engines of 2250 kW and above or having cylinders of more than 300 mm bore
  - for alarm and automatic shutoff purposes for medium and high speed diesel engines of 2250 kW and above or having cylinders of more than 300 mm bore

Oil mist detection arrangements are to be of a type approved and tested in accordance with Ch 3, App 1 and comply with b) to c) below. Engine bearing temperature monitors or equivalent devices used as safety devices have to be of a type approved by the Society for such purposes

Note 1: An equivalent device for high speed engines could be interpreted as measures applied to high speed engines where specific design features to preclude the risk of crankcase explosions are incorporated.

- b) The oil mist detection system and arrangements are to be installed in accordance with the engine designer's and oil mist manufacturer's instructions/recommendations. The following particulars are to be included in the instructions:
- Schematic layout of engine oil mist detection and alarm system showing location of engine crankcase sample points and piping or cable arrangements together with pipe dimensions to detector
  - Evidence of study to justify the selected location of sample points and sample extraction rate (if applicable) in consideration of the crankcase arrangements and geometry and the predicted crankcase atmosphere where oil mist can accumulate
  - The manufacturer's maintenance and test manual
  - Information relating to type or in-service testing of the engine with engine protection system test arrangements having approved types of oil mist detection equipment
- c) A copy of the oil mist detection equipment maintenance and test manual required by item b) is to be provided on board ship
- d) Oil mist detection and alarm information is to be capable of being read from a safe location away from the engine
- e) Each engine is to be provided with its own independent oil mist detection arrangement and a dedicated alarm
- f) Oil mist detection and alarm systems are to be capable of being tested on the test bed and board under engine at standstill and engine running at normal operating conditions in accordance with test procedures that are acceptable to the Society
- g) The oil mist detection arrangements are to provide an alarm indication in the event of a foreseeable functional failure in the equipment and installation arrangements
- h) The oil mist detection system is to provide an indication that any lenses fitted in the equipment and used in determination of the oil mist level have been partially obscured to a degree that will affect the reliability of the information and alarm indication
- i) Where oil mist detection equipment includes the use of programmable electronic systems, the arrangements are to be in accordance with individual Society requirements for such systems
- j) Plans showing details and arrangements of oil mist detection and alarm arrangements are to be submitted for approval in accordance with Tab 2 under item 18
- k) The equipment together with detectors is to be tested when installed on the test bed and on board ship to demonstrate that the detection and alarm system functionally operates. The testing arrangements are to be to the satisfaction of the Society
- l) Where sequential oil mist detection arrangements are provided the sampling frequency and time is to be as short as reasonably practicable
- m) Where alternative methods are provided for the prevention of the build-up of oil mist that may lead to a potentially explosive condition within the crankcase details are to be submitted for consideration of individual Societies. The following information is to be included in the details to be submitted for consideration:
- Engine particulars – type, power, speed, stroke, bore and crankcase volume
  - Details of arrangements prevent the build up of potentially explosive conditions within the crankcase, e.g., bearing temperature monitoring, oil splash temperature, crankcase pressure monitoring, recirculation arrangements
  - Evidence to demonstrate that the arrangements are effective in preventing the build up of potentially explosive conditions together with details of in-service experience
  - Operating instructions and the maintenance and test instructions
- n) Where it is proposed to use the introduction of inert gas into the crankcase to minimise a potential crankcase explosion, details of the arrangements are to be submitted to the Society for consideration.

**2.3.6** When materials other than steel are used for crankcase, requirements in Ch 1, Sec 1, [3.7.2] are to be referred to.

## **2.4 Scavenge manifolds**

### **2.4.1 Fire extinguishing**

For two-stroke crosshead type engines, scavenge spaces in open connection (without valves) to the cylinders are to be connected to a fixed fire-extinguishing system, which is to be entirely independent of the fire-extinguishing system of the machinery space.

### **2.4.2 Blowers**

Where a single two-stroke propulsion engine is equipped with an independently driven blower, alternative means to drive the blower or an auxiliary blower are to be provided ready for use.

### **2.4.3 Relief valves**

Scavenge spaces in open connection to the cylinders are to be fitted with explosion relief valves in accordance with [2.3.4].

## **2.5 Systems**

### **2.5.1 General**

In addition to the requirements of the present sub-article, those given in Ch 1, Sec 10 and in Ch 1, Sec 1, [3.7.2] are to be satisfied. Flexible hoses in the fuel and lubricating oil system are to be limited to the minimum and are to be type approved.

Unless otherwise stated in Ch 1, Sec 10, propulsion engines are to be equipped with external connections for standby pumps for:

- fuel oil supply
- lubricating oil and cooling water circulation.

### **2.5.2 Fuel oil system**

Relief valves discharging back to the suction of the pumps or other equivalent means are to be fitted on the delivery side of the pumps.

In fuel oil systems for propulsion machinery, filters are to be fitted and arranged so that an uninterrupted supply of filtered fuel oil is ensured during cleaning operations of the filter equipment, except when otherwise stated in Ch 1, Sec 10.

- a) *External high pressure fuel delivery lines between the high pressure fuel pumps and fuel injectors are to be protected with a jacketed piping system capable of containing fuel from a high pressure line failure.*

*A jacketed pipe incorporates an outer pipe into which the high pressure fuel pipe is placed, forming a permanent assembly.*

*The jacketed piping system is to include a means for collection of leakages and arrangements are to be provided with an alarm in case of a fuel line failure.*

If flexible hoses are used for shielding purposes, these are to be approved by the Society.

When in fuel oil return piping the pulsation of pressure with peak to peak values exceeds 2 MPa, shielding of this piping is also required as above.

- b) For ships assigned with a restricted navigation notation, the requirements under item a) may be relaxed at the Society's discretion.

### **2.5.3 Lubricating oil system**

Efficient filters are to be fitted in the lubricating oil system when the oil is circulated under pressure.

In such lubricating oil systems for propulsion machinery, filters are to be arranged so that an uninterrupted supply of filtered lubricating oil is ensured during cleaning operations of the filter equipment, except when otherwise stated in Ch 1, Sec 10.

Relief valves discharging back to the suction of the pumps or other equivalent means are to be fitted on the delivery side of the pumps.

The relief valves may be omitted provided that the filters can withstand the maximum pressure that the pump may develop.

Where necessary, the lubricating oil is to be cooled by means of suitable coolers.

### **2.5.4 Charge air system**

- a) Requirements relevant to design, construction, arrangement, installation, tests and certification of exhaust gas turbochargers are given in Ch 1, Sec 17.

- b) When two-stroke propulsion engines are supercharged by exhaust gas turbochargers which operate on the impulse system, provision is to be made to prevent broken piston rings entering turbocharger casings and causing damage to blades and nozzle rings.

## **2.6 Starting air system**

**2.6.1** The requirements given in [3.1] apply.

## **2.7 Control and monitoring**

### **2.7.1 General**

In addition to those of this item, the general requirements given in Part C, Chapter 3 apply.

### **2.7.2 Alarm**

The lubricating oil system of diesel engines with a power equal to or in excess of 37 kW is to be fitted with alarms to give audible and visual warning in the event of an appreciable reduction in pressure of the lubricating oil supply.

### **2.7.3 Governors of main and auxiliary engines**

Each engine, except the auxiliary engines for driving electric generators for which [2.7.6] applies, is to be fitted with a speed governor so adjusted that the engine does not exceed the rated speed by more than 15%.

### **2.7.4 Overspeed protective devices of main and auxiliary engines**

In addition to the speed governor, each:

- main propulsion engine having a rated power of 220 kW and above, which can be declutched or which drives a controllable pitch propeller, and
- auxiliary engine having a rated power of 220 kW and above, except those for driving electric generators, for which [2.7.6], item f) applies,

is to be fitted with a separate overspeed protective device so adjusted that the engine cannot exceed the rated speed  $n$  by more than 20%; arrangements are to be made to test the overspeed protective device.

Equivalent arrangements may be accepted subject to special consideration by the Society in each case.

The overspeed protective device, including its driving mechanism or speed sensor, is to be independent of the governor.

### **2.7.5 Use of electronic governors**

a) Type approval

Electronic governors and their actuators are to be type approved by the Society.

b) Electronic governors for main propulsion engines

If an electronic governor is fitted to ensure continuous speed control or resumption of control after a fault, an additional separate governor is to be provided unless the engine has a manually operated fuel admission control system suitable for its control.

A fault in the governor system is not to lead to sudden major changes in propulsion power or direction of propeller rotation.

Alarms are to be fitted to indicate faults in the governor system.

The acceptance of electronic governors not in compliance with the above requirements will be considered by the Society on a case by case basis, when fitted on ships with two or more main propulsion engines.

c) Electronic governors forming part of a remote control system

When electronic speed governors of main internal combustion engines form part of a remote control system, they are to comply with the following conditions:

- If lack of power to the governor may cause major and sudden changes in the present speed and direction of thrust of the propeller, back up power supply is to be provided;
- Local control of the engines is always to be possible even in the case of failure in any part of the automatic or remote control systems. To this purpose, from the local control position it is to be possible to disconnect the remote signal, bearing in mind that the speed control according to [2.7.3] is not available unless an additional separate governor is provided for such local mode of control.

d) Electronic governors for auxiliary engines driving electric generators

In the event of a fault in the electronic governor system the fuel admission is to be set to "zero".

Alarms are to be fitted to indicate faults in the governor system.

The acceptance of electronic governors fitted on engines driving emergency generators will be considered by the Society on a case by case basis.

### **2.7.6 Governors for auxiliary engines driving electric generators**

a) Prime movers for driving generators of the main and emergency sources of electrical power are to be fitted with a speed governor which will prevent transient frequency variations in the electrical network in excess of  $\pm 10\%$  of the rated frequency with a recovery time to steady state conditions not exceeding 5 seconds, when the maximum electrical step load is switched on or off.

In the case when a step load equivalent to the rated output of a generator is switched off, a transient speed variation in excess of 10% of the rated speed may be acceptable, provided this does not cause the intervention of the overspeed device as required by item f).

b) At all loads between no load and rated power, the permanent speed variation is not to be more than 5% of the rated speed.

c) Prime movers are to be selected in such a way that they meet the load demand within the ship's mains and, when running at no load, can satisfy the requirement in item a) above if suddenly loaded to 50% of the rated power of the generator, followed by the remaining 50% after an interval sufficient to restore speed to steady state. Steady state conditions (see Note 1) are to be achieved in not more than 5 s.

Note 1: Steady state conditions are those at which the envelope of speed variation does not exceed  $\pm 1\%$  of the declared speed at the new power.

- d) Application of the electrical load in more than 2 load steps can only be allowed if the conditions within the ship’s mains permit the use of those auxiliary engines which can only be loaded in more than 2 load steps (see Fig 1 for guidance on 4-stroke diesel engines expected maximum possible sudden power increase) and provided that this is already allowed for in the designing stage.

This is to be verified in the form of system specifications to be approved and to be demonstrated at ship’s trials. In this case, due consideration is to be given to the power required for the electrical equipment to be automatically switched on after blackout and to the sequence in which it is connected.

This also applies to generators to be operated in parallel and where the power is to be transferred from one generator to another, in the event that any one generator is to be switched off.

- e) Emergency generator sets must satisfy the governor conditions as per items a) and b) when:
- their total consumer load is applied suddenly, or
  - their total consumer load is applied in steps, subject to:
    - the total load is supplied within 45 seconds since power failure on the main switchboard
    - the maximum step load is declared and demonstrated
    - the power distribution system is designed such that the declared maximum step loading is not exceeded
    - the compliance of time delays and loading sequence with the above is to be demonstrated at ship’s trials
- f) In addition to the speed governor, auxiliary engines of rated power equal to or greater than 220 kW driving electric generators are to be fitted with a separate overspeed protective device, with a means for manual tripping, adjusted so as to prevent the rated speed from being exceeded by more than 15%.

This device is to automatically shut down the engine.

- g) For alternating current generating sets operating in parallel, the governing characteristics of the prime movers are to be such that, within the limits of 20% and 100% total load, the load on any generating set will not normally differ from its proportionate share of the total load by more than 15% of the rated power in kW of the largest machine or 25% of the rated power in kW of the individual machine in question, whichever is the lesser.

For alternating current generating sets intended to operate in parallel, facilities are to be provided to adjust the governor sufficiently finely to permit an adjustment of load not exceeding 5% of the rated load at normal frequency.

**2.7.7 Engine Power Limitation (EPL) and Shaft Power Limitation (ShaPoLi) systems**

- a) The Overridable Engine Power Limitation (EPL) systems and Overridable Shaft Power Limitation (SHaPoLi) systems are to be of a type approved by the Society. These systems, in particular those of a mechanical type, may also be considered on a case-by-case basis by the Society.
- b) Where technically possible, EPL and SHaPoLi systems are to be controlled from the navigating bridge without the crew’s attendance in the machinery space.

**Figure 1 : Reference values for maximum possible sudden power increases P as a function of brake mean effective pressure, P<sub>me</sub>, at declared power (four-stroke diesel engines)**

P: power increase referred to declared power at site conditions; P<sub>me</sub>: declared power mean effective pressure

**2.7.8 Summary tables**

Diesel engines installed on ships without automation notations are to be equipped with monitoring equipment as detailed in Tab 4 or Tab 5 for main propulsion, in Tab 6 for auxiliary services and in Tab 7 for emergency respectively.

For ships assigned with a restricted navigation notation, the acceptance of a reduction in the monitoring equipment required in Tab 4, Tab 5 and Tab 6 may be considered.

The alarms are to be visual and audible.

The indicators are to be fitted at a normally attended position (on the engine or at the local control station).

**Table 4 : Monitoring of main propulsion cross-head (slow speed) diesel engines**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Main Engine			Auxiliary	
			Slow-down	Shut-down	Control	Stand by Start	Stop
Identification of system parameter	Alarm	Indication					
Fuel oil pressure after filter (engine inlet)		local					
Fuel oil viscosity before injection pumps or fuel oil temperature before injection pumps (for engine running on heavy fuel)		local					
Leakage from high pressure pipes where required	H						
Lubricating oil to main bearing and thrust bearing pressure	L	local					
	LL			X			
Lubricating oil to cross-head bearing pressure when separate	L	local					
	LL			X			
Lubricating oil to camshaft pressure when separate	L	local					
	LL			X			
Turbocharger lubricating oil inlet pressure		local					
Lubricating oil inlet temperature		local					
Thrust bearing pads or bearing outlet temperature	H	local					
Main, crank, cross-head bearing, oil outlet temp	H						
Oil mist concentration in crankcase (or engine bearing temperature monitors or equivalent devices) (5)	H		X				
Cylinder fresh cooling water system inlet pressure	L	local (3)					
Cylinder fresh cooling water outlet temperature or, when common cooling space without individual stop valves, the common cylinder water outlet temperature		local					
Piston coolant inlet pressure on each cylinder (1)	L	local					
Piston coolant outlet temperature on each cylinder (1)		local					
Piston coolant outlet flow on each cylinder (1) (2)	L						
Speed of turbocharger		local					
Scavenging air receiver pressure		local					
Scavenging air box temperature (detection of fire in receiver)		local					
Exhaust gas temperature		local (4)					
Engine speed / direction of speed (when reversible)		local					
	H			X			
Fault in the electronic governor system	X						

(1) Not required, if the coolant is oil taken from the main cooling system of the engine  
 (2) Where outlet flow cannot be monitored due to engine design, alternative arrangement may be accepted  
 (3) For engines of 220 KW and above  
 (4) Indication is required after each cylinder, for engines of 500 kW/cylinder and above  
 (5) For engine of 2250 KW and above or having cylinders of more than 300 mm bore

**Table 5 : Monitoring of main propulsion trunk-piston (medium or high speed) engines**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control					
			Main Engine			Auxiliary		
			Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start
Identification of system parameter								
Fuel oil pressure after filter (engine inlet)		local						
Fuel oil viscosity before injection pumps or fuel oil temperature before injection pumps (for engine running on heavy fuel)		local						
Leakage from high pressure pipes where required	H							
Lubricating oil to main bearing and thrust bearing pressure	L	local						
	LL			X				
Lubricating oil filter differential pressure	H	local						
Turbocharger lubricating oil inlet pressure (1)		local						
Lubricating oil inlet temperature		local						
Oil mist concentration in crankcase (or engine bearing temperature monitors or equivalent devices) (3)	H			X				
Cylinder fresh cooling water outlet temperature or, when common cooling space without individual stop valves, the common cylinder water outlet temperature		local						
Scavenging air receiver pressure		local						
Scavenging air box temperature (detection of fire in receiver)		local						
Exhaust gas temperature		local (2)						
Engine speed / direction of speed (when reversible)		local						
	H			X				
Fault in the electronic governor system	X							

(1) If without integrated self-contained oil lubrication system  
(2) Indication is required after each cylinder, for engines of 500 kW/cylinder and above  
(3) For engine of 2250 KW and above or having cylinders of more than 300 mm bore

**Table 6 : Monitoring of trunk-piston diesel engines used for auxiliary services**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control					
			Engine			Auxiliary		
			Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start
Identification of system parameter								
Fuel oil viscosity or temperature before injection (for engine running on heavy fuel)		local						
Fuel oil pressure		local						
Fuel oil leakage from high pressure pipes	H							
Lubricating oil pressure	L	local		X				
Oil mist concentration in crankcase (or engine bearing temperature monitors or equivalent devices) (1)	H			X				
Pressure or flow of cooling water, if not connected to main system	L	local						
Temperature of cooling water or cooling air		local						
Engine speed		local						
	H			X				
Fault in the electronic governor system	X							

(1) For engine of 2250 KW and above or having cylinders of more than 300 mm bore

Table 7 : Monitoring of emergency diesel engines

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control					
			Engine			Auxiliary		
			Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start
Identification of system parameter								
Fuel oil leakage from high pressure pipes (fuel injection pipes and common rails)	X	local						
Lubricating oil temperature (1)	H	local						
Lubricating oil pressure	L	local						
Activation of oil mist detection arrangements (or activation of the temperature monitoring systems or equivalent devices of: • the engine main and crank bearing oil outlet; or • the engine main and crank bearing) (2)	H	local						
Pressure or flow of cooling water (1)	L	local						
Temperature of cooling water or cooling air		local						
Engine speed		local						
	H			X (1)				

(1) Not applicable to emergency generator of less than 220 kW  
(2) For engines having a power of more than 2250kW or a cylinder bore of more than 300 mm  
**Note 1:** The safety and alarm systems are to be designed to 'fail safe'. The characteristics of the 'fail safe' operation are to be evaluated on the basis not only of the system and its associated machinery, but also the complete installation, as well as the ship.  
**Note 2:** Regardless of the engine output, if shutdowns additional to those above specified except for the overspeed shutdown, they are to be automatically overridden when the engine is in automatic or remote control mode during navigation.  
**Note 3:** The alarm system is to function in accordance with AUT notation, with additional requirements that grouped alarms are to be arranged on the bridge.  
**Note 4:** In addition to the fuel oil control from outside the space, a local means of engine shutdown is to be provided.  
**Note 5:** The local indications are to be provided within the same space as the diesel engines and are to remain operational in the event of failure of the alarm and safety systems.

### 3 Arrangement and installation

#### 3.1 Starting arrangements

##### 3.1.1 Mechanical air starting

- a) Air starting the main and auxiliary engines is to be arranged in compliance with Ch 1, Sec 10, [17.3.1].
- b) The total capacity of air compressors and air receivers is to be in compliance with Ch 1, Sec 10, [17.3.2] and Ch 1, Sec 10, [17.3.3].
- c) The main starting air arrangements for main propulsion or auxiliary diesel engines are to be adequately protected against the effects of backfiring and internal explosion in the starting air pipes. To this end, the following safety devices are to be fitted:
  - An isolating non-return valve, or equivalent, at the starting air supply connection to each engine.
  - A bursting disc or flame arrester:
    - in way of the starting valve of each cylinder, for direct reversing engines having a main starting air manifold
    - at least at the supply inlet to the starting air manifold, for non-reversing engines.

The bursting disc or flame arrester above may be omitted for engines having a bore not exceeding 230 mm.

Other protective devices will be specially considered by the Society.

The requirements of this item c) do not apply to engines started by pneumatic motors.

- d) Compressed air receivers are to comply with the requirements of Ch 1, Sec 3. Compressed air piping and associated air compressors are to comply with the requirements of Ch 1, Sec 10.

### **3.1.2 Electrical starting**

- a) Where main internal combustion engines are arranged for electrical starting, at least two separate batteries are to be fitted. The arrangement is to be such that the batteries cannot be connected in parallel. Each battery is to be capable of starting the main engine when in cold and ready to start condition. The combined capacity of batteries is to be sufficient to provide within 30 min, without recharging, the number of starts required in [3.1.1] b) in the event of air starting.
- b) Electrical starting arrangements for auxiliary engines are to have two separate storage batteries or may be supplied by two separate circuits from main engine storage batteries when these are provided. In the case of a single auxiliary engine, one battery is acceptable. The combined capacity of the batteries is to be sufficient for at least three starts for each engine.
- c) The starting batteries are only to be used for starting and for the engine's alarm and monitoring. Provision is to be made to maintain the stored energy at all times.
- d) Each charging device is to have at least sufficient rating for recharging the required capacity of batteries within 6 hours.

### **3.1.3 Special requirements for starting arrangements for emergency generating sets**

- a) *Emergency generating sets are to be capable of being readily started in their cold condition at a temperature of 0°C. If this is impracticable, or if lower temperatures are likely to be encountered, provision acceptable to the Society shall be made for the maintenance of heating arrangements, to ensure ready starting of the generating sets.*
- b) *Each emergency generating set arranged to be automatically started shall be equipped with starting devices approved by the Society with a stored energy capability of at least three consecutive starts.*  
*The source of stored energy shall be protected to preclude critical depletion by the automatic starting system, unless a second independent means of starting is provided. In addition, a second source of energy shall be provided for an additional three starts within 30 minutes, unless manual starting can be demonstrated to be effective.*
- c) *The stored energy is to be maintained at all times, as follows:*
- *electrical and hydraulic starting systems shall be maintained from the emergency switchboard*
  - *compressed air starting systems shall be provided in accordance with Ch 1, Sec 10, [17.3.4].*
- d) *Where automatic starting is not required, manual starting, such as manual cranking, inertia starters, manually charged hydraulic accumulators, or powder charge cartridges, is permissible where this can be demonstrated as being effective.*
- e) *When manual starting is not practicable, the requirements of b) and c) are to be complied with, except that starting may be manually initiated.*

## **3.2 Turning gear**

**3.2.1** Each engine is to be provided with hand-operated turning gear; where deemed necessary, the turning gear is to be both hand and mechanically-operated.

The turning gear engagement is to inhibit starting operations.

## **3.3 Trays**

**3.3.1** Trays fitted with means of drainage are to be provided in way of the lower part of the crankcase and, in general, in way of the parts of the engine, where oil is likely to spill in order to collect the fuel oil or lubricating oil dripping from the engine.

## **3.4 Exhaust gas system**

**3.4.1** In addition to the requirements given in Ch 1, Sec 10, the exhaust system is to be efficiently cooled or insulated in such a way that the surface temperature does not exceed 220°C (see also Ch 1, Sec 1, [3.7]).

# **4 Type tests, material tests, workshop inspection and testing, certification**

## **4.1 Type testing**

### **4.1.1 Objectives**

The type testing is to be arranged to represent typical foreseen service load profiles, as specified by the engine builder, as well as to cover for required margins due to fatigue scatter and reasonably foreseen in-service deterioration. This applies to:

- Parts subjected to high cycle fatigue (HCF) such as connecting rods, cams, rollers and spring tuned dampers where higher stresses may be provided by means of elevated injection pressure, cylinder maximum pressure, etc.
- Parts subjected to low cycle fatigue (LCF) such as "hot" parts when load profiles such as idle - full load - idle (with steep ramps) are frequently used.
- Operation of the engine at limits as defined by its specified alarm system, such as running at maximum permissible power with the lowest permissible oil pressure and/or highest permissible oil inlet temperature.

**4.1.2 Validity**

- a) Type testing is required for every new engine type intended for installation onboard ships subject to classification.
- b) A type test carried out for a particular type of engine at any place of manufacture will be accepted for all engines of the same type built by licensees or the licensor, subject to each place of manufacture being found to be acceptable to the Society.
- c) A type of engine is defined by:
  - bore and stroke
  - injection method (direct or indirect)
  - valve and injection operation (by cams or electronically controlled)
  - kind of fuel (liquid, dual-fuel, gaseous)
  - working cycle (4-stroke, 2-stroke)
  - turbo-charging system (pulsating or constant pressure)
  - the charging air cooling system (e.g. with or without intercooler)
  - cylinder arrangement (in-line or V) (see Note 1)
  - cylinder power, speed and cylinder pressures (see Note 2)

Note 1: One type test will be considered adequate to cover a range of different numbers of cylinders. However, a type test of an in-line engine may not always cover the V-version. At the discretion of the Society, separate type tests may be required for the V-version. On the other hand, a type test of a V-engine covers the in-line engines, unless the bmep is higher.

Items such as axial crankshaft vibration, torsional vibration in camshaft drives, and crankshafts, etc. may vary considerably with the number of cylinders and may influence the choice of engine to be selected for type testing.

Note 2: The engine is type approved up to the tested ratings and pressures (100% corresponding to MCR).

Provided documentary evidence of successful service experience with the classified rating of 100% is submitted, an increase (if design approved, only crankshaft calculation and crankshaft drawings, if modified) may be permitted without a new type test if the increase from the type tested engine is within:

- 5% of the maximum combustion pressure, or
- 5% of the mean effective pressure, or
- 5% of the rpm

Providing maximum power is not increased by more than 10%, an increase of maximum approved power may be permitted without a new type test provided engineering analysis and evidence of successful service experience in similar field applications (even if the application is not classified) or documentation of internal testing are submitted if the increase from the type tested engine is within:

- 10% of the maximum combustion pressure, or
- 10% of the mean effective pressure, or
- 10% of the rpm

**d) De-rated engine**

If an engine has been design approved, and internal testing per Stage A (see [4.1.4]) is documented to a rating higher than the one type tested, the Type Approval may be extended to the increased power/bmep/rpm upon submission of an Extended Delivery Test Report at:

- Test at over speed (only if nominal speed has increased)
- Rated power, i.e. 100% output at 100% torque and 100% speed corresponding to load point 1 (see Fig 2), 2 measurements with one running hour in between
- Maximum permissible torque (normally 110%) at 100% speed corresponding to load point 3 (see Fig 2) or maximum permissible power (normally 110%) and speed according to nominal propeller curve corresponding to load point 3a (see Fig 2), 0,5 hour
- 100% power at maximum permissible speed corresponding to load point 2 (see Fig 2), 0,5 hour.

- e) An integration test demonstrating that the response of the complete mechanical, hydraulic and electronic system is as predicted maybe carried out for acceptance of sub-systems (Turbo Charger, Engine Control System, Dual Fuel, Exhaust Gas treatment...) separately approved. The scope of these tests is to be proposed by the designer/licensor taking into account of impact on engine.

Figure 2 : Load points

#### 4.1.3 Safety precautions

- Before any test run is carried out, all relevant equipment for the safety of attending personnel is to be made available by the manufacturer/shipyard and is to be operational, and its correct functioning is to be verified.
- This applies especially to crankcase explosive conditions protection, but also over-speed protection and any other shut down function.
- The inspection for jacketing of high-pressure fuel oil lines and proper screening of pipe connections (as required in [4.1.7], item i) is also to be carried out before the test runs.
- Interlock test of turning gear is to be performed when installed.

#### 4.1.4 Test programme

- The type testing is divided into 3 stages:
  - Stage A - internal tests.  
This includes some of the testing made during the engine development, function testing, and collection of measured parameters and records of testing hours. The results of testing required by the Society or stipulated by the designer are to be presented to the Society before starting stage B.
  - Stage B - witnessed tests.  
This is the testing made in the presence of the Surveyor.
  - Stage C - component inspection.  
This is the inspection of engine parts to the extent as required by the Society.
- The complete type testing program is subject to approval by the Society. The extent the Surveyor's attendance is to be agreed in each case, but at least during stage B and C.
- Testing prior to the witnessed type testing (stage B and C), is also considered as a part of the complete type testing program.
- Upon completion of complete type testing (stage A through C), a type test report is to be submitted to the Society for review. The type test report is to contain:
  - overall description of tests performed during stage A. Records are to be kept by the builders QA management for presentation to the Society.
  - detailed description of the load and functional tests conducted during stage B.
  - inspection results from stage C.
- High speed engines for marine use are normally to be subjected to an endurance test of 100 hours at full load. Omission or simplification of the type test may be considered for the type approval of engines with long service experience from non-marine fields or for the extension of type approval of engines of a well-known type, in excess of the limits given in [4.1.2]. Propulsion engines for ships having the service notation **HSC-CAT A**, **HSC-CAT B**, **HSC**, **high speed craft** or **light ship**, high speed craft or light ship that may be used for frequent load changes from idle to full are normally to be tested with at least 500 cycles (idle - full load - idle) using the steepest load ramp that the control system (or operation manual if not automatically controlled) permits. The duration at each end is to be sufficient for reaching stable temperatures of the hot parts.

**4.1.5 Measurements and recordings**

- a) During all testing the ambient conditions (air temperature, air pressure and humidity) are to be recorded.
- b) As a minimum, the following engine data are to be measured and recorded:
  - Engine r.p.m.
  - Torque
  - Maximum combustion pressure for each cylinder (see Note 1)
  - Mean indicated pressure for each cylinder (see Note 1)
  - Charging air pressure and temperature
  - Exhaust gas temperature
  - Fuel rack position or similar parameter related to engine load
  - Turbocharger speed
  - All engine parameters that are required for control and monitoring for the intended use (propulsion, auxiliary, emergency).

Note 1: For engines where the standard production cylinder heads are not designed for such measurements, a special cylinder head made for this purpose may be used. In such a case, the measurements may be carried out as part of Stage A and are to be properly documented. Where deemed necessary e.g. for dual fuel engines, the measurement of maximum combustion pressure and mean indicated pressure may be carried out by indirect means, provided the reliability of the method is documented.

Calibration records for the instrumentation used to collect data as listed above are to be presented to - and reviewed by the attending Surveyor.

Additional measurements may be required in connection with the design assessment.

**4.1.6 Stage A - internal tests**

- a) During the internal tests, the engine is to be operated at the load points important for the engine designer and the pertaining operating values are to be recorded. The load conditions to be tested are also to include the testing specified in the applicable type approval programme.
- b) At least the following conditions are to be tested:
  - Normal case:  
The load points 25%, 50%, 75%, 100% and 110% of the maximum rated power for continuous operation, to be made along the normal (theoretical) propeller curve and at constant speed for propulsion engines (if applicable mode of operation i.e. driving controllable pitch propellers), and at constant speed for engines intended for generator sets including a test at no load and rated speed.
  - The limit points of the permissible operating range. These limit points are to be defined by the engine manufacturer.
  - For high speed engines, the 100 hr full load test and the low cycle fatigue test apply as required in connection with the design assessment.
  - Specific tests of parts of the engine, required by the Society or stipulated by the designer.

**4.1.7 Stage B - witnessed tests**

- a) The tests listed below are to be carried out in the presence of a Surveyor. The achieved results are to be recorded and signed by the attending Surveyor after the type test is completed.
- b) The over-speed test is to be carried out and is to demonstrate that the engine is not damaged by an actual engine overspeed within the overspeed shutdown system set-point. This test may be carried out at the manufacturer's choice either with or without load during the speed overshoot.
- c) The engine is to be operated according to the power and speed diagram (see Fig 2). The data to be measured and recorded when testing the engine at the various load points have to include all engine parameters listed in [4.1.5]. The operating time per load point depends on the engine size (achievement of steady state condition) and on the time for collection of the operating values. Normally, an operating time of 0,5 hour can be assumed per load point, however sufficient time should be allowed for visual inspection by the Surveyor.
- d) The load points (see Fig 2) are:
  - Rated power (MCR), i.e. 100% output at 100% torque and 100% speed corresponding to load point 1, normally for 2 hours with data collection with an interval of 1 hour. If operation of the engine at limits as defined by its specified alarm system (e.g. at alarm levels of lub oil pressure and inlet temperature) is required, the test should be made here
  - 100% power at maximum permissible speed corresponding to load point 2
  - Minimum permissible speed at 100% torque, corresponding to load point 4
  - Minimum permissible speed at 90% torque corresponding to load point 5 (Applicable to propulsion engines only).
  - Part loads e.g. 75%, 50% and 25% of rated power and speed according to nominal propeller curve (i.e. 90.8%, 79.3% and 62.9% speed) corresponding to points 6, 7 and 8 or at constant rated speed setting corresponding to points 9, 10 and 11, depending on the intended application of the engine
  - Crosshead engines not restricted for use with C.P. propellers are to be tested with no load at the associated maximum permissible engine speed.

- e) During all these load points, engine parameters are to be within the specified and approved values.
- f) Operation with damaged turbocharger:  
For 2-stroke propulsion engines, the achievable continuous output is to be determined in the case of turbocharger damage. Engines intended for single propulsion with a fixed pitch propeller are to be able to run continuously at a speed (r.p.m.) of 40% of full speed along the theoretical propeller curve when one turbocharger is out of operation. (The test can be performed by either bypassing the turbocharger, fixing the turbocharger rotor shaft or removing the rotor).
- g) Functional tests:
- Verification of the lowest specified propulsion engine speed according to the nominal propeller curve as specified by the engine designer (even though it works on a water-brake). During this operation, no alarm shall occur.
  - Starting tests, for non-reversible engines and/or starting and reversing tests, for reversible engines, for the purpose of determining the minimum air pressure and the consumption for a start.
  - Governor tests: tests for compliance with [2.7] are to be carried out.
- h) Integration test:  
For electronically controlled diesel engines, integration tests are to verify that the response of the complete mechanical, hydraulic and electronic system is as predicted for all intended operational modes. The scope of these tests is to be agreed with the Society for selected cases based on the FMEA required in Tab 1.
- i) Fire protection measures:  
Screening of pipe connections in piping containing flammable liquids and insulation of hot surfaces:
- The engine is to be inspected for jacketing of high-pressure fuel oil lines, including the system for the detection of leakage, and proper screening of pipe connections in piping containing flammable liquids.
  - Proper insulation of hot surfaces is to be verified while running the engine at 100% load, alternatively at the overload approved for intermittent use. Readings of surface temperatures are to be done by use of Infrared Thermoscanning Equipment. Equivalent measurement equipment may be used when so approved by the Society. Readings obtained are to be randomly verified by use of contact thermometers.

#### **4.1.8 Stage C - Opening up for Inspections**

- a) The crankshaft deflections are to be measured in the specified (by designer) condition (except for engines where no specification exists).
- b) High speed engines for marine use are normally to be stripped down for a complete inspection after the type test.
- c) For all the other engines, after the test run the components of one cylinder for in-line engines and two cylinders for V-engines are to be presented for inspection as follows (engines with long service experience from non-marine fields can have a reduced extent of opening):
- piston removed and dismantled
  - crosshead bearing dismantled
  - guide planes
  - connecting rod bearings (big and small end) dismantled (special attention to serrations and fretting on contact surfaces with the bearing backsides)
  - main bearing dismantled
  - cylinder liner in the installed condition
  - cylinder head, valves disassembled
  - cam drive gear or chain, camshaft and crankcase with opened covers. (The engine must be turnable by turning gear for this inspection.)
- d) For V-engines, the cylinder units are to be selected from both cylinder banks and different crank throws.
- e) If deemed necessary by the surveyor, further dismantling of the engine may be required.

**4.1.9** If an electronically controlled diesel engine has been type tested as a conventional engine the Society may waive tests required by this article provided the results of the individual tests would be similar.

## **4.2 Material and non-destructive tests for engine components**

### **4.2.1 List of components**

Engine components are to be tested in accordance with Tab 8 and with the requirements of NR216 Materials and Welding.

Symbols used on Tab 8 are defined as below:

- C : Society certificate  
Cc : Chemical composition  
CD : Crack detection by MPI (magnetic particul inspection) or DP (dye penetration inspection)  
CH : Crosshead engines  
D : Cylinder bore diameter (mm)  
GJL : Gray cast iron

- GJS : Spheroidal graphite cast iron  
 GS : Cast steel  
 M : Mechanical properties  
 TR : Test report  
 UT : Ultrasonic testing  
 W : Work certificate  
 X : Visual examination of accessible surfaces by the Surveyor.

For components and materials not listed in Tab 8, consideration shall be given by the Society upon full details being submitted and reviewed.

**Table 8 : Summary of required documentation for engine components**

No.	Part (1) (2) (3) (4)	Material properties (5)	Non- destructive examination (6)	Hydraulic testing (7)	Dimensional inspection, including surface condition	Visual inspection (Surveyor)	Applicable to engines:	Component certificate
1	Welded bedplate	W(Cc+M)	W(UT+CD)			fit-up + post-welding	All	C
2	Bearing transverse girders GS	W(Cc+M)	W(UT+CD)			X	All	C
3	Welded frame box	W(Cc+M)	W(UT+CD)			fit-up + post-welding	All	C
4	Cylinder block GJL			W (8)			> 400 kW/cyl	
5	Cylinder block GJS			W (8)			> 400 kW/cyl	
6	Welded cylinder frames	W(Cc+M)	W(UT+CD)			fit-up + post-welding	CH	C
7	Engine block GJL			W (8)			> 400 kW/cyl	
8	Engine block GJS	W(M)		W (8)			> 400 kW/cyl	
9	Cylinder liner	W(Cc+M)		W (8)			D > 300mm	
10	Cylinder head GJL			W			D > 300mm	
11	Cylinder head GJS			W			D > 300mm	
12	Cylinder head GS	W(Cc+M)	W(UT+CD)	W		X	D > 300mm	C
13	Forged cylinder head	W(Cc+M)	W(UT+CD)	W		X	D > 300mm	C
14	Piston crown GS	W(Cc+M)	W(UT+CD)			X	D > 400mm	C
15	Forged piston crown	W(Cc+M)	W(UT+CD)			X	D > 400mm	C
16	Crankshaft: made in one piece	C(Cc+M)	W(UT+CD)		W	Random, of fillets and oil bores	All	C
17	Semi-built Crankshaft (Crankthrow, forged main journal and journals with flange)	C(Cc+M)	W(UT+CD)		W	Random, of fillets and shrink fittings	All	C
18	Exhaust gas valve cage			W			CH	
19	Piston Rod, if applicable	C(Cc+M)	W(UT+CD)			Random	D > 400mm CH	C
20	Cross head	C(Cc+M)	W(UT+CD)			Random	CH	C

No.	Part (1) (2) (3) (4)	Material properties (5)	Non- destructive examination (6)	Hydraulic testing (7)	Dimensional inspection, including surface condition	Visual inspection (Surveyor)	Applicable to engines:	Component certificate
21	Connecting rod with cap	C(Cc+M)	W(UT+CD)		W	Random, of all surfaces, in particular those shot peened	All	C
22	Coupling bolts for crankshaft	C(Cc+M)	W(UT+CD)		W	Random, of interference fit	All	C
23	Bolts and studs for main bearings	W(Cc+M)	W(UT+CD)				D > 300mm	
24	Bolts and studs for cylinder heads	W(Cc+M)	W(UT+CD)				D > 300mm	
25	Bolts and studs for connecting rods	W(Cc+M)	W(UT+CD)		TR of thread making		D > 300mm	
26	Tie rod	W(Cc+M)	W(UT+CD)		TR of thread making	Random	CH	C
27	High pressure fuel injection pump body (9)	W(Cc+M)		W			D > 300mm	W (9)
		W(Cc+M)		TR			D ≤ 300mm	
28	High pressure fuel injection valves (only for those not autofretted) (9)			W			D > 300mm	W (9)
				TR			D ≤ 300mm	
29	High pressure fuel injection pipes including common fuel rail (9)	W(Cc+M)		W for those that are not autofretted			D > 300mm	W (9)
		W(Cc+M)		TR for those that are not autofretted			D ≤ 300mm	
30	High pressure common servo oil system (9)	W(Cc+M)		W			D > 300mm	W (9)
		W(Cc+M)		TR			D ≤ 300mm	
31	Cooler, both sides (9) (10)	W(Cc+M)		W			D > 300mm	W (11)
32	Accumulator (9)	W(Cc+M)		W			All engines with accumulators with a capacity of > 0,5 l	W (11)
33	Piping, pumps, actuators, etc. for hydraulic drive of valves, if applicable (9)	W(Cc+M)		W			> 800 kW/cyl	
34	Engine driven pumps (oil, water, fuel, bilge) other than pumps referred to in item 27 and 33 (9)			W			> 800 kW/cyl	
35	Bearings for main, crosshead, and crankpin	TR(Cc)	TR (UT for full contact between base material and bearing metal)		W		> 800 kW/cyl	

No.	Part (1) (2) (3) (4)	Material properties (5)	Non- destructive examination (6)	Hydraulic testing (7)	Dimensional inspection, including surface condition	Visual inspection (Surveyor)	Applicable to engines:	Component certificate
<p><b>Note 1:</b> Symbols used in this Table are listed in [4.2.1].</p> <p>(1) For turbochargers, see Ch 1, Sec 17.</p> <p>(2) Crankcase explosion relief valves are to be type tested in accordance with Ch 1, App 4 and documented according to [2.3.4].</p> <p>(3) Oil mist detection systems are to be type tested in accordance with Ch 3, App 1 and documented according to [2.3.5]</p> <p>(4) For Speed governor and overspeed protective devices, see [2.7].</p> <p>(5) Material properties include chemical composition and mechanical properties, and also surface treatment such as surface hardening (hardness, depth and extent), peening and rolling (extent and applied force).</p> <p>(6) Non-destructive examination means e.g. ultrasonic testing, crack detection by MPI or DP.</p> <p>(7) Hydraulic testing is applied on the water/oil side of the component. Items are to be tested by hydraulic pressure at the pressure equal to 1,5 times the maximum working pressure. High pressure parts of the fuel injection system are to be tested by hydraulic pressure at the pressure equal to 1,5 maximum working pressure or maximum working pressure plus 300 bar, whichever is the less. Where design or testing features may require modification of these test requirements, special consideration may be given.</p> <p>(8) Hydraulic testing is also required for those parts filled with cooling water and having the function of containing the water which is in contact with the cylinder or cylinder liner.</p> <p>(9) Material certification requirements for pumps and piping components are dependent on the operating pressure and temperature. Requirements given in this Table apply unless alternative requirements are given in Ch 1, Sec 10, Tab 40.</p> <p>(10) Charge air coolers need only be tested on the water side.</p> <p>(11) Material and component certifications are to follow the requirements given in Ch 1, Sec 3 for pressure vessels. Depending on their class, a design assessment may be required.</p>								

### 4.3 Factory Acceptance Test

#### 4.3.1 Safety precautions

- a) Before any test run is carried out, all relevant equipment for the safety of attending personnel is to be made available by the manufacturer / shipyard and is to be operational.
- b) This applies especially to crankcase explosive conditions protection, but also to over-speed protection and any other shut down function.
- c) The overspeed protective device is to be set to a value, which is not higher than the overspeed value that was demonstrated during the type test for that engine. This set point shall be verified by the surveyor.

#### 4.3.2 General

- a) Before any official testing, the engines shall be run-in as prescribed by the engine manufacturer.
- b) Adequate test bed facilities for loads as required in [4.3.3] shall be provided. All fluids used for testing purposes such as fuel, lubrication oil and cooling water are to be suitable for the purpose intended, e.g. they are to be clean, preheated if necessary and cause no harm to engine parts. This applies to all fluids used temporarily or repeatedly for testing purposes only.
- c) Engines are to be inspected for:
  - Jacketing of high-pressure fuel oil lines including the system used for the detection of leakage.
  - Screening of pipe connections in piping containing flammable liquids.
  - Insulation of hot surfaces by taking random temperature readings that are to be compared with corresponding readings obtained during the type test. This shall be done while running at the rated power of engine. Use of contact thermometers may be accepted at the discretion of the attending Surveyor. If the insulation is modified subsequently to the Type Approval Test, the Society may request temperature measurements as required by [4.1.7], item g).
- d) These inspections are normally to be made during the works trials by the manufacturer and the attending surveyor, but at the discretion of the Society parts of these inspections may be postponed to the shipboard testing.

#### 4.3.3 Works trials (Factory Acceptance Test)

##### a) Objectives

The purpose of the works trials is to verify design premises such as power, safety against fire, adherence to approved limits (e.g. maximum pressure), and functionality and to establish reference values or base lines for later reference in the operational phase.

##### b) Records

- 1) The following environmental test conditions are to be recorded:
  - Ambient air temperature
  - Ambient air pressure
  - Atmospheric humidity

- 2) For each required load point, the following parameters are normally to be recorded:
  - Power and speed
  - Fuel index (or equivalent reading)
  - Maximum combustion pressures (only when the cylinder heads installed are designed for such measurement)
  - Exhaust gas temperature before turbine and from each cylinder (to the extent that monitoring is required in Ch 1, Sec 17 and [2.7])
  - Charge air temperature
  - Charge air pressure
  - Turbocharger speed (to the extent that monitoring is required in Ch 1, Sec 17).
- 3) Calibration records for the instrumentation are, upon request, to be presented to the attending Surveyor.
- 4) For all stages at which the engine is to be tested, the pertaining operational values are to be measured and recorded by the engine manufacturer. All results are to be compiled in an acceptance protocol to be issued by the engine manufacturer. This also includes crankshaft deflections if considered necessary by the engine designer.
- 5) In each case, all measurements conducted at the various load points are to be carried out at steady state operating conditions. However, for all load points provision should be made for time needed by the Surveyor to carry out visual inspections. The readings for MCR, i.e. 100% power (rated maximum continuous power at corresponding rpm) are to be taken at least twice at an interval of normally 30 minutes.

c) Test loads

- 1) Test loads for various engine applications are given below. In addition, the scope of the trials may be expanded depending on the engine application, service experience, or other relevant reasons.

Note 1: Alternatives to the detailed tests may be agreed between the manufacturer and the Society when the overall scope of tests is found to be equivalent.

- 2) Propulsion engines driving propeller or impeller only:

- 100% power (MCR) at corresponding speed  $n_0$ : at least 60 min.
- 110% power at engine speed  $1,032n_0$ : Records to be taken after 15 minutes or after steady conditions have been reached, whichever is shorter.

Note 2: 110% test load is only required once for each different engine/turbocharger configuration.

- Approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer.
- 90% (or normal continuous cruise power), 75%, 50% and 25% power in accordance with the nominal propeller curve, the sequence to be selected by the engine manufacturer.
- Reversing manoeuvres (if applicable).

Note 3: After running on the test bed, the fuel delivery system is to be so adjusted that overload power cannot be given in service, unless intermittent overload power is approved by the Society. In that case, the fuel delivery system is to be blocked to that power.

- 3) Engines driving generators for electric propulsion:

- 100% power (MCR) at corresponding speed  $n_0$ : at least 60 min.
- 110% power at engine speed  $n_0$ : 15 min. - after having reached steady conditions.
- Governor tests for compliance with [2.7] are to be carried out.
- 75%, 50% and 25% power and idle, the sequence to be selected by the engine manufacturer.

Note 4: After running on the test bed, the fuel delivery system is to be adjusted so that full power plus a 10% margin for transient regulation can be given in service after installation onboard.

The transient overload capability is required so that the required transient governing characteristics are achieved also at 100% loading of the engine, and also so that the protection system utilised in the electric distribution system can be activated before the engine stalls.

- 4) Engines driving generators for auxiliary purposes:

Tests to be performed as in item c) 3).

- 5) Propulsion engines also driving power take off (PTO) generator:

- 100% power (MCR) at corresponding speed  $n_0$ : at least 60 min.
- 110% power at engine speed  $n_0$ : 15 min. - after having reached steady conditions.
- Approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer.
- 90% (or normal continuous cruise power), 75%, 50% and 25% power in accordance with the nominal propeller curve or at constant speed  $n_0$ , the sequence to be selected by the engine manufacturer.

Note 5: After running on the test bed, the fuel delivery system is to be adjusted so that full power plus a margin for transient regulation can be given in service after installation onboard. The transient overload capability is required so that the electrical protection of downstream system components is activated before the engine stalls. This margin may be 10% of the engine power but at least 10% of the PTO power.

6) Engines driving auxiliaries:

- 100% power (MCR) at corresponding speed  $n_0$ : at least 30 min.
- 110% power at engine speed  $n_0$ : 15 min. - after having reached steady conditions.
- Approved intermittent overload (if applicable): testing for duration as agreed with the manufacturer.
- For variable speed engines, 75%, 50% and 25% power in accordance with the nominal power consumption curve, the sequence to be selected by the engine manufacturer.

Note 6: After running on the test bed, the fuel delivery system is normally to be so adjusted that overload power cannot be delivered in service, unless intermittent overload power is approved. In that case, the fuel delivery system is to be blocked to that power.

d) Turbocharger matching with engine

1) Compressor chart

Turbochargers shall have a compressor characteristic that allows the engine, for which it is intended, to operate without surging during all operating conditions and also after extended periods in operation.

For abnormal, but permissible, operation conditions, such as misfiring and sudden load reduction, no continuous surging shall occur.

In this item, surging and continuous surging are defined as follows:

- Surging means the phenomenon, which results in a high pitch vibration of an audible level or explosion-like noise from the scavenger area of the engine.
- Continuous surging means that surging happens repeatedly and not only once.

2) Surge margin verification

Category C turbochargers used on propulsion engines are to be checked for surge margins during the engine workshop testing as specified below. These tests may be waived if successfully tested earlier on an identical configuration of engine and turbocharger (including same nozzle rings).

- For 4-stroke engines:

The following shall be performed without indication of surging:

- With maximum continuous power and speed (=100%), the speed shall be reduced with constant torque (fuel index) down to 90% power.
- With 50% power at 80% speed (= propeller characteristic for fixed pitch), the speed shall be reduced to 72% while keeping constant torque (fuel index).

- For 2-stroke engines:

The surge margin shall be demonstrated by at least one of the following methods:

- The engine working characteristic established at workshop testing of the engine shall be plotted into the compressor chart of the turbocharger (established in a test rig). There shall be at least 10% surge margin in the full load range, i.e. working flow shall be 10% above the theoretical (mass) flow at surge limit (at no pressure fluctuations), or,
- Sudden fuel cut-off to at least one cylinder shall not result in continuous surging and the turbocharger shall be stabilised at the new load within 20 seconds. For applications with more than one turbocharger the fuel shall be cut-off to the cylinders closest upstream to each turbocharger.

This test shall be performed at two different engine loads:

- The maximum power permitted for one cylinder misfiring.
- The engine load corresponding to a charge air pressure of about 0.6 bar (but without auxiliary blowers running).

- No continuous surging and the turbocharger shall be stabilised at the new load within 20 seconds when the power is abruptly reduced from 100% to 50% of the maximum continuous power.

e) Integration tests

For electronically controlled engines, integration tests are to be made to verify that the response of the complete mechanical, hydraulic and electronic system is as predicted for all intended operational modes and the tests considered as a system are to be carried out at the works. If such tests are technically unfeasible at the works, however, these tests may be conducted during sea trial. The scope of these tests is to be agreed with the Society for selected cases based on the FMEA required in Tab 1

f) Component inspections

Random checks of components to be presented for inspection after works trials are left to the discretion of the Surveyor.

## **4.4 Certification**

### **4.4.1 Type approval certificate**

a) For each type of engine that is required to be approved, a type approval certificate is to be obtained by the engine designer. The process details for obtaining a type approval certificate are given below (see also [1.2]). This process consists of the engine designer obtaining from the Society:

- drawing and specification approval
- conformity of production
- approval of type testing programme
- type testing of engines
- review of the obtained type testing results
- evaluation of the manufacturing arrangements
- issue of a type approval certificate.

The manufacturing facility of the engine presented for the type approval test is to be assessed in accordance with NR320.

b) Type approval certificate renewal

A renewal of type approval certificates will be granted upon:

- The submission of modified documents or new documents with substantial modifications replacing former documents compared to the previous submission(s), or alternatively,
- A declaration that no substantial modifications have been applied since the last issuance of the type approval certificate.

c) Validity of type approval certificate

The limit of the duration facility of the type approval certificate shall comply with requirements of NR 320. The maximum period of validity of a type approval certificate is 5 years.

The type approval certificate will be invalid if there are substantial modifications in the design, in the manufacturing or control processes or in the characteristics of the materials unless approved in advance by the Society.

### **4.4.2 Engine certificate**

a) Each diesel engine manufactured for a shipboard application is to have an engine certificate. This process consists of the engine builder/licensee obtaining design approval of the engine application specific documents, submitting a comparison list of the production drawings to the previously approved engine design drawings referenced in [4.4.1] forwarding the relevant production drawings and comparison list for the use of the Surveyors at the manufacturing plant and shipyard if necessary, engine testing and upon satisfactorily meeting the Rule requirements, the issuance of an engine certificate.

For those cases when a licensor – licensee agreement does NOT apply, an “engine designer” shall be understood as the entity that has the design rights for the engine type or is delegated by the entity having the design rights to modify the design.

b) Society’s requirements for production facilities comprising manufacturing facilities and processes, machining tools, quality assurance, testing facilities, etc. shall be assessed according to NR320 requirements.

### **4.4.3 Certification of engine components**

a) The engine manufacturer is to have a quality control system that is suitable for the actual engine types to be certified by the Society. The quality control system is also to apply to any sub-suppliers. The Society reserves the right to review the system or parts thereof. Materials and components are to be produced in compliance with all the applicable production and quality instructions specified by the engine manufacturer. The Society requires that certain parts are verified and documented by means of Society Certificate (C), Work Certificate (W) or Test Report (TR).

b) Society Certificate (C)

This is a document issued by the Society stating:

- conformity with Rule requirements
- that the tests and inspections have been carried out on the finished certified component itself, or on samples taken from earlier stages in the production of the component, when applicable
- that the inspection and tests were performed in the presence of the Surveyor or in accordance with an Alternative Survey Scheme according to NR320.

c) Work’s Certificate (W)

This is a document signed by the manufacturer stating:

- conformity with requirements
- that the tests and inspections have been carried out on the finished certified component itself, or on samples taken from earlier stages in the production batch of the component, when applicable
- that the tests were witnessed and signed by a qualified representative of the applicable department of the manufacturer.

A Work's Certificate may be considered equivalent to a Society Certificate and endorsed by the Society under the following cases:

- the test was witnessed by the Society Surveyor; or
- an Alternative Survey Scheme according to NR320 is in place between the Society and the manufacturer or material supplier; or
- the Work's certificate is supported by tests carried out by an accredited third party that is accepted by the Society and independent from the manufacturer and/or material supplier.

d) Test Report (TR)

This is a document signed by the manufacturer stating:

- conformity with requirements
- that the tests and inspections have been carried out on samples from the current production batch.

e) The documents above are used for product documentation as well as for documentation of single inspections such as crack detection, dimensional check, etc. If agreed to by the Society, the documentation of single tests and inspections may also be arranged by filling in results on a control sheet following the component through the production.

f) The Surveyor is to review the TR and W for compliance with the agreed or approved specifications. C means that the Surveyor also witnesses the testing, batch or individual, unless an Alternative Survey Scheme, according to NR320, provides other arrangements.

g) The manufacturer is not exempted from responsibility for any relevant tests and inspections of those parts for which documentation is not explicitly requested by the Society.

The manufacturing process and equipment is to be set up and maintained in such a way that all materials and components can be consistently produced to the required standard. This includes production and assembly lines, machining units, special tools and devices, assembly and testing rigs as well as all lifting and transportation devices.

# Section 3 Pressure Equipment

## 1 General

### 1.1 Principles

#### 1.1.1 Scope of the Rules

The boilers and other pressure vessels, associated piping systems and fittings are to be of a design and construction adequate for the service for which they are intended and is to be so installed and protected as to reduce to a minimum any danger to persons on board, due regard being paid to moving parts, hot surfaces and other hazards. The design is to have regard to materials used in construction, the purpose for which the equipment is intended, the working conditions to which it will be subjected and the environmental conditions on board.

So these Rules apply to “pressure equipment” for the following requirements:

- be safe in sight of pressure risk
- be safe in sight of other risks, moving parts, hot surfaces
- ensure capability of propulsion and other essential services.

“Pressure equipment” means pressure vessels, piping ( Ch 1, Sec 10), safety accessories and pressure accessories.

#### 1.1.2 Overpressure risk

Where main or auxiliary boilers and other pressure vessels or any parts thereof may be subject to dangerous overpressure, means are to be provided where practicable to protect against such excessive pressure.

#### 1.1.3 Propulsion capability

Means are to be provided whereby normal operation of main boilers can be sustained or restored even through one of the essential auxiliaries become inoperative. Special consideration is to be given to the malfunctioning of:

- the source of steam supply
- the boiler feed water systems
- the fuel oil supply system for boilers
- the mechanical air supply for boilers.

However the Society, having regard to overall safety considerations, may accept a partial reduction in propulsion capability from normal operation.

#### 1.1.4 Tests

*All boilers and other pressure vessels including their associated fittings which are under internal pressure are to be subjected to appropriate tests including a pressure test before being put into service for the first time (see also [9]).*

## 1.2 Application

### 1.2.1 Pressure vessels covered by the Rules

The requirements of this Section apply to:

- all fired or unfired pressures vessels of metallic construction, including the associated fittings and mountings with maximum allowable pressure greater than 0,5 bar above atmospheric pressure with the exception of those indicated in [1.2.2]
- all boilers and other steam generators, including the associated fittings and mountings with maximum allowable pressure greater than 0,5 bar above atmospheric pressure with the exception of those indicated in [1.2.2].

### 1.2.2 Pressure vessels not covered by the Rules

Among others the following boilers and pressure vessels are not covered by the Rules and are to be considered on a case by case basis:

- a) boilers with design pressure  $p > 10$  MPa
- b) pressure vessel intended for radioactive material
- c) equipment comprising casings or machinery where the dimensioning, choice of material and manufacturing rules are based primarily on requirements for sufficient strength, rigidity and stability to meet the static and dynamic operational effects or other operational characteristics and for which pressure is not a significant design factor. Such equipment may include:
  - engines including turbines and internal combustion engines
  - steam engines, gas/steam turbines, turbo-generators, compressors, pumps and actuating devices
- d) small pressure vessels included in self-contained domestic equipment.

### **1.3 Definitions**

#### **1.3.1 Pressure vessel**

“Pressure vessel” means a housing designed and built to contain fluids under pressure including its direct attachments up to the coupling point connecting it to other equipment. A vessel may be composed of more than one chamber.

#### **1.3.2 Fired pressure vessel**

Fired pressure vessel is a pressure vessel which is completely or partially exposed to fire from burners or combustion gases or otherwise heated pressure vessel with a risk of overheating.

##### **a) Boiler**

Boiler is one or more fired pressure vessels and associated piping systems used for generating steam or hot water at a temperature above 120°C.

Any equipment directly connected to the boiler, such as economisers, superheaters and safety valves, is considered as part of the boiler, if it is not separated from the steam generator by means of any isolating valve. Piping connected to the boiler is considered as part of the boiler upstream of the isolating valve and as part of the associated piping system downstream of the isolating valve.

##### **b) Thermal oil heater**

Thermal oil heater is one or more fired pressure vessels and associated piping systems in which organic liquids (thermal oils) are heated. When heated by electricity thermal oil heater is considered as an unfired pressure vessel.

#### **1.3.3 Unfired pressure vessel**

Any pressure vessel which is not a fired pressure vessel is an unfired pressure vessel.

##### **a) Heat exchanger**

A heat exchanger is an unfired pressure vessel used to heat or cool a fluid with an another fluid. In general heat exchangers are composed of a number of adjacent chambers, the two fluids flowing separately in adjacent chambers. One or more chambers may consist of bundles of tubes.

##### **b) Steam generator**

A steam generator is a heat exchanger and associated piping used for generating steam. In general in these Rules, the requirements for boilers are also applicable for steam generators, unless otherwise indicated.

#### **1.3.4 Safety accessories**

“Safety accessories” means devices designed to protect pressure equipment against the allowable limits being exceeded. Such devices include:

- devices for direct pressure limitation, such as safety valves, bursting disc safety devices, buckling rods, controlled safety pressure relief systems, and
- limiting devices, which either activate the means for correction or provide for shutdown or shutdown and lockout, such as pressure switches or temperature switches or fluid level switches and safety related measurement control and regulation devices.

#### **1.3.5 Design pressure**

The design pressure is the pressure used by the manufacturer to determine the scantlings of the vessel. This pressure cannot be taken less than the maximum working pressure and is to be limited by the set pressure of the safety valve, as prescribed by the applicable Rules. Pressure is indicated as gauge pressure above atmospheric pressure, vacuum is indicated as negative pressure.

#### **1.3.6 Design temperature**

- a) Design temperature is the actual metal temperature of the applicable part under the expected operating conditions, as modified in Tab 1. This temperature is to be stated by the manufacturer and is to take in account of the effect of any temperature fluctuations which may occur during the service.
- b) The design temperature is not to be less than the temperatures stated in Tab 1, unless specially agreed between the manufacturer and the Society on a case by case basis.

#### **1.3.7 Volume**

Volume V means the internal volume of a chamber, including the volume of nozzles to the first connection or weld and excluding the volume of permanent internal parts.

#### **1.3.8 Boiler heating surface**

Heating surface is the area of the part of the boiler through which the heat is supplied to the medium, on the side exposed to fire or hot gases.

#### **1.3.9 Maximum steam output**

Maximum steam output is the maximum quantity of steam than can be produced continuously by the boiler or steam generator operating under the design steam conditions.

**Table 1 : Minimum design temperature**

Type of vessel	Minimum design temperature
Pressure parts of pressure vessels and boilers not heated by hot gases or adequately protected by insulation	Maximum temperature of the internal fluid
Pressure vessel heated by hot gases	25°C in excess of the temperature of the internal fluid
Water tubes of boilers mainly subjected to convection heat	25°C in excess of the temperature of the saturated steam
Water tubes of boilers mainly subjected to radiant heat	50°C in excess of the temperature of the saturated steam
Superheater tubes of boilers mainly subjected to convection heat	35°C in excess of the temperature of the saturated steam
Superheater tubes of boilers mainly subjected to radiant heat	50°C in excess of the temperature of the saturated steam
Economiser tubes	35°C in excess of the temperature of the internal fluid
For combustion chambers of the type used in wet-back boilers	50°C in excess of the temperature of the internal fluid
For furnaces, fire-boxes, rear tube plates of dry-back boilers and other pressure parts subjected to similar rate of heat transfer	90°C in excess of the temperature of the internal fluid

**1.3.10 Toxic and corrosive substances**

Toxic and corrosive substances are those which are listed in the IMO “International Maritime Dangerous Goods Code (IMDG Code)”, as amended.

**1.3.11 Liquid and gaseous substances**

- a) liquid substances are liquids having a vapour pressure at the maximum allowable temperature of not more than 0,5 bar above normal atmospheric pressure
- b) gaseous substances are gases, liquefied gases, gases dissolved under pressure, vapours and also those liquids whose vapour pressure at the maximum allowable temperature is greater than 0,5 bar above normal atmospheric pressure.

**1.3.12 Ductile material**

For the purpose of this Section, ductile material is a material having an elongation over 12%.

**1.3.13 Incinerator**

Incinerator is a shipboard facility for incinerating solid garbage approximating in composition to household garbage and liquid garbage deriving from the operation of the ship (e.g. domestic garbage, cargo-associated garbage, maintenance garbage, operational garbage, cargo residue, and fishing gear), as well as for burning sludge with a flash point above 60°C.

These facilities may be designed to use the heat energy produced.

Incinerators are not generally pressure vessels, however when their fittings are of the same type than those of boilers the requirements for these fittings apply.

**1.3.14 Gas combustion unit (GCU)**

A gas combustion unit (GCU) is an equipment fitted on gas carriers or gas-fuelled ships, allowing the disposal of the excess vapour from LNG tanks by thermal oxidation.

Gas combustion units are not generally pressure vessels; however when their fittings are of the same type than those of boilers the requirements for these fittings apply.

**1.4 Classes**

**1.4.1 Significant parameters**

Pressure vessels are classed in three class in consideration of:

- the type of equipment: pressure vessel or steam generator
- the state (gaseous or liquid) of the intended fluid contents
- the substances listed or not in the IMDG Code
- the design pressure  $p$ , in MPa
- the design temperature  $T$ , in °C
- the actual thickness of the vessel  $t_A$ , in mm
- the volume  $V$ , in litres.

**1.4.2 Pressure vessel classification**

Pressure vessels are classed as indicated in Tab 2.

**Table 2 : Pressure vessel classification**

Equipment	Class 1	Class 2	Class 3
Steam generators or boilers	$p > 3,2$ and $V > 2$ or $p V > 20$ and $V > 2$	if not class 1 or class 3	$p V \leq 5$ or $V \leq 2$
Pressure vessels for toxic substances	all	–	–
Pressure vessels for corrosive substances	$p > 20$ or $p V > 20$ or $T > 350$	if not in class 1	–
Pressure vessels for gaseous substances	$p > 100$ or $p V > 300$	$V > 1$ and $p V > 100$ and not in class 1	all pressure vessels which are not class 1 or class 2
Pressure vessels for liquid substances	$V > 10$ and $p V > 1000$ and $p > 50$	$V \leq 10$ and $p > 100$ or $1 < p \leq 50$ and $p V > 1000$	all pressure vessels and heat exchangers which are not class 1 or class 2
Pressure vessels for thermal oil	$p > 1,6$ or $T > 300$	if not class 1 or class 3	$p \leq 0,7$ and $T \leq 150$
Pressure vessels for fuel oil, lubricating oil or flammable hydraulic oil	$p > 1,6$ or $T > 150$	if not class 1 or class 3	$p \leq 0,7$ and $T \leq 60$
Whatever type of equipment	$t_A > 40$	$15 < t_A \leq 40$	–

**Note 1:** Whenever the class is defined by more than one characteristic, the equipment is to be considered belonging to the highest class of its characteristics, independently of the values of the other characteristics.

### 1.4.3 Implication of class

The class of a pressure vessel has, among others, implication in:

- design
- material allowance
- welding design
- efficiency of joints
- examination and non-destructive tests
- thermal stress relieving.

See Tab 26.

## 1.5 Applicable Rules

### 1.5.1 Alternative standards

- Boilers and pressure vessels are to be designed, constructed, installed and tested in accordance with the applicable requirements of this Section.
- The acceptance of national and international standards as an alternative to the requirements of this Section may be considered by the Society on a case by case basis.

## 1.6 Documentation to be submitted

### 1.6.1 General

Documents mentioned in the present sub-article are to be submitted for class 1 and class 2 and not for class 3, unless the equipment is considered as critical.

### 1.6.2 Boilers and steam generators

The plans listed in Tab 3 are to be submitted.

The drawings listed in Tab 3 are to contain:

- the constructional details of all pressure parts, such as shells, headers, tubes, tube plates, nozzles
- strengthening members, such as stays, brackets, opening reinforcements and covers
- installation arrangements, such as saddles and anchoring system

as well as the information and data indicated in Tab 4.

### 1.6.3 Pressure vessels

The plans listed in Tab 5 are to be submitted.

The drawings listed in Tab 5 are to contain the constructional details of:

- pressure parts, such as shells, headers, tubes, tube plates, nozzles, opening reinforcements and covers
- strengthening members, such as stays, brackets and reinforcements.

**Table 3 : Drawings to be submitted for boilers and steam generators**

No.	A/I	Item
1	I	General arrangement plan, including valves and fittings
2	A	Material specifications
3	A	Sectional assembly
4	A	Evaporating parts
5	A	Superheater
6	A	De-superheater
7	A	Economiser
8	A	Air heater
9	A	Tubes and tube plates
10	A	Nozzles and fittings
11	A	Safety valves and their arrangement
12	A	Boiler seating
13	I	Fuel oil burning arrangement
14	I	Forced draught system
15	I	Refractor or insulation arrangement
16	A	Boiler instrumentation, monitoring and control system
17	A	Type of safety valves and their lift, discharge rate and setting
18	A	Welding details, including at least: <ul style="list-style-type: none"> <li>• typical weld joint design</li> <li>• welding procedure specifications</li> <li>• post-weld heat treatment</li> </ul>

**Note 1:** A = to be submitted for approval ; I = to be submitted for information

**Table 4 : Information and data to be submitted for boilers and steam generators**

No.	Item
1	Design pressure and temperature
2	Pressure and temperature of the superheated steam
3	Pressure and temperature of the saturated steam
4	Maximum steam production per hour
5	Evaporating surface of the tube bundles and water-walls
6	Heating surface of the economiser, superheater and air-heater
7	Surface of the furnace
8	Volume of the combustion chamber
9	Temperature and pressure of the feed water
10	Type of fuel to be used and fuel consumption at full steam production
11	Number and capacity of burners

**Table 5 : Drawings, information and data to be submitted for pressure vessels and heat exchangers**

No.	A/I	Item
1	I	General arrangement plan, including nozzles and fittings
2	A	Sectional assembly
3	A	Safety valves (if any) and their arrangement
4	A	Material specifications
5	A	Welding details, including at least: <ul style="list-style-type: none"> <li>• typical weld joint design</li> <li>• welding procedure specifications</li> <li>• post-weld heat treatments</li> </ul>
6	I	Design data, including at least design pressure and design temperatures (as applicable)
7	A	For seamless (extruded) pressure vessels, the manufacturing process, including: <ul style="list-style-type: none"> <li>• a description of the manufacturing process with indication of the production controls normally carried out in the manufacturer's works</li> <li>• details of the materials to be used (specification, yield point, tensile strength, impact strength, heat treatment)</li> <li>• details of the stamped marking to be applied</li> </ul>
8	I	Type of fluid or fluids contained

**Note 1:** A = to be submitted for approval ; I = to be submitted for information

**1.6.4 Incinerators**

Incinerators are to be considered on a case by case basis, based on their actual arrangement, using the applicable requirements for boilers and pressure vessels.

**1.6.5 Gas combustion units**

Gas combustion units are to be considered on a case by case basis, based on their actual arrangement, using the applicable requirements for boilers and pressure vessels.

The documents listed in Tab 6 are to be submitted.

**Table 6 : Documentation to be submitted for gas combustion units**

No.	I/A (1)	Document (2)
1	A	General arrangement plan
2	I	For each intended operating case: <ul style="list-style-type: none"> <li>• description, including firing and shut-off sequences, purging sequence, etc.</li> <li>• minimum and maximum allowed gas flow rate</li> <li>• maximum flue gas temperature</li> </ul>
3	I	Material specification
4	A	Details of refractor or insulation arrangement, as applicable
5	A	Details of combustion air and dilution air systems
6	A	Diagram of the gas supply system with details of the piping (pipe material, thickness, type of the connections)
7	A	Details of electrical equipment (including safety characteristics)
8	A	Details of control, monitoring and safety systems
9	I	Procedure for workshop and shipboard tests
(1) A = to be submitted for approval I = to be submitted for information (2) Diagrams are also to include, where applicable, the local and remote control systems, monitoring systems and automation systems		

**2 Design and construction - Scantlings of pressure parts**

**2.1 General**

**2.1.1 Application**

- a) In general, the formulae in the present Article do not take into account additional stresses imposed by effects other than pressure, such as stresses deriving from the static and dynamic weight of the pressure vessel and its content, external loads from connecting equipment and foundations, etc. For the purpose of the Rules these additional loads may be neglected, provided it can reasonably be presumed that the actual average stresses of the vessel, considering all these additional loads, would not increase more than 10% with respect to the stresses calculated by the formulae in this Article.
- b) Where it is necessary to take into account additional stresses, such as dynamic loads, the Society reserves the right to ask for additional requirements on a case by case basis.

**2.1.2 Alternative requirements**

When pressure parts are of an irregular shape, such as to make it impossible to check the scantlings by applying the formulae of this Article, the approval is to be based on other means, such as burst and/or deformation tests on a prototype or by another method agreed upon between the manufacturer and the Society.

**2.2 Materials**

**2.2.1 Materials for high temperatures**

- a) Materials for pressure parts having a design temperature exceeding the ambient temperature are to be selected by the Manufacturer and to have mechanical and metallurgical properties adequate for the design temperature. Their allowable stress limits are to be determined as a function of the temperature, as per [2.3.2].
- b) When the design temperature of pressure parts exceeds 400°C, alloy steels are to be used. Other materials are subject of special consideration by the Society.

**2.2.2 Materials for low temperatures**

Materials for pressure parts having a design temperature below the ambient temperature are to have notch toughness properties suitable for the design temperature.

**2.2.3 Cast iron**

Grey cast iron is not to be used for:

- a) class 1 and class 2 pressure vessels
- b) class 3 pressure vessels with design pressure  $p > 1.6$  MPa or product  $p \cdot V > 1000$ , where V is the internal volume of the pressure vessel in litres
- c) Bolted covers and closures of pressure vessels having a design pressure  $p > 1$  MPa, except for covers intended for boiler shells, for which [3.2.4], item e) applies.

Spheroidal cast iron may be used subject to the agreement of the Society following special consideration. However, it is not to be used for parts, having a design temperature exceeding 350°C.

**2.2.4 Valves and fittings for boilers**

- a) Ductile materials are to be used for valves and fittings intended to be mounted on boilers. The material is to have mechanical and metallurgical characteristics suitable for the design temperature and for the thermal and other loads imposed during the operation.
- b) Grey cast iron is not to be used for valves and fittings which are subject to dynamic loads, such as safety valves and blow-down valves, and in general for fittings and accessories having design pressure  $p$  exceeding 0,3 MPa and design temperature  $T$  exceeding 220°C.
- c) Spheroidal cast iron is not to be used for parts having a design temperature  $T$  exceeding 350°C.
- d) Bronze is not to be used for parts having design temperature  $T$  exceeding 220°C for normal bronzes and 260°C for bronzes suitable for high temperatures. Copper and aluminium brass are not to be used for fittings with design temperature  $T$  above 200°C and copper-nickel fittings with design temperature  $T$  exceeding 300°C.

**2.2.5 Alternative materials**

In the case of boilers or pressure vessels constructed in accordance with one of the standards considered acceptable by the Society as per [1.5], the material specifications are to be in compliance with the requirements of the standard used.

**2.3 Permissible stresses**

**2.3.1** The permissible stresses  $K$ , in  $N/mm^2$ , for steels, to be used in the formulae of this Article, may be determined from Tab 7, Tab 8, Tab 9 and Tab 10, where  $R_m$  is the ultimate strength of the material, in  $N/mm^2$ . For intermediate values of the temperature, the value of  $K$  is to be obtained by linear interpolation.

**Table 7 : Permissible stresses K for carbon steels intended for boilers and thermal oil heaters**

Carbon steel	T (°C)	≤ 50	100	150	200	250	300	350	400

(1) Normalised and tempered  
(2) Normalised and tempered or quenched and tempered

**2.3.2 Direct determination of permissible stress**

The permissible stresses K, where not otherwise specified, may be taken as indicated below.

a) Steel:

The permissible stress is to be the minimum of the values obtained by the following formulae:

$$K = \frac{R_{m,20}}{2,7}$$

$$K = \frac{R_{S,MIN,T}}{A}$$

$$K = \frac{S_A}{A}$$

where:

R<sub>m,20</sub> : Minimum tensile strength at ambient temperature (20°C), in N/mm<sup>2</sup>

R<sub>S,MIN,T</sub> : Minimum between R<sub>eH</sub> and R<sub>p0,2</sub> at the design temperature T, in N/mm<sup>2</sup>

- $S_A$  : Average stress to produce creep rupture in 100000 hours, in N/mm<sup>2</sup>, at the design temperature T
- A : Safety factor taken as follows, when reliability of  $R_{S,MIN,T}$  and  $S_A$  values are proved to the Society's satisfaction:
- 1,6 for boilers and other steam generators
  - 1,5 for other pressure vessels
  - specially considered by the Society if average stress to produce creep rupture in more than 100000 hours is used instead of  $S_A$

In the case of steel castings, the permissible stress K, calculated as above, is to be decreased by 20%. Where steel castings are subjected to non-destructive tests, a smaller reduction up to 10% may be taken into consideration by the Society.

b) Spheroidal cast iron:

The permissible stress is to be the minimum of the values obtained by the following formulae:

$$K = \frac{R_{m,20}}{4,8}$$

$$K = \frac{R_{S,MIN,T}}{3}$$

c) Grey cast iron:

The permissible stress is obtained by the following formula:

$$K = \frac{R_{m,20}}{10}$$

d) Copper alloys:

The permissible stress is obtained by the following formula:

$$K = \frac{R_{m,T}}{4}$$

where:

$R_{m,T}$  : Minimum tensile strength at the design temperature T, in N/mm<sup>2</sup>

e) Aluminium and aluminium alloys:

The permissible stress is to be the minimum of the values obtained by the following formulae:

$$K = \frac{R_{m,T}}{4}$$

$$K = \frac{R_{e,H}}{1,5}$$

where:

$R_{e,H}$  : Minimum yield stress, in N/mm<sup>2</sup>

f) Additional conditions:

- in special cases, the Society reserves the right to apply values of permissible stress K lower than those specified above, in particular for lifting appliance devices and steering gear devices
- in the case of boilers or other steam generators, the permissible stress K is not to exceed 170 N/mm<sup>2</sup>
- for materials other than those listed above the permissible stress is to be agreed with the Society on a case by case basis.

## 2.4 Cylindrical, spherical and conical shells with circular cross-sections subject to internal pressure

### 2.4.1 Cylindrical shell thickness

- a) The minimum thickness of cylindrical, spherical and conical shells with circular cross-sections is not to be less than the value  $t$ , in mm, calculated by one of the following formulae, as appropriate. Cylindrical tube plates pierced by a great number of tube holes are to have thickness calculated by the applicable formulae in [2.4.3], [2.4.4], [2.4.5] and [2.9.2].
- b) The thicknesses obtained by the formulae in [2.4.3], [2.4.4] and [2.4.5] are "net" thicknesses, as they do not include any corrosion allowance. The thickness obtained by the above formulae is to be increased by 0,75 mm. See also [2.4.7].

### 2.4.2 Efficiency

- a) The values of efficiency  $e$  to be used in the formulae in [2.4.3], [2.4.4] and [2.4.5] are indicated in Tab 11.
- b) The manufacturer may propose a factor  $e$  lower than those indicated in Tab 11 where consistent with the factor used in the formulae of [2.4.3], [2.4.4] and [2.4.5] and with the provisions of specific requirements according to class as per [4.9], [4.10] or [4.11]. The proposed efficiency factor is to be agreed by the Society.

Table 11 : Efficiency of unpierced shells

Case	e
Seamless shells	1,00
Shells of class 1 vessels (1)	1,00
Shells of class 2 vessels (with partial radiographic examination of butt-joints)	0,85
Shells of class 2 vessels with actual thickness ≤ 15 mm (without radiographic examination of butt-joints)	0,75
(1) In special cases the Society reserves the right to take a factor e < 1, depending on the welding procedure adopted for the welded joint.	

### 2.4.3 Cylindrical shells

- a) When the ratio external diameter/inside diameter is equal to or less than 1,5, the minimum thickness of cylindrical shells is given by the following formula:

$$t = \frac{pD}{(2K - p)e}$$

where:

- p : Design pressure, in MPa  
 D : Inside diameter of vessel, in mm  
 K : Permissible stress, in N/mm<sup>2</sup>, obtained as specified in [2.3]  
 e : Efficiency of welded joint, the value of which is given in [2.4.2].

- b) The minimum thickness of shells having ratio external diameter/inside diameter exceeding 1,5 is subject of special consideration.

### 2.4.4 Spherical shells

- a) When the ratio external diameter/inside diameter is equal to or less than 1,5, the minimum thickness of spherical shells is given by the following formula:

$$t = \frac{pD}{(4K - p)e}$$

For the meaning of the symbols, see [2.4.3].

- b) The minimum thickness of shells having ratio external diameter/inside diameter exceeding 1,5 is subject of special consideration.

### 2.4.5 Conical shells

- a) The following formula applies to conical shells of thickness not exceeding 1/6 of the external diameter in way of the large end of the cone:

$$t = \frac{pD}{(2K - p)e \cdot \cos \varphi}$$

For the meaning of the symbols, see [2.4.3].

D is measured in way of the large end of the cone and  $\varphi$  is the angle of slope of the conical section of the shell to the pressure vessel axis (see Fig 1). When  $\varphi$  exceeds 75°, the shell thickness is to be taken as required for flat heads, see [2.7].

- b) The minimum thickness of shells having thickness exceeding 1/6 of the external diameter in way of the large end of the cone is subject of special consideration.
- c) Conical shells may be made of several ring sections of decreasing thickness. The minimum thickness of each section is to be obtained by the formula in a) using for D the maximum diameter of the considered section.
- d) In general, the junction with a sharp angle between the conical shell and the cylindrical or other conical shell, having different angle of slope, is not allowed if the angle of the generating line of the shells to be assembled exceeds 30°.
- e) The shell thickness in way of knuckles is subject of special consideration by the Society.

Figure 1 : Conic shells

**2.4.6 Minimum thickness of shells**

Irrespective of the value calculated by the formulae in [2.4.3], [2.4.4] or [2.4.5], the thickness *t* of shells is not to be less than one of the following values, as applicable:

- for pressure vessels:  $t = 3 + D/1500$  mm
- for unpierced plates of boilers:  $t = 6,0$  mm
- for boiler cylindrical tube plates:  $t = 9,5$  mm.

No corrosion allowance needs to be added to the above values.

**2.4.7 Corrosion allowance**

The Society reserves the right to increase the corrosion allowance value in the case of vessels exposed to particular accelerating corrosion conditions. The Society may also consider the reduction of this factor where particular measures are taken to effectively reduce the corrosion rate of the vessel.

**2.5 Dished heads subject to pressure on the concave (internal) side**

**2.5.1 Dished head for boiler headers**

Dished heads for boiler headers are to be seamless.

**2.5.2 Dished head profile**

The following requirements are to be complied with for the determination of the profile of dished heads (see Fig 2 (a) and (b)).

a) Ellipsoidal heads:

$$H \geq 0,2 D$$

where:

*H* : External depth of head, in mm, measured from the start of curvature at the base.

b) Torispherical heads:

$$R_{IN} \leq D$$

$$r_{IN} \geq 0,1 D$$

$$r_{IN} \geq 3 t$$

$$H \geq 0,18 D$$

where:

*R<sub>IN</sub>* : Internal radius of the spherical part, in mm

*r<sub>IN</sub>* : Internal knuckle radius, in mm

*H* : External depth of head calculated by the following formula (see Fig 2 (b)):

$$H = R_E - [(R_E - 0,5 D) \cdot (R_E + 0,5 D - 2 r_E)]^{0,5}$$

where:

*R<sub>E</sub>* : External radius of the spherical part, in mm

*r<sub>E</sub>* : External knuckle radius, in mm.

Figure 2 : Dished head profiles

2.5.3 Required thickness of solid dished heads

a) The minimum thickness of solid (not pierced) hemispherical, torispherical, or ellipsoidal unstayed dished heads, subject to pressure on the concave (internal) side, is to be not less than the value  $t$ , in mm, calculated by the following formula:

$$t = \frac{pDC}{2Ke}$$

where:

$C$  : Shape factor, obtained from the graph in Fig 3, as a function of  $H/D$  and  $t/D$ .

For other symbols, see [2.4.3].

b) The thickness obtained by the formula in item a) is "net" thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 0,75 mm. See also [2.4.7].

Figure 3 : Shape factor for dished heads

**2.5.4 Composed torispherical heads**

- a) Torispherical heads may be constructed with welded elements of different thicknesses (see Fig 4).
- b) Where a torispherical head is built in two sections, the thickness of the torispherical part is to be obtained by the formula in [2.5.3], while the thickness of the spherical part may be obtained by the formula in [2.4.4].
- c) The spherical part may commence at a distance from the knuckle not less than:

$$0,5 \cdot (R_{IN} \cdot t)^{0,5}$$

where:

$R_{IN}$  : Internal radius of the spherical part, in mm

$t$  : Knuckle thickness, in mm.

**Figure 4 : Composed torispherical head**

**2.5.5 Minimum thickness of dished heads**

Irrespective of the values calculated in [2.5.2] and [2.5.3], the thickness  $t$  of dished heads is not to be less than:

- $3 + D_E / 1500$  mm for normal pressure vessels
- 6 mm for boiler pressure vessels.

No corrosion allowance needs to be added to the above values.

**2.5.6 Connection of heads to cylindrical shells**

The heads are to be provided, at their base, with a cylindrical skirt not less than  $2t$  in length and with a thickness in no case less than the Rule thickness of a cylindrical shell of the same diameter and the same material, calculated by the formula given in [2.4.3] using the same efficiency factor  $e$  adopted for calculation of the head thickness. Fig 5 and Fig 6 show typical admissible attachments of dished ends to cylindrical shells.

In particular, hemispherical heads not provided with the above skirt are to be connected to the cylindrical shell if the latter is thicker than the head, as shown in Fig 5.

Other types of connections are subject to special consideration by the Society.

**Figure 5 : Typical attachment of dished heads to cylindrical shells**

- Types shown in (a), (b) and (c) are acceptable for all pressure vessels.
- Type shown in (d) is acceptable for class 2 and class 3 pressure vessels.
- Types shown in (e) and (f) are acceptable for class 3 pressure vessels only.

Figure 6 : Connection of hemispherical head to the cylindrical shell

## 2.6 Dished heads subject to pressure on the convex (external) side

2.6.1 The calculation of the minimum thickness is to be performed according to a standard accepted by the Society.

In addition, the thickness of torispherical or ellipsoidal heads under external pressure is no to be less than 1,2 times the thickness required for a head of the same shape subject to internal pressure.

## 2.7 Flat heads

### 2.7.1 Unstayed flat head minimum thickness

a) The minimum thickness of unstayed flat heads is not to be less than the value  $t$ , in mm, calculated by the following formula:

$$t = D \left( \frac{100p}{CK} \right)^{0,5}$$

where:

$p$  : Design pressure, in MPa

$K$  : Permissible stress, in N/mm<sup>2</sup>, obtained as specified in [2.3]

$D$  : Diameter of the head, in mm. For circular section heads, the diameter  $D$  is to be measured as shown in Fig 7 and Fig 8 for various types of heads. For rectangular section heads, the equivalent value for  $D$  may be obtained from the following formula:

$$D = a \left[ 3,4 - 2,4 \left( \frac{a}{b} \right) \right]^{0,5}$$

$a$  and  $b$  being the smaller and larger side of the rectangle, respectively, in mm

$C$  : The values given below, depending on the various types of heads shown in Fig 7 and Fig 8:

Fig 7(a) :  $C = 400$  for circular heads

Fig 7(b) :  $C = 330$  for circular heads

Fig 7(c) :  $C = 350$  for circular heads

Fig 7(d) :  $C = 400$  for circular heads and  $C = 250$  for rectangular heads

Fig 7(e) :  $C = 350$  for circular heads and  $C = 200$  for rectangular heads

Fig 7(f) :  $C = 350$  for circular heads

Fig 7(g) :  $C = 300$  for circular heads

Fig 7(h) :  $C = 350$  for circular heads and  $C = 200$  for rectangular heads

Fig 8(i) :  $C = 350$  for circular heads and  $C = 200$  for rectangular heads

Fig 8(j) :  $C = 200$  for circular heads

Fig 8(k) :  $C = 330$  for circular heads

Fig 8(l) :  $C = 300$  for circular heads

Fig 8(m) :  $C = 300$  for circular heads

Fig 8(n) :  $C = 400$  for circular heads

Fig 8(o) :  $C =$  value obtained from the following formula, for circular heads:

$$C = \frac{100}{0,3 + \frac{1,9Fh}{pD^3}}$$

where:

$h$  : Radial distance, in mm, from the pitch centre diameter of bolts to the circumference of diameter  $D$ , as shown in Fig 8(o)

$F$  : Total bolt load, in N, to be taken as the greater of the following values  $F_1$  and  $F_2$ :

$$F_1 = 0,785 D p (D + m b)$$

$$F_2 = 9,81 y D b$$

with:

b : Effective half contact width of the gasket, in mm, calculated as follows:

$$b = 0,5 N \text{ for } N \leq 13 \text{ mm, and}$$

$$b = 1,8 N^{0,5} \text{ for } N > 13 \text{ mm}$$

where N is the geometric contact width of the gasket, in mm, as indicated in Fig 8(o)

m, y : Adimensional coefficients, whose values are given in Tab 12, depending on the type of gasket.

The adoption of one of the above-mentioned heads is subject to the Society's approval depending upon its use. Types of heads not shown in Fig 7 and Fig 8 are to be the subject of special consideration by the Society.

b) The thickness obtained by the formulae in a) is "net" thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 1 mm. See also [2.4.7].<sup>3</sup>

### 2.7.2 Stayed flat head minimum thickness

For the minimum thickness of stayed flat heads, see [2.12.3].

Figure 7 : Types of unstayed flat heads (1)

Figure 8 : Types of unstayed flat heads (2)

**Table 12 : Coefficients m and y**

Type of gasket	m	y
Self-sealing, metal or rubber (e.g. O-ring)	0	0
Rubber with cotton fabric	10	0,88
Rubber with reinforcing fabric with or without metal wire:		
- 3 layers	18	4,85
- 2 layers	20	6,4
- 1 layers	22	8,2
Synthetic fibre with suitable binders:		
- 3,0 mm thick	16	3,5
- 1,5 mm thick	22	8,2
Organic fibre	14	2,4
Metal spiral lined with synthetic fibre:		
- carbon steel	20	6,4
- stainless steel	24	9,9
Synthetic fibre with plain metal lining:		
- copper	28	14,0
- iron	30	16,8
- stainless steel	30	20,0
Solid metal:		
- copper	38	28,7
- iron	44	39,8
- stainless steel	52	57,5

## 2.8 Openings and branches (nozzles)

### 2.8.1 Nozzles thickness

a) The thickness  $e_b$ , in mm, of nozzles attached to shells and headers of boilers is not to be less than:

$$e_b = \frac{d_E}{25} + 2,5$$

where  $d_E$  is the outside diameter of nozzle, in mm.

The thickness of the nozzle is, however, to be not less than the thickness required for the piping system attached to the vessel shell calculated at the vessel design pressure, and need not to be greater than the thickness of the shell to which it is connected.

b) The thickness of the nozzle attached to shells and headers of other pressure vessels is not to be less than the thickness required for the piping system attached to the vessel shell calculated at the vessel design pressure, and need not be greater than the thickness of the shell to which it is connected.

c) Where a branch is connected by screwing, the thickness of the nozzle is to be measured at the root of the thread.

### 2.8.2 Nozzle connection to vessel shell

a) In general, the axis of the nozzle is not to form an angle greater than 15° with the normal to the shell.

b) Fig 30, Fig 31, Fig 32 and Fig 33 show some typical acceptable connections of nozzles to shells. Other types of connections are to be considered by the Society on a case by case basis.

### 2.8.3 Openings in shells

a) In general, the largest dimensions of the openings in shells are not to exceed:

- for shells up to 1500 mm in diameter  $D_E$ :  
1/2  $D_E$ , but not more than 500 mm
- for shells over 1500 mm in diameter  $D_E$ :  
1/3  $D_E$ , but not more than 1000 mm,

where  $D_E$  is the vessel external diameter, in mm.

Greater values may be considered by the Society on a case by case basis.

b) In general, in oval or elliptical openings the ratio major diameter/minor diameter is not to exceed 2.

2.8.4 Openings compensation in cylindrical shells

a) Compensation methods

For cylindrical shells with openings, the efficiency of the main body is to be satisfied by one of the following methods:

- by increasing the wall thickness of main body compared with that of the cylindrical shell without opening: see Fig 9
- by branches which have been provided with a wall thickness of that required on account of the internal pressure: see Fig 10 and Fig 11
- by reinforcing pads or rings analogous to increasing the wall thickness: see Fig 12 and Fig 13
- by a combination of previous reinforcement

b) Definitions

Effective lengths  $l_{rs}$  required for calculation of efficiency and of compensations is to be taken as:

$$l_{rs} = \min(\sqrt{Dt_a}, l_{s1})$$

where:

D : Outside diameter, in mm

$t_a$  : Available thickness, in mm

$l_{s1}$  : Transition length, in mm, according to Fig 9 and Fig 10

Figure 9 : Reinforcement by increasing the wall thickness of the main body with opening

Figure 10 : Reinforcement by set-through and full penetration welded branch

Figure 11 : Reinforcement by welded on branch

Figure 12 : Opening with reinforcing pad

Figure 13 : Opening with reinforcing pad and full penetration branch

c) Basic calculation

The required wall thickness without allowance of a cylindrical shell is determined with the following formula (see [2.4.3]):

$$t = \frac{pD}{(2K-p)e}$$

With the available thickness  $t_a$ , we obtain the available efficiency  $e_a$  and the maximum diameter  $d_{obmax}$  of an unreinforced opening when the average stress of the main body is equal to the permissible stress K:

$$e_a = \frac{pD_i}{(2K-p)t_a}$$

$$d_{obmax} = 2 \left[ \frac{l_{rs}}{e_a} - l_{rs} \right]$$

where:

$D_i$  : Internal diameter of the main body, in mm

d) Isolated opening reinforcement

The reinforcement of isolated openings as indicated in Fig 9 to Fig 13 are to be in respect with:

$$\frac{A_p}{A_f} \leq \frac{K}{p} - 0,5$$

where:

- K : Permissible stress in the shell, in N/mm<sup>2</sup>
- A<sub>f</sub> : Total area of cross section (wall and branch and pad)
- A<sub>p</sub> : Total area under pressure p.

In Fig 9 to Fig 13,  $\ell_{rs}$ ,  $\ell_{rb}$  and  $\ell_{rbi}$  are effective lengths for calculation of efficiencies and compensation, equal to:

- for shell:

$$\ell_{rs} = \min(\sqrt{(D + e_{rs})e_{rs}}, \ell_{s1})$$

- for external branch projection:

$$\ell_{rb} = \min(\sqrt{(d_{ib} + e_{rb})e_{rb}}, \ell_{b1})$$

- for internal branch projection:

$$\ell_{rbi} = \min(0,5\sqrt{(d_{ib} + e_{rb})e_{rb}}, \ell_{b2})$$

e) Condition of isolated openings

- Full case

Adjacent openings are to be treated as isolated openings if the centre distance  $P_\phi$ , in accordance with Fig 16, is not less than:

$$\frac{\left(\frac{d_{ib1}}{2} + e_{rb1}\right)}{\cos\Psi_1} + \frac{\left(\frac{d_{ib2}}{2} + e_{rb2}\right)}{\cos\Psi_2} + 2\sqrt{(d_{is} + e_{rs})e_{rs}}$$

For variable definition see Fig 14 and Fig 15.

- Simplification

- For openings without branch:  
 $e_{rb} = 0$  and  $\Psi = 0$
- For openings with nozzles perpendicular to shell:

The openings are to be treated as isolated openings if the centre distance  $P_\phi$  in accordance with Fig 16 is not less than:

$$\left(\frac{d_{ib1}}{2} + e_{rb1}\right) + \left(\frac{d_{ib2}}{2} + e_{rb2}\right) + 2\sqrt{(d_{is} + e_{rs})e_{rs}}$$

**Figure 14 : Angle definition for cylindrical shell with oblique branch**

Figure 15 : Angle definition for cylindrical shell with non-radial branch

f) Adjacent openings

Where the condition of isolated openings is not fulfilled, the compensation is to be calculated, using Fig 16, as per the following formula:

$$\frac{A_p}{A_i} \leq \frac{K}{p} - 0,5$$

Figure 16 : Load diagram for cylindrical shell with adjacent branches

- a : Circumferential direction
- b : Longitudinal direction

**2.8.5 Openings in dished heads**

- a) The openings in dished heads may be circular, elliptical or oval.
- b) The largest diameter of the non-compensated opening is not to exceed one half of the external diameter of the head.
- c) The opening is to be so situated that its projection, or its reinforcement projection in the case of compensated openings, is completely contained inside a circle having its centre at the centre of the head and a diameter of 0,8 D, D being the external diameter of the head (see Fig 17). However, a small reinforced opening for drainage may be accepted outside the indicated area.
- d) In the case of non-compensated openings (for this purpose, flanged openings are also to be considered as non-compensated), the head thickness is not to be less than that calculated by the formula in [2.5.3] using the greatest of the shape factors C obtained from the graph in Fig 3 as a function of:
 
$$H/D \text{ and } t/D \text{ or } H/D \text{ and } d \cdot (t \cdot D)^{-0,5},$$
 where d is the diameter of the largest non-compensated opening in the head, in mm. For oval and elliptical openings, d is the width of the opening in way of its major axis.
- e) In all cases the diameter D of the head base, the head thickness t and the diameter d of the largest non-compensated opening are to be such as to meet the following requirements:
  - the position of non-compensated openings in the heads is to be as shown in Fig 17
  - for flanged openings, the radius r of the flanging (see Fig 17) is not to be less than 25 mm
  - the thickness of the flanged part may be less than the Rule thickness.

**Figure 17 : Openings on dished heads**

**2.8.6 Opening compensation in dished heads**

- a) Where openings are cut in dished heads and the proposed thickness of the head is less than that calculated by the formula in [2.5.3] with the greatest of the shape factor C according to [2.5.3] the opening is to be compensated.
- b) Fig 30, Fig 31, Fig 32 and Fig 33 show typical connections of nozzles and compensating rings.
- c) The opening is considered sufficiently compensated when the head thickness t is not less than that calculated in accordance with [2.5.3] and using the shape-factor C obtained from the graph in Fig 3 using the value:

$$\left(d - \frac{A}{t}\right) \cdot (t \cdot D)^{-0,5}$$

instead of:

$$d \cdot (t \cdot D)^{-0,5}$$

where:

- A : Area, in mm<sup>2</sup>, of the total transverse section of the compensating parts
- t : Actual thickness of the head, in mm, in the zone of the opening under consideration.

- d) When  $A/t > d$ , the coefficient C is to be determined using the curve corresponding to the value:

$$d \cdot (t \cdot D)^{-0,5} = 0$$

- e) If necessary, calculations are to be repeated.

**2.8.7 Compensation criteria**

In the evaluation of the area A, the following is also to be taken into consideration:

- a) The material that may be considered for compensating an opening is that located around the opening up to a distance l from the edge of the opening. The distance l, in mm, is the lesser obtained from the following formulae:

$$l = 0,5 d$$

$$l = (2 \cdot R_{IN} \cdot t)^{0,5}$$

where:

d : Diameter of the opening, in mm

R<sub>IN</sub> : Internal radius of the spherical part, in mm, in the case of hemispherical or torispherical heads

In the case of ellipsoidal heads, R<sub>IN</sub> is to be calculated by the following formula (see Fig 2 (a)):

$$R_{IN} = \frac{[a^4 - x^2(a^2 - b^2)]^{3/2}}{a^4 b}$$

where;

a : Half the major axis of the elliptical meridian section of the head, in mm

b : Half the minor axis of the above section, in mm

x : Distance between the centre of the hole and the rotation axis of the shell, in mm.

- b) In the case of nozzles or pads welded in the hole, the section corresponding to the thickness in excess of that required is to be considered for the part which is subject to pressure and for a depth h, in mm, both on the external and internal sides of the head, not greater than:

$$(d_B \cdot t_B)^{0,5}$$

where d<sub>B</sub> and t<sub>B</sub> are the diameter of the opening and the thickness of the pad or nozzle, in mm, respectively.

- c) The area of the welding connecting nozzle and pad reinforcements may be considered as a compensating section.
- d) If the material of reinforcement pads, nozzles and collars has a permissible stress lower than that of the head material, the area A, to be taken for calculation of the coefficient C, is to be reduced proportionally.

**2.8.8 Openings in flat end plates**

The maximum diameter of an unreinforced opening in a flat end plate is to be determined from the equation:

$$d_{max} = 8e_{rh} \left[ 1,5 \frac{e_{rh}^2}{e_{ch}^2} - 1 \right]$$

where:

e<sub>rh</sub> : Actual thickness of the flat end, in mm

e<sub>ch</sub> : Required calculated thickness of the flat end, in mm.

**2.8.9 Opening compensation in flat end plate**

Reinforcement of branch openings is to be achieved by taking account of locally disposed material, including the attachment welds, in excess of the minimum requirements for end plate and branch thickness as shown in Fig 18. The branch thickness is to be increased where required. Compensation is to be considered adequate when the compensating area Y is equal to or greater than the area X requiring compensation.

Area X is to be obtained by multiplying 25% of the inside radius of the branch by the thickness of the flat end plate, calculated for the part of the end plate under consideration.

Area Y is to be measured in a plane through the axis of the branch parallel to the surface of the flat end plate, and is to be calculated as follows:

- a) for that part of the branch which projects outside the boiler, calculate the full sectional area of the branch up to a distance ℓ<sub>b</sub> from the actual outer surface of the flat end plate and deduct from it the sectional area that the branch would have within the same distance if its thickness were calculated in accordance with equation given in [2.4.3]
- b) add to it the full sectional area of that part of the branch that projects inside the boiler (if any) up to a distance ℓ<sub>b</sub> from the inside surface of the flat end plate
- c) add to it the sectional area of the fillet welds
- d) add to it the area obtained by multiplying the difference between the actual flat end plate thickness and its thickness calculated for the part of the end plate under consideration by the length ℓ<sub>s</sub>
- e) add to it the area of the compensating plate (if any) within the limits of reinforcement shown in Fig 18.

Where material having a lower allowable stress than that of the flat end plate is taken as compensation, its effective area is to be reduced in the ratio of the allowable stresses at the calculation temperature. No credit is to be taken for the additional strength of material having a higher allowable stress than that of the flat end plate

Welds attaching branches and compensating plates are to be capable of transmitting the full strength of the reinforcing area and all other loadings to which they may be subjected.

Figure 18 : Compensation for branch in flat end plate

- $e_{cp}$  : Thickness calculated in accordance with equation in [2.8.1] for the part under consideration
- $e_{cb}$  : Thickness calculated taking efficiency = 1
- $l_b$  : The smaller of the two values:  
 $2,5 e_{rep}$  and  $(2,5 e_b + e_{rp})$
- $l_s$  : The greater of the two values:  
 $(e_{rep} + 75)$  and  $(d_{ib} / 4)$

Area Y is not to be less than area X.

Note 1 : The compensating plate is required only in cases where area Y would otherwise be less than area X.

**2.8.10 Covers**

- a) Circular, oval and elliptical inspection openings are to be provided with steel covers. Inspection openings with a diameter not exceeding 150 mm may be closed by blind flanges.
- b) The thickness of the opening covers is not to be less than the value  $t$ , in mm, given by the following formula:

$$t = 1,22 \cdot a \cdot \left(\frac{pC}{K}\right)^{0,5}$$

where:

- a : The minor axis of the oval or elliptical opening, measured at half width of gasket, in mm
- b : The major axis of the oval or elliptical opening, measured at half width of the gasket, in mm
- C : Coefficient in Tab 13 as a function of the ratio  $b/a$  of the axes of the oval or elliptical opening, as defined above. For intermediate values of the ratio  $b/a$ , the value of C is to be obtained by linear interpolation.

For circular openings the diameter  $d$ , in mm, is to be used in the above formula instead of  $a$ .

- c) The thickness obtained by the formula in item a) is "net" thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 1 mm for classification purpose. See also [2.4.7].

Table 13 : Coefficient C for oval or elliptical covers

b/a	1,00	1,05	1,10	1,15	1,20	1,25	1,30	1,40	1,50	1,60
C	0,206	0,220	0,235	0,247	0,259	0,271	0,282	0,302	0,321	0,333
b/a	1,70	1,80	1,90	2,00	2,50	3,00	3,50	4,00	4,50	5,00
C	0,344	0,356	0,368	0,379	0,406	0,433	0,449	0,465	0,473	0,480

**2.9 Regular pattern openings - Tube holes**

**2.9.1 Definition**

Openings may be considered as regular pattern openings when not less than three non isolated openings are disposed in regularly staggered rows in longitudinal or circular direction of a shell.

In such a case, instead of a direct calculation of the compensation of openings, the thickness of the shell could be calculated by application of applicable formulae given in [2.4], [2.5] with a reduced efficiency  $e$  as indicated in [2.9.2] and [2.9.3].

This requirement apply for pressure vessels and for boiler.

**2.9.2 Efficiency factor of tube holes in cylindrical tube plates**

The efficiency factor  $e$  of pipe holes in cylindrical shells pierced by tube holes is to be determined by direct calculation or by another suitable method accepted by the Society. In the case of cylindrical holes of constant diameter and radial axis, the efficiency factor  $e$  may be determined by the following formula (see Fig 19):

$$e = \frac{1}{\frac{s}{s-d} \cdot (1 - (0,5 \cdot \sin^2 \alpha)) + m \cdot \sin 2\alpha}$$

where:

- $s$  : Pitch of the hole row considered, in mm
- $d$  : Diameter of holes, in mm. The hole diameter  $d$  may be reduced by the amount  $Y/e_{cp}$  where  $Y$  is the compensating area, in  $mm^2$ , of nozzle and welds and  $e_{cp}$  the calculated unpierced shell thickness, see [2.8.9] and Fig 18
- $\alpha$  : Angle between the axis of hole row considered and the axis of the cylinder ( $\alpha = 0^\circ$  if the hole row is parallel to the cylinder generating line;  $\alpha = 90^\circ$  for circumferential hole row)
- $m$  : Coefficient depending upon the ratio  $d/s$ , as obtained from Tab 14. For intermediate values of  $d/s$ , the value of  $m$  is to be obtained by linear interpolation.

The value of  $e$  actually used is to be the smallest calculated value for either longitudinal, diagonal or circumferential rows of holes.

**Figure 19 : Hole pattern in cylindrical shells**

**Table 14 : Coefficient m**

$d/s$	0,30	0,35	0,40	0,45	0,50	0,55	0,60	0,65	0,70	0,75	0,80
$m$	0,137	0,175	0,220	0,274	0,342	0,438	0,560	0,740	1,010	1,420	2,060

**2.9.3 Welded shells with tube holes and efficiency factor of different hole patterns**

Where shells have welding butts and/or different groups of hole patterns, the value to be assumed for the efficiency  $e$  in the formulae is the minimum of the values calculated separately for each type of welding (as per [2.4.2]) and for each configuration of holes (as per [2.9.1]).

**2.9.4 Rectangular section headers**

- a) For seamless type headers of rectangular section design, the wall thickness  $t$ , in mm, in way of corner fillets and the thickness  $t_1$ , in mm, of any drilled wall is not to be less than those given by the following formulae, as appropriate (see Fig 20):

$$t = \left( \frac{100pM_1}{K} \right)^{0,5}$$

$$t_1 = \left( \frac{100pM_2}{eK} \right)^{0,5}$$

where (see also Fig 20):

- $t$  : Wall thickness at the corners, in mm
- $t_1$  : Thickness of drilled wall, in mm
- $p$  : Design pressure, in MPa
- $K$  : Permissible stress, in  $N/mm^2$ , obtained as specified in [2.3]
- $a$  : Internal half width of the header, in a direction parallel to the wall under consideration, in mm
- $b$  : Internal half width of the header, in a direction normal to the wall under consideration, in mm
- $c$  : Distance between the axis of the hole row considered and the centreline of the header wall, in mm

e : Efficiency factor of holes in the wall, determined by the following formulae:

$$e = \frac{s-d}{s} \quad \text{for } d < a$$

$$e = \frac{s-0,67d}{s} \quad \text{for } a \leq d < 1,3a$$

$$e = \frac{s-0,33d}{s} \quad \text{for } d \geq 1,3a$$

where:

s : Pitch of the holes, in mm, of the longitudinal or diagonal row under consideration. For a staggered pattern of holes the pitch of the diagonal row is to be considered

d : Diameter of the holes, in mm

M<sub>1</sub> : Coefficient to be calculated by the following formula:

$$M_1 = \frac{a^2 + b^2 - ab}{50}$$

M<sub>2</sub> : Coefficient (to be taken always positive) to be calculated by one of the following formulae, as appropriate:

- For a non-staggered pattern of holes:

$$M_2 = \frac{b^2 - \frac{1}{2}a^2 - ab + \frac{3}{2}c^2}{50}$$

- For a staggered pattern of holes:

$$M_2 = \frac{b^2 - \frac{1}{2}a^2 - ab}{50} \cos \alpha$$

where  $\alpha$  is the angle between the axis of the diagonal row of the holes under consideration and the axis of the header, in the case of a staggered pattern of holes.

b) The thickness obtained by the formulae in a) is "net" thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 1,5 mm. See also [2.4.7].

Figure 20 : Rectangular section headers

## 2.10 Water tubes, superheaters and economiser tubes of boilers

### 2.10.1

a) The thickness of tubes of evaporating parts, economisers and superheaters exposed to gases which are subject to internal pressure is not to be less than the value  $t$  given by the following formula:

$$t = \frac{pd}{2K+p} + 0,3$$

where:

p : Design pressure, in MPa

K : Permissible stress, in N/mm<sup>2</sup>, obtained as specified in [2.3]

d : Outside diameter of tube, in mm.

However, irrespective of the value calculated by the formulae in item a), the thickness  $t$  of tubes is not to be less than the values given in Tab 15.

b) The values of  $t$  determined by the above-mentioned formula are to be considered as theoretical values for straight tubes, not taking account of the manufacturing tolerance. Where the tubes are not sized precision tubes, the thickness calculated by the formula in item a) is to be increased by 12,5% to take into account the manufacturing tolerance. For bent tubes, the thickness of the thinner part in way of the bend is not to be less than that given by the formula.

- c) Whenever abnormal corrosion and erosion may occur during service, the corrosion constant of 0,3 in the formula may be increased to the satisfaction of the Society.
- d) The thickness of tubes which form an integral part of the boiler and which are not exposed to combustion gases is to comply with the requirements for steam pipes (see Ch 1, Sec 10, [15]).

**Table 15 : Minimum thickness of water tubes**

Outside diameter, in mm	Minimum thickness in mm of tubes subject to internal pressure of cylindrical boilers and water tube boilers having the feed water system	
	Closed type, if equipped with suitable devices for reducing the oxygen concentration in the water	Open type, not equipped with suitable devices for reducing the oxygen concentration in the water
< 38	1,8	2,9
38 - 48,3	2,0	2,9
51 - 63,5	2,4	2,9
70	2,6	3,2
76,1 - 88,9	2,9	3,2
101,6 - 127	3,6	–

**2.11 Additional requirements for fired pressure vessels**

**2.11.1 Insulation for headers and combustion chambers**

Those parts of headers and/or combustion chambers which are not protected by tubes and are exposed to radiant heat or to high temperature gases are to be covered by suitable insulating material.

**2.11.2 Connections of tubes to drums and tube plates**

Tubes are to be adequately secured to drums and/or tube plates by expansion, welding or other appropriate procedure.

- a) Where the tubes are secured by expanding or equivalent process, the height of the shoulder bearing the tube, measured parallel to the tube axis, is to be at least 1/5 of the hole diameter, but not less than 9 mm for tubes normal to the tube plate or 13 mm for tubes angled to the tube plate. The tubes ends are not to project over the other face of the tube plate more than 6 mm.
- b) The tube ends intended to be expanded are to be partially annealed when the tubes have not been annealed by the manufacturer.

**2.12 Additional requirements for vertical boilers and fire tube boilers**

**2.12.1 General**

The scantlings of the shells of vertical boilers and fire tube boilers are to be determined in accordance with [2.4].

**2.12.2 Ends of vertical boilers**

- a) The minimum thickness of the dished ends forming the upper part of vertical boilers and subject to pressure on their concave face is to be determined in accordance with [2.5].
- b) When the end is supported in its centre by an uptake, the minimum thickness *t*, in mm, is to be calculated with the following formula:

$$t = 0,77 \cdot \frac{pR_i}{K}$$

where:

- p* : Design pressure, in MPa
- K* : Permissible stress, in N/mm<sup>2</sup>, obtained as specified in [2.3]
- R<sub>i</sub>* : Radius of curvature at the centre of the end measured internally. *R<sub>i</sub>* is not to exceed the external diameter of the shell.

- c) The thickness obtained by the formula in item b) is “net” thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 0,7 mm. See also [2.4.7].
- d) For ends supported by an uptake at their centre, the corner radius measured internally is not to be less than 4 times the end thickness or 65 mm, whichever is the lesser and the inside radius of curvature on the flange to uptake is not to be less than twice the end thickness or 25 mm, whichever is the lesser.

2.12.3 Supported flat head

a) Breathing space

- Stays are to give breathing space around the furnace tube connections and tube nests and equally divide the unstayed areas. Breathing space between furnace tube and tube nests are to be a minimum of 50 mm or 5% of the shell outside diameter, whichever is the larger, but need not be more than 100 mm.
- Breathing space between furnace tube and shell depends on the thickness of the plate of the type of end and of the dimensions of the boiler but is to be not less than 50 mm or, for bowling hoop furnaces tubes, not less than 75 mm.

b) The thickness of stayed flat heads, or of heads supported by flanges, is not to be less than the value t, in mm, given by the following formula:

$$t = D \left[ \frac{100p}{CC_1K(1 + C_2B^2)} \right]^{0.5}$$

where:

B : Ratio of the thickness of the large washer or doubler, where fitted, to the thickness of the plate:

$$B = t_1 / t$$

The value of B is to be taken between 0,67 and 1

K : Permissible stress, in N/mm<sup>2</sup>, obtained as specified in [2.3]

C : C = 1 when the plate is not exposed to flame

C = 0,88 when the plate is exposed to flame

C<sub>1</sub> : C<sub>1</sub> = 462 when the plate is supported by welded stays

C<sub>1</sub> = 704 for plates supported by flanges or equivalent

C<sub>2</sub> : C<sub>2</sub> = 0 when no doublers are fitted

C<sub>2</sub> = 0,85 when a complete doubling plate is fitted, adequately joined to the base plate.

The value of D is to be in accordance with the following provisions:

- In the parts of the flat heads between the stays:

D : D = diameter, in mm, of the largest circle which can be drawn through the centre of at least three stays without enclosing any other stay, where the stays are not evenly spaced (see Fig 21); or

$D = (a^2 + b^2)^{0.5}$  where the stays are evenly spaced, considering the most unfavourable condition,

where:

a : Distance between two adjacent rows of stays, in mm

b : Pitch of stays in the same row, in mm

Figure 21 :

Key:

- 1 : Boundaries of areas supported by individual stays
- 2 : To establish the area supported by bar stays or stay tubes in boundary rows, the boundary of the loaded area is to terminate at the centre of the associated main circle
- 3 : Main circles, diameter b
- 4 : Bar stays
- 5 : Stay tubes
- 6 : Termination of boundary areas where stay tubes are situated in the boundary rows only.

- In the parts of the flat heads between the stays and the boundaries, where flat heads are generally supported by flanges or shapes, or connected to other parts of the boiler:

D : Diameter, in mm, of the largest circle which can be drawn through not less than three points of support (stay centres or points of tangency of the circle with the contour line). To this end, the contour of the part under consideration is to be drawn at the beginning of the flanging or connection curve if its inside radius does not exceed 2,5 times the thickness of the plate, or, where such radius is greater, at the above-mentioned distance (of 2,5 times the thickness of the plate) from the ideal intersection with other surfaces (see Fig 21).

- When applying the formulae for calculation of thickness of heads covered by this sub-article, the position of plates in the most unfavourable condition is to be considered.
- Where various types of supports are provided, the value of  $C_1$  should be the arithmetic mean of the values of  $C_1$  appropriate to each type of support.
- The thickness obtained by the formulae in a), is "net" thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 1 mm. See also [2.4.7].

#### 2.12.4 Flat tube plates

- Flat tube plates in tube bundles

The thickness of the parts of flat tube plates contained in the tube bundle and supported by stay tubes is not to be less than the value  $t$ , in mm, given by the following formula:

$$t = s \left( \frac{p}{2,8K} \right)^{0,5}$$

where:

$p$  : Design pressure, in MPa

$K$  : Permissible stress, in N/mm<sup>2</sup>, obtained as specified in [2.3]

$s$  : Pitch of stay tubes, taken as the greatest mean pitch of the stay tubes supporting a quadrilateral portion of the plate, in mm.

Moreover the spacing of tube holes (diameter  $d$ ) is to be such that the minimum width, in mm, of any ligament between the tube holes is to be not less than:

- for expanded tubes:  
(0,125  $d$  + 12,5) mm
- for welded tubes:
  - for gas entry temperatures greater than 800°C:  
(0,125  $d$  + 9) mm, but need not exceed 15 mm
  - for gas entry temperatures less than or equal to 800°C:  
0,125  $d$  + 7) mm, but need not exceed 15 mm.

Moreover the calculated thickness of tube plates is to be not less than the following:

- 12 mm where the tubes are expanded into the tube plate when the diameter of the tube hole does not exceed 50 mm, or 14 mm when the diameter of the tube hole is greater than 50 mm, or
- 6 mm where the tubes are attached to the tube plate by welding only.

- Flat tube plates of combustion chamber in vertical boilers

Where tube plates contained in the tube bundle are simultaneously subject to compression due to the pressure in the combustion chamber, their thickness, as well as complying with the requirements in item a) is not to be less than the value  $t$ , in mm, given by the following formula:

$$t = \frac{p l s_1}{1,78(s_1 - d)K}$$

where:

$l$  : Depth of the combustion chamber, in mm

$s_1$  : Horizontal pitch of tubes, in mm

$d$  : Inside diameter of plain tubes, in mm.

For the meaning of other symbols, see item a).

- Tube plates outside tube bundles

For those parts of tube plates which are outside the tube bundle, the formula in [2.13.3] is to be applied, using the following coefficients  $C_1$  and  $C_2$ :

$$C_1 = 390$$

$$C_2 = 0,55$$

Doublers are only permitted where the tube plate does not form part of a combustion chamber.

## d) Tube plates not supported by stays

Flat tube plates which are not supported by stay tubes (e.g. in heat exchangers), are subject of special consideration by the Society (see also [2.14]).

## e) Stay and stay tube scantling

- the diameter of solid stays of circular cross-section is not to be less than the value  $d$  calculated by the following formula:

$$d = \left( \frac{pA}{K} \right)^{0.5}$$

where:

$d$  : Minimum diameter, in mm, of the stay throughout its length

$A$  : Area supported by the stay, in mm<sup>2</sup>

$K$  :  $K = R_m / 7$

$R_m$  : Minimum ultimate tensile strength of the stay material, in N/mm<sup>2</sup>.

The cross section of tube stays is to be equivalent to that of a solid stay supporting the same area, whose diameter is calculated by the above formula.

Stays which are not perpendicular to the supported surface are to be of an adequately increased diameter depending on the component of the force normal to the plate.

- where articulated stays are used, articulation details are to be designed assuming a safety factor for articulated elements not less than 5 with respect to the value of  $R_m$  and a wear allowance of 2 mm.

The articulation is to be of the fork type and the clearance of the pin in respect of the holes is not to exceed 1,5 mm. The pin is to bear against the jaws of the fork and its cross-sectional area is not to be less than 80% of the cross-sectional area of the stay. The width of material around the holes is not to be less than 13 mm.

- where stays are flanged for joining to the plate, the thickness of the flange is not to be less than one half the diameter of the stay.
- for welded connections of stays to tube plates, see Fig 37.

## f) Stay and stay tubes construction:

- in general, doublers are not to be fitted in plates exposed to flame
- as far as possible, stays are to be fitted perpendicularly to the supported surface
- long stays in double front boilers and, in general, stays exceeding 5 m in length, are to be supported at mid-length
- where the ends of stay tubes are of increased thickness, the excess material is to be obtained by forging and not by depositing material by means of welding
- after forging, the ends of stay tubes are to be stress relieved.

## g) Gusset stays

Tube plate may be supported by gusset stays with full penetration welds to plate and shell.

The general shape and the scantling are to be in accordance with a standard accepted by the Society.

## h) Girders

Where tops of combustion chambers, or similar structures, are supported by girders of rectangular section associated with stays, the thickness of the single girder or the aggregate thickness of all girders, at mid-length, is not to be less than the value  $t$  determined by the appropriate formula below, depending upon the number of stays.

- In case of an odd number of stays:

$$t = \frac{pL(L-s)}{0,25R_m a^2} \cdot \frac{n+1}{n}$$

- In case of an even number of stays:

$$t = \frac{pL(L-s)}{0,25R_m a^2} \cdot \frac{n+2}{n+1}$$

where:

$p$  : Design pressure, in MPa

$a$  : Depth of the girder plate at mid-length, in mm

$L$  : Length of girder between supports, in mm

$s$  : Pitch of stays, in mm

$n$  : Number of stays on the girder

$l$  : Distance between centres of girders, in mm

$R_m$  : Minimum ultimate tensile strength of the material used for the plates, in N/mm<sup>2</sup>.

The above formulae refer to the normal arrangement where:

- the stays are regularly distributed over the length L
- the distance from the supports of the outer stays does not exceed the uniform pitch s
- when the tops of the combustion chambers are connected to the sides with curved parts with an external radius less than 0,5 l, the distance of end girders from the inner part of the side surface does not exceed l
- when the curvature radius mentioned under item just above exceeds 0,5 l, the distance of the end girders from the beginning of the connection does not exceed 0,5 l.

In other cases a direct calculation is to be made using a safety factor not less than 5, with respect to the minimum value of the tensile strength  $R_m$ .

i) Ogee rings

The thickness of ogee rings connecting the furnaces to the shell in vertical auxiliary boilers (see Fig 22), where the latter support the weight of the water above the furnace, is not to be less than the value t, in mm, given by the following formula:

$$t = [1,02 \cdot 10^{-3} \cdot p D_A \cdot (D_A - d_A)]^{0,5} + 1$$

where:

p : Design pressure, in MPa

$D_A$  : Inside diameter of boiler shell, in mm

$d_A$  : Inside diameter of the lower part of the furnace where it joins the ogee ring, in mm.

**Figure 22 : Ogee ring**

**2.12.5 Fire tubes**

- a) The thickness of fire tubes subject to external pressure in cylindrical boilers is not to be less than the value t, in mm, calculated by the following formula:

$$t = \frac{pd}{0,15R_m} + 1,8$$

where:

p : Design pressure, in MPa

d : Outside diameter of tube, in mm

$R_m$  : Minimum ultimate tensile strength of the tube material, in N/mm<sup>2</sup>.

The minimum acceptable thickness is given in Tab 16.

- b) The values of t determined by the above-mentioned formula are to be considered as theoretical values for straight tubes, not taking account of the manufacturing tolerance. Where the tubes are not sized precision tubes, the thickness calculated by the formula in a) is to be increased by 12,5% to take into account the manufacturing tolerance. In the case of bent tubes, the thickness of the thinner part in way of the bend is not to be less than that given by the above formula.
- c) Whenever abnormal corrosion and erosion may occur during service the corrosion constant of 1,8 in the formula may be increased to the satisfaction of the Society.

**Table 16 : Minimum thickness of fire tubes**

Nominal outside diameter	Lowest nominal thickness t
$d \leq 88,9$	3,00
$88,9 < d \leq 114,3$	3,15
$114,3 < d \leq 139,7$	3,50
$139,7 < d \leq 168,3$	3,99

**2.12.6 Furnaces general points**

a) Thermal design of furnace tubes.

The heat input for a given furnace tube inside diameter is not to exceed a value compatible with the chosen design temperature. Burners with a fixed firing rate are not to be used for heat inputs exceeding 1 MW per furnace tube.

- b) The minimum thickness of furnaces is to be calculated for elastic buckling and plastic deformation in accordance with the requirements of a Standard for pressure vessels subject to external pressure accepted by the Society.
- c) However, the minimum thicknesses of furnaces and cylindrical ends of combustion chambers of fire tube boilers are to be not less than the value t given by the appropriate formulae in [2.12.7], [2.12.8] and [2.12.9].
- d) The thickness of furnaces is not to be less than 8 mm for plain furnace and 10 mm for corrugated furnace and the stays are to be spaced such that the thickness does not exceed 22 mm.
- e) All the thicknesses obtained for furnaces by the formulae in [2.12.7], [2.12.8], [2.12.9] and [2.12.4] are “net” thicknesses, as they do not include any corrosion allowance. The thicknesses obtained by the above formulae are to be increased by 1 mm. See also [2.4.7].

**2.12.7 Plain furnace tubes**

a) Plain furnace tube

The minimum thickness t of plain cylindrical furnaces is to be not less than the greater value, in mm, obtained from the following formulae:

$$t = \frac{B}{2} \left[ 1 + \sqrt{1 + \frac{0,12D \cdot u}{(1 + 5D/L)B}} \right]$$

$$t = D^{0,6} [(LS_2p)/(2,6E)]^{0,4}$$

where:

$$B = \frac{pDS_1}{2R_{s,MIN,T}(1 + 0,1D/L)}$$

$S_1$  : Safety factor, equal to 2,5

L : Unstayed length of furnace, in mm

u : Departure from circularity, in %, equal to:

$$u = \frac{2(D_{max} - D_{min})}{D_{max} + D_{min}} \times 100$$

u is to be taken as 1,5% for plain furnace tubes

$S_2$  : Safety factor for buckling, equal to:

- 3 for  $u \leq 1,5\%$
- 4 for  $1,5\% < u \leq 2\%$

E : Elastic modulus, in MPa, at design temperature T, in °C, and equal to:

$$E = 208800 - 93,4 T$$

b) Stiffeners

Stiffeners welded to furnaces tubes according to a standard accepted by the Society may be considered as providing effective stiffening (reduction of L in upper formulae).

**2.12.8 Corrugated furnace tubes**

The minimum thickness of corrugated furnace tubes, in mm, is to be determined by:

$$t = \frac{pD_E}{0,26R_m}$$

where:

$D_E$  : External diameter of the furnace, in mm, measured at the bottom of the corrugation.

This formula apply for Fox and Morisson type furnaces tubes. The scantling of furnaces of other types and the use of stiffeners are to be especially considered by the Society.

**2.12.9 Hemispherical furnaces**

The minimum thickness  $t$ , in mm, of hemispherical furnaces is not to be less than the value given by the following equation:

$$t = \frac{pD_E}{120}$$

**2.13 Bottles containing pressurised gases**

**2.13.1 General**

- a) The following requirements apply to bottles intended to contain pressurised and/or liquefied gases at ambient temperature, made by seamless manufacturing processes.
- b) In general, such bottles are to have an outside diameter not exceeding 420 mm, a length not exceeding 2000 mm and capacity not exceeding 150 litres (see also [3.4.1]).
- c) For bottles exceeding the above capacity and dimensions, the following requirements may be applied at the discretion of the Society.

**2.13.2 Cylindrical shell**

The wall thickness of the cylindrical shell is not to be less than the value  $t$ , in mm, determined by the following formula:

$$t = \frac{p_H D_E}{2K + p_H}$$

where:

$p_H$  : Hydrostatic test pressure, in MPa. This pressure is to be taken as 1,5 times the setting pressure of the safety valves with the following exceptions:

- in addition, for CO<sub>2</sub> bottles, this pressure is not to be less than 25 MPa
- for refrigerants, the value of hydrostatic test pressure is given in Part F, Chapter 7

$D_E$  : Outside diameter of tube, in mm

$$K = R_{S,MIN} / 1,3$$

$R_{S,MIN}$  : Value of the minimum yield strength ( $R_{eH}$ ), or 0,2% proof stress ( $R_{p0,2}$ ), at the ambient temperature, in N/mm<sup>2</sup>. In no case is the value  $R_{S,MIN}$  to exceed:

- 0,75  $R_m$  for normalised steels
- 0,90  $R_m$  for quenched and tempered steels.

**2.13.3 Dished heads**

Dished ends are to comply with the following requirements:

- a) Hemispherical ends: the thickness of the ends is to be not less than the thickness calculated for spherical shells in accordance with [2.4.4]
- b) Convex ends: see Fig 23
- c) Concave base ends: see Fig 24
- d) Ends with openings: see Fig 25
- e) Other types of ends are to be specially considered by the Society.

**Figure 23 : Dished convex ends**

Figure 24 : Dished concave ends

Figure 25 : Heads with openings

## 2.14 Heat exchangers

### 2.14.1 Scantlings

- a) Vessels are to be designed in accordance with the applicable requirements stated in [2.4] and [2.5].
- b) Tubes are to be designed in accordance with [2.10.1].
- c) Tube plates are to be designed in accordance with a standard accepted by the Society.

### 2.14.2 Thermal oil heat exchangers

The provisions of [2.14.1] apply also to thermal oil heat exchangers. However, irrespective of the thickness obtained by the formula in [2.10.1], the tube thickness of oil fired and exhaust fired thermal oil heaters is to be not less than the values indicated in Tab 17.

Table 17 : Minimum thickness of thermal oil heat exchanger tubes

Outside diameter, in mm	Minimum thickness, in mm, of tubes subject to internal pressure of oil fired and exhaust fired thermal oil heaters
< 63,5	2,4
70 - 89	2,9
> 89	3,6

### 3 Design and construction - Equipment

#### 3.1 All pressure vessels

##### 3.1.1 Drainage

- a) Each air pressure vessel is to be fitted with a drainage device allowing the evacuation of any oil or water accumulated in the vessel.
- b) Drainage devices are also to be fitted on other vessels, in particular steam vessels, in which condensation water is likely to accumulate.

#### 3.2 Boilers and steam generators

##### 3.2.1 Safety valve arrangement

- a) Every steam boiler and every steam generator with a total heating surface of 50 m<sup>2</sup> and above is to be provided with not less than two spring loaded safety valves of adequate capacity. For steam boilers and steam generators having heating surface less than 50 m<sup>2</sup>, only one safety valve need be fitted.
- b) Where a superheater is an integral part of the boiler, at least one safety valve is to be located on the steam drum and at least one at the superheater outlet. The valves fitted at the superheater outlet may be considered as part of the boiler safety valves required in item a), provided that their capacity does not account for more than 25% of the total capacity required in [3.2.2], unless specially considered by the Society.
- c) Where fitted, superheaters which may be shut-off from the boiler are to be provided with at least one safety valve; such valve(s) cannot be considered as part of the boiler safety valves required in item a).
- d) In the case of boilers fitted with a separate steam accumulator, safety valves may be fitted on the accumulator if no shut-off is provided between it and the boiler and if the connecting pipe is of a size sufficient to allow the whole steam production to pass through, without increasing the boiler pressure more than 10% above the design pressure.

##### 3.2.2 Relieving capacity of safety valves

- a) The relieving capacity of each safety valve Q, in kg/h, is to be determined by the appropriate formula below in order that:

$$Q \geq W$$

- saturated steam:

$$Q = \frac{C \cdot A \cdot (10 \cdot P + 1,05)}{100}$$

- superheated steam:

$$Q = \frac{C \cdot A \cdot (10 \cdot P + 1,05)}{100} \times \sqrt{\frac{V}{V_s}}$$

where:

W : Maximum steam production, in kg/h, as defined by the maximum power of the heating equipment; otherwise the value of W is to be based on evaporating capacities (referring to evaporating surfaces of the boiler concerned) less than the following:

- 14 kg/(m<sup>2</sup>·h) for exhaust gas heated boilers
- 29 kg/(m<sup>2</sup>·h) for oil fired boilers
- 60 kg/(m<sup>2</sup>·h) for water walls of oil fired boilers

A : Aggregate area, in mm<sup>2</sup>, of the orifices in way of the seat of the valve, deducting the obstructions corresponding to the guides and the conformation of the valve in full lift position

p : Maximum working pressure of the boiler or other steam generator, in MPa. For superheated steam safety valves, P is to be the pressure at the superheater outlet

C : Coefficient with the following values:

- 4,8 for ordinary safety valves, i.e. where the valve lift is at least 1/24 of the internal diameter of the seat
- 10 for high lift safety valves, i.e. where the valve lift is at least 1/12 of the internal diameter of the seat
- 20 for full lift safety valves, i.e. where the valve lift is at least 1/4 of the internal diameter of the valve

Higher values of coefficient C may be admitted for safety valves of approved type and having undergone, in the presence of the Surveyor or according to a procedure considered as equivalent by the Society, capacity tests with conditions of pressure and temperature comparable to those of the plant considered. In such a case, coefficient C is to be, as a rule, taken as 90% of the resulting value from the capacity test

- $v$  : Specific volume of saturated steam at the pressure corresponding to the superheater outlet
- $v_s$  : Specific volume of superheated steam at the temperature corresponding to the superheater outlet.
- b) When the safety valves are fitted at the superheater outlet. Their relieving capacity is to be such that, during the discharge of safety valves, a sufficient quantity of steam is circulated through the superheater to avoid damage.
- c) The orifice diameter in way of the safety valves seat is not to be less than 40 mm. Where only one safety valve need be fitted, the orifice minimum diameter is not to be less than 50 mm. Valves of large relieving capacity with 15 mm minimum diameter may be accepted for boilers with steam production not exceeding 2000 kg/h.
- d) Independently of the above requirements, the aggregate capacity of the safety valves is to be such as to discharge all the steam that can be generated without causing a transient pressure rise of more than 10% over the design pressure.

### 3.2.3 Miscellaneous safety valve requirements

- a) Safety valves operated by pilot valves

The arrangement on the superheater of large relieving capacity safety valves, operated by pilot valves fitted in the saturated steam drum, is to be specially considered by the Society.

- b) Safety valve setting

- safety valves are to be set under steam in the presence of the Surveyor to a pressure not higher than 1,03 times the design pressure
- safety valves are to be so constructed that their setting may not be increased in service and their spring may not be expelled in the event of failure. In addition, safety valves are to be provided with simple means of lifting the plug from its seat from a safe position in the boiler or engine room
- where safety valves are provided with means for regulating their relieving capacity, they are to be so fitted that their setting cannot be modified when the valves are removed for surveys.

- c) Safety valve fitting on boiler

- the safety valves of a boiler are to be directly connected to the boiler and separated from other valve bodies
- where it is not possible to fit the safety valves directly on the superheater headers, they are to be mounted on a strong nozzle fitted as close as practicable to the superheater outlet. The cross-sectional area for passage of steam through restricted orifices of the nozzles is not to be less than 1/2 the aggregate area of the valves, calculated with the formulae of [2.3.2] when  $C \leq 10$ , and not less than the aggregate area of the valves when  $C > 10$
- safety valve bodies are to be fitted with drain pipes of a diameter not less than 20 mm for double valves, and not less than 12 mm for single valves, leading to the bilge or to the hot well. Valves or cocks are not to be fitted on drain pipes.

- d) Exhaust pipes

- the minimum cross-sectional area of the exhaust pipes of safety valves which have not been experimentally tested is not to be less than  $C$  times the aggregate area  $A$
- the cross-sectional area of the exhaust manifold of safety valves is to be not less than the sum of the areas of the individual exhaust pipes connected to it
- silencers fitted on exhaust manifolds are to have a free passage area not less than that of the manifolds
- the strength of exhaust manifolds and pipes and associated silencers is to be such that they can withstand the maximum pressure to which they may be subjected, which is to be assumed not less than 1/4 of the safety valve setting pressure
- in the case that the discharges from two or more valves are led to the same exhaust manifold, provision is to be made to avoid the back pressure from the valve which is discharging influencing the other valves
- exhaust manifolds are to be led to the open and are to be adequately supported and fitted with suitable expansion joints or other means so that their weight does not place an unacceptable load on the safety valve bodies.

- e) Steam generator heated by steam

Steam heated steam generators are also to be protected against possible damage resulting from failure of the heating coils. In this case, the area of safety valves calculated as stated in [3.2.2] may need to be increased to the satisfaction of the Society, unless suitable devices limiting the flow of steam in the heating coils are provided.

### 3.2.4 Access arrangement

- a) Boilers are to be provided with openings in sufficient number and size to permit internal examination, cleaning and maintenance operations. In general, all pressure vessels which are part of a boiler with inside diameter exceeding 1200 mm, and those with inside diameter exceeding 800 mm and length exceeding 2000 mm, are to be provided with access manholes.
- b) Manholes are to be provided in suitable locations in the shells, headers, domes, and steam and water drums, as applicable. The "net" (actual hole) dimension of elliptical or similar manholes is to be not less than 300mm x 400mm. The "net" diameter of circular manholes (actual hole) cannot be less than 400 mm. The edges of manholes are to be adequately strengthened to provide compensation for vessel openings in accordance with [2.8.4], [2.8.6] and [2.8.9], as applicable.

- c) In pressure vessels which are part of a boiler and are not covered by the requirement in item a) above, or where an access manhole cannot be fitted, at least the following openings are to be provided, as far as practicable:
- head holes: minimum dimensions:  
220mm x 320mm (320 mm diameter if circular)
  - handholes: minimum dimensions: 87mm x 103mm
  - sight holes: minimum diameter: 50 mm.
- d) Sight holes may only be provided when the arrangement of manholes, head holes, or handholes is impracticable.
- e) Covers for manholes and other openings are to be made of ductile steel, dished or welded steel plates or other approved design. Grey cast iron may be used only for small openings, such as handholes and sight holes, provided the design pressure  $p$  does not exceed 1 MPa and the design temperature  $T$  does not exceed 220°C.
- f) Covers are to be of self-closing internal type. Small opening covers of other type may be accepted by the Society on a case by case basis.
- g) Covers of the internal type are to have a spigot passing through the opening. The clearance between the spigot and the edge of the opening is to be uniform for the whole periphery of the opening and is not to exceed 1,5 mm.
- h) Closing devices of internal type covers, having dimensions not exceeding 180mm x 230mm, may be fitted with a single fastening bolt or stud. Larger closing devices are to be fitted with at least two bolts or studs.
- i) Covers are to be designed so as to prevent the dislocation of the required gasket by the internal pressure. Only continuous ring gaskets may be used for packing.

### **3.2.5 Fittings**

- a) In general, cocks and valves are to be designed in accordance with the requirements in Ch 1, Sec 10, [2.7.2].
- b) Cocks, valves and other fittings are to be connected directly or as close as possible to the boiler shell.
- c) Cocks and valves for boilers are to be arranged in such a way that it can be easily seen when they are open or closed and so that their closing is obtained by a clockwise rotation of the actuating mechanism.

### **3.2.6 Boiler burners**

Burners are to be arranged so that they cannot be withdrawn unless the fuel supply to the burners is cut off.

### **3.2.7 Allowable water levels**

- a) In general, for water tube boilers the lowest permissible water level is just above the top row of tubes when the water is cold. Where the boiler is designed not to have fully submerged tubes, when the water is cold, the lowest allowable level indicated by the manufacturer is to be indicated on the drawings and submitted to the Society for consideration.
- b) For fire tube boilers with combustion chamber integral with the boiler, the minimum allowable level is to be at least 50 mm above the highest part of the combustion chamber.
- c) For vertical fire tube boilers the minimum allowable level is 1/2 of the length of the tubes above the lower tube sheet.

### **3.2.8 Steam outlets**

- a) Each boiler steam outlet, if not serving safety valves, integral superheaters and other appliances which are to have permanent steam supply during boiler operation, is to be fitted with an isolating valve secured either directly to the boiler shell or to a standpipe of substantial thickness, as short as possible, and secured directly to the boiler shell.
- b) The number of auxiliary steam outlets is to be reduced to a minimum for each boiler.
- c) Where several boilers supply steam to common mains, the arrangement of valves is to be such that it is possible to positively isolate each boiler for inspection and maintenance. In addition, for water tube boilers, non-return devices are to be fitted on the steam outlets of each boiler.
- d) Where steam is used for essential auxiliaries (such as whistles, steam operated steering gears, steam operated electric generators, etc.) and when several boilers are fitted on board, it is to be possible to supply steam to these auxiliaries with any one of these boilers out of operation.
- e) Each steam stop valve exceeding 150 mm nominal diameter is to be fitted with a bypass valve.

### **3.2.9 Feed check valves**

- a) Each fired boiler supplying steam to essential services is to be fitted with at least two feed check valves connected to two separate feed lines. For unfired steam generators a single feed check valve may be allowed.
- b) Feed check valves are to be secured directly to the boiler or to an integral economiser. Water inlets are to be separated. Where, however, feed check valves are secured to an economiser, a single water inlet may be allowed provided that each feed line can be isolated without stopping the supply of feed water to the boiler.
- c) Where the economisers may be bypassed and cut off from the boiler, they are to be fitted with pressure-limiting type valves, unless the arrangement is such that excessive pressure cannot occur in the economiser when cut off.
- d) Feed check valves are to be fitted with control devices operable from the stokehold floor or from another appropriate location. In addition, for water tube boilers, at least one of the feed check valves is to be arranged so as to permit automatic control of the water level in the boiler.
- e) Provision is to be made to prevent the feed water from getting in direct contact with the heated surfaces inside the boiler and to reduce, as far as possible and necessary, the thermal stresses in the walls.

### **3.2.10 Drains**

Each superheater, whether or not integral with the boiler, is to be fitted with cocks or valves so arranged that it is possible to drain it completely.

### **3.2.11 Water sample**

- a) *Every boiler is to be provided with means to supervise and control the quality of the feed water. Suitable arrangements are to be provided to preclude, as far as practicable, the entry of oil or other contaminants which may adversely affect the boiler.*
- b) For this purpose, boilers are to be fitted with at least one water sample cock or valve. This device is not to be connected to the water level standpipes.
- c) Suitable inlets for water additives are to be provided in each boiler.

### **3.2.12 Marking of boilers**

- a) Each boiler is to be fitted with a permanently attached plate made of non-corrosive metal, with indication of the following information, in addition to the identification marks (name of manufacturer, year and serial number):
  - the design pressure
  - the design temperature
  - the test pressure and the date of the test.
- b) Markings may be directly stamped on the vessel if this does not produce notches having an adverse influence on its behaviour in service.
- c) For lagged vessels, these markings are also to appear on a similar plate fitted above the lagging.

## **3.3 Thermal oil heaters and thermal oil installation**

### **3.3.1 General**

- a) The following requirements apply to thermal oil heaters in which organic liquids (thermal oils) are heated by oil fired burners, exhaust gases or electricity to temperatures below their initial boiling point at atmospheric pressure.
- b) Thermal oils are only to be used within the limits set by the manufacturer.
- c) Means are to be provided for manual operation. During manual operation, the automated functioning of at least the temperature control device on the thermal oil side as well as the flow monitoring is to be maintained.
- d) Means are to be provided to take samples of thermal oil.

### **3.3.2 Thermal oil heater design**

- a) Heaters are to be so constructed that neither the surfaces nor the thermal oil becomes excessively heated at any point. The flow of the thermal oil is to be ensured by forced circulation.
- b) The surfaces which come into contact with the thermal oil are to be designed for the design pressure, subject to the minimum pressure of 1 MPa.
- c) Copper and copper alloys are not permitted.
- d) Heaters heated by exhaust gas are to be provided with inspection openings at the exhaust gas intake and outlet.
- e) Oil fired heaters are to be provided with inspection openings for examination of the combustion chamber. The opening for the burner may be considered as an inspection opening, provided its size is sufficient for this purpose.
- f) Heaters are to be fitted with means enabling them to be completely drained.
- g) Thermal oil heaters heated by exhaust gas are to be fitted with a permanent system for extinguishing and cooling in the event of fire, for instance a pressure water spraying system.

### **3.3.3 Safety valves of thermal oil heaters**

Each heater is to be equipped with at least one safety valve having a discharge capacity at least equal to the increase in volume of the thermal oil at the maximum heating power. During discharge the pressure may not increase above 10% over the design pressure.

### **3.3.4 Pressure vessels of thermal oil heaters**

The design pressure of all vessels which are part of a thermal oil system, including those open to the atmosphere, is to be taken not less than 0,2 MPa.

### **3.3.5 Equipment of the expansion, storage and drain tanks**

For the equipment to be installed on expansion, storage and drain tanks, see Ch 1, Sec 10, [13].

### **3.3.6 Marking**

Each thermal oil heater and other pressure vessels which are part of a thermal oil installation are to be fitted with a permanently attached plate made of non-corrosive metal, with indication of the following information, in addition to the identification marks (name of manufacturer, year and serial number):

- Heaters
  - maximum allowable heating power
  - design pressure
  - maximum allowable discharge temperature
  - minimum flow rate
  - liquid capacity
- Vessels
  - design pressure
  - design temperature
  - capacity.

## **3.4 Special types of pressure vessels**

### **3.4.1 Seamless pressure vessels (bottles)**

Each bottle is to be marked with the following information:

- name or trade name of the manufacturer
- serial number
- type of gas
- capacity
- test pressure
- empty weight
- test stamp.

### **3.4.2 Steam condensers**

- a) The water chambers and steam spaces are to be fitted with doors for inspection and cleaning.
- b) Where necessary, suitable diaphragms are to be fitted for supporting tubes.
- c) Condenser tubes are to be removable.
- d) High speed steam flow, where present, is to be prevented from directly striking the tubes by means of suitable baffles.
- e) Suitable precautions are to be taken in order to avoid corrosion on the circulating water side and to provide an efficient grounding.

## **3.5 Other pressure vessels**

### **3.5.1 Safety valves arrangement**

- a) General:
  - pressure vessels which are part of a system are to be provided with safety valves, or equivalent devices, if they are liable to be isolated from the system safety devices. This provision is also to be made in all cases in which the vessel pressure can rise, for any reason, above the design pressure
  - in particular, air pressure vessels which can be isolated from the safety valves ensuring their protection in normal service are to be fitted with another safety device, such as a rupture disc or a fusible plug, in order to ensure their discharge in case of fire. This device is to discharge to the open
  - safety devices ensuring protection of pressure vessels in normal service are to be rated to operate before the pressure exceeds the maximum working pressure by more than 5%
  - where two or more pressure vessels are interconnected by a piping system of adequate size so that no branch of piping may be shut off, it is sufficient to provide them with one safety valve and one pressure gauge only.

b) Heat exchangers

Special attention is to be paid to the protection against overpressure of vessels, such as heat exchangers, which have parts that are designed for a pressure which is below that to which they might be subjected in the case of rupture of the tubular bundles or coils contained therein and that have been designed for a higher pressure.

**3.5.2 Other requirements**

a) Access arrangement

The access requirements for boilers stated in [3.2.4] are also applicable for other pressure vessels.

b) Corrosion protection

Vessels and equipment containing media that might lead to accelerated corrosion are to be suitably protected.

c) Marking:

- each pressure vessel is to be fitted with a permanently attached plate made of non-corrosive metal, with indication of the following information, in addition to the identification marks (name of manufacturer, year and serial number):
  - the design pressure
  - the design temperature
  - the test pressure and the date of the test
- markings may be directly stamped on the vessel if this does not produce notches having an adverse influence on its behaviour in service
- for smaller pressure vessels the indication of the design pressure only may be sufficient.

## **4 Design and construction - Fabrication and welding**

### **4.1 General**

#### **4.1.1 Base materials**

- a) These requirements apply to boilers and pressure vessels made of steel of weldable quality.
- b) Fabrication and welding of vessels made of other materials are to be the subject of special consideration.

#### **4.1.2 Welding**

- a) Weldings are to be performed in accordance with welding procedures approved by the Society.
- b) Manual and semi-automatic welding is to be performed by welders qualified by the Society.
- c) The conditions under which the welding procedures, welding equipment and welders operate are to correspond to those specified in the relevant approvals or qualifications.
- d) Both ordinary and special electric arc welding processes are covered in the following requirements.

#### **4.1.3 Cutting of plates**

- a) Plates are to be cut by flame cutting, mechanical machining or a combination of both processes. For plates having a thickness less than 25 mm, cold shearing is admitted provided that the sheared edge is removed by machining or grinding for a distance of at least one quarter of the plate thickness with a minimum of 3 mm.
- b) For flame cutting of alloy steel plates, preheating is to be carried out if necessary.
- c) The edges of cut plates are to be examined for laminations, cracks or any other defect detrimental to their use.

#### **4.1.4 Forming of plates**

- a) The forming processes are to be such as not to impair the quality of the material. The Society reserves the right to require the execution of tests to demonstrate the suitability of the processes adopted. Forming by hammering is not allowed.
- b) Unless otherwise justified, cold formed shells are to undergo an appropriate heat treatment if the ratio of internal diameter after forming to plate thickness is less than 20. This heat treatment may be carried out after welding.
- c) Before or after welding, hot formed plates are to be normalised or subjected to another treatment suitable for their steel grade, if hot forming has not been carried out within an adequate temperature range.
- d) Plates which have been previously butt-welded may be formed under the following conditions:

- Hot forming

After forming, the welded joints are to be subjected to X-ray examination or equivalent. In addition, mechanical tests of a sample weld subjected to the same heat treatment are to be carried out.

- Cold forming

Cold forming is only allowed for plates having a thickness not exceeding:

- 20 mm for steels having minimum ultimate tensile strength  $R_m$  between 360 N/mm<sup>2</sup> and 410 N/mm<sup>2</sup>
- 15 mm for steels having  $R_m$  between 460 N/mm<sup>2</sup> and 510 N/mm<sup>2</sup> as well as for steels 0,3Mo, 1Mn0,5Mo, 1Mn0,5MoV and 0,5Cr0,5Mo.

Cold forming is not allowed for steels 1Cr0,5Mo and 2,25Cr1Mo.

- Weld reinforcements are to be carefully ground smooth prior to forming.
- A proper heat treatment is to be carried out after forming, if the ratio of internal diameter to thickness is less than 36, for steels: 460 N/mm<sup>2</sup>, 510 N/mm<sup>2</sup>, 0,3Mo, 1Mn0,5Mo, 1Mn0,5MoV and 0,5Cr0,5Mo.
- After forming, the joints are to be subjected to X-ray examination or equivalent and to a magnetic particle or liquid penetrant test.
- Refer to Fig 26 for definition of thickness to be taken in account.

## 4.2 Welding design

### 4.2.1 Main welded joints

- a) All joints of class 1 and 2 pressure parts of boilers and pressure vessels are to be butt-welded, with the exception of welding connecting flat heads or tube sheets to shells, for which partial penetration welds or fillet welds may be accepted.

Fig 26 show examples of acceptable welding for class 1 and 2 pressure vessels.

- b) Joints of class 3 pressure vessels are also subject to the requirement in a), however connection of dished heads to shells by lap welds may be accepted. Fig 27 shows some acceptable details of circumferential lap welds for class 3 pressure vessels.

### 4.2.2 Shell longitudinal and circumferential welds

Longitudinal and circumferential joints are to be welded from both sides of the plate. Welding from one side may be allowed only when there is evidence that the welding process permits a complete penetration and a sound weld root. If a backing strip is used, it is to be removed after welding and prior to any non-destructive examination. However, the backing strip may be retained in circumferential joints of class 2 vessels, having a thickness not exceeding 15 mm, and of class 3 vessels, provided that the material of the backing strip is such as not to adversely affect the weld.

**Figure 26 : Example of acceptable joints and thickness to be considered for forming and post-weld heat treatment**

Key

- 1 : Nozzle (set in); 2 : Flange; 3 : Nozzle (set on); 4 : Reinforcing plate; 5 : Non-pressure part;  
 6 : Pad (set in); 7 : Pad (set on); 8 : Manhole frame; 9 : Flat plate.

Figure 27 : Example of acceptable lap-joints

Details (b) and (c) may be used only for pressure vessels having internal diameter less than 600mm.

#### 4.2.3 Plates of unequal thickness

- If plates of unequal thickness are butt-welded and the difference between thicknesses is more than 3 mm, the thicker plate is to be smoothly tapered for a length equal to at least four times the offset, including the width of the weld. For longitudinal joints the tapering is to be made symmetrically on both sides of the plate in order to obtain alignment of middle lines.
- If the joint is to undergo radiographic examination, the thickness of the thicker plate is to be reduced to that of the thinner plate next to the joint and for a length of at least 30 mm.

#### 4.2.4 Dished heads

- For connection of a hemispherical end with a cylindrical shell, the joint is to be arranged in a plane parallel to that of the largest circle perpendicular to the axis of the shell and at such a distance from this plane that the tapering of the shell made as indicated in [2.5.6] is wholly in the hemisphere.
- For torispherical ends made of parts assembled by welding, no welded joint is normally admitted along a parallel in the knuckle nor at a distance less than 50 mm from the beginning of the knuckle.

#### 4.2.5 Welding location

The location of main welded joints is to be chosen so that these joints are not submitted to appreciable bending stresses.

#### 4.2.6 Accessories and nozzles

- Attachment of accessories by welds crossing main welds or located near such welds is to be avoided; where this is impracticable, welds for attachment of accessories are to completely cross the main welds rather than stop abruptly on or near them.
- Openings crossing main joints or located near main joints are also to be avoided as far as possible.
- Doubling plates for attachment of accessories such as fixing lugs or supports are to be of sufficient size to ensure an adequate distribution of loads on pressure parts; such doubling plates are to have well rounded corners. Attachment of accessories such as ladders and platforms directly on the walls of vessels such that they restrain their free contraction or expansion is to be avoided.
- Welded connections of nozzles and other fittings, either with or without local compensation, are to be of a suitable type, size and preparation in accordance with the approved plans.

#### 4.2.7 Connections of stays to tube plates

- Where stays are welded, the cross-sectional area of the weld is to be at least 1,25 times the cross-section of the stay.
- The cross-sectional area of the end welding of welded stay tubes is to be not less than 1,25 times the cross-sectional area of the stay tube.

#### 4.2.8 Type of weldings

Fig 28, Fig 29, Fig 30, Fig 31, Fig 32, Fig 33, Fig 34, Fig 35, Fig 36 and Fig 37 indicate the type and size of weldings of typical pressure vessel connections. Any alternative type of welding or size is to be the subject of special consideration by the Society.

Figure 28 : Types of joints for unstayed flat heads (1)

Figure 29 : Types of joints for unstayed flat heads (2)

Figure 30 : Types of joints for nozzles and reinforced rings (1)

Figure 31 : Types of joints for nozzles and reinforcing rings (2)

Figure 32 : Types of joints for nozzles and reinforcing rings (3)

Figure 33 : Types of joints for nozzles (4)

Note: Where preparations of Fig 33 are carried out, the shell is to be carefully inspected to ascertain the absence of lamination.

Figure 34 : Types of joints for flanges to nozzles

Figure 35 : Types of joints for tubesheets to shell (1)

Figure 36 : Types of joints for tubesheets to shells (2)

Figure 37 : Type of joints for stays and stay tubes

### **4.3 Miscellaneous requirements for fabrication and welding**

#### **4.3.1 Welding position**

- a) As far as possible, welding is to be carried out in the downhand horizontal position and arrangements are to be foreseen so that this can be applied in the case of circumferential joints.
- b) When welding cannot be performed in this position, tests for qualification of the welding process and the welders are to take account thereof.

#### **4.3.2 Cleaning of parts to be welded**

- a) Parts to be welded are, for a distance of at least 25 mm from the welding edges, to be carefully cleaned in order to remove any foreign matter such as rust, scale, oil, grease and paint.
- b) If the weld metal is to be deposited on a previously welded surface, all slag or oxide is to be removed to prevent inclusions.

#### **4.3.3 Protection against adverse weather conditions**

- a) Welding of pressure vessels is to be done in a sheltered position free from draughts and protected from cold and rain.
- b) Unless special justification is provided, no welding is to be performed if the temperature of the base metal is less than 0°C.

#### **4.3.4 Interruption in welding**

If, for any reason, welding is stopped, care is to be taken on restarting to obtain a complete fusion.

#### **4.3.5 Backing weld**

When a backing weld is foreseen, it is to be carried out after suitable chiseling or chipping at the root of the first weld, unless the welding process applied does not call for such an operation.

#### **4.3.6 Appearance of welded joints**

- a) Welded joints are to have a smooth surface without under-thickness; their connection with the plate surface is to be gradual without undercutting or similar defects.
- b) The weld reinforcement of butt welds, on each side of the plate, is not to exceed the following thickness:
  - 2,5 mm for plates having a thickness not exceeding 12 mm
  - 3 mm for plates having a thickness greater than 12 mm but less than 25 mm
  - 5 mm for plates having a thickness at least equal to 25 mm.

### **4.4 Preparation of parts to be welded**

#### **4.4.1 Preparation of edges for welding**

- a) Grooves and other preparations of edges for welding are to be made by machining, chipping or grinding. Flame cutting may also be used provided that the zones damaged by this operation are removed by machining, chipping or grinding. For alloy steel plates, preheating is to be provided, if needed, for flame cutting.
- b) Edges prepared are to be carefully examined to check that there are no defects detrimental to welding.

#### **4.4.2 Abutting of parts to be welded**

- a) Abutting of parts to be welded is to be such that surface misalignment of plates does not exceed:
  - 10% of the thickness of the plate with a maximum of 3 mm for longitudinal joints
  - 10% of the thickness of the plate plus 1 mm with a maximum of 4 mm for circumferential joints.
- b) For longitudinal joints, middle lines are to be in alignment within 10% of the thickness of the thinner plate with a maximum of 3 mm.
- c) Plates to be welded are to be suitably retained in position in order to limit deformation during welding. The arrangements are to be such as to avoid modification of the relative position of parts to be welded and misalignment, after welding, exceeding the limits indicated above.
- d) Temporary welds for abutting are to be carried out so that there is no risk of damage to vessel shells. Such welds are to be carefully removed after welding of the vessel and before any heat treatment. Non-destructive testing of the corresponding zones of the shell may be required by the Surveyor if considered necessary.
- e) Accessories such as doubling plates, brackets and stiffeners are to be suitable for the surface to which they are to be attached.

### **4.5 Tolerances after construction**

#### **4.5.1 General**

The sizes and shape of vessels are to be checked after welding for compliance with the design taking into account the tolerances given below. The Society reserves the right to stipulate smaller values for these tolerances for vessels subjected to special loads.

Any defect in shape is to be gradual and there is to be no flat area in way of welded joints.

Measurements are to be taken on the surface of the parent plate and not on the weld or other raised part.

#### **4.5.2 Straightness**

The straightness of cylindrical shells is to be such that their deviation from the straight line does not exceed 0,6% of their length, with a maximum of 15 mm for each 5 m of length.

#### **4.5.3 Out-of-roundness**

- a) Out-of-roundness of cylindrical shells is to be measured either when set up on end or when laid flat on their sides; in the second case, measures of diameters are to be repeated after turning the shell through 90° about its axis and out-of-roundness is to be calculated from the average of the two measures of each diameter.
- b) For any transverse section, the difference between the maximum and minimum diameters is not to exceed 1% of the nominal diameter  $D$  with a maximum of:  
 $(D + 1250) / 200$ ,  $D$  being expressed in mm.

For large pressure vessels, this limit may be increased by a maximum of 0,2% of the internal diameter of the vessel. Any possible out-of-roundness within the above limit is to be gradual and there are to be no localised deformations in way of the welded joints.

#### **4.5.4 Irregularities**

Irregularities in profile of cylindrical shells, checked by a 20° gauge, are not to exceed 5% of the thickness of the plate plus 3 mm. This value may be increased by 25% if the length of the irregularity does not exceed one quarter of the distance between two circumferential seams, with a maximum of 1 mm.

### **4.6 Preheating**

#### **4.6.1**

- a) Preheating, to be effectively maintained during the welding operation, may be required by the Society when deemed necessary in relation to a number of circumstances, such as the type of steel, thickness of the base material, welding procedure and technique, type of restraint, and heat treatment after welding, if any.
- b) The preheating temperature is to be determined accordingly. However, a preheating temperature of approximately 150°C is required for 0,5Mo or 1Cr0,5Mo type steel, and approximately 250°C for 2,25Cr1Mo type steel.
- c) These requirements also apply to welding of nozzles, fittings, steam pipes and other pipes subject to severe conditions.

### **4.7 Post-weld heat treatment**

#### **4.7.1 General**

- a) When post-weld heat treatment of a vessel is to be carried out, such treatment is to consist of:
  - heating the vessel slowly and uniformly up to a temperature suitable for the grade of steel
  - maintaining this temperature for a duration determined in relation to the actual thickness  $t_A$  of the vessel and the grade of steel
  - slowly cooling the vessel in the furnace down to a temperature not exceeding 400°C, with subsequent cooling allowed out of the furnace in still air.
- b) As far as possible, vessels are to be heat treated in a single operation. However, when the sizes of the vessels are such that heat treatment requires several operations, care is to be taken such that all the parts of the vessels undergo heat treatment in a satisfactory manner. In particular, a cylindrical vessel of great length may be treated in sections in a furnace if the overlap of the heated sections is at least 1500 mm and if parts outside the furnace are lagged to limit the temperature gradient to an acceptable value.

#### **4.7.2 Thermal stress relieving**

Upon completion of all welding, including connections of nozzles, doublers and fittings, pressure vessels of classes 1 and 2, boilers and associated parts are to be subjected to an effective stress relieving heat treatment in the following cases:

- boilers and steam generators for thicknesses higher than 20 mm or, depending upon the type of steel, for lower thicknesses as required for class 1 pressure vessels.
- pressure vessels of classes 1 and 2 containing fluids at a temperature not less than the ambient temperature, where the thickness exceeds that indicated in Tab 18

Applications at temperatures less than the ambient temperature and/or steels other than those indicated above are to be the subject of special consideration by the Society.

Stress relieving heat treatment is not to be required when the minimum temperature of the fluid is at least 30°C higher than the KV-notch impact test temperature specified for the steel; this difference in temperature is also to be complied with for welded joints (both in heat-affected zones and in weld metal).

Pressure vessels and pipes of class 3 and associated parts are not required to be stress relieved, except in specific cases.

**Table 18 : Thermal stress relieving**

Grade	Thickness (mm) above which post-weld heat treatment is required	
	Boilers	Unfired pressure vessels
R <sub>m</sub> = 360 N/mm <sup>2</sup> Grade HA R <sub>m</sub> = 410 N/mm <sup>2</sup> Grade HA	14,5	14,5
R <sub>m</sub> = 360 N/mm <sup>2</sup> Grade HB R <sub>m</sub> = 410 N/mm <sup>2</sup> Grade HB	20	30
R <sub>m</sub> = 360 N/mm <sup>2</sup> Grade HD R <sub>m</sub> = 410 N/mm <sup>2</sup> Grade HD	20	38
R <sub>m</sub> = 460 N/mm <sup>2</sup> Grade HB R <sub>m</sub> = 510 N/mm <sup>2</sup> Grade HB	20	25
R <sub>m</sub> = 460 N/mm <sup>2</sup> Grade HD R <sub>m</sub> = 510 N/mm <sup>2</sup> Grade HD	20	35
0,3Mo 1Mn 0,5Mo 1Mn 0,5MoV 0,5Cr 0,5Mo	20	20
1Cr 0,5Mo 2,25Cr 1Mo	ALL	ALL

**4.7.3 Heat treatment procedure**

The temperature of the furnace at the time of introduction of the vessel is not to exceed 400°C.

- a) The heating rate above 400°C is not to exceed:
  - 220°C per hour if the maximum thickness is not more than 25 mm, or
  - (5500 / t<sub>A</sub>)°C per hour, with a minimum of 55°C per hour, if the maximum thickness t<sub>A</sub>, in mm, is more than 25 mm
- b) The cooling rate in the furnace is not to exceed:
  - -280°C per hour if the maximum thickness is not more than 25 mm, or
  - -(7000 / t<sub>A</sub>)°C per hour, with a minimum of -55°C per hour, if the maximum thickness t<sub>A</sub>, in mm, is more than 25 mm.

Unless specially justified, heat treatment temperatures and duration for maintaining these temperatures are to comply with the values in Tab 19.

**Table 19 : Heat treatment procedure**

Grade	Temperatures	Time per 25 mm of maximum thickness	Minimum time
Carbon steels	580-620°C	1 hour	1 hour
0,3Mo 1Mn 0,5Mo 1Mn 0,5MoV 0,5Cr 0,5Mo	620-660°C	1 hour	1 hour
1Cr 0,5Mo	620-660°C	1 hour	2 hours
2,25Cr 1Mo	600-750°C (1)	2 hours	2 hours
(1) The temperature is to be chosen, with a tolerance of ± 20°C, in this temperature range in order to obtain the required mechanical characteristics			

**4.7.4 Alternatives**

When, for special reasons, heat treatment is carried out in conditions other than those given in [4.7.2], all details regarding the proposed treatment are to be submitted to the Society, which reserves the right to require tests or further investigations in order to verify the efficiency of such treatment.

**4.7.5 Execution of heat treatment**

Furnaces for heat treatments are to be fitted with adequate means for controlling and recording temperature; temperatures are to be measured on the vessel itself. The atmosphere in the furnaces is to be controlled in order to avoid abnormal oxidation of the vessel.

#### **4.7.6 Treatment of test plates**

Test plates are normally to be heated at the same time and in the same furnace as the vessel.

When separate heat treatment of test plates cannot be avoided, all precautions are to be taken such that this treatment is carried out in the same way as for the vessel, specifically with regard to the heating rate, the maximum temperature, the duration for maintaining this temperature and the cooling conditions.

#### **4.7.7 Welding after heat treatment**

- a) Normally, welding after heat treatment is only allowed if:
  - the throat of welding fillets does not exceed 10 mm
  - the largest dimension of openings in the vessel for the accessories concerned does not exceed 50 mm.
- b) Any welding of branches, doubling plates and other accessories on boilers and pressure vessels after heat treatment is to be submitted for special examination by the Society.

### **4.8 Welding samples**

#### **4.8.1 Test plates for welded joints**

- a) Test plates of sufficient size, made of the same grade of steel as the shell plates, are to be fitted at each end of the longitudinal joints of each vessel so that the weld in the test plates is the continuation of these welded joints. There is to be no gap when passing from the deposited metal of the joint to the deposited metal of the test plate.
- b) No test plate is required for circumferential joints if these joints are made with the same process as longitudinal joints. Where this is not the case, or if there are only circumferential joints, at least one test plate is to be welded separately using the same welding process as for the circumferential joints, at the same time and with the same welding materials.
- c) Test plates are to be stiffened in order to reduce as far as possible warping during welding. The plates are to be straightened prior to their heat treatment which is to be carried out in the same conditions as for the corresponding vessel (see also [4.7.6]).
- d) After radiographic examination, the following test pieces are to be taken from the test plates:
  - one test piece for tensile test on welded joint
  - two test pieces for bend test, one direct and one reverse
  - three test pieces for impact test
  - one test piece for macrographic examination.

#### **4.8.2 Mechanical tests of test plates**

- a) The tensile strength on welded joint is not to be less than the minimum specified tensile strength of the plate.
- b) The bend test pieces are to be bent through an angle of 180° over a former of 4 times the thickness of the test piece. There is to be no crack or defect on the outer surface of the test piece exceeding in length 1,5 mm transversely or 3 mm longitudinally. Premature failure at the edges of the test piece is not to lead to rejection. As an alternative, the test pieces may be bent through an angle of 120° over a former of 3 times the thickness of the test piece.
- c) The Charpy V-notch impact test is to be made with specimens having the notch alternately located in the centre of the weld or in the heat affected zone (most critical location based on procedure qualification results). For austenitic stainless steel, all notches are to be in the centre of the weld. The impact energy is to be measured at the temperature prescribed for the base material being joined. The average impact energy values are not to be less than the values given in NR216 Materials for the steel grade concerned.
- d) The test piece for macrographic examination is to permit the examination of a complete transverse section of the weld. This examination is to demonstrate good penetration without lack of fusion, large inclusions and similar defects. In case of doubt, a micrographic examination of the doubtful zone may be required.

#### **4.8.3 Re-tests**

- a) If one of the test pieces yields unsatisfactory results, two similar test pieces are to be taken from another test plate.
- b) If the results for these new test pieces are satisfactory and if it is proved that the previous results were due to local or accidental defects, the results of the re-tests may be accepted.

### **4.9 Specific requirements for class 1 vessels**

#### **4.9.1 General**

The following requirements apply to class 1 pressure vessels, as well as to pressure vessels of other classes whose scantling has been determined using an efficiency of welded joint  $e$  greater than 0,90.

#### **4.9.2 Non-destructive tests**

- a) All longitudinal and circumferential joints of class 1 vessels are to be subject of 100% radiographic or equivalent examination with the following exceptions:
  - for pressure vessels or parts designed to withstand external pressures only, at the Society's discretion, the extent may be reduced up to approximately 30% of the length of the joints. In general, the positions included in the examinations are to include all welding crossings

- for vessels not intended to contain toxic or dangerous matters, made of carbon steels having thickness below 20 mm when the joints are welded by approved automatic processes at the Society's discretion, the extent may be reduced up to approximately 10% of the length of the joints. In general, the positions included in the examinations are to include all welding crossings
  - for circumferential joints having an external diameter not exceeding 175 mm, at the Society's discretion, the extent may be reduced up to approximately 10% of the total length of the joints.
- b) Fillet welds for parts such as doubling plates, branches or stiffeners are to undergo a spot magnetic particle test for at least 10% of their length. If magnetic particle tests cannot be used, it is to be replaced by liquid penetrant test.
- c) Welds for which non destructive tests reveal unacceptable defects, such as cracks or areas of incomplete fusion, are to be rewelded and are then to undergo a new non destructive examination

#### **4.9.3 Number of test samples**

- a) During production, at least one test plate for each 20 m of length (or fraction) of longitudinal weldings is to be tested as per [4.8.2].
- b) During production, at least one test plate for each 30 m of length (or fraction) of circumferential welding is to be tested as per [4.8.2].
- c) When several vessels made of plates of the same grade of steel, with thicknesses varying by not more than 5 mm, are welded successively, only one test plate may be accepted per each 20 m of length of longitudinal joints (or fraction) and per each 30 m of circumferential welding (or fraction) provided that the welders and the welding process are the same. The thickness of the test plates is to be the greatest thickness used for these vessels.

### **4.10 Specific requirements for class 2 vessels**

#### **4.10.1 General**

For vessels whose scantlings have been determined using an efficiency of welded joint  $e$  greater than 0,90, see [4.9.1].

#### **4.10.2 Non-destructive tests**

All longitudinal and circumferential joints of class 2 vessels are to be subjected to radiographic or equivalent examination to an extent of 10% of each weld length. This examination is to cover all the junctions between welds.

This extension may be increased at the Society's discretion depending on the actual thickness of the welded plates.

For actual thickness  $\leq 15$  mm, this examination can be omitted. In this case, the value of the efficiency should be as indicated in Tab 11.

#### **4.10.3 Number of test samples**

In general, the same requirements of [4.9.3] apply also to class 2 pressure vessels. However, test plates are required for each 50 m of longitudinal and circumferential weldings (or fraction).

### **4.11 Specific requirements for class 3 vessels**

- 4.11.1** For vessels whose scantlings have been determined using an efficiency of welded joint  $e$  greater than 0,90, see [4.9.1]. Heat treatment, mechanical tests and non-destructive tests are not required for welded joints of other class 3 vessels.

## **5 Design and construction - Control and monitoring**

### **5.1 Boiler control and monitoring system**

#### **5.1.1 Local control and monitoring**

Means to effectively operate, control and monitor the operation of oil fired boilers and their associated auxiliaries are to be provided locally. The functional condition of the fuel, feed water and steam systems and the boiler operational status are to be indicated by pressure gauges, temperature indicators, flow-meter, lights or other similar devices.

#### **5.1.2 Emergency shut-off**

Means are to be provided to shut down boiler forced draft or induced draft fans and fuel oil service pumps from outside the space where they are located, in the event that a fire in that space makes their local shut-off impossible.

**5.1.3 Water level indicators**

- a) Each boiler is to be fitted with at least two separate means for indicating the water level. One of these means is to be a level indicator with transparent element. The other may be either an additional level indicator with transparent element or an equivalent device. Level indicators are to be of an approved type.
- b) The transparent element of level indicators is to be made of glass, mica or other appropriate material.
- c) Level indicators are to be located so that the water level is readily visible at all times. The lower part of the transparent element is not to be below the safety water level defined by the builder.
- d) Level indicators are to be fitted either with normally closed isolating cocks, operable from a position free from any danger in case of rupture of the transparent element or with self-closing valves restricting the steam release in case of rupture of this element.

**5.1.4 Water level indicators - Special requirements for water tube boilers**

- a) For water tube boilers having an athwarships steam drum more than 4 m in length, a level indicator is to be fitted at each end of the drum.
- b) *Water tube boilers serving turbine propulsion machinery are to be fitted with a high-water-level audible and visual alarm (see also Tab 21).*

**5.1.5 Water level indicators - Special requirements for fire tube boilers (vertical and cylindrical boilers)**

- a) For cylindrical boilers, the two water level indicators mentioned in [5.1.3] are to be distributed at each end of the boiler; i.e. double front cylindrical boilers are to have two level indicators on each front.
- b) A system of at least two suitably located and remote controlled gauge-cocks may be considered as the equivalent device mentioned in [5.1.3] for cylindrical boilers having a design pressure lower than 1 MPa, for cylindrical boilers having a diameter lower than 2 m and for vertical boilers having height lower than 2,3 m. Gauge-cocks are to be fixed directly on the boiler shell.
- c) Where level indicators are not fixed directly on the boiler shell, but on level pillars, the internal diameter of such pillars is not to be less than the value  $d_N$  given in Tab 20. Level pillars are to be either fixed directly on the boiler shell or connected to the boiler by pipes fitted with cocks secured directly to the boiler shell. The internal diameter of these pipes  $d_C$  is not to be less than the values given in Tab 20. The upper part of these pipes is to be arranged so that there is no bend where condense water can accumulate. These pipes are not to pass through smoke boxes or uptakes unless they are located inside metallic ducts having internal diameter exceeding by not less than 100 mm the external diameter of the pipes. Fig 38 shows the sketch of a level pillar arrangement.

**Table 20 : Minimum internal diameters  $d_N$  and  $d_C$**

Internal diameter of the boiler	$d_N$ (mm)	$d_C$ (mm)
$D > 3$ m	60	38
$2,30 \text{ m} \leq D \leq 3$ m	50	32
$D < 2,30$ m	45	26

**Figure 38 : Level pillar arrangement**

**5.1.6 Pressure control devices**

- a) Each boiler is to be fitted with a steam pressure gauge so arranged that its indications are easily visible from the stokehold floor. A steam pressure gauge is also to be provided for superheaters which can be shut off from the boiler they serve.
- b) Pressure gauges are to be graduated in units of effective pressure and are to include a prominent legible mark for the pressure that is not to be exceeded in normal service.
- c) Each pressure gauge is to be fitted with an isolating cock.
- d) Double front boilers are to have a steam pressure gauge arranged in each front.

**5.1.7 Temperature control devices**

Each boiler fitted with a superheater is to have an indicator or recorder for the steam temperature at the superheater outlet.

**5.1.8 Automatic shut-off of oil fired propulsion and auxiliary boilers**

- a) Each burner is to be fitted with a flame scanner designed to automatically shut off the fuel supply to the burner in the event of flame failure. In the case of failure of the flame scanner, the fuel to the burner is to be shut off automatically.
- b) A low water condition is to automatically shut off the fuel supply to the burners. The shut-off is to operate before the water level reaches a level so low as to affect the safety of the boiler and no longer be visible in the gauge glass. Means are to be provided to minimise the risk of shut-off provoked by the effect of roll and pitch and/or transients. This shut-off system need not be installed in auxiliary boilers which are under local supervision and are not intended for automatic operation.
- c) Forced draft failure is to automatically shut off the fuel supply to the burners.
- d) Loss of boiler control power is to automatically shut off the fuel supply to the burners.

**5.1.9 Alarms**

Any actuation of the fuel-oil shut-off listed in [5.1.8] is to operate a visual and audible alarm.

**5.1.10 Additional requirements for boilers fitted with automatic control systems**

- a) The flame scanner required in [5.1.8], item a) is to operate within 6 seconds from the flame failure.
- b) A timed boiler purge with all air registers open is to be initiated manually or automatically when boilers are fitted with an automatic ignition system. The purge time is based on a minimum of 4 air changes of the combustion chamber and furnace passes. Forced draft fans are to be operating and air registers and dampers are to be open before the purge time commences.
- c) Means are to be provided to bypass the flame scanner control system temporarily during a trial-for-ignition for a period of 15 seconds from the time the fuel reaches the burners. Except for this trial-for-ignition period, no means are to be provided to bypass one or more of the burner flame scanner systems unless the boiler is locally controlled.
- d) Where boilers are fitted with an automatic ignition system, and where residual fuel oil is used, means are to be provided for lighting of burners with igniters lighting properly heated residual fuel oil. In the case of flame failure, the burner is to be brought back into automatic service only in the low-firing position.
- e) An alarm is to be activated whenever a burner operates outside the limit conditions stated by the manufacturer.
- f) Immediately after normal shutdown, an automatic purge of the boiler equal to the volume and duration of the pre-purge is to occur. Following automatic fuel valve shut-off, the air flow to the boiler is not to automatically increase; post-purge in such cases is to be carried out under manual control.
- g) Propulsion and auxiliary boilers associated with propulsion machinery intended for centralised, unattended operations are to comply with the requirements of Part C, Chapter 3.

**5.2 Pressure vessel instrumentation**

**5.2.1**

- a) Pressure vessels are to be fitted with the necessary devices for checking pressure, temperature and level, where it is deemed necessary.
- b) In particular, each air pressure vessel is to be fitted with a local manometer.

**5.3 Thermal oil heater control and monitoring**

**5.3.1 Local control and monitoring**

Suitable means to effectively operate, control and monitor the operation of thermal oil heaters and their associated auxiliaries are to be provided locally. The functional condition of the fuel, thermal oil circulation, forced draft and flue gas systems is to be indicated by pressure gauges, temperature indicators, flow-meter, lights or other similar devices.

**5.3.2 Flow control and monitoring**

- a) A flow indicator of the thermal oil is to be provided.
- b) The flow detection is to be representative of the flow in each heated element.
- c) The flow detection is not to be based on a measurement of the pressure-drop through the heating element.
- d) Oil fired or exhaust gas heaters are to be provided with a flow monitor limit-switch. If the flow rate falls below a minimum value the firing system is to be switched off and interlocked.

**5.3.3 Leakage monitoring**

Oil tanks are to be equipped with a leakage detector which, when actuated, shuts down and interlocks the thermal oil firing system. If the oil fired heater is on stand-by, the starting of the burner is to be blocked if the leakage detector is actuated.

**5.4 Control and monitoring requirements**

**5.4.1** Tab 21, Tab 22, Tab 23 and Tab 24 summarise the control and monitoring requirements for main propulsion boilers, auxiliary boilers, oil fired thermal oil heaters and exhaust gas thermal oil heaters and incinerators, respectively.

**Table 21 : Main propulsion boilers**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Boiler			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop

## 6 Additional requirements for shell type exhaust gas heated economizers that may be isolated from the steam plant system

### 6.1 Application

6.1.1 The requirements in [6] are applicable to shell type exhaust gas heated economizers that are intended to be operated in a flooded condition and that may be isolated from the steam plant system.

### 6.2 Design and construction

6.2.1 Design and construction of shell type economizers are to pay particular attention to the welding, heat treatment and inspection arrangements at the tube plate connection to the shell.

### 6.3 Pressure relief

6.3.1 Where a shell type economizer is capable of being isolated from the steam plant system, it is to be provided with at least one safety valve, and when it has a total heating surface of 50 m<sup>2</sup> or more, it is to be provided with at least two safety valves in accordance with [3.2].

6.3.2 To avoid the accumulation of condensate on the outlet side of safety valves, the discharge pipes and/or safety valve housings are to be fitted with drainage arrangements from the lowest part, directed with continuous fall to a position clear of the economizer where it will not pose threats to either personnel or machinery. No valves or cocks are to be fitted in the drainage arrangements.

6.3.3 Full details of the proposed arrangements to satisfy [6.3.1] to [6.3.2] are to be submitted for approval.

### 6.4 Pressure indication

6.4.1 Every shell type economizer is to be provided with a means of indicating the internal pressure. A means of indicating the internal pressure is to be located so that the pressure can be easily read from any position from which the pressure may be controlled.

### 6.5 Lagging

6.5.1 Every shell type economizer is to be provided with removable lagging at the circumference of the tube end plates to enable ultrasonic examination of the tube plate to shell connection.

### 6.6 Feed water

6.6.1 Every economizer is to be provided with arrangements for pre-heating and de-aeration, addition of water treatment or combination thereof to control the quality of feed water to within the manufacturer's recommendations.

### 6.7 Operating instructions

6.7.1 The manufacturer is to provide operating instructions for each economiser which is to include reference to:

- Feed water treatment and sampling arrangements
- Operating temperatures – exhaust gas and feed water temperatures
- Operating pressure
- Inspection and cleaning procedures
- Records of maintenance and inspection
- The need to maintain adequate water flow through the economizer under all operating conditions
- Periodical operational checks of the safety devices to be carried out by the operating personnel and to be documented accordingly
- Procedures for using the exhaust gas economizer in the dry condition
- Procedures for maintenance and overhaul of safety valves.

## 7 Design requirements for boil-off gas combustion units

### 7.1 Operating cases

7.1.1 Gas combustion units are to be capable of operating at least in the following conditions:

- a) for gas carriers:
  - normal boil-off handling in laden conditions
  - reduced boil-off handling in ballast conditions
  - during inerting and purging operations.
- b) for gas-fuelled ships:
  - boil-off handling during periods of slow steaming and/or no consumption from propulsion or other services of the ship
  - during LNG bunkering, inerting and purging operations.

## **7.2 Availability**

### **7.2.1 Main components of the GCU(s):**

- mechanical non-static components such as fans,
- electronic cards pertaining to the control and monitoring system,

are to be duplicated so that the nominal capacity of the GCU(s) can be sustained or restored in case of single failure of such components.

**7.2.2** The time necessary to restore the GCU operation in case of a component failure is to be consistent with the expected operating profile of the GCU and with the increase rate of the pressure in the tanks. In this respect, spare components ready for installation in a short time may be considered in lieu of duplicated components.

## **7.3 Gas combustion equipment**

### **7.3.1 General**

The gas combustion unit is to exhibit no visible flame.

### **7.3.2 Flue gas temperature**

The flue gas temperature at the GCU outlet, after possible dilution, is not to exceed 535°C.

Note 1: The attention is drawn to certain national or international rules that may impose different temperature limits.

In case of emergency shut-down of the GCU, the flue gas temperature is not to exceed the aforementioned value. Otherwise, an emergency water cooling system is to be provided.

### **7.3.3 Combustion chamber**

The combustion chamber is to be of suitable form such as not to present pockets where gas may accumulate.

The flame length is to remain within the gas combustion chamber in all expected operating cases, irrespective of the gas composition and gas pressure.

The combustion chamber is to be fitted with at least two flame monitoring devices, one for the alarm activation and one to shut off the gas supply in the case of flame failure.

### **7.3.4 Means for ignition**

Each gas burner is to be fitted with at least two means for ignition, such as electrical igniters or pilot burners supplied with oil fuel.

## **7.4 Gas supply**

### **7.4.1 Gas piping system**

The gas piping system fitted to the GCU is to comply with the relevant provisions of IGC Code, Chapter 16 or IGF Code, Section 9, as appropriate.

### **7.4.2 Inerting**

Provisions are to be made for inerting and gas-freeing the portion of the gas piping system located in the GCU compartment.

Note 1: Where it is demonstrated that the natural gas-freeing of the GCU burner and of its gas supply piping is efficient, the connection to the inert gas system may be omitted, subject to the flag authorities agreement.

## **7.5 Instrumentation and safeties**

**7.5.1** The GCU control system as well as the related systems are to be of a type approved by the Society.

**7.5.2** The alarm and safety systems are to be provided in accordance with Tab 25.

Table 25 : Gas combustion units alarm and safety systems

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring	Automatic safety actions		
	Alarms	Automatic shut down of the GCU	Activation of the master gas valve	Other automatic actions
Identification of system parameter				
Gas supply - pressure	L	X		
Gas supply - temperature	L+H	X		
Combustion fans, dilution fans or combined fans - failure	X			Start of the stand-by fan
Flame - loss	X	X		
Flame monitoring device - failure	X			
Flue gas at the stack outlet - temperature	H HH	X		
GCU stop from any cause	X			Activation of the block-and-bleed valves (1)
Control power supply - failure	X			
Double wall gas piping system (2) - gas leakage	X	X	X	
Double wall gas piping system (2) - lost of exhaust ventilation	X	X	X	
Single wall gas piping system - gas detection in the GCU space (3)	X	X	X	De-energization of the non-safe electrical equipment
Single wall gas piping system - loss of ventilation in the GCU space (3)	X	X	X	De-energization of the non-safe electrical equipment
(1) For gas carriers and gas-fuelled ships. Refer to IGC Code, reg. 16.4.5 or IGF Code, reg. 9.4.4 as applicable				
(2) For gas carriers and gas-fuelled ships. Refer to IGC Code, reg. 16.4.6.3 or IGF Code, Table 1, as applicable				
(3) Only for gas-fuelled ships. Refer to IGF Code, reg. 5.6.3.3 and Table 1				

## 8 Arrangement and installation

### 8.1 Foundations

**8.1.1** For boilers and pressure vessels bolting down to their foundations, see Ch 1, Sec 1, [3.3.1]. Where necessary, they are also to be secured to the adjacent hull structures by suitable ties.

Where chocks are required to be fitted between the boilers and their foundations, they are to be of cast iron or steel.

### 8.2 Boilers

#### 8.2.1 Thermal expansion

Means are to be provided to compensate thermal expansion of boilers.

#### 8.2.2 Minimum distance of boilers from vertical bulkheads and fuel tanks

- The distance between boilers and vertical bulkheads is to be not less than the minimum distance necessary to provide access for inspection and maintenance of the structure adjacent to the boiler.
- In addition to the requirement in a), the distance of boilers from fuel oil tanks is to be such as to prevent the possibility that the temperature of the tank bulkhead may approach the flash point of the oil.
- In any event, the distance between a boiler and a vertical bulkhead is not to be less than 450 mm.

#### 8.2.3 Minimum distance of boilers from double bottom

- Where double bottoms in way of boilers may be used to carry fuel oil, the distance between the top of the double bottom and the lower metal parts of the boilers is not to be less than:
  - 600 mm, for cylindrical boilers
  - 750 mm, for water tube boilers.
- The minimum distance of vertical tube boilers from double bottoms not intended to carry oil may be 200 mm.

#### 8.2.4 Minimum distance of boilers from ceilings

- A space sufficient for adequate heat dissipation is to be provided on the top of boilers.
- Oil tanks are not permitted to be installed in spaces above boilers.

### **8.2.5 Installation of boilers on engine room flats**

Where boilers are installed on an engine room flat and are not separated from the remaining space by means of a watertight bulkhead, a coaming of at least 200 mm in height is to be provided on the flat. The area surrounded by the coaming may be drained into the bilge.

### **8.2.6 Drip trays and gutterways**

Boilers are to be fitted with drip trays and gutterways in way of burners so arranged as to prevent spilling of oil into the bilge.

### **8.2.7 Hot surfaces**

Hot surfaces with which the crew are likely to come into contact during operation are to be suitably guarded or insulated. See Ch 1, Sec 1, [3.7.1].

### **8.2.8 Registers fitted in the smoke stacks of oil fired boilers**

Where registers are fitted in smoke stacks, they are not to obstruct more than two thirds of the cross-sectional area of gas passage when closed. In addition, they are to be provided with means for locking them in open position when the boiler is in operation and for indicating their position and degree of opening.

## **8.3 Pressure vessels**

### **8.3.1 Safety devices on multiple pressure vessels**

Where two or more pressure vessels are interconnected by a piping system of adequate size so that no branch of piping may be shut off, it is sufficient to provide them with one safety valve and one pressure gauge only.

## **8.4 Thermal oil heaters**

**8.4.1** In general, the requirements of [8.2] for boilers are also applicable to thermal oil heaters.

# **9 Material test, workshop inspection and testing, certification**

## **9.1 Material testing**

### **9.1.1 General**

Materials, including welding consumables, for the constructions of boilers and pressure vessels are to be certified by the material manufacturer in accordance with the appropriate material specification.

### **9.1.2 Boilers, other steam generators, and oil fired and exhaust gas thermal oil heaters**

In addition to the requirement in [9.1.1], testing of materials intended for the construction of pressure parts of boilers, other steam generators, oil fired thermal oil heaters and exhaust gas thermal oil heaters is to be witnessed by the Surveyor.

### **9.1.3 Class 1 pressure vessels and heat exchangers**

In addition to the requirement in [9.1.1], testing of materials intended for the construction of class 1 pressure parts of pressure vessels and heat exchangers is to be witnessed by the Surveyor.

This requirement may be waived at the Society's discretion for mass produced small pressure vessels (such as accumulators for valve controls, gas bottles, etc.).

## **9.2 Workshop inspections**

### **9.2.1 Boilers and individually produced class 1 and 2 pressure vessels**

The construction, fitting and testing of boilers and individually produced class 1 and 2 pressure vessels are to be attended by the Surveyor, at the builder's facility.

### **9.2.2 Mass produced pressure vessels**

Construction of mass produced pressure vessels which are type approved by the Society need not be attended by the Surveyor.

## **9.3 Hydrostatic tests**

### **9.3.1 General**

Hydrostatic tests of all class 1, 2 and 3 pressure vessels are to be witnessed by the Surveyor with the exception of mass produced pressure vessels which are built under the conditions stated in [9.2.2].

### 9.3.2 Testing pressure

- a) Upon completion, pressure parts of boilers and pressure vessels are to be subjected to a hydraulic test under a pressure  $p_t$  defined below as a function of the design pressure  $p$ :
- $p_t = 1,5 p$  where  $p \leq 4$  MPa
  - $p_t = 1,4 p + 0,4$  where  $4 \text{ MPa} < p \leq 25 \text{ Mpa}$
  - $P_t = p + 10,4$  where  $p > 25$  MPa
- b) The test pressure may be determined as a function of a pressure lower than  $p$ ; however, in such case, the setting and characteristics of the safety valves and other overpressure protective devices are also to be determined and blocked as a function of this lower pressure.
- c) If the design temperature exceeds 300°C, the test pressure  $p_t$  is to be as determined by the following formula:

$$p_t = 1,5 \cdot \frac{K_{100}}{K} \cdot p$$

where:

$p$  : Design pressure, in MPa

$K_{100}$  : Permissible stress at 100°C, in N/mm<sup>2</sup>

$K$  : Permissible stress at the design temperature, in N/mm<sup>2</sup>.

- d) Consideration is to be given to the reduction of the test pressure below the values stated above where it is necessary to avoid excessive stress. In any event, the general membrane stress is not to exceed 90% of the yield stress at the test temperature.
- e) Economisers which cannot be shut off from the boiler in any working condition are to be submitted to a hydraulic test under the same conditions as the boilers.
- f) Economisers which can be shut off from the boiler are to be submitted to a hydraulic test at a pressure determined as a function of their actual design pressure  $p$ .

### 9.3.3 Hydraulic test of boiler and pressure vessel accessories

- a) Boilers and pressure vessel accessories are to be tested at a pressure  $p_t$  which is not less than 1,5 times the design pressure  $p$  of the vessels to which they are attached.
- b) The test pressure may be determined as a function of a pressure lower than  $p$ ; however, in such case, the setting and characteristics of the safety valves and other overpressure protective devices are also to be determined and blocked as a function of this lower pressure.

### 9.3.4 Hydraulic test procedure

- a) The hydraulic test specified in [9.3.1] is to be carried out after all openings have been cut out and after execution of all welding work and of the heat treatment, if any. The vessel to be tested is to be presented without lagging, paint or any other lining and the pressure is to be maintained long enough for the Surveyor to proceed with a complete examination.
- b) Hydraulic tests of boilers are to be carried out either after installation on board, or at the manufacturer's plant. Where a boiler is hydrotested before installation on board, the Surveyor may, if deemed necessary, request to proceed with a second hydraulic test on board under a pressure at least equal to 1,1  $p$ . For this test, the boiler may be fitted with its lagging. However, the Surveyor may require this lagging to be partially or entirely removed as necessary.
- c) For water tube boilers, the hydraulic test may also be carried out separately for different parts of the boiler upon their completion and after heat treatment. For drums and headers, this test may be carried out before drilling the tube holes, but after welding of all appendices and heat treatment. When all parts of the boiler have been separately tested and following assembly the boiler is to undergo a hydraulic test under a pressure of 1,25  $p$ .

### 9.3.5 Hydraulic tests of condensers

Condensers are to be subjected to a hydrostatic test at the following test pressures:

- Steam space: 0,1 MPa
- Water space: maximum pressure which may be developed by the pump with closed discharge valve increased by 0,07 MPa. However, the test pressure is not to be less than 0,2 MPa. When the characteristics of the pump are not known, the hydrostatic test is to be carried out at a pressure not less than 0,35 MPa.

## 9.4 Certification

### 9.4.1 Certification of boilers and individually produced pressure vessels

Boilers and individually produced pressure vessels of classes 1, 2 and 3 are to be certified by the Society in accordance with the procedures stated in Part A.

### 9.4.2 Mass produced pressure vessels

Small mass produced pressure vessels of classes 1, 2 and 3 may be accepted provided they are type approved by the Society in accordance with the procedures stated in Part A.

**Table 26 : Pressure vessel certification**

Class	Drawing / Calculation		Material testing		Hydraulic test	
	Manufacturer	The Society	Manufacturer	The Society	Manufacturer	The Society
1	X	review	X	witness + workshop inspection	X	witness
2	X	review	X	review	X	witness
3	X	–	X	review	X	witness

**Note 1:** Certificates of the Manufacturer and the Society to be issued for all cases for pressure vessels covered by the Rules of the Society.

# Section 4 Steam Turbines

## 1 General

### 1.1 Application

#### 1.1.1 Propulsion turbines and turbines for essential services

The requirements of this Section apply to:

- a) all propulsion turbines
- b) turbines intended for auxiliary services essential for safety and navigation, or for driving cargo pumps in tankers.

#### 1.1.2 Auxiliary turbines driving generators

In addition to the requirements contained in this Section, auxiliary turbines driving electric generators are to comply with those of Ch 2, Sec 4 of the Rules.

### 1.2 Documentation to be submitted

**1.2.1** For propulsion turbines and turbines intended for driving machinery for essential services, the plans and data listed in Tab 1 are to be submitted.

All listed plans are to be constructional plans complete with all dimensions and are to contain full indication of the types of materials employed.

**Table 1 : Documents to be submitted**

No.	A/I (1)	Item
1	I	Sectional assembly
2	A	Rotors and discs, revolving and stationary blades for each turbine
3	A	Fastening details of revolving and stationary blades
4	A	Casings
5	A	Schematic diagram of control and safety devices
6	I	General specification of the turbine, including an operation and instruction manual
7	I	Maximum power and corresponding maximum rotational speed, and the values of pressure and temperature at each stage
8	A	Material specifications of the major parts, including their physical, chemical and mechanical properties, the data relevant to rupture and creep at elevated temperatures, when the service temperature exceeds 400°C, the fatigue strength, the corrosion resistance and the heat treatments
9	I	Distribution box
10	A	Strength calculations of rotors, discs and blades and blade vibration calculations
11	A	Where the rotors, stators or other components of turbines are of welded construction, all particulars on the design of welded joints, welding conditions, heat treatments and non-destructive examinations after welding
(1) A = to be submitted for approval I = to be submitted for information		

## 2 Design and construction

### 2.1 Materials

#### 2.1.1 Rotating components

- a) Rotors, shafts and discs of turbines are to be of forged steel. In general, the forgings are to have minimum tensile strength  $R_m$  within the limits in Tab 2.
- b) Rotors of small turbines may be built of special cast steels.
- c) Turbine blades are to be built of corrosion-resistant materials.

**Table 2 : Limits of  $R_m$**

Steel	$R_m$ limits (N/mm <sup>2</sup> )
Carbon and carbon-manganese steel	$400 < R_m < 600$
Alloy steels for rotors	$500 < R_m < 800$
Alloy steels for discs and other forgings	$500 < R_m < 1000$

**2.1.2 Static components**

The casings and diaphragms of turbines are to be built of forged or cast steels capable of withstanding the pressures and temperatures to which they are subjected. Cast iron may be used for temperatures up to 300°C. Additionally, requirements mentioned in Ch 1, Sec 1, [3.7.2] are to be applied when other materials than steel are used for components in contact with flammable fluids

**2.2 Design and constructional details**

**2.2.1 Rotors and stators**

- a) All components of turbines are to be free from defects and are to be built and installed with tolerances and clearances such as to allow thermal expansion and to minimise the distortions of casings and rotors in all expected service conditions.
- b) Particular care is to be devoted to preventing condensation water from accumulating in the blade spaces of the casings. Adequate drain tubes and cocks are to be arranged in a suitable position, in the lower parts of the casings. Cocks are to be easy to operate.
- c) When labyrinth packings are used, the steam supply pipes to the sealing system are to be so arranged that condensed steam may not enter the turbine.
- d) Particular attention is to be paid to the connection of pipes to the turbine stators in order to avoid abnormal loads in service.
- e) Smooth fillets are to be provided at changes of section of rotors, discs and blade roots. The holes in discs are to be well rounded and polished.

**2.2.2 Bearings**

- a) Turbine bearings are to be so located that their lubrication is not impaired by overheating from adjacent hot parts.
- b) Lubricating oil is to be prevented from dripping on high temperature parts.
- c) Suitable arrangements for cooling the bearings after the turbines have been stopped may also be required, at the discretion of the Society.

**2.2.3 Turning gear**

- a) Main propulsion turbines are to be equipped with turning gear for both directions of rotation. The rotors of auxiliary turbines are to be capable of being turned by hand.
- b) The engagement of turning gear is to be visually indicated at the control platform.
- c) An interlock is to be provided to ensure that the turbine cannot be started up when the turning gear is engaged.

**2.2.4 Astern power for main propulsion**

- a) The main propulsion turbine is to have sufficient power for running astern. The astern power is considered to be sufficient if it is able to attain astern revolutions equivalent to at least 70% of the rated ahead revolutions for a period of at least 30 minutes.
- b) For main propulsion machinery with reverse gearing, controllable pitch propellers or an electrical transmission system, astern running is not to cause any overloading of the propulsion machinery.
- c) During astern running, the main condenser and the ahead turbines are not to be excessively overheated.

**2.2.5 Interlock**

The simultaneous admission of steam to the ahead and astern turbines is to be prevented by interlocks. Brief overlapping of the ahead and astern valves during manoeuvring may be permitted.

**2.2.6 Turbine exhaust**

- a) Sentinel valves or other equivalent means are to be provided at the exhaust end of all turbines. The valve discharge outlets are to be clearly visible and suitably guarded, as necessary.
- b) Where, in auxiliary steam turbines, the inlet steam pressure exceeds the pressure for which the exhaust casing and associated piping up to the exhaust valve are designed, means to relieve the excess pressure are to be provided.

**2.2.7 Water accumulation prevention**

- a) Non-return valves or other approved means are to be fitted in bled steam connections to prevent steam and water returning into the turbines.
- b) Bends are to be avoided in steam piping in which water may accumulate.

### **2.2.8 Steam strainers**

Efficient steam strainers are to be provided close to the inlets to ahead and astern high pressure turbines or alternatively at the inlets to manoeuvring valves.

### **2.2.9 Emergency arrangements**

- a) In single screw ships fitted with cross compound steam turbines, the arrangements are to be such as to enable safe navigation when the steam supply to any one of the turbines is required to be isolated. For this emergency operation purpose the steam may be led directly to the low pressure (L.P.) turbine and either the high pressure (H.P.) or medium pressure (M.P.) turbine can exhaust direct to the condenser.

Adequate arrangements and controls are to be provided for these operating conditions so that the pressure and temperature of the steam will not exceed those which the turbines and condenser can safely withstand.

The necessary pipes and valves for these arrangements are to be readily available and properly marked. A fit up test of all combinations of pipes and valves is to be performed prior to the first sea trials.

The permissible power/speeds when operating without one of the turbines (all combinations) is to be specified and information provided on board.

The operation of the turbines under emergency conditions is to be assessed for the potential influence on shaft alignment and gear teeth loading conditions.

- b) Ships classed for unrestricted service and fitted with a steam turbine propulsion plant and only one main boiler are to be provided with means to ensure emergency propulsion in the event of failure of the main boiler.

## **2.3 Welded fabrication**

**2.3.1** The manufacturer's requirements relative to the welding of turbine rotors or major forged or cast pieces, where permitted, are to be readily identifiable when the plans are submitted to the Society for approval. Requirements relative to fabrication, welding, heat treatments, examinations, testing and acceptance will be stipulated on a case by case basis.

In general, all weldings are to be carried out by qualified welders in accordance with qualified welding procedures and using approved consumables.

## **2.4 Control, monitoring and shut-off devices**

### **2.4.1 Governors**

- a) Turbines for main propulsion machinery equipped with controllable pitch propellers, disengaging couplings or electrical transmission systems are to be fitted with an additional speed governor which, in the event of a sudden loss of load, prevents the revolutions from increasing to the trip speed.
- b) The speed increase of turbines driving electric generators -except those for electrical propeller drive- resulting from a change from full load to no-load may not exceed 5% on the resumption of steady running conditions. The transient speed increase resulting from a sudden change from full load to no-load conditions is not to exceed 10% and is to be separated by a sufficient margin from the trip speed.

### **2.4.2 Overspeed devices**

- a) Each main and auxiliary turbine is to be provided with an overspeed protective device to prevent the rotational speed from exceeding the maximum rotational by more than 15%. The device is to be actuated by the turbine shaft.
- b) Where two or more steam turbines are coupled to the same gear wheel, the Society may accept the fitting of only one overspeed device for all the coupled turbines.
- c) For turbines driving electric generators, the overspeed protective device mentioned in a) is also to be fitted with a means for manual tripping.
- d) Where exhaust steam from auxiliary systems is led to the main turbine, provision is to be made to cut off the steam automatically when the overspeed protective device is activated.

### **2.4.3 Rotor axial displacement**

A quick-closing valve is to be provided which automatically shuts off the steam supply in the event of axial displacement of the rotor beyond the permissible limits stated by the manufacturer. The device controlling the valve is to be actuated by the turbine shaft.

### **2.4.4 Emergency oil supply**

For the emergency lubricating oil supply, see Ch 1, Sec 10, [12.5].

### **2.4.5 Bearing lubrication failure**

- a) Main ahead turbines are to be provided with a quick-closing valve which automatically shuts off the steam supply in the event of a dangerous reduction in oil pressure in the bearing lubricating system.
- b) This arrangement is to be such as to ensure the admission of steam to the astern turbine for braking purposes.

**2.4.6 Shut-off arrangement**

- a) Arrangements are to be provided for shutting off the steam to the main turbines by a suitable hand trip device controlling the steam admission valve situated at the control platform and at the turbine itself.
- b) Hand tripping for auxiliary turbines is to be arranged in the proximity of the turbine overspeed protective device.
- c) The hand trip device is any device which is operated manually irrespective of the way the action is performed, i.e. mechanically or by means of external power.
- d) The quick-closing valves are also to be manually operable at the turbine and from the control platform.
- e) Re-setting of the quick-closing valve device may be effected only at the turbine or from the control platform with the control valves in the closed position.
- f) Where the valves are operated by hydraulic oil systems fitted for automatic operation, they are to be fed by two pumps: one main pump and one standby pump. In any event, the standby pump is to be independent. In special cases, at the Society's discretion, a hand-operated pump may be accepted as a standby pump.
- g) The starting up of any turbine is to be possible only when the quick-closing devices are ready for operation.
- h) A quick-closing device is to be provided which automatically shuts off the steam supply in the event of an increase in pressure or water level in the condenser beyond the permissible limits.

**2.4.7 Summary Tables**

Tab 3 and Tab 4 summarise the minimum control and monitoring requirements for main propulsion and auxiliary turbines, respectively.

**Table 3 : Main propulsion turbine**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Turbine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
• Main turbine speed		local					
	H			X			
					X		
• Main turbine axial displacement	X	local		X			
• Main turbine vibration	H	local					
<b>Lubricating oil</b>							
• Supply pressure		local					
	L			X (2)			
• Level of gravity tank	L (1)	local					
(1) Sensor to be located near the normal level							
(2) This is not to prevent astern operation for braking							

**Table 4 : Auxiliary turbine**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Turbine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Overspeed	H	local		X			
Rotor displacement	X	local		X			
Vibration	H	local					
Lubricating oil supply pressure	L			X			
Lubricating oil level in gravity tank	L						

### **3 Arrangement and installation**

#### **3.1 Foundations**

**3.1.1** Shipyards and Manufacturers are to take care that foundations of turbines and connected reduction gears are to be designed and built so that hull movements do not give rise to significant movements between reduction gears and turbines. In any event, such movements are to be absorbed by suitable couplings.

#### **3.2 Jointing of mating surfaces**

**3.2.1** The mating flanges of casings are to form a tight joint without the use of any interposed material.

#### **3.3 Piping installation**

**3.3.1** Pipes and mains connected to turbine casings are to be fitted in such a way as to minimise the thrust loads and moments.

#### **3.4 Hot surfaces**

**3.4.1** Hot surfaces with which the crew are likely to come into contact during operation are to be suitably guarded or insulated. See Ch 1, Sec 1, [3.7].

#### **3.5 Alignment**

**3.5.1** The Shipyard and the Manufacturer are to take particular care in the alignment of turbine-reduction gearing, taking account of all causes which may alter the alignment from cold conditions to normal service conditions.

When a structural tank is fitted in way of the turbine or gearing foundations, the expected tank temperature variations are to be taken into account during alignment operations.

Propulsion turbines are to be fitted with indicators showing the axial movements of rotors with respect to casings and the sliding movements of casings on the sliding feet.

#### **3.6 Circulating water system**

**3.6.1** The circulating water system with vacuum ejectors is to be so arranged that water may not enter the low pressure turbines.

#### **3.7 Gratings**

**3.7.1** Gratings and any other structures in way of the sliding feet or flexible supports are to be so arranged that turbine casing expansion is not restricted.

#### **3.8 Drains**

**3.8.1** Turbines and the associated piping systems are to be equipped with adequate means of drainage.

#### **3.9 Instruments**

**3.9.1** Main and auxiliary turbines are to be fitted with callipers and micrometers of a suitable type for verifying the alignment of rotors and pinion and gear-wheel shafts.

This check is to be performed to the Surveyor's satisfaction at the time of installation.

### **4 Material tests, workshop inspection and testing, certification**

#### **4.1 Material tests**

##### **4.1.1 Parts to be tested**

The materials for the construction of the parts listed in Tab 5 are to be tested in compliance with the requirements of NR216 Materials and Welding.

Magnetic particle or liquid penetrant tests are required for the parts listed in Tab 5 and are to be effected by the Manufacturer in positions agreed upon by the Surveyor, where Manufacturer's experience shows defects are most likely to occur.

For important structural parts of the turbine, in addition to the above-mentioned non-destructive tests, examination of welded seams by approved methods of inspection may be required.

Where there are grounds to doubt the soundness of any turbine component, non-destructive tests using approved detecting methods may be required.

#### **4.1.2 Special auxiliary turbines**

In the case of auxiliary turbines with a steam inlet temperature of up to 250°C, the extent of the tests stated in Tab 5 may be limited to the disc and shaft materials.

### **4.2 Inspections and testing during construction**

#### **4.2.1 Inspections during construction**

The following inspections and tests are to be carried out in the presence of the Surveyor during the construction of all turbines which are indicated in [1.1.1]. For shipboard tests, see Ch 1, Sec 18, [3.7].

- material tests, as required (see [4.1])
- welded fabrication (see [4.2.2])
- non-destructive examination of turbine blades (see [4.2.3])
- hydrostatic tests (see [4.2.4])
- safety valves (see [4.2.5])
- thermal stability test of rotor (see [4.2.6])
- rotor balancing and overspeed test (see [4.2.7] and [4.2.8])
- shop trials (see [4.2.9]).

#### **4.2.2 Welded fabrication**

Welded fabrication and testing is to be attended by the Surveyor, as may be deemed necessary by the Society.

#### **4.2.3 Turbine blades**

When turbine blades are calculated using a permissible stress  $K > R_m/4$ , all turbine rotor blades are to be checked by dye penetrants or other equivalent method.

#### **4.2.4 Hydrostatic tests**

- a) Turbine and nozzle casings are to be subjected to a hydrostatic test at the greater of the following test pressures:
- b) 1,5 times the working pressure
- c) 1,5 times the starting pressure
- d) However, the test pressure is not to be less than 0,2N/mm<sup>2</sup>.
- e) The turbine casings may be temporarily subdivided by diaphragms in order to obtain different pressure values for the various stages, if necessary.
- f) Where it is not possible to perform hydrostatic tests, the manufacturer may submit to the Society, for consideration, alternative proposals for testing the integrity of turbine casings and the absence of defects therein.
- g) For the bodies of quick-closing, safety, manoeuvring and control valves, the test pressure is to be 1,5 times the maximum allowable working pressure of the boiler (approval pressure). The sealing efficiency of these valves when closed is to be tested at 1,1 times the working pressure.
- h) Intermediate coolers and heat exchangers are to be subjected to a hydrostatic test at 1,5 times the working pressure.
- i) Pressure piping, valves and other fittings are to be subjected to hydrostatic tests in compliance with the normal requirements for these items.

#### **4.2.5 Safety valves**

All valves required in [2.4] are to be tested at their setting pressure in the presence of the Surveyor, as specified by the turbine manufacturer.

#### **4.2.6 Thermal stability test of rotors**

Solid forged and welded rotors of propulsion turbines are to be subjected to a thermal stability test where the service temperature exceeds 400°C. This test is to be carried out after heat treatment and rough machining or at a later stage of fabrication, in accordance with a procedure approved by the Society.

#### **4.2.7 Balancing of rotors**

Finished rotors, complete with all fittings and blades, are to be dynamically balanced in a balancing machine of appropriate sensitivity in relation to the size of the rotor. Normally this test is to be carried out with the primary part of the flexible coupling, if any.

**4.2.8 Overspeed test of rotors**

Finished rotors, complete with all fittings and blades, are to be subjected for at least 3 minutes to an overspeed test at the greater of the following values:

- 5% above the setting speed of the overspeed tripping device
- 15% above the maximum design speed.

The Society may waive this requirement provided that it can be demonstrated by the manufacturer, using an acceptable direct calculation procedure, that the rotor is able to safely withstand the above values of overspeed and that rotors are free from defects, as verified by means of non-destructive tests.

**4.2.9 Shop trials**

Where turbines are subjected to a trial run at the factory, the satisfactory functioning of the control, safety and monitoring equipment is to be verified by the Manufacturer during the trial run. Such verification is in any event to take place not later than the commissioning of the plant aboard ship.

In general, propulsion steam turbines are to be subjected to a works trial under steam but without load, up to the service rotational speed, as far as possible. In the course of the works trials, the overspeed devices for both main and auxiliary turbines are to be set.

**4.3 Certification**

**4.3.1 Turbines required to be certified**

For turbines required to be certified as per [1.1.1], Society’s certificates (C) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.1]) are required for material tests of rotating components and blades listed in Tab 5 and for works trials as per [4.2.1]. Provided the manufacturer has a quality assurance system accepted by the Society, a reduced number of inspections in the presence of the Surveyor may be agreed.

**4.3.2 Turbines not required to be certified**

For turbines not required to be certified as per [1.1.1], manufacturer’s certificates including details of tests and inspections carried out at the shop are to be submitted. The acceptance of these turbines is, however, subject to their satisfactory performance during dock and sea trials.

**4.3.3 Type approved turbines**

For mass produced turbines which are requested to be type approved by the Society, the tests and trials on a prototype are to be carried out in the presence of the Surveyor as stated in [4.3.1]. The minimum required attendance of the Surveyor at the production tests and trials will be agreed between the manufacturer and the Society on a case by case basis.

**Table 5 : Material and non-destructive tests**

Turbine component	Material tests (mechanical properties and chemical composition)	Non-destructive tests	
		Magnetic particle or liquid penetrant	Ultrasonic or X Ray examination
Rotating parts (turbine rotors, shafts, stiff and flexible couplings, bolts for couplings and other dynamically stressed parts, integral pinions and gears)	all	all	sample
Stationary parts (castings and plates for casings)	all	spot as agreed between the Manufacturer and the Surveyor	–
Blades	sample	sample	sample
Piping and associated fittings	as required in the appropriate Section of the Rules	as required in the appropriate Section of the Rules	as required in the appropriate Section of the Rules

# Section 5 Gas Turbines

## 1 General

### 1.1 Application

#### 1.1.1 Propulsion turbines and turbines for essential services

The requirements of this Section apply to:

- a) all propulsion turbines
- b) turbines intended for auxiliary services essential for safety and navigation.

#### 1.1.2 Turbines for auxiliary generators

In addition to the requirements contained in this Section, auxiliary turbines driving electric generators are to comply with the applicable requirements of Ch 3, Sec 3.

#### 1.1.3 Dual fuel (DF) gas turbines

Specific requirements for dual fuel (DF) gas turbines are given in [5], in addition to the requirements applicable to all kinds of gas turbines given in [1] to [4].

#### 1.1.4 Type approval

Turbines intended for propulsion and essential services are to be type approved by the Society.

### 1.2 Definition of rated power

**1.2.1** Rated power is the maximum constant power that the turbine can develop at constant speed in the range of air inlet temperature between 0°C and 35°C. This power is to be considered with 0 intake and exhaust losses and with an air relative humidity of 60%.

### 1.3 Documentation to be submitted

**1.3.1** For propulsion turbines and turbines intended for driving machinery for essential services, the plans listed in Tab 1 are to be submitted.

The listed constructional plans are to be complete with all dimensions and are to contain full indication of the types of materials used.

**Table 1 : Documents to be submitted**

No.	A/I (1)	Item
1	I	Sectional assembly
2	A	Detailed drawings of rotors, casings, blades, combustion chambers and heat exchangers (2)
3	A	Material specifications of the major parts, including their physical, chemical and mechanical properties, the data relevant to rupture and creep at elevated temperatures, the fatigue strength, the corrosion resistance and the heat treatments (2)
4	A	Where the rotors, stators or other components of turbines are of welded construction, all particulars on the design of welded joints, welding procedures and sequences, heat treatments and non-destructive examinations after welding (2)
5	I	General specification of the turbine, including instruction manual, description of structures and specification of the properties of fuel and lubricating oil to be used
6	I	Details of operating conditions, including the pressure and temperature curves in the turbine and compressor at the rated power and corresponding rotational speeds, and details of permissible temporary operation beyond the values for the rated power
7	A	Diagrammatic layout of the fuel system, including control and safety devices, and of the lubricating oil system
8	A	Cooling system layout, if applicable
<p>(1) A = to be submitted for approval; I = to be submitted for information</p> <p>(2) As an alternative, the Society may, on a case by case basis, consider reviewing a number of selected packages relative to important and critical parts of the turbine, where all the design, construction, inspection, testing and acceptance criteria used by the manufacturer are clearly described, provided the Quality Assurance system of the manufacturer is approved and certified by the Society.</p>		

No.	A/I (1)	Item

10	I	Maintenance and overhaul procedures
11	A	Stress and temperature analysis in blades, rotors and combustion chamber (2)
12	A	Life time calculation of hot and high stress parts (2)
13	A	Blade and rotor vibration analysis (2)
14	A	Details of automatic safety devices together with failure mode and effect analysis (FMEA) (2)
<p>(1) A = to be submitted for approval; I = to be submitted for information</p> <p>(2) As an alternative, the Society may, on a case by case basis, consider reviewing a number of selected packages relative to important and critical parts of the turbine, where all the design, construction, inspection, testing and acceptance criteria used by the manufacturer are clearly described, provided the Quality Assurance system of the manufacturer is approved and certified by the Society.</p>		

## 2 Design and Construction

### 2.1 Materials

#### 2.1.1 Approved materials

- a) Gas turbine materials are to fulfil the requirements imposed by the operating conditions of the individual components. In the choice of materials, account is to be taken of effects such as creep, thermal fatigue, oxidation and corrosion to which individual components are subject when in service. Evidence of the suitability of the materials is to be supplied to the Society in the form of details of their chemical and mechanical properties and of the heat treatment applied. Where composite materials are used, their method of manufacture is to be described.
- b) Turbine blades are to be built of corrosion and heat-resistant materials.
- c) Requirements mentioned in Ch 1, Sec 1, [3.7.2] are to be applied when other materials than steel are used for components in contact with flammable fluids

### 2.2 Stress analyses

#### 2.2.1 Calculation

- a) The manufacturer is to submit the results of calculation of the stresses on each rotor under the most severe service conditions.
- b) Fatigue analysis on each rotor, taking into account the stress concentrations, is also to be submitted.
- c) The results of previous in-service experience on similar applications may be considered by the Society as an alternative to items a) and b) above.

The calculations and analyses (see also [1.3.1]) are to be carried out in accordance with criteria agreed by the Society. Data on the design service life and test results used to substantiate calculation assumptions are also to be provided.

#### 2.2.2 Vibrations

The range of service speeds is not to give rise to unacceptable bending vibrations or to vibrations affecting the entire installation. Calculations of the critical speeds including details of their basic assumptions are to be submitted.

### 2.3 Design and constructional details

#### 2.3.1 Rotors and stators

- a) All components of turbines and compressors are to be free from defects and are to be built and installed with tolerances and clearances in order to allow thermal expansion and to minimise the distortions of casings and rotors in all expected service conditions.
- b) Adequate drain tubes and cocks are to be arranged in a suitable position, in the lower parts of the casings. Cocks are to be easily operated.
- c) Suitable protective devices are to be provided in order to prevent heat, noise or possible failure of rotating parts from causing injury to personnel. If, to this end, the whole gas turbine is enclosed in a protective covering, the covering is to be adequately ventilated inside.
- d) Particular attention is to be paid to the connection in the casings of pipes to the turbine stators in order to avoid abnormal loads in service.
- e) Smooth fillets are to be provided at changes of sections of rotors, discs and blade roots. The holes in discs are to be well rounded and polished.

### **2.3.2 Access and inspection openings**

- a) Access to the combustion chambers is to be ensured. Means are to be provided to inspect the burner cans or combustion chamber without having to remove the gas generator.
- b) Inspection openings are to be provided to allow the gas turbine flow path air to be inspected with special equipment, e.g. a bore-scope or similar, without the need for dismantling.

### **2.3.3 Bearings**

- a) Turbine bearings are to be so located that their lubrication is not impaired by overheating from hot gases or adjacent hot parts.
- b) Lubricating oil or fuel oil is to be prevented from dripping on high temperature parts.
- c) Suitable arrangements for cooling the bearings after the turbines have been stopped are to be provided, if necessary to prevent bearing cooking.
- d) Roller bearings are to be identifiable and are to have a life adequate for their intended purpose. In any event, their life cannot be less than 40000 hours.

### **2.3.4 Turning gear**

- a) Main propulsion turbines are to be equipped with turning gear or a starter for cranking. The rotors of auxiliary turbines are to be capable of being turned by hand.
- b) The engagement of the turning gear or starter is to be visually indicated at the control platform.
- c) An interlock is to be provided to ensure that the main turbine cannot be started up when the turning gear is engaged.

### **2.3.5 Cooling**

The turbines and their external exhaust system are to be suitably insulated or cooled to avoid excessive outside temperature.

### **2.3.6 Air supply**

- a) The air intake ducting is to be equipped to prevent extraneous substances from entering the compressor and turbine.
- b) Measures are to be taken to control the salinity of the combustion air, to meet the manufacturer's specification.
- c) Cleaning equipment is to be provided to remove deposits from compressors and turbines.
- d) Means are to be provided to prevent the formation of ice in the air intake.

### **2.3.7 Turbine exhaust arrangement**

- a) The gas exhaust arrangement is to be designed in such a way as to prevent the entrance of gases into the compressor.
- b) Silencers or other equivalent arrangements are to be provided in the gas exhaust, to limit the airborne noise at one metre distance from the turbine to not more than 110 dB (A) in unmanned machinery spaces and not more than 90 dB (A) in manned spaces.

### **2.3.8 Multi-turbine installations**

Multi-turbine installations are to have separate air inlets and exhaust systems to prevent recirculation through the idle turbine.

### **2.3.9 Fuel**

- a) Where the turbine is designed to burn non-distillate fuels, a fuel treatment system is to be provided to remove, as far as practicable, the corrosive constituents of the fuel or to inhibit their action in accordance with the manufacturer's specification.
- b) Suitable means are to be provided to remove the deposits resulting from the burning of the fuel while avoiding abrasive or corrosive action, if applicable.
- c) Gas turbines burning boil-off gases of liquefied gas cargo tanks will be specially considered by the Society taking into account the requirements of Pt D, Ch 9, Sec 16.

### **2.3.10 Start-up equipment**

- a) Gas turbines are to be fitted with start-up equipment enabling them to be started up from the "shutdown" condition.
- b) Provisions are to be made so that any dangerous accumulation of liquid or gaseous fuel inside the turbines is thoroughly removed before any attempt at starting or restarting.
- c) Starting devices are to be so arranged that firing operation is discontinued and the main fuel valve is closed within a pre-determined time when ignition is failed.
- d) The minimum number of starts is to be such as to satisfy the requirements of Ch 1, Sec 1, [1.4.2].

### **2.3.11 Astern power**

For main propulsion machinery with reverse gearing, controllable pitch propellers or an electrical transmission system, astern running is not to cause any overloading of the propulsion machinery.

### **2.3.12 Emergency operation**

- a) In installations with more than one propeller and connected shafting and more than one turbine, the failure of any gas turbine unit connected to a shafting line is not to affect the continued, independent operation of the remaining units.
- b) In installations with only one propeller and connected shafting, driven by two or more main turbines, care is to be taken to ensure that, in the event of one of the turbines failing, the others are able to continue operation independently.
- c) Ships classed for unrestricted service and fitted with only one propeller and connected shafting driven by a gas turbine are to be provided with means to ensure emergency propulsion in the event of failure of the main turbine.

## **2.4 Welded fabrication**

**2.4.1** The manufacturer's requirements relative to the welding of turbine rotors or major forged or cast pieces, where permitted, are to be readily identifiable by the Society in the plans submitted for approval.

In general, all weldings are to be carried out by qualified welders in accordance with qualified welding procedures using approved consumables.

## **2.5 Control, monitoring and shut-off devices**

### **2.5.1 Control and monitoring arrangement**

For each main propulsion system, the associated control and monitoring equipment is to be grouped together at each location from which the turbine may be controlled.

### **2.5.2 Governors and speed control system**

- a) Propulsion turbines which may be operated in no-load conditions are to be fitted with a control system capable of limiting the speed to a value not exceeding 10% of the maximum continuous speed.
- b) Turbines for main propulsion machinery equipped with controllable pitch propellers, disengaging couplings or an electrical transmission system are to be fitted with a speed governor which, in the event of a sudden loss of load, prevents the revolutions from increasing to the trip speed.
- c) In addition to the speed governor, turbines driving electric generators are to be fitted with a separate overspeed protective device, with a means for manual tripping, adjusted so as to prevent the rated speed from being exceeded by more than 15%.
- d) The speed increase of turbines driving electric generators - except those for electrical propeller drive - resulting from a change from full load to no-load is not to exceed 5% on the resumption of steady running conditions. The transient speed increase resulting from a sudden change from full load to no-load conditions is not to exceed 10% and is to be separated by a sufficient margin from the trip speed. Alternative requirements may be considered by the Society on a case by case basis based on the actual turbine design and arrangement.

### **2.5.3 Monitoring system**

The main operating parameters (pressure, temperature, rpm, etc.) are to be adequately monitored and displayed at the control console.

### **2.5.4 Emergency shut-off**

- a) An emergency push-button shut-off device is to be provided at the control console.
- b) Any shut-off device provided in pursuance of the above is to shut off the fuel supply as near the burners as possible.

### **2.5.5 Quick-closing devices**

- a) Gas turbines are to be equipped with a quick closing device (shut-down device) which automatically shuts off the fuel supply to the turbines at least where required by Tab 2, unless the FMEA proves otherwise.
- b) Re-setting of the quick-closing device may be effected only at the turbine or from the control platform with the fuel supply control valve in the closed position.
- c) When the devices are operated by hydraulic oil systems fitted for automatic operation, they are to be fed by two pumps: one main pump and one standby pump. In any event, the standby pump is to be independent. In special cases, a hand-operated pump may be accepted as a standby pump.
- d) The starting up of any turbine is to be possible only when the quick-closing devices are ready for operation.

### **2.5.6 Automatic temperature controls**

The following turbine services are to be fitted with automatic temperature controls so as to maintain steady state conditions within the normal operating range of the main gas turbine:

- a) lubricating oil supply and discharge
- b) fuel oil supply (or, alternatively, automatic control of fuel oil viscosity)
- c) exhaust gas in specific locations of the flow gas path as determined by the manufacturer.

**2.5.7 Indicators, alarm and shutdown**

Tab 2 indicates the minimum control and monitoring requirements for main propulsion and auxiliary turbines. Alarms can be added or omitted, taking into account the result of FMEA.

**Table 2 : Main propulsion and auxiliary turbines**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control

(1) Alarm to be activated at the suitable setting points prior to arriving the critical condition for the activation of shutdown devices							

**3 Arrangement and installation**

**3.1 Foundations**

**3.1.1** Manufacturers and Shipyards are to arrange foundations of turbines and connected reduction gears to be so designed and built that hull movements do not give rise to significant movements between reduction gears and turbines. In any event, such movements are to be absorbed by suitable couplings.

**3.2 Joints of mating surfaces**

**3.2.1** The mating flanges of casings are to form a tight joint without the use of any interposed material.

**3.3 Piping installation**

**3.3.1** Pipes and mains connected to turbine and compressor casings are to be fitted in such a way as to minimise the thrust loads and moments. If flexible hoses are used for this purpose, they are to comply with the requirements in Ch 1, Sec 10, [2.6].

### **3.4 Hot surfaces**

**3.4.1** Hot surfaces with which the crew are likely to come into contact during operation are to be suitably guarded or insulated. See Ch 1, Sec 1, [3.7].

### **3.5 Alignment**

#### **3.5.1**

- a) The Manufacturer is to take particular care in the alignment of turbine-reduction gearing, taking account of all causes which may alter the alignment from cold conditions to normal service conditions.
- b) When a structural tank is fitted in way of the turbine or gearing foundations, the expected tank temperature variations are to be taken into account during alignment operations.
- c) Propulsion turbines are to be fitted with indicators showing the axial movements of rotors with respect to casings and the sliding movements of casings on the sliding feet. Such indicators are to be fitted in an easily visible position. This requirement does not apply to turbines fitted with roller bearings.

### **3.6 Gratings**

**3.6.1** Gratings and any other structures in way of the sliding feet or flexible supports are to be so arranged that turbine casing expansion is not restricted.

### **3.7 Drains**

**3.7.1** Turbines and the associated piping systems are to be equipped with adequate means of drainage.

### **3.8 Instruments**

**3.8.1** Main and auxiliary turbines are to be fitted with callipers and micrometers of a suitable type for verifying the alignment of rotors and pinion and gear-wheel shafts, when necessary.

At the time of installation on board, this check is to be performed in the presence and to the satisfaction of the Surveyor.

## **4 Material tests, workshop inspection and testing, certification**

### **4.1 Type tests - General**

**4.1.1** Upon finalisation of the design for production of every new turbine type intended for installation on board ships, one turbine is to be presented for type testing as required below.

A type test carried out for a particular type of turbine at any manufacturer's works will be accepted for all turbines of the same type built by licensees and licensors.

Turbines which are subjected to type testing are to be tested in accordance with the scope specified below, it being taken for granted that:

- the turbine is optimised as required for the conditions of the type test
- the investigations and measurements required for reliable turbine operation have been carried out during preliminary internal tests by the turbine manufacturer
- the documentation to be submitted as required in [1.3.1] has been examined and, when necessary, approved by the Society and the latter has been informed regarding the nature and extent of investigations carried out during pre-production stages.

### **4.2 Type tests of turbines not admitted to an alternative inspection scheme**

#### **4.2.1 General**

Turbines for which the Manufacturer is not admitted to testing and inspections according to an alternative inspection scheme (see NR320, Sec 1, [3.2]), are to be type tested in the presence of the Surveyor in accordance with the following requirements.

The type test is subdivided into three stages:

- a) Stage A - Preliminary internal tests carried out by the manufacturer

Stage A includes functional tests and collection of operating values including testing hours during the internal tests, the relevant results of which are to be presented to the Surveyor during the type test. Testing hours of components which are inspected are to be stated by the manufacturer.

- b) Stage B - Type approval test

The type approval test is to be carried out in the presence of the Surveyor.

c) Stage C - Inspection of main turbine components.

After completion of the test programme, the main turbine components are to be inspected.

The turbine manufacturer is to compile all results and measurements for the turbine tested during the type test in a type test report, which is to be submitted to the Society.

#### **4.2.2 Stage A - Internal tests (functional tests and collection of operating data)**

- a) During the internal tests the turbine is to be operated at the load points considered important by the turbine manufacturer and the relevant operating values are to be recorded.
- b) The load points may be selected according to the range of application.
- c) Functional tests under normal operating conditions include:
  - 1) The load points 25%, 50%, 75%, 100% of the rated power for which type approval is requested, to be carried out:
    - along the nominal (theoretical) propeller curve and at constant speed, for propulsion turbines
    - at constant speed, for turbines intended for generating sets.
  - 2) The limit points of the permissible operating range.  
These limit points are to be defined by the turbine manufacturer.
- d) An alternative testing program may be agreed between the manufacturer and the Society on a case by case basis.

#### **4.2.3 Stage B - Type approval tests in the presence of the Surveyor**

During the type test, the tests listed below are to be carried out in the presence of the Surveyor and the results are to be recorded in a report signed by both the turbine manufacturer and the Surveyor.

Any departures from this programme are to be agreed upon by the manufacturer and the Society.

a) Load points

The load points at which the turbine is to be operated according to the power/speed diagram are those listed below. The data to be measured and recorded when testing the turbine at various load points are to include all necessary parameters for turbine operation.

The operating time per load point depends on the turbine characteristics (achievement of steady-state condition) and the time for collection of the operating values.

Normally, an operating time of 0,5 hour per load point can be assumed.

At the maximum continuous power as per the following item (1) an operating time of two hours is required. Two sets of readings are to be taken at a minimum interval of one hour.

- 1) test at maximum continuous power P: i.e. 100% output at 100% torque and 100% speed.
- 2) test at maximum permissible torque (normally 110% of nominal torque T) at 100% speed; or test at maximum permissible power and speed according to the nominal propeller curve.
- 3) tests at partial loads, e.g. 75%, 50%, 25% of maximum continuous power P and speed according to the nominal propeller curve.

b) Additional tests

- test at lowest turbine speed according to the nominal propeller curve
- starting tests
- governor tests
- testing and rating of the safety systems.

#### **4.2.4 Evaluation of test results**

The results of the tests and checks required by [4.2.3] will be evaluated by the attending Surveyor. Normally the main operating data to be recorded during the tests are those listed in [4.3.4].

The values of temperatures and pressures of media, such as cooling media, lubricating oil, exhaust gases, etc., are to be within limits which, in the opinion of the Surveyor, are appropriate for the characteristics of the turbine tested.

#### **4.2.5 Stage C - Inspection of turbine components**

Immediately after the test run as per [4.2.3], a selected number of components agreed between the manufacturer and the Society are to be presented for inspection to the Surveyor.

### **4.3 Type tests of turbines admitted to an alternative inspection scheme**

#### **4.3.1 General**

Turbines admitted to testing and inspections according to an alternative inspection scheme (see NR320, Sec 1, [3.2]) are to be type tested in the presence of the Surveyor in accordance with the following requirements.

The selection of the turbine to be tested from the production line is to be agreed upon with the Surveyor.

### **4.3.2 Type test**

The programme of the type test is to be in general as specified below, P being the rated power and n the corresponding speed. Any departures from this programme are to be agreed upon by the manufacturer and the Society.

- a) 6 hours at full power
- b) 10 hours shared at different partial loads (25%, 50%, 75% and 90% of power P);
- c) 2 hours at intermittent loads
- d) starting tests
- e) testing of speed governor, overspeed device and lubricating oil system failure alarm device
- f) testing of the minimum speed along the nominal (theoretical) propeller curve, for main propulsion turbines driving fixed pitch propellers, and of the minimum speed with no brake load, for main propulsion turbines driving controllable pitch propellers or for auxiliary turbines.

The tests at the above-mentioned outputs are to be combined together in working cycles which are to be repeated in succession for the entire duration within the limits indicated.

In particular, the full power test is to be carried out at the end of each cycle.

The partial load tests specified in (b) are to be carried out:

- along the nominal (theoretical) propeller curve and at constant speed, for propulsion turbines
- at constant speed, for turbines intended for generating sets.

In the case of prototype turbines, the duration and programme of the type test will be specially considered by the Society.

### **4.3.3 Alternatives**

In cases of turbines for which the manufacturer submits documentary evidence proving successful service experience or results of previous bench tests, the Society may, at its discretion, allow a type test to be carried out, in the presence of the Surveyor according to a programme to be agreed upon in each instance.

### **4.3.4 Data to be recorded**

During the type test, at least the following particulars are to be recorded:

- a) ambient air temperature, pressure and atmospheric humidity in the test room
- b) cooling medium temperature at the inlet of the turbine
- c) characteristics of the fuel and lubricating oil used during the test
- d) turbine speed
- e) brake power
- f) brake torque
- g) intake and exhaust losses
- h) lubricating oil pressure and temperature
- i) exhaust gas temperature in locations of the flow gas path selected by the manufacturer
- j) minimum starting air pressure and flow rate necessary to purge and start the turbine in cold condition, if applicable.

### **4.3.5 Inspection of main turbine components and evaluation of test results**

The provisions of [4.2.4] and [4.2.5] are to be complied with, as far as applicable.

## **4.4 Material tests**

**4.4.1** The materials for the construction of the parts listed in Tab 3 are to be tested in compliance with the requirements of NR216 Materials and Welding.

Magnetic particle or liquid penetrant tests are required for the parts listed in Tab 3 and are to be effected by the Manufacturer in positions agreed upon by the Surveyor, where Manufacturer's experience shows defects are most likely to occur.

For important structural parts of the turbine, in addition to the above-mentioned non-destructive tests, examination of welded seams by approved methods of inspection may be required.

Where there are grounds to doubt the soundness of any turbine component, non-destructive tests using approved detecting methods may be required.

**Table 3 : Material and non-destructive tests**

Turbine component	Material tests (Mechanical properties and chemical composition)	Non-destructive tests	
		Magnetic particle or liquid penetrant	Ultrasonic or X Ray examination
Rotating parts (compressors and turbine rotors, shafts, stiff and flexible couplings, bolts for couplings and other dynamically stressed parts, integral pinions and gears)	all	all	all
Stationary parts (castings for casings intended for a temperature exceeding 230°C and plates for casings intended for a temperature exceeding 370°C or pressure exceeding 4 Mpa)	all	spot as agreed between the Manufacturer and the Surveyor	–
Blades	sample	sample	sample
Piping and associated fittings	as required in the appropriate Section of the Rules	as required in the appropriate Section of the Rules	as required in the appropriate Section of the Rules

**4.5 Inspections and testing during construction**

**4.5.1 Inspections during construction**

The following inspections and tests are to be carried out in the presence of a Surveyor during the construction of all turbines which are indicated in [1.1.1]. For on-board trials see Ch 1, Sec 18, [3.8].

- Material tests as required (see Ch 1, Sec 4, [4.1])
- Welding fabrication (see [4.5.2])
- Hydrostatic tests (see [4.5.3])
- Rotor balancing and overspeed test (see [4.5.4] and [4.5.5])
- Shop trials (See [4.5.6]).

**4.5.2 Welding fabrication**

Welding fabrication and testing is to be attended by the Surveyor, as may be deemed necessary by the Society.

**4.5.3 Hydrostatic tests**

Finished casing parts and heat exchangers are to be subjected to hydrostatic testing at 1,5 times the maximum permissible working pressure. If it is demonstrated by other means that the strength of casing parts is sufficient, a tightness test at 1,1 times the maximum permissible working pressure may be accepted by the Society. Where the hydrostatic test cannot be performed, alternative methods for verifying the integrity of the casings may be agreed between the manufacturer and the Society on a case by case basis.

**4.5.4 Balancing of rotors**

Finished rotors, complete with all fittings and blades, are to be dynamically balanced in a balancing machine of appropriate sensitivity in relation to the size of the rotor. Normally this test is to be carried out with the primary part of the flexible coupling, if any.

**4.5.5 Overspeed test of rotors**

Finished rotors, complete with all fittings and blades, are to be subjected for at least 3 minutes to an overspeed test at the greater of the following values:

- 5% above the setting speed of the overspeed tripping device
- 15% above the maximum design speed.

The Society may waive this requirement provided that it can be demonstrated by the manufacturer, using an acceptable direct calculation procedure, that the rotor is able to safely withstand the above overspeed values and that rotors are free from defects, as verified by means of non-destructive tests.

**4.5.6 Shop trials**

For shop trials, see [4.2.3] and [4.3.2].

**4.6 Certification**

**4.6.1 Type approval certificate and its validity**

Subject to the satisfactory outcome of the type tests and inspections specified in [4.2] or [4.3], the Society will issue to the engine manufacturer a "Type Approval Certificate" valid for all turbines of the same type.

#### **4.6.2 Testing certification**

a) Turbines admitted to an alternative inspection scheme

Works' certificates (W) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.3]) are required for components and tests indicated in Tab 3 and tests and trials listed in [4.5.1]. However, the Society reserves the right to request that the shop trials be witnessed by a Surveyor on a case by case basis.

b) Engines not admitted to an alternative inspection scheme

Society's certificates (C) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.1]) are required for material tests of rotating components and blades listed in Tab 3 and for works trials as per [4.5.3] and [4.5.4].

Works' certificates (W) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.3]) are required for the other items listed in Tab 3 and for trials described in [4.5.2], [4.5.5] and [4.5.6].

### **5 Additional requirements for dual fuel (DF) gas turbines**

#### **5.1 Design principles**

**5.1.1** DF gas turbines are to be designed so as to operate safely with any gas composition within the ship specification range, taking into account the possible variations of the gas composition during the voyage. Tests are to be carried out to demonstrate their ability in this respect.

**5.1.2** DF gas turbines and associated gas treatment and gas supply systems as well as their control system are to be so designed and arranged as to allow the proper operation of the turbine taking into account the expected variations of the gas characteristics, in particular:

- lower heating value
- specific gravity
- gas temperature
- ambient temperature.

**5.1.3** The fuel supply to DF gas turbines is to be capable of being switched over from gas fuel to oil fuel while the turbine is running, without significant fluctuation of the turbine output nor of the rotational speed.

**5.1.4** Prior to a normal stop, a DF gas turbine is to be switched over from gas fuel to oil fuel.

**5.1.5** After each gas operation of a DF gas turbine not followed by an oil fuel operation, the turbine including the exhaust system is to be purged during a sufficient time in order to discharge the gas which may be present.

**5.1.6** DF gas turbines are to be fitted with a control system allowing a steady running with stable combustion, with any kind of gas as mentioned in [5.1.1] above, throughout the operating speed range of the turbine. Automatic switch over to oil fuel may however be accepted at low loads.

**5.1.7** Gas fuel and oil fuel supply systems to DF gas turbines are to be so designed and controlled as to avoid any excessive gas delivery to the turbine, which may result in overspeed, in particular while the turbine is running with gas fuel and oil fuel at the same time.

**5.1.8** Arrangements are to be made to avoid the condensation of heavy hydrocarbons or water in the turbine gas inlet system. Where this is achieved by heating the gas fuel, a superheat of at least 28°C above the dew point is to be observed to ensure that no liquid may appear in the gas system downstream of the heater. Where necessary, the gas piping system is to be heat traced to avoid any condensation, in particular during the turbine start-up.

#### **5.2 Control, alarms and safety systems**

**5.2.1** Control systems of DF gas turbines are to be type-approved by the Society.

**5.2.2** The alarm and safety systems are to be provided in accordance with Tab 4.

#### **5.3 Type tests**

**5.3.1** DF gas turbines are to be subjected to specific type tests in gas mode and dual fuel mode, according to an approved program.

**Table 4 : Dual fuel gas turbine alarm and safety systems**

Parameter	Alarms	Automatic safety actions			
		Activation of the block-and-bleed valves	Activation of the master gas valve	Switch over to oil fuel mode	Engine shut down
Gas supply - abnormal pressure	L+H	X		X	
Gas supply - abnormal temperature	L+H	X		X	
Gas admission valve - failure	X	X		X	
Turbine stop from any cause	X	X			
<b>Note 1:</b> Symbol convention: H = High, L = Low, X = function is required					

# Section 6 Gearing

## 1 General

### 1.1 Application

1.1.1 Unless otherwise specified, the requirements of this Section apply to:

- reduction and/or reverse enclosed gears intended for propulsion plants with a transmitted power of 220 kW and above
- other reduction and step-up enclosed gears with a transmitted power of 110 kW and above.

These requirements, however, may be applied to the enclosed gears, whose gear set is intended to transmit a maximum continuous power less than those specified above at the request of the Society.

The provisions of Article [2] apply only to cylindrical involute spur or helical gears with external or internal teeth.

The provisions of Article [3] apply only to bevel gears (straight or oblique teeth). Application of other specific methods for the design of bevel gears could be taken into consideration by the Society.

Additional requirements for gears fitted to ships having an **ICE** notation are given in Part F, Chapter 8.

### 1.2 Documentation to be submitted

#### 1.2.1 Documents

Before starting construction, all plans, specifications and calculations listed in Tab 1 are to be submitted to the Society.

#### 1.2.2 Data

The data listed in Tab 2 or Tab 3 and in Tab 4 are to be submitted with the documents required in [1.2.1].

**Table 1 : Documents to be submitted for gearing**

No.	A/I (2)	Description of the document (1)
1	A	Constructional drawings of shafts and flanges
2	A	Constructional drawings of pinions and wheels, including: <ul style="list-style-type: none"> <li>a) specification and details of hardening procedure:               <ul style="list-style-type: none"> <li>• core and surface mechanical characteristics</li> <li>• diagram of the depth of the hardened layer as a function of hardness values</li> </ul> </li> <li>b) specification and details of the finishing procedure:               <ul style="list-style-type: none"> <li>• finishing method of tooth flanks (hobbling, shaving, lapping, grinding, shot-peening)</li> <li>• surface roughness for tooth flank and root fillet</li> <li>• tooth flank corrections (helix modification, crowning, tip-relief, end-relief), if any</li> <li>• flank tolerance class according to ISO 1328-1:2013</li> </ul> </li> </ul>
3	A	Shrinkage calculation for shrunk-on pinions, wheels rims and/or hubs with indication of the minimum and maximum shrinkage allowances
4	I	Calculation of load capacity of the gears
5	A/I (3)	Constructional drawings of casings
6	A	Functional diagram of the lubricating system, with indication of the: <ul style="list-style-type: none"> <li>• specified grade of lubricating oil</li> <li>• expected oil temperature in service</li> <li>• kinematic viscosity of the oil</li> </ul>

8	I	Longitudinal and transverse cross-sectional assembly of the gearing, with indication of the type of clutch
9	I	Data form for calculation of gears (4)
10	I	Detailed justification of material quality used for gearing calculation (ML, MQ, or ME according to ISO 6336-5)
<p>(1) Constructional drawings are to be accompanied by the specification of the materials employed including the chemical composition, heat treatment and mechanical properties and, where applicable, the welding details, welding procedure and stress relieving procedure.</p> <p>(2) Submission of the drawings may be requested:           <ul style="list-style-type: none"> <li>• for approval, shown as "A" in the Table</li> <li>• for information, shown as "I" in the Table.</li> </ul> </p> <p>(3) "A" for welded casing, "I" otherwise</p> <p>(4) The forms are given in Tab 2, Tab 3 and Tab 4.</p>		

**Table 2 : Data to be submitted for cylindrical gears**

Symbol	Values		Unit	Description
	Pinion	Wheel		
a			mm	Operating centre distance
$b_B$			mm	Common face width (for double helix gear, width of one helix)
A			-	Flank tolerance class according to ISO 1328-1:2013
$b_s$			mm	Web thickness
$s_R$			mm	Rim thickness
$R_{m,rim}$			N/mm <sup>2</sup>	Ultimate tensile strength of the rim material
B			mm	Total face width of double helix gears, including gap
$d_s$			mm	Shrinkage diameter
$m_n$			mm	Normal module
$\alpha_n$			deg or rad	Normal pressure angle at reference cylinder
$\beta$			deg or rad	Helix angle at reference cylinder
x			-	Addendum modification coefficient
z			-	Number of teeth
P			kW	Transmitted power
n			rpm	Rotational speed
$d_a$			mm	Tip diameter
$\rho_{a0}$			mm	Tip radius of the tool
$h_{fp}$			mm	Basic rack dedendum
HRC			-	Rockwell hardness
$R_{Zf}$			$\mu\text{m}$	Mean peak-to-valley flank roughness of the gear pair
$R_Z$			$\mu\text{m}$	Mean peak-to-valley roughness of the gear pair
$R_{e,s}$			N/mm <sup>2</sup>	Minimum yield strength of the shaft material
$\nu_{40}$			mm <sup>2</sup> /s	Nominal kinematic viscosity of oil at 40°C
pr			mm	Protuberance of the tool
q			mm	Material allowance for finish machining
$d_{ext}$			mm	External shaft diameter
$d_{int}$			mm	Internal shaft diameter
$\ell$			mm	Bearing span
$Z_E$			N <sup>1/2</sup> /mm	Elasticity factor

**Table 3 : Data to be submitted for bevel gears**

## 2 Design of gears - Determination of the load capacity of cylindrical gears

### 2.1 Symbols, units, definitions

#### 2.1.1 Symbols and units

The meaning of the main symbols used in this Article is specified below.

Other symbols introduced in connection with the definition of influence factors are defined in the appropriate sub-articles.

- A : Flank tolerance class according to ISO 1328-1:2013
- a : Operating centre distance, in mm
- b : Effective face width, in mm (for double helix gear,  $b = 2 b_B$ )
- $b_B$  : Common face width, in mm (for double helix gear, width of one helix)
- $b_S$  : Web thickness, in mm
- B : Total face width of double helix gear, including gap, in mm
- d : Reference diameter, in mm
- $d_a$  : Tip diameter, in mm
- $d_b$  : Base diameter, in mm
- $d_{ext}$  : External diameter of shaft, in mm
- $d_{int}$  : Internal diameter of shaft, in mm
- $d_f$  : Root diameter, in mm
- $d_s$  : Shrinkage diameter, in mm
- $d_w$  : Working pitch diameter, in mm
- $F_t$  : Nominal tangential load, in N
- $F_\beta$  : Total helix deviation, in  $\mu\text{m}$
- h : Tooth depth, in mmHB
- $h_{fp}$  : Basic rack dedendum, in mm
- HB : Brinell hardness, in  $\text{N}/\text{mm}^2$
- HRC : Rockwell hardness
- HV : Vickers hardness, in  $\text{N}/\text{mm}^2$
- k : Gear axial position on shaft with respect to the bearings
- $\ell$  : Bearing span, in mm
- $m_n$  : Normal module, in mm
- $m_t$  : Transverse module, in mm
- n : Rotational speed, in rpmP
- P : Transmitted power, in kW
- pr : Protuberance of the tool, in mm
- q : Material allowance for finish machining, in mm

- $R_{m,rim}$  : Ultimate tensile strength of the rim material, in N/mm<sup>2</sup>  
 $R_{e,s}$  : Minimum yield strength of the shaft material, in N/mm<sup>2</sup>  
 $R_Z$  : Mean peak-to-valley roughness of the gear pair, in  $\mu\text{m}$   
 $R_{Zf}$  : Mean peak-to-valley flank roughness of the gear pair, in  $\mu\text{m}$   
 $s_R$  : Rim thickness, in mm  
 $T$  : Transmitted torque, in kN.m  
 $u$  : Reduction ratio  
 $v$  : Linear velocity at pitch diameter, in m/s  
 $x$  : Addendum modification coefficient  
 $z$  : Number of teeth  
 $z_n$  : Virtual number of teeth  
 $\alpha_a$  : Transverse profile angle at tooth tip  
 $\alpha_n$  : Normal pressure angle at reference cylinder  
 $\alpha_t$  : Transverse pressure angle at reference cylinder  
 $\alpha_{tw}$  : Transverse pressure angle at working pitch cylinder  
 $\beta$  : Helix angle at reference cylinder  
 $\beta_b$  : Base helix angle  
 $\epsilon_\alpha$  : Transverse contact ratio  
 $\epsilon_\beta$  : Overlap ratio  
 $\epsilon_\gamma$  : Total contact ratio  
 $\nu_{40}$  : Nominal kinematic viscosity of oil at 40°C, in mm<sup>2</sup>/s  
 $\rho_{a0}$  : Tip radius of the tool, in mm  
 $\sigma_F$  : Tooth root bending stress, in N/mm<sup>2</sup>  
 $\sigma_{FE}$  : Endurance limit for tooth root bending stress, in N/mm<sup>2</sup>  
 $\sigma_{FP}$  : Permissible tooth root bending stress, in N/mm<sup>2</sup>  
 $\sigma_H$  : Contact stress, in N/mm<sup>2</sup>  
 $\sigma_{H,lim}$  : Endurance limit for contact stress, in N/mm<sup>2</sup>  
 $\sigma_{HP}$  : Permissible contact stress, in N/mm<sup>2</sup>

Subscripts:

- 1 for pinion, i.e. the gear having the smaller number of teeth
- 2 for wheel.

### 2.1.2 Geometrical definitions

In the calculation of surface durability,  $b$  is the minimum face width on the pitch diameter between pinion and wheel.

In tooth strength calculations,  $b_1$  and  $b_2$  are the face widths at the respective tooth roots. In any case,  $b_1$  or  $b_2$  are not to be taken greater than  $b$  by more than one module  $m_n$  (in case of width of one gear much more important than the other).

For internal gear,  $z_2$ ,  $a$ ,  $d_2$ ,  $d_{a2}$ ,  $d_{b2}$ ,  $x_2$  and  $d_{w2}$  are to be taken negative.

$$u = \frac{z_2}{z_1}$$

Note 1:  $u > 0$  for external gears,  $u < 0$  for internal gears.

$$\tan \alpha_t = \frac{\tan \alpha_n}{\cos \beta}$$

$$d_i = \frac{z_i \cdot m_n}{\cos \beta}$$

$$d_{bi} = d_i \cdot \cos \alpha_t$$

$$d_{w1} = \frac{2 \cdot a}{1 + u}$$

$$d_{w2} = \frac{2 \cdot a \cdot u}{1 + u}$$

$$d_{fi} = d_i + 2 \cdot m_n \cdot x_i - 2 \cdot h_{fi}$$

$$h_i = 0,5 (d_{ai} - d_{fi})$$

$$\cos \alpha_{tw} = \frac{d_{b1} + d_{b2}}{2a}$$

$$\sin \beta_b = \sin \beta \cdot \cos \alpha_n$$

$$Z_{ni} = \frac{Z_i}{\cos\beta \cdot (\cos\beta_b)^2}$$

$$\cos\alpha_{ai} = \frac{d_{bi}}{d_{ai}}$$

$$\varepsilon_\alpha = \frac{Z_1}{2\pi} (\tan\alpha_{a1} - \tan\alpha_{wt}) + \frac{Z_2}{2\pi} (\tan\alpha_{a2} - \tan\alpha_{wt})$$

$$\varepsilon_\beta = \frac{b \cdot \sin\beta}{\pi \cdot m_n}$$

$$\varepsilon_\gamma = \varepsilon_\alpha + \varepsilon_\beta$$

$$F_{\beta i} = 2^{0,5 \cdot (Q_i - 5)} \cdot (0,1 \cdot |d_i|^{0,5} + 0,63 \cdot b_B^{0,5} + 4,2)$$

$$T_i = \frac{60}{2\pi} \cdot \frac{P}{n_i}$$

$$F_i = \frac{P}{n_i} \cdot \frac{60}{\pi \cdot d_i} \cdot 10^6$$

$$v_i = \frac{\pi \cdot n_i \cdot d_{wi}}{60 \cdot 10^3}$$

## 2.2 Principle

### 2.2.1

a) The following requirements apply to cylindrical involute spur or helical gears with external or internal teeth, and provide a method for the calculation of the load capacity with regard to:

- the surface durability (contact stress)
- the tooth root bending stress.

The cylindrical gears for marine application are to comply with the following restrictions:

- $1,2 < \varepsilon_\alpha < 2,5$
- $\beta < 30^\circ$
- $s_R > 3,5 m_n$

The relevant formulae are provided in [2.4] and [2.5].

The influence factors common to the formulae are given in [2.3].

b) Gears, for which the conditions of validity of some factors or formulae are not satisfied, will be given special consideration by the Society.

c) Other methods of determination of load capacity will be given special consideration by the Society. Any alternative calculations are to comply with the ISO 6336 series standard.

## 2.3 General influence factors

### 2.3.1 General

General influence factors are defined in [2.3.2], [2.3.3], [2.3.4], [2.3.5] and [2.3.6]. Alternative values may be used provided they are derived from appropriate measurements.

### 2.3.2 Application factor $K_A$

The application factor  $K_A$  accounts for dynamic overloads from sources external to the gearing (driven and driving machines).

The values of  $K_A$  are given in Tab 5.

### 2.3.3 Load sharing factor $K_\gamma$

The load sharing factor  $K_\gamma$  accounts for the uneven sharing of load on multiple path transmissions, such as epicyclic gears or tandem gears.

The values of  $K_\gamma$  are given in Tab 6.

**Table 5 : Application factor  $K_A$**

Type of installation			$K_A$
Main gears (propulsion)	Diesel engine	with hydraulic coupling	1,05
		with elastic coupling	1,30
		with other type of coupling	1,50
	Turbine		1,05
	Electric motor		1,05
Auxiliary gears	Diesel engine	with hydraulic coupling	1,00
		with elastic coupling	1,20
		with other type of coupling	1,40
	Electric motor		1,00

**Table 6 : Load sharing factor  $K_\gamma$**

Type of gear		$K_\gamma$
Dual tandem gear	without quill shaft <b>(1)</b>	1,15
	with quill shaft <b>(1)</b>	1,10
Epicyclic gear	with 3 planetary gears and less	1,00
	with 4 planetary gears	1,20
	with 5 planetary gears	1,30
	with 6 planetary gears and more	1,40

**(1)** A quill shaft is a torsionally flexible shaft intended to improve the load distribution between the gears.

**2.3.4 Dynamic factor  $K_V$  (method B)**

The dynamic factor  $K_V$  accounts for the additional internal dynamic loads acting on the tooth flanks and due to the vibrations of the pinion and the wheel.

The calculation of the dynamic factor  $K_V$  is defined in Tab 7, where:

$N$  : Resonance ratio, i.e. ratio of the pinion speed to the resonance speed:

$N = n_1 / n_{E1}$ , with:

$n_{E1}$  : Resonance speed, in rpm, defined by the following formula:

$$n_{E1} = \frac{30000}{\pi z_1} \cdot \sqrt{\frac{c_{\gamma\alpha}}{m_{red}}}$$

where:

$m_{red}$  : Reduced mass of gear pair, in kg/mm

In case of external gears, estimated calculation of  $m_{red}$  is given in Tab 8

$c_{\gamma\alpha}$  : Mesh stiffness, in N/(mm·µm).

For gears with  $\beta \leq 30^\circ$ , the calculation of  $c_{\gamma\alpha}$  is detailed in Tab 9.

The value of  $N$  determines the range of vibrations:

- subcritical range, when  $N \leq N_s$
- main resonance range, when  $N_s < N < 1,15$   
This field is not permitted
- intermediate range, when  $1,15 \leq N \leq 1,50$   
This field is normally to be avoided. Some alternative and more precise calculation could be accepted and special consideration will be given by the Society
- supercritical range, when  $1,50 < N$ .

The lower limit of resonance  $N_s$  is defined as follows:

• if  $F_t K_A / b \geq 100$  N/mm:

$$N_s = 0,85$$

• if  $F_t K_A / b < 100$  N/mm:

$$N_s = 0,5 + 0,35 \sqrt{\frac{F_t K_A}{100b}}$$

Table 7 : Dynamic factor  $K_V$

Resonance domain	Factor $K_V$
$N \leq N_s$	$K_V = N (C_{v1} B_p + C_{v2} B_f + C_{v3} B_k) + 1$
$N > 1,50$	$K_V = C_{v5} B_p + C_{v6} B_f + C_{v7}$

**Note 1:**

$B_p$  : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications:

$$B_p = \frac{c' \cdot f_{pb,eff}}{K_A \cdot (F_t/b)}$$

with:

$c'$  : Single stiffness defined in Tab 9

$f_{pb,eff}$  : Effective base pitch deviation, in  $\mu\text{m}$ , equal to:  $f_{pb,eff} = f_{pb} - y_\alpha$   
with  $f_{pb}$  defined in Tab 14 and  $y_\alpha$  defined in Tab 15

$B_f$  : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications:  
 $B_f = B_p$

$B_k$  : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications:

$$B_k = \left| 1 - \frac{c' \cdot C_a}{K_A \cdot F_t/b} \right|$$

with:

$$C_a = \frac{1}{18} \cdot \left( \frac{\sigma_{Hlim}}{97} - (18,45) \right)^2 + 1,5$$

When material of the pinion is different from that of the wheel:  $C_a = 0,5 (C_{a1} + C_{a2})$

$C_{v1}$  : Factor for pitch deviation effects:  $C_{v1} = 0,32$

$C_{v2}$  : Factor for tooth profile deviation effects:

- if  $1 < \epsilon_\gamma \leq 2$  :  $C_{v2} = 0,34$
- if  $2 < \epsilon_\gamma$  :  $C_{v2} = 0,57 / (\epsilon_\gamma - 0,3)$

$C_{v3}$  : Factor for cyclic variation effect in mesh stiffness:

- if  $1 < \epsilon_\gamma \leq 2$  :  $C_{v3} = 0,23$
- if  $2 < \epsilon_\gamma$  :  $C_{v3} = 0,096 / (\epsilon_\gamma - 1,56)$

$C_{v5}$  : Factor:  $C_{v5} = 0,47$

$C_{v6}$  : Factor:

- if  $1 < \epsilon_\gamma \leq 2$  :  $C_{v6} = 0,47$
- if  $2 < \epsilon_\gamma$  :  $C_{v6} = 0,12 / (\epsilon_\gamma - 1,74)$

$C_{v7}$  : Factor:

- if  $1 < \epsilon_\gamma \leq 1,5$  :  $C_{v7} = 0,75$
- if  $1,5 < \epsilon_\gamma \leq 2,5$  :  $C_{v7} = 0,125 \sin[\pi(\epsilon_\gamma - 2)] + 0,875$
- if  $2,5 < \epsilon_\gamma$  :  $C_{v7} = 1$

Table 8 : Estimated calculation of reduced mass  $m_{red}$

Gear rim	Rim ratio	$m_{red}$ , in kg/mm
$s_{Ri} = 0$	$1 - q_i^4 = 1$	$m_{red} = \frac{\pi}{8} \cdot \left( \frac{d_{a1} + d_{f1}}{2 d_{b1}} \right)^2 \cdot \frac{(d_{f1} + d_{a1})^2}{4 \cdot \left( \frac{1}{\rho_1} + \frac{1}{\rho_2 \cdot u^2} \right)}$
$s_{Ri} \neq 0$	$q_i = \frac{2 \cdot (d_{fi} - 2 \cdot s_{Ri})}{d_{fi} + d_{ai}}$	$m_{red} = \frac{\pi}{8} \cdot \left( \frac{d_{a1} + d_{f1}}{2 d_{b1}} \right)^2 \cdot \frac{(d_{f1} + d_{a1})^2}{4 \cdot \left[ \frac{1}{(1 - q_1^4) \cdot \rho_1} + \frac{1}{(1 - q_2^4) \cdot \rho_2 \cdot u^2} \right]}$

**Note 1:**

$\rho_i$  is the density of gearing material ( $\rho = 7,83 \cdot 10^{-6}$  for steel)

**Table 9 : Mesh stiffness  $c_{\gamma\alpha}$  (method B)**

Specific load	$c_{\gamma\alpha}$ in N/(mm.μm) (1)
$F_t K_A / b \geq 100$ N/mm	$c_{\gamma\alpha} = c' (0,75 \epsilon_\alpha + 0,25) = c'_{th} C_M C_R C_B \cos\beta (0,75 \epsilon_\alpha + 0,25)$
$F_t K_A / b < 100$ N/mm	$c_{\gamma\alpha} = c' (0,75 \epsilon_\alpha + 0,25) = c'_{th} C_M C_R C_B \cos\beta \left( \frac{F_t K_A / b}{100} \right)^{0,25} (0,75 \epsilon_\alpha + 0,25)$

(1) When  $\epsilon_\alpha < 1,2$ :  $c_{\gamma\alpha}$  may be reduced up to 10% in case of spur gears.

**Note 1:**

$c'$  : Single stiffness, in N/(mm.μm)  
 $c'_{th}$  : Theoretical mesh stiffness, in N/(mm.μm), equal to:

$$c'_{th} = \frac{1}{0,04723 + \frac{0,15551}{z_{n1}} + \frac{0,25791}{z_{n2}} - 0,00635 x_1 - 0,00193 x_2 - \frac{0,11654 x_1}{z_{n1}} - \frac{0,24188 x_2}{z_{n2}} + 0,00529 x_1^2 + 0,00182 x_2^2}$$

where the following limitations are to be verified:

- $x_1 \geq x_2$ , and
- $-0,5 \leq x_1 + x_2 \leq 2,0$

For internal gears,  $z_{n2}$  should be replaced by infinity

$C_M$  : Measurements correction factor, equal to:  
 $C_M = 0,8$

$C_R$  : Gear blank factor:

- for solid disc gears ( $s_R = 0$ ):  
 $C_R = 1,0$
- otherwise:  

$$C_R = 1 + \frac{\ln(b_s/b)}{5 \cdot e^{s_R/5m_n}}$$

with the following limitations:  
 $0,2 \leq b_s / b \leq 1,2$  and  $s_R / m_n \geq 1$

$C_B$  : Basic rack factor, equal to:

$$C_B = 1 + 0,5 \cdot \left( 1,2 - \frac{h_{IP}}{m_n} \right) \cdot [1,0 - 0,02 \cdot (20 - \alpha_n)]$$

When pinion basic rack dedendum is different from that of the wheel,  $C_B = 0,5 (C_{B1} + C_{B2})$ .

**2.3.5 Face load distribution factors  $K_{H\beta}$  and  $K_{F\beta}$  (method C)**

The face load distribution factors,  $K_{H\beta}$  for contact stress and  $K_{F\beta}$  for tooth root bending stress, account for the effects of non-uniform distribution of load across the face width.

a) The values of  $K_{H\beta}$  are given in Tab 10. They apply only to gears with:

- wheel, case, wheel shaft and bearings of stiff construction
- pinion on a solid or hollow shaft with an inner diameter ratio not exceeding 0,5 and located symmetrically between the bearings
- no effect of clearances
- no external loads acting on the pinion shaft.

Note 1: Gears for which the above conditions are not satisfied will be given special consideration by the Society.

The calculation of the initial equivalent misalignment  $F_{\beta x}$  is defined in Tab 11.

The calculations of the running-in allowance  $\gamma\beta$  and the running-in factor  $\chi\beta$  are defined in Tab 12.

The calculation of the mesh misalignment due to deformations of shafts depends on the constant of the pinion  $K'$  and the distance  $s$  of the pinion. They are defined in Tab 13.

b)  $K_{F\beta}$  is to be determined using the following formula:

$$K_{F\beta} = K_{H\beta} \frac{1}{1 + h/b_B + (h/b_B)^2}$$

where  $b/h$  is the smaller of  $b_{B1}/h_1$  and  $b_{B2}/h_2$  but is not to be taken lower than 3.

**2.3.6 Transverse load distribution factors  $K_{H\alpha}$  and  $K_{F\alpha}$  (method B)**

The transverse load distribution factors,  $K_{H\alpha}$  for contact stress and  $K_{F\alpha}$  for tooth root bending stress, account for the effects of pitch and profile errors on the transversal load distribution between two or more pairs of teeth in mesh.

The values of  $K_{H\alpha}$  and  $K_{F\alpha}$  are given in Tab 14.

**Table 10 : Face load factor for contact stress  $K_{H\beta}$**

	Calculated face width	Factor $K_{H\beta}$

Table 13 : Constant of the pinion  $K'$  and distance of the pinion  $s$

Arrangement (1)	Constant $K'$ with stiffening	Constant $K'$ without stiffening (2)
	0,48	0,8
	- 0,48	- 0,8
	1,33	1,33
	- 0,36	- 0,6
	- 0,6	- 1,0

- (1) The following limitation is to be verified except when helix correction is applied:  
 $s / l < 0,3$
- (2) No stiffening is assumed when  $d_1 / d_{sh} < 1,15$  or when the pinion is keyed or shrunk to the shaft.

**Table 14 : Transverse load factors  $K_{H\alpha}$  and  $K_{F\alpha}$**

	Factors $K_{H\alpha}$ and $K_{F\alpha}$	Limitations
$\varepsilon_\gamma \leq 2$	$K_{H\alpha} = K_{F\alpha} = \frac{\varepsilon_\gamma}{2} \left[ 0,9 + 0,4 \frac{c_{\gamma\alpha}(f_{pb} - \gamma_\alpha)}{F_{tH}/b} \right]$	$\frac{\varepsilon_\gamma}{\varepsilon_\alpha Z_\varepsilon^2} \geq K_{H\alpha} \geq 1$
$\varepsilon_\gamma > 2$	$K_{H\alpha} = K_{F\alpha} = 0,9 + 0,4 \sqrt{\frac{2(\varepsilon_\gamma - 1)}{\varepsilon_\gamma} \frac{c_{\gamma\alpha}(f_{pb} - \gamma_\alpha)}{F_{tH}/b}}$	$\frac{\varepsilon_\gamma}{0,25 \varepsilon_\alpha + 0,75} \geq K_{F\alpha} \geq 1$

**Note 1:**  
 $c_{\gamma\alpha}$  : Mesh stiffness, in N/mm.μm, defined in Tab 9  
 $f_{pb}$  : Larger value of the base pitch deviation of pinion or wheel, in μm.  
 Default value:  $f_{pb} = 0,3 (m_n + 0,4 |d_{bil}|^{0,5} + 4) \cdot 2^{0,5(Q_i - 5)}$   
 In case of optimum profile correction,  $f_{pb}$  is to be replaced by  $f_{pb} / 2$   
 $\gamma_\alpha$  : Running-in allowance, in μm, defined in Tab 15  
 $F_{tH}$  : Determinant tangential load in transverse plane, in N:  
 $F_{tH} = F_t \cdot K_A \cdot K_V \cdot K_{H\beta}$

**Table 15 : Running-in allowance  $\gamma_\alpha$**

Material	$\gamma_\alpha$ , in μm	Limitations
St, St (cast), GTS (perl.), GGG (perl.), GGG (bai.), V, V (cast)	$\gamma_\alpha = \frac{160}{\sigma_{H,lim}} f_{pb}$	<ul style="list-style-type: none"> <li>if 5 m/s &lt; v ≤ 10 m/s: <math>\gamma_\alpha \leq 12800 / \sigma_{H,lim}</math></li> <li>if 10 m/s &lt; v: <math>\gamma_\alpha \leq 6400 / \sigma_{H,lim}</math></li> </ul>
GGG (ferr.), GG	$\gamma_\alpha = 0,275 f_{pb}$	<ul style="list-style-type: none"> <li>if 5 m/s &lt; v ≤ 10 m/s: <math>\gamma_\alpha \leq 22</math></li> <li>if 10 m/s &lt; v: <math>\gamma_\alpha \leq 11</math></li> </ul>
Eh, IF, NT (nitr.), NV (nitr.), NV (nitrocar.)	$\gamma_\alpha = 0,075 f_{pb}$	$\gamma_\alpha \leq 3$

**Note 1:**  $f_{pb}$  is defined in Tab 14 and  $\sigma_{H,lim}$  is defined in [2.4.9].  
**Note 2:** When material of the pinion differs from that of the wheel:  $\gamma_\alpha = 0,5 (\gamma_{\alpha 1} + \gamma_{\alpha 2})$

## 2.4 Calculation of surface durability

### 2.4.1 General

The criterion for surface durability is based on the contact stress (hertzian pressure)  $\sigma_H$  on the pitch point or at the inner point of single pair contact.

The contact stress  $\sigma_H$ , defined in [2.4.2], is not to exceed the permissible contact stress  $\sigma_{Hp}$  defined in [2.4.8].

### 2.4.2 Contact stress $\sigma_H$

The contact stress  $\sigma_H$ , in N/mm<sup>2</sup>, is to be determined as follows.

- for the pinion:

$$\sigma_H = Z_B \cdot \sigma_{H0} \sqrt{K_A \cdot K_\gamma \cdot K_V \cdot K_{H\beta} \cdot K_{H\alpha}}$$

- for the wheel:

$$\sigma_H = Z_D \cdot \sigma_{H0} \sqrt{K_A \cdot K_\gamma \cdot K_V \cdot K_{H\beta} \cdot K_{H\alpha}}$$

where:

$Z_B, Z_D$  : Single pair mesh factors, respectively for pinion and for wheel, defined in [2.4.3]

$K_A$  : Application factor (see [2.3.2])

$K_\gamma$  : Load sharing factor (see [2.3.3])

$K_V$  : Dynamic factor (see [2.3.4])

$K_{H\beta}$  : Face load distribution factor (see [2.3.5])

$K_{H\alpha}$  : Transverse load distribution factor (see [2.3.6])

$$\sigma_{H0} = Z_H \cdot Z_E \cdot Z_\varepsilon \cdot Z_\beta \sqrt{\frac{F_t}{d_1 \cdot b} \cdot \frac{|u| + 1}{|u|}}$$

with:

$Z_H$  : Zone factor, defined in [2.4.4]

$Z_E$  : Elasticity factor, defined in [2.4.5]

$Z_\varepsilon$  : Contact ratio factor, defined in [2.4.6]

$Z_\beta$  : Helix angle factor, defined in [2.4.7].

**2.4.3 Single pair mesh factors  $Z_B$  and  $Z_D$**

The single pair mesh factors  $Z_B$  for pinion and  $Z_D$  for wheel account for the influence on contact stresses of the tooth flank curvature at the inner point of single pair contact in relation to  $Z_H$ . These factors transform the contact stress determined at the pitch point to contact stresses, considering the flank curvature at the inner point of single pair contact.

$Z_B$  and  $Z_D$  are to be determined as follows:

a) for spur gears ( $\epsilon_\beta = 0$ ):

- $Z_B = M_1$  or 1, whichever is the greater, with:

$$M_1 = \frac{\tan \alpha_{tw}}{\sqrt{\left[ \sqrt{\left( \frac{d_{a1}}{d_{b1}} \right)^2 - 1 - \frac{2\pi}{Z_1}} \right] \cdot \left[ \sqrt{\left( \frac{d_{a2}}{d_{b2}} \right)^2 - 1 - (\epsilon_\alpha - 1) \frac{2\pi}{Z_2}} \right]}}$$

- $Z_D = M_2$  or 1, whichever is the greater, with:

$$M_2 = \frac{\tan \alpha_{tw}}{\sqrt{\left[ \sqrt{\left( \frac{d_{a2}}{d_{b2}} \right)^2 - 1 - \frac{2\pi}{Z_2}} \right] \cdot \left[ \sqrt{\left( \frac{d_{a1}}{d_{b1}} \right)^2 - 1 - (\epsilon_\alpha - 1) \frac{2\pi}{Z_1}} \right]}}$$

b) for helical gears:

- if  $\epsilon_\beta \geq 1$ :  
 $Z_B = Z_D = 1$
- if  $\epsilon_\beta < 1$ :  
 $Z_B = M_1 - \epsilon_\beta (M_1 - 1)$  or 1, whichever is the greater  
 $Z_D = M_2 - \epsilon_\beta (M_2 - 1)$  or 1, whichever is the greater.

Note 1: For gears with  $\epsilon_\alpha \leq 1$ , a specific analysis of the decisive contact stress along the path of contact is necessary.

Note 2: For internal gears,  $Z_D = 1$ .

**2.4.4 Zone factor  $Z_H$**

The zone factor  $Z_H$  accounts for the influence on the hertzian pressure of tooth flank curvature at the pitch point and transforms the tangential force at the reference cylinder to normal force at the pitch cylinder.

$Z_H$  is to be determined as follows:

$$Z_H = \frac{\sqrt{2 \cdot \cos \beta_b \cdot \cos \alpha_{tw}}}{\sqrt{(\cos \alpha_i)^2 \cdot \sin \alpha_{tw}}}$$

**2.4.5 Elasticity factor  $Z_E$**

The elasticity factor  $Z_E$  accounts for the influence of the metal properties (module of elasticity  $E$  and Poisson's ratio  $\nu$ ) on the hertzian pressure.

For steel gears:  $Z_E = 189,8 \text{ N}^{1/2}/\text{mm}$ .

Note 1: Refer to ISO 6336-2 for other materials.

**2.4.6 Contact ratio factor  $Z_\epsilon$**

The contact ratio factor  $Z_\epsilon$  accounts for the influence of the transverse contact ratio and the overlap ratio on the specific surface load of gears.

$Z_\epsilon$  is to be determined as follows:

a) for spur gears ( $\epsilon_\beta = 0$ ):

$$Z_\epsilon = \sqrt{\frac{4 - \epsilon_\alpha}{3}}$$

b) for helical gears:

- for  $\epsilon_\beta \geq 1$ :

$$Z_\epsilon = \frac{\sqrt{1}}{\sqrt{\epsilon_\alpha}}$$

- for  $\epsilon_\beta < 1$ :

$$Z_\epsilon = \sqrt{\frac{4 - \epsilon_\alpha}{3} \cdot (1 - \epsilon_\beta) + \frac{\epsilon_\beta}{\epsilon_\alpha}}$$

**2.4.7 Helix angle factor  $Z_\beta$**

The helix angle factor  $Z_\beta$  accounts for the influence of helix angle on the surface durability, allowing for such variables as the distribution of the load along the lines of contact.

$Z_\beta$  is to be determined as follows:

$$Z_\beta = \frac{1}{\sqrt{\cos\beta}}$$

**2.4.8 Permissible contact stress  $\sigma_{HP}$**

The permissible contact stress  $\sigma_{HP}$ , in N/mm<sup>2</sup>, is to be determined separately for pinion and wheel, using the following formula:

$$\sigma_{HP} = \frac{\sigma_{H,lim}}{S_H} \cdot Z_{NT} \cdot Z_L \cdot Z_V \cdot Z_R \cdot Z_W \cdot Z_X$$

where:

- $\sigma_{H,lim}$  : Endurance limit for contact stress, defined in [2.4.9]
- $Z_{NT}$  : Life factor for contact stress, defined in [2.4.10]
- $Z_L, Z_V, Z_R$ : Lubrication, speed and roughness factors, respectively, defined in [2.4.11]
- $Z_W$  : Hardness ratio factor, defined in [2.4.12]
- $Z_X$  : Size factor for contact stress, defined in [2.4.13]
- $S_H$  : Safety factor for contact stress, defined in [2.4.14].

**2.4.9 Endurance limit for contact stress  $\sigma_{H,lim}$**

The endurance limit for contact stress  $\sigma_{H,lim}$  is the limit of repeated contact stress which can be permanently endured.

The values to be adopted for  $\sigma_{H,lim}$  are given, in N/mm<sup>2</sup>, with the following formula, in relation to the type of steel employed and the heat treatment performed:

$$\sigma_{H,lim} = A \cdot x + B$$

where:

- A, B : Constants determined in Tab 16
  - x : Surface hardness HB or HV, in N/mm<sup>2</sup>. The limitations  $x_{min}$  and  $x_{max}$  on surface hardness are indicated in Tab 16.
- Special consideration will be given to other values of  $\sigma_{H,lim}$ , depending on the material category and specification of the steel employed.

**Table 16 : Constants A and B and limitations on surface hardness HB or HV**

	Quality (1)	A	B (N/mm <sup>2</sup> )	Hardness	$x_{min}$ (N/mm <sup>2</sup> )	$x_{max}$ (N/mm <sup>2</sup> )

(1) The requirements for each material quality are defined in ISO 6336-5.

**2.4.10 Life factor for contact stress Z<sub>NT</sub>**

The life factor Z<sub>NT</sub> accounts for the influence of limited service life on the permissible contact stress.

Some values of Z<sub>NT</sub> are given for information in Tab 17.

The value of Z<sub>NT</sub> to be used will be given special consideration by the Society, depending on the equipment’s arrangement and use.

**Table 17 : Life factor Z<sub>NT</sub>**

Material	Number of load cycles N <sub>L</sub>	Z <sub>NT</sub>
St, St (cast), GTS (perl.), GGG (perl.), GGG (bai.), V, V (cast), Eh, IF	N <sub>L</sub> ≤ 10 <sup>5</sup> or static	1,6
	N <sub>L</sub> = 5 · 10 <sup>7</sup>	1,0

	N <sub>L</sub> = 2 · 10 <sup>6</sup>	1,0
	N <sub>L</sub> = 10 <sup>10</sup>	0,85 up to 1,0
NV (nitrocar.)	N <sub>L</sub> ≤ 10 <sup>5</sup> or static	1,1
	N <sub>L</sub> = 2 · 10 <sup>6</sup>	1,0
	N <sub>L</sub> = 10 <sup>10</sup>	0,85 up to 1,0

### 2.4.11 Lubricant factor $Z_L$ , speed factor $Z_V$ and roughness factor $Z_R$

The lubricant factor  $Z_L$  accounts for the influence of the type of the lubricant and the influence of its viscosity, the speed factor  $Z_V$  accounts for the influence of the pitch line velocity, and the roughness factor  $Z_R$  accounts for the influence of the surface roughness on the surface endurance capacity.

These factors are to be determined as follows:

a) Lubricant factor  $Z_L$

$$Z_L = C_{ZL} + \frac{4 \cdot (1,0 - C_{ZL})}{\left(1,2 + \frac{134}{v_{40}}\right)^2}$$

where:

$C_{ZL}$  : Constant for lubricant factor, equal to:

- for  $\sigma_{H,lim} < 850 \text{ N/mm}^2$ :  
 $C_{ZL} = 0,83$
- if  $850 \text{ N/mm}^2 \leq \sigma_{H,lim} \leq 1200 \text{ N/mm}^2$ :

$$C_{ZL} = \frac{\sigma_{H,lim}}{4375} + 0,6357$$

- if  $\sigma_{H,lim} > 1200 \text{ N/mm}^2$ :  
 $C_{ZL} = 0,91$

b) Speed factor  $Z_V$

$$Z_V = C_{ZV} + \frac{2 \cdot (1,0 - C_{ZV})}{\sqrt{0,8 + \frac{32}{v}}}$$

where:

$C_{ZV}$  : Constant for speed factor, equal to:

$$C_{ZV} = C_{ZL} + 0,02$$

c) Roughness factor  $Z_R$

$$Z_R = \left(\frac{3}{R_{Z10}}\right)^{C_{ZR}}$$

where:

$R_{Z10}$  : Mean relative peak-to-valley roughness for the gear pair, in  $\mu\text{m}$ , equal to:

$$R_{Z10} = R_{Zi} \left(\frac{10}{\rho_{red}}\right)^{1/3}$$

$\rho_{red}$  : Relative radius of curvature, in mm, equal to:

$$\rho_{red} = \frac{0,5 \cdot d_{b1} \cdot d_{b2} \cdot \tan \alpha_{wt}}{d_{b1} + d_{b2}}$$

$d_b$  being taken negative for internal gears

$R_{Zi}$  : Mean peak-to-valley flank roughness for the gear pair, in  $\mu\text{m}$ , equal to:

$$R_{Zi} = \frac{R_{Zi1} + R_{Zi2}}{2}$$

$C_{ZR}$  : Constant for roughness factor, equal to:

- if  $\sigma_{H,lim} < 850 \text{ N/mm}^2$ :  
 $C_{ZR} = 0,15$
- if  $850 \text{ N/mm}^2 \leq \sigma_{H,lim} \leq 1200 \text{ N/mm}^2$ :

$$C_{ZR} = 0,32 - \frac{\sigma_{H,lim}}{5000}$$

- if  $\sigma_{H,lim} > 1200 \text{ N/mm}^2$ :  
 $C_{ZR} = 0,08$

### 2.4.12 Hardness ratio factor $Z_W$

The hardness ratio factor  $Z_W$  accounts for the increase of the surface durability in the following cases:

a) Surface-hardened with through-hardened wheel

- if  $HB < 130$ :

$$Z_W = 1,2 \cdot \left(\frac{3}{R_{ZH}}\right)^{0,15}$$

- if  $130 \leq HB \leq 470$ :

$$Z_W = \left( 1,2 - \frac{HB - 130}{1700} \right) \cdot \left( \frac{3}{R_{ZH}} \right)^{0,15}$$

- if  $HB > 470$ :

$$Z_W = \left( \frac{3}{R_{ZH}} \right)^{0,15}$$

where:

$R_{ZH}$  : Equivalent roughness, in  $\mu\text{m}$ , equal to:

$$R_{ZH} = \frac{R_{Zf1} (10/\rho_{red})^{0,33} \cdot (R_{Zf1}/R_{Zf2})^{0,66}}{(v_{40} \cdot v/1500)^{0,33}}$$

$\rho_{red}$  being the relative radius of curvature defined in [2.4.11].

- b) Through-hardened pinion and wheel with pinion substantially harder than the wheel (in that case, the hardness factor is to be applied only to the wheel)

- if  $HB_1 / HB_2 < 1,2$ :

$$Z_W = 1,0$$

- if  $1,2 \leq HB_1 / HB_2 \leq 1,7$ :

$$Z_W = 1 + \left( 0,00898 \frac{HB_1}{HB_2} - 0,00829 \right) \cdot (u - 1,0)$$

- if  $HB_1 / HB_2 > 1,7$ :

$$Z_W = 1,0 + 0,00698 (u - 1,0)$$

Note 1: In any cases,  $Z_W \geq 1$

Note 2: If  $u > 20$ ,  $u = 20$  is to be taken.

### 2.4.13 Size factor $Z_X$

The size factor  $Z_X$  accounts for the influence of tooth dimensions on permissible contact stress and reflects the non-uniformity of material properties.

$Z_X$  is in general equal to 1.

The value of  $Z_X$  to be used will be given special consideration by the Society depending on the material.

### 2.4.14 Safety factor for contact stress $S_H$

The values to be adopted for safety factor for contact stress  $S_H$  are given in Tab 18.

**Table 18 : Safety factor for contact stress  $S_H$**

Type of installation		$S_H$
Main gears (propulsion)	single machinery	1,25
	duplicate machinery	1,20
Auxiliary gears		1,15

## 2.5 Calculation of tooth bending strength

### 2.5.1 General

The criterion for the tooth root bending strength is based on the local tensile stress at the tooth root in the direction of the tooth height.

The tooth root bending stress  $\sigma_F$ , defined in [2.5.2], is not to exceed the permissible tooth root bending stress  $\sigma_{FP}$  defined in [2.5.8].

### 2.5.2 Tooth root bending stress $\sigma_F$

The tooth root bending stress  $\sigma_F$  is to be determined as follows:

$$\sigma_F = \frac{F_t}{b \cdot m_n} Y_F \cdot Y_S \cdot Y_\beta \cdot Y_B \cdot Y_{DT} \cdot K_A \cdot K_V \cdot K_{F\beta} \cdot K_{F\alpha}$$

where:

- $Y_F$  : Tooth form factor, defined in [2.5.3]
- $Y_S$  : Stress correction factor, defined in [2.5.4]
- $Y_\beta$  : Helix angle factor, defined in [2.5.5]
- $Y_B$  : Rim thickness factor, defined in [2.5.6]

- $Y_{DT}$  : Deep tooth factor, defined in [2.5.7]  
 $K_A$  : Application factor (see [2.3.2])  
 $K_V$  : Load sharing factor (see [2.3.3])  
 $K_V$  : Dynamic factor (see [2.3.4])  
 $K_{F\beta}$  : Face load distribution factor (see [2.3.5])  
 $K_{F\alpha}$  : Transverse load distribution factor (see [2.3.6]).

When a shot peening treatment of the tooth root is applied according to a process agreed by the Society, a reduction of the bending stress  $\sigma_F$  (depending on the material category, but without being over 10%) could be taken in consideration only for carburized case-hardened steel gears.

### 2.5.3 Tooth form factor $Y_F$ (method B)

The tooth form factor  $Y_F$  takes into account the effect of the tooth form on the nominal bending stress, assuming the load applied at the outer point of a single pair tooth contact.

In the case of helical gears, the form factors are to be determined in the normal section, i.e. for the virtual spur gear with the virtual number of teeth  $z_n$ .

$Y_F$  is to be determined separately for the pinion and the wheel, using the following formula:

$$Y_F = \frac{6 \frac{h_{Fe}}{m_n} \cos \alpha_{Fen}}{\left(\frac{s_{Fn}}{m_n}\right)^2 \cos \alpha_n}$$

where:

$h_{Fe}$  : Bending moment arm, in mm:

- for external gears:

$$\frac{h_{Fe}}{m_n} = \frac{1}{2} \left[ (\cos \gamma_e - \sin \gamma_e \tan \alpha_{Fen}) \frac{d_{en}}{m_n} \right] - \frac{1}{2} \left[ z_n \cos \left( \frac{\pi}{3} - \theta \right) + \left( \frac{G}{\cos \theta} - \frac{\rho_{fPv}}{m_n} \right) \right]$$

- for internal gears:

$$\frac{h_{Fe}}{m_n} = \frac{1}{2} \left[ (\cos \gamma_e - \sin \gamma_e \tan \alpha_{Fen}) \frac{d_{en}}{m_n} \right] - \frac{1}{2} \left[ z_n \cos \left( \frac{\pi}{6} - \theta \right) - \sqrt{3} \left( \frac{G}{\cos \theta} - \frac{\rho_{fPv}}{m_n} \right) \right]$$

$s_{Fn}$  : Tooth root chord at the critical section, in mm:

- for external gears:

$$\frac{s_{Fn}}{m_n} = z_n \sin \left( \frac{\pi}{3} - \theta \right) + \sqrt{3} \left( \frac{G}{\cos \theta} - \frac{\rho_{fPv}}{m_n} \right)$$

- for internal gears:

$$\frac{s_{Fn}}{m_n} = z_n \sin \left( \frac{\pi}{6} - \theta \right) + \left( \frac{G}{\cos \theta} - \frac{\rho_{fPv}}{m_n} \right)$$

$\rho_{fPv}$  : Fillet radius at the basic rack, in mm:

- for external gears:

$$\rho_{fPv} = \rho_{a0}$$

- for internal gears:

$$\rho_{fPv} = \rho_{a0} + m_n \cdot \frac{(x_2 + h_{fp}/m_n - \rho_{a0}/m_n)^{1.95}}{3,156 \cdot 1,036^{z_2}}$$

$G$  : Parameter defined by the following formula:

$$G = \frac{\rho_{fPv}}{m_n} - \frac{h_{fp}}{m_n} + x$$

$\theta$  : Parameter defined by the following formula:

$$\theta = \frac{2G}{z_n} \tan \theta - H$$

This transcendental equation is to be calculated by iteration

H : Parameter defined by the following formulae:

- for external gears:

$$H = \frac{2}{z_n} \left( \frac{\pi}{2} - \frac{E}{m_n} \right) - \frac{\pi}{3}$$

- for internal gears:

$$H = \frac{2}{z_n} \left( \frac{\pi}{2} - \frac{E}{m_n} \right) - \frac{\pi}{6}$$

E : Parameter defined by the following formula:

$$E = \frac{\pi}{4} m_n - h_{fp} \tan \alpha_n + \frac{s_{pr}}{\cos \alpha_n} - (1 - \sin \alpha_n) \frac{\rho_{a0}}{\cos \alpha_n}$$

$s_{pr}$  : Residual fillet undercut, in mm:

$$s_{pr} = pr - q$$

The parameters of the virtual gears are defined as follows:

$\alpha_{Fen}$  : Load direction angle:

$$\alpha_{Fen} = \alpha_{en} - \gamma_e$$

$\gamma_e$  : Parameter defined by the following formula:

$$\gamma_e = \frac{0,5 \pi + 2 \cdot \tan \alpha_n \cdot x}{z_n} + \text{inv} \alpha_n - \text{inv} \alpha_{en}$$

with inv, involute function, equal to:

$$\text{inv} \alpha = \tau \alpha \nu \alpha - \alpha$$

$\alpha_{en}$  : Form factor pressure angle:

$$\cos \alpha_{en} = \frac{d_{bn}}{d_{en}}$$

$d_{bn}$  : Virtual base diameter, in mm:

$$d_{bn} = d_n \cos \alpha_n$$

with:

$d_n$  : Virtual reference diameter, in mm:

$$d_n = \frac{d}{(\cos \beta_b)^2} = m_n z_n$$

$d_{en}$  : Parameter defined by the following formula:

$$d_{en} = \frac{2z}{|z|} \sqrt{\left[ \frac{\sqrt{d_{an}^2 - d_{bn}^2} - \frac{\pi d \cos \beta \cos \alpha_n}{|z|} (\varepsilon_{\alpha n} - 1)}{2} \right]^2 + \frac{d_{bn}^2}{4}}$$

with:

$d_{an}$  : Virtual tip diameter, in mm:

$$d_{an} = d_n + d_a - d$$

$\varepsilon_{\alpha n}$  : Virtual transverse contact ratio:

$$\varepsilon_{\alpha n} = \frac{\varepsilon_{\alpha}}{(\cos \beta_b)^2}$$

#### 2.5.4 Stress correction factor $Y_s$ (method B)

The stress correction factor  $Y_s$  is used to convert the nominal bending stress to local tooth root stress, assuming the load is applied at the outer point of a single pair tooth contact. It takes into account the influence of:

- the bending moment
- the proximity of the load application to the critical section.

$Y_s$  is to be determined as follows:

$$Y_s = (1,2 + 0,13L) q_s^{\left( \frac{1}{1,21 + (2,3/L)} \right)}$$

where:

$$L = \frac{s_{Fn}}{h_{Fe}}$$

with  $s_{Fn}$  and  $h_{Fe}$  defined in [2.5.3]

$q_s$  : Notch parameter:

$$q_s = \frac{s_{Fn}}{2\rho_F}$$

with  $s_{Fn}$  defined in [2.5.3]

Note 1: The notch parameter should be within the range:

$$1 \leq q_s < 8$$

$\rho_F$  : Radius of root fillet, in mm:

$$\frac{\rho_F}{m_n} = \frac{\rho_{fPv}}{m_n} + \frac{2G^2}{\cos\theta \cdot (|z_n| \cdot \cos^2\theta - 2G)}$$

### 2.5.5 Helix angle factor $Y_\beta$

The helix angle factor  $Y_\beta$  converts the tooth root stress of a virtual spur gear to that of the corresponding helical gear, taking into account the oblique orientation of the lines of mesh contact.

$Y_\beta$  is to be determined as follows:

if  $\epsilon_\beta \leq 1$  and  $\beta \leq 30^\circ$ :  $Y_\beta = 1 - \epsilon_\beta \beta / 120$

if  $\epsilon_\beta \leq 1$  and  $\beta > 30^\circ$ :  $Y_\beta = 1 - 0,25 \epsilon_\beta$

if  $\epsilon_\beta > 1$  and  $\beta \leq 30^\circ$ :  $Y_\beta = 1 - \beta / 120$

if  $\epsilon_\beta > 1$  and  $\beta > 30^\circ$ :  $Y_\beta = 0,75$

### 2.5.6 Rim thickness factor $Y_B$

The rim thickness factor  $Y_B$  is a simplified factor used to de-rate thin rimmed gears. For critically loaded applications, this method should be replaced by a more comprehensive analysis.

$Y_B$  is to be determined as follows:

- for external gears:

- when  $s_R / h \geq 1,2$ :

$$Y_B = 1,0$$

- when  $1,2 > s_R / h > 0,5$ :

$$Y_B = 1,6 \ln\left(2,242 \frac{h}{s_R}\right)$$

Note 1:  $s_R / h \leq 0,5$  is to be avoided.

- for internal gears:

- when  $s_R / m_n \geq 3$ :

$$Y_B = 1,0$$

- when  $3 > s_R / m_n > 1,75$ :

$$Y_B = 1,15 \ln\left(8,324 \frac{m_n}{s_R}\right)$$

Note 2:  $s_R / h \leq 1,75$  is to be avoided.

### 2.5.7 Deep tooth factor $Y_{DT}$

The deep tooth factor  $Y_{DT}$  adjusts the tooth root stress to take into account high precision gears and contact ratios within the range  $2,05 < \epsilon_{an} \leq 2,5$  (where  $\epsilon_{an}$  is defined in [2.5.3]).

$Y_{DT}$  is to be determined as follows:

- if  $\epsilon_{an} > 2,5$  and  $A \leq 4$ :  $Y_{DT} = 0,7$
- if  $2,05 < \epsilon_{an} \leq 2,5$  and  $A \leq 4$ :  $Y_{DT} = -0,666 \epsilon_{an} + 2,366$
- otherwise:  $Y_{DT} = 1,0$

### 2.5.8 Permissible tooth root bending stress $\sigma_{FP}$

The permissible tooth root bending stress  $\sigma_{FP}$  is to be determined separately for pinion and for wheel, using the following formula:

$$\sigma_{FP} = \frac{\sigma_{FE}}{S_F} \cdot Y_d \cdot Y_{NT} \cdot Y_{\delta relT} \cdot Y_{R relT} \cdot Y_X$$

where:

$\sigma_{FE}$  : Endurance limit for tooth root bending stress, defined in [2.5.9]

$Y_d$  : Design factor, defined in [2.5.10]

$Y_{NT}$  : Life factor for tooth root bending stress, defined in [2.5.11]

$Y_{\delta relT}$  : Relative notch sensitive factor, defined in [2.5.12]

$Y_{R relT}$  : Relative surface factor, defined in [2.5.13]

- $Y_x$  : Size factor for tooth root bending stress, defined in [2.5.14]  
 $S_F$  : Safety factor for tooth root bending stress, defined in [2.5.15].

**2.5.9 Endurance limit for tooth root bending stress  $\sigma_{FE}$**

The endurance limit for tooth root bending stress  $\sigma_{FE}$  is the local tooth root stress which can be permanently endured.

The values to be adopted for  $\sigma_{FE}$  are given, in N/mm<sup>2</sup>, with the following formula, in relation to the type of steel employed and the heat treatment performed:

$$\sigma_{FE} = A \times B$$

where:

A, B : Constants determined in Tab 19

x : Surface hardness HB or HV, in N/mm<sup>2</sup>. The limitations  $x_{min}$  and  $x_{max}$  on surface hardness are indicated in Tab 19.

Special consideration will be given to other values of  $\sigma_{FE}$ , depending on the material category and specification of the steel employed.

**Table 19 : Constants A and B and limitations on surface hardness HB or HV**

Material	Quality (1)	A	B (N/mm <sup>2</sup> )	Hardness	$x_{min}$ (N/mm <sup>2</sup> )	$x_{max}$ (N/mm <sup>2</sup> )

(1) The requirements for each material quality are defined in ISO 6336-5.

### 2.5.10 Design factor Y<sub>d</sub>

The design factor Y<sub>d</sub> takes into account the influence of load reversing and shrink fit prestressing on the tooth root strength.

Y<sub>d</sub> is to be determined as follows:

- for gears with occasional part load in reverse direction, such as main wheel in reverse gearboxes:

$$Y_d = 0,9$$

- for idler gears (driven and driving tooth for each cycle i.e. alternating load):

$$Y_d = 0,7$$

- for shrunk on pinions and wheel rims:

$$Y_d = 1 - \sigma_T / \sigma_{FE}$$

with:

$\sigma_{FE}$  : Endurance limit for tooth root bending stress (see [2.5.9])

$\sigma_T$  : Tangential stress induced by the shrinkage at the tooth root diameter.

The maximum equivalent stress induced by the shrinkage in the inner diameter of the rim is not to exceed 80% of the yield strength of the rim material.

- otherwise:

$$Y_d = 1,0$$

### 2.5.11 Life factor Y<sub>NT</sub>

The life factor Y<sub>NT</sub> accounts for the influence of limited service life on the permissible tooth root bending stress.

Some values of Y<sub>NT</sub> are given in Tab 20 for information.

The value Y<sub>NT</sub> to be used will be given special consideration by the Society depending on the equipment's arrangement and use.

**Table 20 : Life factor Y<sub>NT</sub>**

Material	Number of load cycles N <sub>L</sub>	Y <sub>NT</sub>
St, St (cast), GTS (perl.), GGG (perl.), GGG (bai.), V, V (cast), Eh, IF	N <sub>L</sub> ≤ 10 <sup>3</sup> or static	2,5
	N <sub>L</sub> = 3 · 10 <sup>6</sup>	1,0
	N <sub>L</sub> = 10 <sup>10</sup>	0,85 up to 1,0
GGG (ferr.), GG, NT (nitr.), NV (nitr.)	N <sub>L</sub> ≤ 10 <sup>3</sup> or static	1,6
	N <sub>L</sub> = 3 · 10 <sup>6</sup>	1,0
	N <sub>L</sub> = 10 <sup>10</sup>	0,85 up to 1,0
NV (nitrocar.)	N <sub>L</sub> ≤ 10 <sup>3</sup> or static	1,1
	N <sub>L</sub> = 3 · 10 <sup>6</sup>	1,0
	N <sub>L</sub> = 10 <sup>10</sup>	0,85 up to 1,0

**2.5.12 Relative notch sensitivity factor  $Y_{\delta_{relT}}$**

The relative notch sensitivity factor  $Y_{\delta_{relT}}$  indicates the extent to which the theoretically concentrated stress lies above the fatigue endurance limit.

$Y_{\delta_{relT}}$  is to be determined as follows:

$$Y_{\delta_{relT}} = \frac{1 + \sqrt{\rho' \cdot 0,2 \cdot (1 + 2q_s)}}{1 + \sqrt{\rho' \cdot 1,2}}$$

where:

- $q_s$  : Notch parameter, as defined in [2.5.4]
- $\rho'$  : Slip-layer thickness, in mm, defined in Tab 21.

**Table 21 : Slip-layer thickness  $\rho'$**

Material	$\rho'$ (mm)
GG, $R_m = 150 \text{ N/mm}^2$	0,3124
GG, GGG (ferr.) $R_m = 300 \text{ N/mm}^2$	0,3095
NT, NV	0,1005
St, $R_e = 300 \text{ N/mm}^2$	0,0833
St, $R_e = 400 \text{ N/mm}^2$	0,0445
V, GTS, GGG (perl. bai.), $R_e = 500 \text{ N/mm}^2$	0,0281
V, GTS, GGG (perl. bai.), $R_e = 600 \text{ N/mm}^2$	0,0194
V, GTS, GGG (perl. bai.), $R_e = 800 \text{ N/mm}^2$	0,0064
V, GTS, GGG (perl. bai.), $R_e = 1000 \text{ N/mm}^2$	0,0014
Eh, IF	0,0030

**2.5.13 Relative surface factor  $Y_{R_{relT}}$**

The relative surface factor  $Y_{R_{relT}}$  takes into account the dependence of the root strength on the surface condition on the tooth root fillet (roughness).

The values to be adopted for  $Y_{R_{relT}}$  are given in Tab 22 in relation to the type of steel employed.

They are valid only when scratches or similar defects deeper than  $12 R_a$  are not present.

**Table 22 : Relative surface factor  $Y_{R_{relT}}$**

Material	$Y_{R_{relT}}$	
	$R_z < 1$	$1 \leq R_z \leq 40$
V, V (cast), GGG (perl.), GGG (bai.), Eh, IF	1,120	$1,674 - 0,529 (R_z + 1)^{0,1}$
St, St (cast)	1,070	$5,306 - 4,203 (R_z + 1)^{0,01}$
GG, GGG (ferr.), NT, NV	1,025	$4,299 - 3,259 (R_z + 1)^{0,0058}$
<b>Note 1:</b>		
$R_z$ : Mean peak-to-valley roughness, in $\mu\text{m}$ : $R_z = 6 R_a$ with $R_a$ : Arithmetic mean roughness.		

**2.5.14 Size factor  $Y_x$**

The size factor  $Y_x$  takes into account the decrease of the strength with increasing size.

The values to be adopted for  $Y_x$  are given in Tab 23 in relation to the type of steel employed and the value of the normal module  $m_n$ .

**Table 23 : Size factor  $Y_x$**

Material	Normal module	$Y_x$
St, V, V (cast), GGG (perl.), GGG (bai.), GTS (perl.)	$m_n \leq 5$	1,00
	$5 < m_n < 30$	$1,03 - 0,006 m_n$
	$m_n \geq 30$	0,85
Eh, IF, NT, NV	$m_n \leq 5$	1,00
	$5 < m_n < 25$	$1,05 - 0,01 m_n$
	$m_n \geq 25$	0,80
GG, GGG (ferr.)	$m_n \leq 5$	1,00
	$5 < m_n < 25$	$1,075 - 0,015 m_n$
	$m_n \geq 25$	0,70

**2.5.15 Safety factor for tooth root bending stress  $S_F$**

The values to be adopted for the safety factor for tooth root bending stress  $S_F$  are given in Tab 24.

**Table 24 : Safety factor for tooth root bending stress  $S_F$**

Type of installation	$S_F$	
Main gears (propulsion)	single machinery	1,60
	duplicate machinery	1,55
Auxiliary gears	single machinery	1,45
	duplicate machinery	1,40

**2.6 Calculation of scuffing resistance**

**2.6.1 General**

The following calculations are requested for equipment running in supercritical domain, i.e. when  $N > 1,5$  (see [2.3.4]).

The criterion for scuffing resistance is based on the calculation of the flash temperature method. According to this method, the risk of scuffing is assessed as a function of the properties of gear material, the lubricant characteristics, the surface roughness of tooth flanks, the sliding velocities and the load.

The interfacial contact temperatures are calculated as the sum of the interfacial bulk temperature of the moving interface and the fluctuating flash temperature of the moving faces in contact.

The maximum value of the interfacial contact temperature reduced by oil temperature is not to exceed 0,8 times the scuffing temperature reduced by oil temperature:

$$(\Theta_{B,Max} - \Theta_{oil}) \leq 0,8 (\Theta_s - \Theta_{oil})$$

where:

$\Theta_{B,Max}$  : Maximum contact temperature along the path of contact, in °C, defined in [2.6.2]

$\Theta_{oil}$  : Oil temperature, in °C

$\Theta_s$  : Scuffing temperature, in °C, defined in [2.6.11].

Additionally, the difference between the scuffing temperature and the contact temperature along the path is not to be below 30°C:

$$(\Theta_s - \Theta_{B,Max}) \geq 30^\circ\text{C}$$

Other methods of determination of the scuffing resistance could be accepted by the Society.

**2.6.2 Contact temperature  $\Theta_B$**

The maximum contact temperature  $\Theta_{B,Max}$  along the path of contact, in °C, is calculated as follows:

$$\Theta_{B,Max} = \Theta_{Mi} + \Theta_{fi,Max}$$

where:

$\Theta_{Mi}$  : Interfacial bulk temperature, in °C, defined in [2.6.10]

$\Theta_{fi,Max}$  : Maximum flash temperature along the path of contact, in °C, defined in [2.6.3].

The flash temperature should be calculated on at least ten points along the path of contact and the maximum of these values has to be used for the calculation of maximum contact temperature.

**2.6.3 Flash temperature  $\Theta_{fl}$**

The flash temperature  $\Theta_{fl}$  at any point along the path of contact, in °C, is calculated with the following formula:

$$\Theta_{fl} = \mu_m \cdot X_M \cdot X_J \cdot X_G \cdot (X_T \cdot w_{Bt})^{0,75} \cdot \frac{v^{0,5}}{a^{0,25}}$$

where:

- $\mu_m$  : Mean coefficient of friction, defined in [2.6.4]
- $X_M$  : Thermo-elastic factor, in  $K \cdot N^{-3/4} \cdot s^{-1/2} \cdot m^{-1/2} \cdot mm$ , defined in [2.6.5]
- $X_J$  : Approach factor, defined in [2.6.6]
- $X_G$  : Geometry factor, defined in [2.6.7]
- $X_T$  : Load sharing factor, defined in [2.6.8]
- $w_{Bt}$  : Transverse unit load, in N/mm, defined in [2.6.9].

**2.6.4 Mean coefficient of friction  $\mu_m$**

An estimation of the mean coefficient of friction  $\mu_m$  of common working conditions could be used with the following formula:

$$\mu_m = 0,06 \cdot \left( \frac{w_{Bt}}{v_{g\Sigma C} \cdot \rho_{relC}} \right)^{0,2} \cdot X_L \cdot X_R$$

where:

- $w_{Bt}$  : Transverse unit load, in N/mm, defined in [2.6.9]
- $v_{g\Sigma C}$  : Sum of tangential velocities in pitch point, in m/s:  
 $v_{g\Sigma C} = 2 v \sin \alpha_{tw}$   
 with v not taken greater than 50 m/s
- $\rho_{relC}$  : Transverse relative radius of curvature, in mm:

$$\rho_{relC} = \frac{u}{(1+u)^2} \cdot a \cdot \sin \alpha_{tw}$$

- $X_L$  : Lubricant factor, given in Tab 25
- $X_R$  : Roughness factor, equal to:

$$X_R = \left( \frac{R_{zf1} + R_{zf2}}{2} \right)^{0,25}$$

**Table 25 : Lubricant factor  $X_L$**

Type of lubricant	$X_L$ (1)
Mineral oils	$X_L = 1,0 \eta_{oil}^{-0,05}$
Water soluble polyglycols	$X_L = 0,6 \eta_{oil}^{-0,05}$
Non water soluble polyglycols	$X_L = 0,7 \eta_{oil}^{-0,05}$
Polyalphaolefins	$X_L = 0,8 \eta_{oil}^{-0,05}$
Phosphate esters	$X_L = 1,3 \eta_{oil}^{-0,05}$
Traction fluids	$X_L = 1,5 \eta_{oil}^{-0,05}$
(1) $\eta_{oil}$ is the dynamic viscosity at oil temperature $\Theta_{oil}$ .	

**2.6.5 Thermo-elastic factor  $X_M$**

The thermo-elastic factor  $X_M$  accounts for the influence of the material properties of pinion and wheel:

$$X_M = 1000 \frac{E_r^{0,25}}{B_M}$$

where:

- $E_r$  : Reduced modulus of elasticity, in N/mm<sup>2</sup>:

$$E_r = \frac{2}{(1-\nu_1)/E_1 + (1-\nu_2)/E_2}$$

- $E_1, E_2$  : Moduli of elasticity of pinion and wheel material, in N/mm<sup>2</sup>
- $\nu_1, \nu_2$  : Poisson's ratios of pinion and wheel material
- $B_M$  : Mean thermal contact coefficient, in  $N \cdot mm^{-1/2} \cdot m^{-1/2} \cdot s^{-1/2} \cdot K^{-1}$ , equal to:  
 $B_M = (B_{M1} + B_{M2}) / 2$

- $B_{Mi}$  : Thermal contact coefficient of pinion material ( $i = 1$ ) and wheel material ( $i = 2$ ), given in  $N \cdot mm^{-1/2} \cdot m^{-1/2} \cdot s^{-1/2} \cdot K^{-1}$  and equal to:  
 $B_{Mi} = (0,001 \lambda_{Mi} \rho_{Mi} c_{Mi})^{0,5}$   
 An average value of  $435 N \cdot mm^{-1/2} \cdot m^{-1/2} \cdot s^{-1/2} \cdot K^{-1}$  for martensitic steels could be used when thermo-elastic coefficient is not known
- $\lambda_{Mi}$  : Heat conductivity of pinion material ( $i = 1$ ) and wheel material ( $i = 2$ ), in  $N \cdot s^{-1} \cdot K^{-1}$
- $\rho_{Mi}$  : Density of pinion material ( $i = 1$ ) and wheel material ( $i = 2$ ), in  $kg \cdot m^{-3}$
- $c_{Mi}$  : Specific heat per unit mass of pinion material ( $i = 1$ ) and wheel material ( $i = 2$ ), in  $J \cdot kg^{-1} \cdot K^{-1}$ .

**2.6.6 Approach factor  $X_J$**

The approach factor  $X_J$  takes empirically into account an increased scuffing risk in the beginning of the approach path, due to mesh starting without any previously built up oil film. The approach factor at any point should be calculated according to the following formula:

- when pinion drives the wheel:
  - for  $\Gamma \geq 0$ :  
 $X_J = 1$
  - for  $\Gamma < 0$ , provided that  $X_J \geq 1$ :

$$X_J = 1 + \frac{C_{eff} - C_{a2}}{50} \left( \frac{-\Gamma}{\Gamma_E - \Gamma_A} \right)^3$$

- when wheel drives the pinion:
  - for  $\Gamma \leq 0$ :  
 $X_J = 1$
  - for  $\Gamma > 0$ , provided that  $X_J \geq 1$ :

$$X_J = 1 + \frac{C_{eff} - C_{a1}}{50} \left( \frac{\Gamma}{\Gamma_E - \Gamma_A} \right)^3$$

where:

- $C_{eff}$  : Optimal tip relief, in  $\mu m$ :

$$C_{eff} = \frac{K_A K_Y F_t}{b \cdot \cos \alpha_t \cdot c_Y}$$

- $K_A$  : Application factor (see [2.3.2])
- $K_Y$  : Load sharing factor (see [2.3.3])
- $c_{\sigma Y}$  : Mesh stiffness, in  $N/(mm \cdot \mu m)$  (see Tab 9)
- $C_{ai}$  : Tip relief of pinion or wheel, in  $\mu m$
- $\Gamma$  : Parameter of the point on the line of action, defined in Tab 26
- $\Gamma_A$  : Parameter of the lower end point of the path of contact, defined in Tab 26
- $\Gamma_E$  : Parameter of the upper end point of the path of contact, defined in Tab 26.

**Table 26 : Parameter  $\Gamma$  on the line of action**

Point	$\Gamma$
A : Lower end point of the path of contact	$\Gamma_A = -\frac{z_2}{z_1} \left( \frac{\tan \alpha_{a2}}{\tan \alpha_{wt}} - 1 \right)$
AU : Lower end point of buttressing effect	$\Gamma_{AU} = \Gamma_A + 0,2 \sin \beta_b$
AB : Intermediate point between A and B	$\Gamma_{AB} = 0,5 (\Gamma_A + \Gamma_B)$
B : Lower point of single pair tooth contact	$\Gamma_B = \frac{\tan \alpha_{a1}}{\tan \alpha_{wt}} - 1 - \frac{2\pi}{z_1 \tan \alpha_{wt}}$
C : Point with parameter equal to 0	$\Gamma_C = 0$
M : Intermediate point between A and E	$\Gamma_M = 0,5 (\Gamma_A + \Gamma_E)$
D : Upper point of single pair tooth contact	$\Gamma_D = -\frac{z_2}{z_1} \left( \frac{\tan \alpha_{a2}}{\tan \alpha_{wt}} - 1 \right) + \frac{2\pi}{z_1 \tan \alpha_{wt}}$
DE : Intermediate point between D and E	$\Gamma_{DE} = 0,5 (\Gamma_D + \Gamma_E)$
EU : Upper end point of buttressing effect	$\Gamma_{EU} = \Gamma_E - 0,2 \sin \beta_b$
E : Upper end point of the path of contact	$\Gamma_E = \frac{\tan \alpha_{a1}}{\tan \alpha_{wt}} - 1$

### 2.6.7 Geometry factor $X_G$

The geometry factor  $X_G$  is calculated according to the following conditions:

- for external gear pair:

$$X_G = 0,51 X_{\alpha\beta}(u+1)^{0,5} \frac{|(1+\Gamma)^{0,5} - (1-\Gamma/u)^{0,5}|}{(1+\Gamma)^{0,25} (u-\Gamma)^{0,25}}$$

- for internal gear pair:

$$X_G = 0,51 X_{\alpha\beta}(u-1)^{0,5} \frac{|(1+\Gamma)^{0,5} - (1+\Gamma/u)^{0,5}|}{(1+\Gamma)^{0,25} (u+\Gamma)^{0,25}}$$

where:

$X_{\alpha\beta}$  : Angle factor, equal to:

$$X_{\alpha\beta} = 1,22 (\sin \alpha_{wt})^{0,25} (\cos \alpha_{wt})^{-0,5} (\cos \beta_b)^{0,25}$$

$\Gamma$  : Parameter of the point on the line of action, defined in Tab 26.

### 2.6.8 Load sharing factor $X_\Gamma$

The load sharing factor  $X_\Gamma$  accounts for the load sharing of succeeding pairs of meshing teeth. It is defined as a function of the value of the parameter in the line of action, increasing at the approach path of transverse double contact.

- for narrow helical gears ( $\epsilon_\gamma < 2$ ) with unmodified profiles:

$$X_\Gamma = X_{\Gamma,u} X_{but}$$

- for narrow helical gears ( $\epsilon_\gamma < 2$ ) with profile modification:

$$X_\Gamma = X_{\Gamma,m} X_{but}$$

- for wide helical gears ( $\epsilon_\gamma \geq 2$ ) with unmodified profiles:

$$X_\Gamma = \frac{1}{\epsilon_\alpha} X_{but}$$

- for wide helical gears ( $\epsilon_\gamma \geq 2$ ) with profile modification:

$$X_\Gamma = X_{\Gamma,wm} X_{but}$$

where:

$X_{but}$  : Buttrressing factor:

- for  $\Gamma < \Gamma_{AU}$ :

$$X_{but} = X_{butA} - \frac{\Gamma - \Gamma_A}{\Gamma_{AU} - \Gamma_A} (X_{butA} - 1)$$

- for  $\Gamma_{AU} \leq \Gamma \leq \Gamma_{EU}$ :

$$X_{but} = 1$$

- for  $\Gamma_{EU} < \Gamma$ :

$$X_{but} = X_{butE} - \frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_{EU}} (X_{butE} - 1)$$

Note 1:  $X_{but}$  is to be taken equal to 1 if  $C_{ai} \geq C_{eff}$

$X_{butA}$ ,  $X_{butE}$  : Buttrressing factors at, respectively, lower and upper end points of the path of contact:

$$X_{butA} = X_{butE} = 1 + 0,3 \epsilon_\beta, \text{ provided that}$$

$$X_{butA} = X_{butE} < 1,3$$

$X_{\Gamma,u}$  : Load sharing factor for unmodified profiles:

- for  $\Gamma < \Gamma_B$ :

$$X_{\Gamma,u} = \frac{A-3}{12} + \frac{1}{3} \frac{\Gamma - \Gamma_A}{\Gamma_B - \Gamma_A}$$

- for  $\Gamma_B \leq \Gamma \leq \Gamma_D$ :

$$X_{\Gamma,u} = 1$$

- for  $\Gamma_D < \Gamma$ :

$$X_{\Gamma,u} = \frac{A-3}{12} + \frac{1}{3} \frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_D}$$

Note 2: A is to be taken at least equal to 7.

$X_{\Gamma,m}$  : Load sharing factor for profile modification:

- for  $\Gamma < \Gamma_{AB}$ , provided that  $X_{\Gamma,m} \geq 0$ :

$$X_{\Gamma,m} = \left(1 - \frac{C_{a2}}{C_{eff}}\right) \frac{1}{3} + \left(\frac{1}{3} + \frac{2 C_{a2}}{3 C_{eff}}\right) \frac{\Gamma - \Gamma_A}{\Gamma_B - \Gamma_A}$$

- for  $\Gamma_{AB} \leq \Gamma < \Gamma_B$ , provided that  $X_{\Gamma,m} \leq 1$ :

$$X_{\Gamma,m} = \left(1 - \frac{C_{a1}}{C_{eff}}\right) \frac{1}{3} + \left(\frac{1}{3} + \frac{2C_{a1}}{3C_{eff}}\right) \frac{\Gamma - \Gamma_A}{\Gamma_B - \Gamma_A}$$

- for  $\Gamma_B \leq \Gamma \leq \Gamma_D$ :

$$X_{\Gamma,m} = 1$$

- for  $\Gamma_D < \Gamma \leq \Gamma_{DE}$ , provided that  $X_{\Gamma,m} \leq 1$ :

$$X_{\Gamma,m} = \left(1 - \frac{C_{a2}}{C_{eff}}\right) \frac{1}{3} + \left(\frac{1}{3} + \frac{2C_{a2}}{3C_{eff}}\right) \frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_D}$$

- for  $\Gamma_{DE} < \Gamma$ , provided that  $X_{\Gamma,m} \geq 0$ :

$$X_{\Gamma,m} = \left(1 - \frac{C_{a1}}{C_{eff}}\right) \frac{1}{3} + \left(\frac{1}{3} + \frac{2C_{a1}}{3C_{eff}}\right) \frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_D}$$

$X_{\Gamma,wm}$  : Load sharing factor for profile modification:

- for  $\Gamma < \Gamma_{AB}$ , provided that  $X_{\Gamma,wm} \geq 0$ :

$$X_{\Gamma,wm} = \left(1 - \frac{C_{a2}}{C_{eff}}\right) \frac{1}{\epsilon_\alpha} + \frac{(\epsilon_\alpha - 1)C_{a1} + (3\epsilon_\alpha + 1)C_{a2}}{2\epsilon_\alpha(\epsilon_\alpha + 1)C_{eff}} \frac{\Gamma - \Gamma_A}{\Gamma_B - \Gamma_A}$$

- for  $\Gamma_{AB} \leq \Gamma \leq \Gamma_{DE}$ , provided that  $X_{\Gamma,wm} \leq 1$ :

$$X_{\Gamma,wm} = \frac{1}{\epsilon_\alpha} + \frac{(\epsilon_\alpha - 1)(C_{a1} + C_{a2})}{2\epsilon_\alpha(\epsilon_\alpha + 1)C_{eff}}$$

- for  $\Gamma_{DE} < \Gamma$ , provided that  $X_{\Gamma,wm} \geq 0$ :

$$X_{\Gamma,wm} = \left(1 - \frac{C_{a1}}{C_{eff}}\right) \frac{1}{\epsilon_\alpha} + \frac{(\epsilon_\alpha - 1)C_{a2} + (3\epsilon_\alpha + 1)C_{a1}}{2\epsilon_\alpha(\epsilon_\alpha + 1)C_{eff}} \frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_{DE}}$$

$C_{eff}$  : Optimal tip relief, in  $\mu\text{m}$  (see [2.6.6])

$C_{ai}$  : Tip relief of pinion or wheel, in  $\mu\text{m}$

$\Gamma_i$  : Parameter of any point on the line of action, given in Tab 26.

### 2.6.9 Transverse unit load $w_{Bt}$

The transverse unit load  $w_{Bt}$  is calculated according to the following formula:

$$w_{Bt} = K_A \cdot K_V \cdot K_{H\beta} \cdot K_{H\alpha} \cdot K_\gamma \cdot \frac{F_t}{b}$$

where:

$K_A$  : Application factor (see [2.3.2])

$K_V$  : Dynamic factor (see [2.3.4])

$K_{H\beta}$  : Face load distribution factor (see [2.3.5])

$K_{H\alpha}$  : Transverse load distribution factor (see [2.3.6])

$K_\gamma$  : Load sharing factor (see [2.3.3]).

### 2.6.10 Interfacial bulk temperature $\Theta_{Mi}$

The interfacial bulk temperature  $\Theta_{Mi}$  may be suitably averaged from the two overall bulk temperatures of the teeth in contact,  $\Theta_{M1}$  and  $\Theta_{M2}$ . The following estimation could be used in general configurations:

$$\Theta_{Mi} = \Theta_{oil} + 0,47 X_S X_{mp} \Theta_{fl,m}$$

where:

$\Theta_{oil}$  : Oil temperature, in  $^\circ\text{C}$

$X_S$  : Lubrication system factor:

- for spray lubrication:  $X_S = 1,2$

- for dip lubrication:  $X_S = 1,0$

- for meshes with additional spray for cooling purpose:  $X_S = 1,0$

- for gears submerged in oil, provided sufficient cooling:  $X_S = 0,2$

$X_{mp}$  : Multiple mating pinion factor:

$$X_{mp} = \frac{3 + n_p}{4}$$

$n_p$  : Number of mesh in contact

$\Theta_{fl,m}$  : Average flash temperature on the path of contact, in °C.  
The average temperature should be calculated on at least ten equidistant points on the path line of contact between  $\Gamma_A$  and  $\Gamma_E$ .

**2.6.11 Scuffing temperature  $\Theta_s$**

The scuffing temperature  $\Theta_s$  may be determined according to the following formula:

$$\Theta_s = 80 + (0,85 + 1,4 X_W) X_L (S_{FZG} - 1)^2$$

where:

$X_W$  : Structural factor given in Tab 27

$X_L$  : Lubricant factor given in Tab 25

$S_{FZG}$  : Load stage where scuffing occurs, according to gear tests, such as Ryder, FZG-Ryder, FZG L-42 or FZG A/8 3/90.

**Table 27 : Structural factor  $X_W$**

Material	$X_W$
Through-hardened steel	1,00
Phosphated steel	1,25
Copper-plated steel	1,50
Bath or gas nitrided steel	1,50
Hardened carburized steel, with austenite content less than 10%	1,15
Hardened carburized steel, with austenite content between 10% and 20%	1,00
Hardened carburized steel, with austenite content above 20%	0,85
Austenite steel (stainless steel)	0,45

**3 Design of gears - Determination of the load capacity of bevel gears**

**3.1 Symbols, units, definitions**

**3.1.1 Symbols and units**

The meaning of the main symbols used in this Article is specified below.

Other symbols introduced in connection with the definition of influence factors are defined in the appropriate sub-articles.

A : Flank tolerance class according to ISO 1328-1:2013

$a_v$  : Virtual operating centre distance, in mm

$a_{vn}$  : Virtual operating centre distance, in mm

b : Effective face width, in mm

$d_e$  : Outer pitch diameter, in mm

$d_{ext}$  : External diameter of shaft, in mm

$d_{int}$  : Internal diameter of shaft, in mm

$d_m$  : Mean pitch diameter, in mm

$d_s$  : Shrinkage diameter of the wheel, in mm

$d_v$  : Virtual reference diameter, in mm

$d_{va}$  : Virtual tip diameter, in mm

$d_{van}$  : Virtual tip diameter, in mm

$d_{vb}$  : Virtual base diameter, in mm

$d_{vbn}$  : Virtual base diameter, in mm

$d_{vf}$  : Virtual root diameter, in mm

$d_{vn}$  : Virtual reference diameter, in mm

$F_{mt}$  : Nominal tangential load, in N

$F_\beta$  : Total helix deviation, in  $\mu m$

$g_{v\alpha}$  : Length of path of contact, in mm

$g_{van}$  : Length of path of contact, in mm

$h_{aP}$  : Basic rack addendum, in mm

$h_{fP}$  : Basic rack dedendum, in mm

$h_v$  : Virtual tooth depth, in mm

HB : Brinell hardness, in N/mm<sup>2</sup>

HPX : Rockwell hardness

HV	: Vickers hardness, in N/mm <sup>2</sup>
k	: Gear axial position on shaft with respect to the bearings
$l$	: Bearing span, in mm
$l_{bm}$	: Length of the line of contact, in mm
$l'_{bm}$	: Length of the line of contact, in mm
$m_{et}$	: Outer transverse module, in mm
$m_{mn}$	: Mean normal module, in mm
$m_{mt}$	: Mean transverse module, in mm
n	: Rotational speed, in rpm
P	: Transmitted power, in kW
$p_{et}$	: Transverse base pitch, in mm
$p_r$	: Protuberance of the tool, in mm
q	: Material allowance for finish machining, in mm
$r_{c0}$	: Cutter radius, in mm
$r_e$	: Outer cone distance, in mm
$R_{e,\sigma}$	: Minimum yield strength of the shaft material, in N/mm <sup>2</sup>
$\rho_m$	: Mean cone distance, in mm
$R_{m,rim}$	: Ultimate tensile strength of the rim material, in N/mm <sup>2</sup>
$R_Z$	: Mean peak-to-valley roughness, in $\mu\text{m}$
$R_{Zf}$	: Mean peak-to-valley flank roughness, in $\mu\text{m}$
$s_R$	: Rim thickness, in mm
T	: Transmitted torque, in kN·m
u	: Reduction ratio
$u_v$	: Virtual reduction ratio
$v_{mt}$	: Linear speed at mean pitch diameter, in m/s
$x_h$	: Addendum modification coefficient
$x_s$	: Thickness modification coefficient
z	: Number of teeth
$Z_v$	: Virtual number of teeth
$Z_{vn}$	: Virtual number of teeth
$\alpha_n$	: Normal pressure angle
$\alpha_{vt}$	: Virtual transverse pressure angle
$\beta_m$	: Mean helix angle
$\beta_{vb}$	: Virtual base helix angle
$\delta$	: Pitch angle
$\epsilon_{v\alpha}$	: Virtual transverse contact ratio
$\epsilon_{van}$	: Virtual transverse contact ratio
$\epsilon_{v\beta}$	: Virtual overlap ratio
$\epsilon_{v\gamma}$	: Virtual total contact ratio
$\nu_{40}$	: Nominal kinematic viscosity of oil at 40°C, in mm <sup>2</sup> /s
$\rho_{a0}$	: Tip radius of the tool, in mm
$\sigma_F$	: Tooth root bending stress, in N/mm <sup>2</sup>
$\sigma_{FE}$	: Endurance limit for tooth root bending stress, in N/mm <sup>2</sup>
$\sigma_{FP}$	: Permissible tooth root bending stress, in N/mm <sup>2</sup>
$\sigma_H$	: Contact stress, in N/mm <sup>2</sup>
$\sigma_{H,lim}$	: Endurance limit for contact stress, in N/mm <sup>2</sup>
$\sigma_{HP}$	: Permissible contact stress, in N/mm <sup>2</sup> .

Subscripts:

- 1 for pinion, i.e. the gear having the smaller number of teeth
- 2 for wheel.

### 3.1.2 Geometrical definitions

In the calculation of surface durability,  $b$  is the minimum face width on the pitch diameter between pinion and wheel.

In tooth strength calculations,  $b_1$  and  $b_2$  are the face widths at the respective tooth roots. In any case,  $b_1$  or  $b_2$  are not to be taken greater than  $b$  by more than one module  $m_{mn}$  (in case of width of one gear much more important than the other).

a) General geometrical definitions

$$u = \frac{Z_2}{Z_1}$$

$$d_{ei} = \frac{Z_i m_{mn}}{\cos \beta_m} + b_i \sin \delta_i$$

$$r_e = \frac{d_{e1}}{2 \sin \delta_1} = \frac{d_{e2}}{2 \sin \delta_2}$$

$$r_m = r_e - 0,5 b$$

$$m_{et} = \frac{d_{e1}}{Z_1} = \frac{d_{e2}}{Z_2}$$

$$m_{mt} = \frac{r_m m_{et}}{r_e}$$

$$d_{mi} = \frac{Z_i m_{mn}}{\cos \beta_m}$$

b) Geometrical definitions of virtual cylindrical gears in transverse section (suffix v)

$$z_{vi} = \frac{Z_i}{\cos \delta_i}$$

$$u_v = \frac{z_{v2}}{z_{v1}}$$

$$\tan \alpha_{vt} = \frac{\tan \alpha_n}{\cos \beta_m}$$

$$\sin \beta_{vb} = \sin \beta_m \cdot \cos \alpha_n$$

$$d_{vi} = \frac{d_{mi}}{\cos \delta_i}$$

$$a_v = 0,5 (d_{v1} + d_{v2})$$

$$d_{v\alpha} = d_{vi} + 2 h_{aPi}$$

$$d_{v\beta} = d_{vi} \cos \alpha_{vt}$$

$$d_{v\phi} = d_{vi} + 2 m_{mn} x_{hi} - 2 h_{fPi}$$

$$h_{vt} = 0,5 (d_{vai} - d_{vfi})$$

$$p_{e\tau} = m_{mt} \pi \cos \alpha_{vt}$$

$$(g_{v\alpha} = 0,5 (\sqrt{d_{va1}^2 - d_{vb1}^2} + \sqrt{d_{va2}^2 - d_{vb2}^2}) - a_v \sin \alpha_{vt})$$

$$\left( \epsilon_{v\alpha} = \frac{g_{v\alpha}}{p_{et}} \right)$$

$$\left( \epsilon_{v\beta} = \frac{b \sin \beta_m}{\pi m_{mn}} \right)$$

$$(\epsilon_{v\gamma} = \sqrt{\epsilon_{v\alpha}^2 + \epsilon_{v\beta}^2})$$

- if  $\epsilon_{v\beta} < 1$ :

$$\ell_{bm} = \frac{b \epsilon_{v\alpha}}{\cos \beta_{vb} \cdot \epsilon_{v\gamma}^2} \cdot \sqrt{\epsilon_{v\gamma}^2 - (2 - \epsilon_{v\alpha})^2 \cdot (1 - \epsilon_{v\beta})^2}$$

- if  $\epsilon_{v\beta} \geq 1$ :

$$\ell_{bm} = \frac{b \epsilon_{v\alpha}}{\cos \beta_{vb} \cdot \epsilon_{v\gamma}}$$

$$\ell'_{bm} = \ell_{\beta\mu} \cos \beta_{vb}$$

c) Geometrical definitions of virtual cylindrical gears in normal section (suffix vn)

$$z_{vni} = \frac{z_{vi}}{\cos \beta_m \cdot (\cos \beta_{vb})^2}$$

$$d_{vni} = m_{mn} z_{vni}$$

$$a_{vn} = 0,5 (d_{vn1} + d_{vn2})$$

$$d_{v\alpha v1} = d_{vni} + 2 h_{aPi}$$

$$d_{v\beta v1} = d_{vni} \cos \alpha_v$$

$$g_{van} = 0,5 (\sqrt{d_{van1}^2 - d_{vbn1}^2} + \sqrt{d_{van2}^2 - d_{vbn2}^2}) - a_{vn} \sin \alpha_n$$

$$\epsilon_{v\alpha n} = \frac{\epsilon_{v\alpha}}{(\cos \beta_{vb})^2}$$

d) Definitions of transmissions characteristics

$$T_i = \frac{60}{2\pi} \cdot \frac{P}{n_i}$$

$$F_{mt} = \frac{P}{n_1} \cdot \frac{60}{\pi d_{m1}} \cdot 10^6$$

$$v_{mt} = \frac{\pi n_1}{60} \cdot \frac{d_{m1}}{10^3} = \frac{\pi n_2}{60} \cdot \frac{d_{m2}}{10^3}$$

$$F_{\beta i} = 2^{0,5 \cdot (Q_i - 5)} \cdot (0,1 \cdot d_{vi}^{0,5} + 0,63 \sqrt{b} + 4,2)$$

## 3.2 Principle

### 3.2.1

a) The following requirements apply to bevel spur or helical gears with external teeth, and provide a method for the calculation of the load capacity with regard to:

- the surface durability (contact stress)
- the tooth root bending stress.

The bevel gears for marine application are to comply with the following restrictions:

- $1,2 < \epsilon_{v\alpha} < 2,5$
- $\beta_m < 30^\circ$
- $s_R > 3,5 m_{mn}$

The relevant formulae are provided in [3.4] and [3.5].

The influence factors common to the formulae are given in [3.3].

b) Gears, for which the conditions of validity of some factors or formulae are not satisfied, will be given special consideration by the Society.

c) Other methods of determination of load capacity will be given special consideration by the Society. Any alternative calculations are to comply with ISO 6336 series standards.

## 3.3 General influence factors

### 3.3.1 General

General influence factors are defined in [3.3.2], [3.3.3], [3.3.4], [3.3.5] and [3.3.6]. Alternative values may be used provided they are derived from appropriate measurements.

### 3.3.2 Application factor $K_A$

The application factor  $K_A$  accounts for dynamic overloads from sources external to the gearing (driven and driving machines).

The values of  $K_A$  to be used are given in Tab 5.

### 3.3.3 Load sharing factor $K_\gamma$

The load sharing factor  $K_\gamma$  accounts for the uneven sharing of load on multiple path transmissions, such as epicyclic gears or tandem gears.

The values of  $K_\gamma$  to be used are given in Tab 6.

### 3.3.4 Dynamic factor $K_v$

The dynamic factor  $K_v$  accounts for the additional internal dynamic loads acting on the tooth flanks and due to the vibrations of the pinion and wheel.

The calculation of the dynamic factor  $K_v$  is defined in Tab 28, where:

$N$  : Resonance ratio, i.e. ratio of the pinion speed to the resonance speed:

$$N = n_1 / n_{E1}, \text{ with:}$$

$n_{E1}$  : Resonance speed, in rpm, defined by the following formula:

$$n_{E1} = \frac{30000}{\pi \cdot Z_1} \cdot \sqrt{\frac{C_\gamma}{m_{red}}}$$

where:

$m_{red}$  : Reduced mass of gear pair, in kg/mm. Estimated calculation of  $m_{red}$  is given by the following formula:

$$m_{red} = \frac{\rho \cdot 10^{-6} \cdot \pi}{8} \cdot \frac{d_{m1}^2}{(\cos \alpha_n)^2} \cdot \frac{u^2}{1 + u^2}$$

$\rho$  : Density of gearing material, equal to:

$$\rho = 7,83 \text{ for steel}$$

$c_\gamma$  : Mesh stiffness, in N/(mm.µm):

$$c_\gamma = 20 C_F C_b$$

$C_F$  and  $C_b$  being the correction factors for non average conditions defined in Tab 29.

The value of N determines the range of vibrations:

- subcritical range, when  $N \leq 0,75$
- main resonance range, when  $0,75 < N < 1,25$

This field is not permitted

- intermediate range, when  $1,25 \leq N \leq 1,50$

This field is normally to be avoided. Some alternative and more precise calculation could be accepted and special consideration will be given by the Society

- supercritical range, when  $1,50 < N$ .

### 3.3.5 Face load distribution factors $K_{H\beta}$ and $K_{F\beta}$

The face load distribution factors,  $K_{H\beta}$  for contact stress and  $K_{F\beta}$  for tooth root ending stress, account for the effects of non-uniform distribution of load across the face width.

a) The calculation of  $K_{H\beta}$  is to be defined according to the mounting conditions of pinion and wheel:

- neither member cantilever mounted:

$$K_{H\beta} = 1,575 / C_b$$

- one member cantilever mounted:

$$K_{H\beta} = 1,650 / C_b$$

- both members cantilever mounted:

$$K_{H\beta} = 1,875 / C_b$$

where  $C_b$  is the correction factor defined in Tab 29

b)  $K_{F\beta}$  is to be determined using the following formula:

$$K_{F\beta} = K_{H\beta} / K_{F0}, \text{ with:}$$

$K_{F0}$  : Lengthwise curvature factor. It is to be taken above 1,0 and below 1,15 considering the following formula:

$$K_{F0} = 0,211 \cdot \left( \frac{r_{c0}}{r_m} \right)^{\frac{0,279}{\log(\sin \beta_m)}} + 0,789$$

### 3.3.6 Transverse load distribution factors $K_{H\alpha}$ and $K_{F\alpha}$

The transverse load distribution factors,  $K_{H\alpha}$  for contact stress and  $K_{F\alpha}$  for tooth root bending stress, account for the effects of pitch and profile errors on the transversal load distribution between two or more pairs of teeth in mesh.

The values of  $K_{H\alpha}$  and  $K_{F\alpha}$  are given in Tab 30.

## 3.4 Calculation of surface durability

### 3.4.1 General

The criterion for surface durability is based on the contact stress (hertzian pressure)  $\sigma_H$  on the pitch point or at the inner point of single pair contact.

The contact stress  $\sigma_H$ , defined in [3.4.2], is not to exceed the permissible contact stress  $\sigma_{HP}$  defined in [3.4.9].

Table 28 : Dynamic factor  $K_v$

Resonance domain	Factor $K_v$
$N \leq 0,75$	$K_v = N (C_{v1} B_p + C_{v2} B_f + C_{v3}) + 1$
$N > 1,50$	$K_v = C_{v5} B_p + C_{v6} B_f + C_{v7}$

**Note 1:**

$B_p$  : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications:

$$B_p = \frac{c' f_{p,eff}}{K_A (F_{mt}/b)}$$

with:

$c'$  : Single stiffness, in N/(mm· $\mu$ m):  
 $c' = 14 C_F C_b$ , with  $C_F$  and  $C_b$  defined in Tab 29

$f_{p,eff}$  : Effective base pitch deviation, in  $\mu$ m:  
 $f_{p,eff} = f_{pt} - y_\alpha$   
 with  $f_{pt}$  defined in Tab 30 and  $y_\alpha$  defined in Tab 31

$B_f$  : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications:  
 $B_f = B_p$

$C_{v1}$  : Factor for pitch deviation effects:  
 $C_{v1} = 0,32$

$C_{v2}$  : Factor for tooth profile deviation effects:

- if  $1 < \varepsilon_{v\gamma} \leq 2$ :  
 $C_{v2} = 0,34$
- if  $2 < \varepsilon_{v\gamma}$ :  
 $C_{v2} = \frac{0,57}{\varepsilon_{v\gamma} - 0,3}$

$C_{v3}$  : Factor for cyclic variation effect in mesh stiffness:

- if  $1 < \varepsilon_{v\gamma} \leq 2$ :  
 $C_{v3} = 0,23$
- if  $2 < \varepsilon_{v\gamma}$ :  
 $C_{v3} = \frac{0,096}{\varepsilon_{v\gamma} - 1,56}$

$C_{v5}$  : Factor equal to:  $C_{v5} = 0,47$

$C_{v6}$  : Factor:

- if  $1 < \varepsilon_{v\gamma} \leq 2$ :  
 $C_{v6} = 0,47$
- if  $2 < \varepsilon_{v\gamma}$ :  
 $C_{v6} = \frac{0,12}{\varepsilon_{v\gamma} - 1,74}$

$C_{v7}$  : Factor:

- if  $1 < \varepsilon_{v\gamma} \leq 1,5$ :  
 $C_{v7} = 0,75$
- if  $1,5 < \varepsilon_{v\gamma} \leq 2,5$ :  
 $C_{v7} = 0,125 \sin[\pi (\varepsilon_{v\gamma} - 2)] + 0,875$
- if  $2,5 < \varepsilon_{v\gamma}$ :  
 $C_{v7} = 1$

Table 29 : Correction factors  $C_F$  and  $C_b$

Conditions	Factors $C_F$ and $C_b$
if $F_{mt} K_A / b_e \geq 100$ N/mm	$C_F = 1$
if $F_{mt} K_A / b_e < 100$ N/mm	$C_F = (F_{mt} K_A / b_e) / 100$
if $b_e / b \geq 0,85$	$C_b = 1$
if $b_e / b < 0,85$	$C_b = (b_e / b) / 0,85$

$b_e$  : Effective face width, the real length of contact pattern. When  $b_e$  is not supplied,  $b_e = 0,85 b$  could be used.

Table 30 : Transverse load factors  $K_{H\alpha}$  and  $K_{F\alpha}$

	Factors $K_{H\alpha}$ and $K_{F\alpha}$	Limitations
$\varepsilon_{v\gamma} \leq 2$	$K_{H\alpha} = K_{F\alpha} = \frac{\varepsilon_{v\gamma}}{2} \cdot \left( 0,9 + 0,4 \cdot \frac{c_{\gamma} \cdot (f_{pt} - y_{\alpha})}{F_{mtH}/b} \right)$	$\frac{\varepsilon_{v\gamma}}{\varepsilon_{v\alpha} \cdot Z_{LS}^2} \geq K_{H\alpha} \geq 1$
$\varepsilon_{v\gamma} > 2$	$K_{H\alpha} = K_{F\alpha} = 0,9 + 0,4 \cdot \sqrt{\frac{2 \cdot (\varepsilon_{v\gamma} - 1) \cdot c_{\gamma} \cdot (f_{pt} - y_{\alpha})}{\varepsilon_{v\gamma} \cdot F_{mtH}/b}}$	$\frac{\varepsilon_{v\gamma}}{\varepsilon_{v\alpha} \cdot Y_{\varepsilon}} \geq K_{F\alpha} \geq 1$
<p><b>Note 1:</b></p> <p><math>c_{\gamma}</math> : Mesh stiffness, in N/mm.<math>\mu</math>m, defined in [3.3.4]  <math>f_{pt}</math> : Larger value of the single pitch deviation of pinion or wheel, in <math>\mu</math>m.                      Default value: <math>f_{pt} = 0,3 (m_{mn} + 0,4  d_{vbi} ^{0,5} + 4) \cdot 2^{0,5(Q_1-5)}</math>                      In case of optimum profile correction, <math>f_{pt}</math> is to be replaced by <math>f_{pt} / 2</math></p> <p><math>y_{\alpha}</math> : Running-in allowance, in <math>\mu</math>m, defined in Tab 31  <math>F_{mtH}</math> : Determinant tangential load at mid-face width on the reference cone, in N:  <math>F_{mtH} = F_{mt} \cdot K_A \cdot K_{\gamma} \cdot K_{H\beta}</math></p>		

Table 31 : Running-in allowance  $y_{\alpha}$

**3.4.2 Contact stress  $\sigma_H$**

The contact stress  $\sigma_H$  is to be determined as follows:

$$\sigma_H = \sigma_{H0} \cdot \sqrt{K_A \cdot K_{\gamma} \cdot K_{\zeta} \cdot K_{H\beta} \cdot K_{H\alpha}}$$

where:

- $K_A$  : Application factor (see [3.3.2])
- $K_{\gamma}$  : Load sharing factor (see [3.3.3])
- $K_{\zeta}$  : Dynamic factor (see [3.3.4])
- $K_{H\beta}$  : Face load distribution factor (see [3.3.5])
- $K_{H\alpha}$  : Transverse load distribution factor (see [3.3.6])

$$\sigma_{H0} = Z_{M-B} \cdot Z_H \cdot Z_E \cdot Z_{LS} \cdot Z_{\beta} \cdot Z_K \cdot \sqrt{\frac{F_{mt}}{d_{v1} \cdot \ell_{bm}} \cdot \frac{u_v + 1}{u_v}}$$

with:

- $Z_{M-B}$  : Mid-zone factor, defined in [3.4.3]
- $Z_H$  : Zone factor, defined in [3.4.4]
- $Z_E$  : Elasticity factor, defined in [3.4.5]
- $Z_{LS}$  : Load-sharing factor, defined in [3.4.6]
- $Z_{\beta}$  : Helix angle factor, defined in [3.4.7]
- $Z_K$  : Bevel gear ratio factor, defined in [3.4.8].

**3.4.3 Mid-zone factor  $Z_{M-B}$**

The mid-zone factor  $Z_{M-B}$  accounts for the difference of contact pressure between the pitch point and the determinant point of load application.

$Z_{M-B}$  is to be determined as follows:

$$Z_{M-\beta} = \frac{\tan \alpha_{vt}}{\sqrt{\left[ \sqrt{\frac{d_{va1}^2}{d_{vb1}^2} - 1} - \left( F_1 \cdot \frac{\pi}{z_{v1}} \right) \right] \cdot \left[ \sqrt{\frac{d_{va2}^2}{d_{vb2}^2} - 1} - \left( F_2 \cdot \frac{\pi}{z_{v2}} \right) \right]}}$$

where  $F_1$  and  $F_2$  are defined according to the following conditions:

- if  $0 \leq \epsilon_{v\beta} < 1$ :  
 $F_1 = 2 + (\epsilon_{v\alpha} - 2) \cdot \epsilon_{v\beta}$   
 $F_2 = 2 \epsilon_{v\alpha} - 2 + (2 - \epsilon_{v\alpha}) \cdot \epsilon_{v\beta}$
- if  $\epsilon_{v\beta} \geq 1$ :  
 $F_1 = \epsilon_{v\alpha}$   
 $F_2 = \epsilon_{v\alpha}$

#### 3.4.4 Zone factor $Z_H$

The zone factor  $Z_H$  accounts for the influence on the hertzian pressure of tooth flank curvature at the pitch point.

$Z_H$  is to be determined as follows:

$$Z_H = 2 \cdot \sqrt{\frac{\cos \beta_{vb}}{\sin(2 \cdot \alpha_{vt})}}$$

#### 3.4.5 Elasticity factor $Z_E$

The elasticity factor  $Z_E$  accounts for the influence of the metal properties (module of elasticity  $E$  and Poisson's ratio  $\nu$ ) on the hertzian pressure.

The values of  $Z_E$  to be used are given in [2.4.5].

#### 3.4.6 Load-sharing factor $Z_{LS}$

The load-sharing factor  $Z_{LS}$  accounts for load sharing between two or more pairs of teeth.

$Z_{LS}$  is to be determined as follows:

- if  $\epsilon_{v\gamma} > 2$  and  $\epsilon_{v\beta} > 1$ :

$$Z_{LS} = \left\{ 1 + 2 \left[ 1 - \left( \frac{2}{\epsilon_{v\gamma}} \right)^{1.5} \right] \cdot \sqrt{1 - \frac{4}{\epsilon_{v\gamma}^2}} \right\}^{-0.5}$$

- if  $\epsilon_{v\gamma} \leq 2$ :  
 $Z_{LS} = 1$
- otherwise, an alternative calculation should be supplied and will be given special consideration by the Society.

#### 3.4.7 Helix angle factor $Z_\beta$

The helix angle factor  $Z_\beta$  accounts for the influence of helix angle on the surface durability, allowing for such variables as the distribution of the load along the lines of contact.

$Z_\beta$  is to be determined as follows:

$$Z_\beta = \frac{1}{\sqrt{\cos \beta_m}}$$

#### 3.4.8 Bevel gear factor $Z_k$

The bevel gear factor  $Z_k$  is an empirical factor which accounts for the difference between bevel and cylindrical gears loading.

$Z_k$  is to be determined as follows:

$$Z_k = 0,8$$

#### 3.4.9 Permissible contact stress $\sigma_{HP}$

The permissible contact stress  $\sigma_{HP}$ , in  $N/mm^2$ , is to be determined separately for pinion and wheel, using the following formula:

$$\sigma_{HP} = \frac{\sigma_{H,lim}}{S_H} \cdot Z_{NT} \cdot Z_L \cdot Z_V \cdot Z_R \cdot Z_W \cdot Z_X$$

where:

- $\sigma_{H,lim}$  : Endurance limit for contact stress, defined in [3.4.10]
- $Z_{NT}$  : Life factor for contact stress, defined in [3.4.11]
- $Z_L, Z_V, Z_R$ : Lubrication, speed and roughness factors, respectively, defined in [3.4.12]
- $Z_Q$  : Hardness ratio factor, defined in [3.4.13]
- $Z_E$  : Size factor for contact stress, defined in [3.4.14]
- $\Sigma_H$  : Safety factor for contact stress, defined in [3.4.15].

**3.4.10 Endurance limit for contact stress  $\sigma_{H,lim}$**

The endurance limit for contact stress  $\sigma_{H,lim}$ , in N/mm<sup>2</sup>, is the limit of repeated contact stress which can be permanently endured. The values to be adopted for  $\sigma_{H,lim}$  are given in [2.4.9] in relation to the type of steel employed and the heat treatment performed.

**3.4.11 Life factor for contact stress  $Z_{NT}$**

The life factor  $Z_{NT}$  accounts for the influence of limited service life on the permissible contact stress.

Some values of  $Z_{NT}$  are given in Tab 17 for information.

The value of  $Z_{NT}$  to be used will be given special consideration by the Society depending on the equipment's arrangement and use.

**3.4.12 Lubrication factor  $Z_L$ , speed factor  $Z_V$  and roughness factor  $Z_R$**

The lubricant factor  $Z_L$  accounts for the influence of the type of the lubricant and the influence of its viscosity, the speed factor  $Z_V$  accounts for the influence of the pitch line velocity, and the roughness factor  $Z_R$  accounts for the influence of the surface roughness on the surface endurance capacity.

These factors are to be determined according to the formulae of [2.4.11], using the following parameters:

$\omega_{mt}$  : Linear speed at mean pitch diameter, in m/s. It is to replace  $\omega$  in the calculation of  $Z_V$

$\rho_{red}$  : Relative radius of curvature, in mm:

$$\rho_{red} = \frac{a_v \cdot \sin \alpha_{vt}}{\cos \beta_{vb}} \cdot \frac{u_v}{(1 + u_v)^2}$$

**3.4.13 Hardness ratio factor  $Z_W$**

The hardness ratio factor  $Z_W$  accounts for the increase of the surface durability. This factor is to be determined according to the formulae of [2.4.12], using the following parameters:

$\omega_{mt}$  : Linear speed at mean pitch diameter, in m/s. It is to replace  $\omega$  in the calculations

$\rho_{red}$  : Relative radius of curvature, in mm, as defined in [3.4.12]

$u_{\omega}$  : Virtual reduction ratio. It is to replace  $u$  in the calculations.

**3.4.14 Size factor  $Z_X$**

The size factor  $Z_X$  accounts for the influence of tooth dimensions on permissible contact stress and reflects the non-uniformity of material properties.

$Z_X$  is in general equal to 1.

The value  $Z_X$  to be used will be given special consideration by the Society depending on the material.

**3.4.15 Safety factor for contact stress  $S_H$**

The values to be adopted for the safety factor for contact stress  $S_H$  are given in Tab 18.

**3.5 Calculation of tooth bending strength**

**3.5.1 General**

The criterion for tooth root bending stress is based on the local tensile stress at the tooth root in the direction of the tooth height.

The tooth root bending stress  $\sigma_F$ , defined in [3.5.2], is not to exceed the permissible tooth root bending stress  $\sigma_{FP}$  defined in [3.5.8].

**3.5.2 Tooth root bending stress  $\sigma_F$**

The tooth root bending stress  $\sigma_F$  is to be determined as follows:

$$\sigma_F = \frac{F_{mt}}{b \cdot m_{mn}} \cdot Y_{Fa} \cdot Y_{Sa} \cdot Y_e \cdot Y_{LS} \cdot Y_K \cdot K_A \cdot K_V \cdot K_V \cdot K_{F\beta} \cdot K_{F\alpha}$$

where:

$Y_{Fa}$  : Tooth form factor, defined in [3.5.3]

$Y_{Sa}$  : Stress correction factor, defined in [3.5.4]

$Y_e$  : Contact ratio factor, defined in [3.5.5]

$Y_{LS}$  : Load sharing factor, defined in [3.5.6]

$Y_K$  : Bevel gear factor, defined in [3.5.7]

$K_A$  : Application factor (see [3.3.2])

$K_V$  : Load sharing factor (see [3.3.3])

$K_V$  : Dynamic factor (see [3.3.4])

$K_{F\beta}$  : Face load distribution factor (see [3.3.5])

$K_{F\alpha}$  : Transverse load distribution factor (see [3.3.6]).

When a shot-peening treatment of the tooth root is applied according to a process agreed by the Society, a reduction of the bending stress  $\sigma_F$  (depending on the material category, but without being over 10%) could be taken in consideration only for carburized case-hardened steel gears.

### 3.5.3 Tooth form factor $Y_{Fa}$

The tooth form factor  $Y_{Fa}$  takes into account the effect of the tooth form on the nominal bending stress, assuming the load applied at the outer point of a single pair tooth contact of the virtual cylindrical gears in normal section.

$Y_{Fa}$  is to be determined separately for the pinion and for the wheel, using the following formula:

$$Y_{Fa} = \frac{6 \cdot \frac{h_{Fa}}{m_{mn}} \cdot \cos \alpha_{Fan}}{\left(\frac{S_{Fn}}{m_{mn}}\right)^2 \cdot \cos \alpha_n}$$

where:

$h_{Fa}$  : Bending moment arm, in mm:

$$\frac{h_{Fa}}{m_{mn}} = \frac{1}{2} \left[ (\cos \gamma_a - \sin \gamma_a \cdot \tan \alpha_{Fan}) \cdot \frac{d_{van}}{m_{mn}} - z_{vn} \cdot \cos \left( \frac{\pi}{3} - \theta \right) - \left( \frac{G}{\cos \theta} - \frac{\rho_{a0}}{m_{mn}} \right) \right]$$

$S_{Fn}$  : Tooth root chord at the critical section, in mm:

$$\frac{S_{Fn}}{m_{mn}} = z_{vn} \cdot \sin \left( \frac{\pi}{3} - \theta \right) + \sqrt{3} \cdot \left( \frac{G}{\cos \theta} - \frac{\rho_{a0}}{m_{mn}} \right)$$

$G$  : Parameter defined by:

$$G = \frac{\rho_{a0}}{m_{mn}} - \frac{h_{fp}}{m_{mn}} + x_h$$

$\theta$  : Parameter defined by:

$$\theta = \frac{2 \cdot G}{z_{vn}} \cdot \tan \theta - H$$

This transcendental equation is to be calculated by iteration

$H$  : Parameter defined by:

$$H = \frac{2}{z_{vn}} \cdot \left( \frac{\pi}{2} - \frac{E}{m_{mn}} \right) - \frac{\pi}{3}$$

$E$  : Parameter defined by:

$$E = \left( \frac{\pi}{4} - x_s \right) m_{mn} - h_{fp} \tan \alpha_n + \frac{s_{pr}}{\cos \alpha_n} - (1 - \sin \alpha_n) \frac{\rho_{a0}}{\cos \alpha_n}$$

$s_{pr}$  : Residual fillet undercut, in mm:

$$s_{pr} = pr - q$$

The parameters of the virtual gears are defined as follows:

$\alpha_{Fan}$  : Load direction angle:

$$\alpha_{Fan} = \alpha_{an} - \gamma_a$$

$\gamma_a$  : Parameter defined by:

$$\gamma_a = \frac{0,5 \cdot \pi + 2(\tan \alpha_n \cdot x_h + x_s)}{z_{vn}} + \text{inv} \alpha_n - \text{inv} \alpha_{an}$$

with inv, involute function, equal to:

$$\text{inv} \alpha = \tau \alpha \nu \alpha - \alpha$$

$\alpha_{an}$  : Form factor pressure angle:

$$\cos \alpha_{an} = \frac{d_{vbn}}{d_{van}}$$

### 3.5.4 Stress correction factor $Y_{Sa}$

The stress correction factor  $Y_{Sa}$  is used to convert the nominal bending stress to local tooth root stress.

$Y_{Sa}$  is to be determined as follows:

$$Y_{Sa} = (1,2 + 0,13L_a) \cdot q_s^{\frac{1}{1,21 + (2,3)/L_a}}$$

where:

$$L_a = \frac{S_{Fn}}{h_{Fa}}$$

with  $s_{Fn}$  and  $h_{Fa}$  defined in [3.5.3]

$q_s$  : Notch parameter:

$$q_s = \frac{S_{Fn}}{2\rho_F}$$

with  $s_{Fn}$  defined in [3.5.3]

Note 1: The notch parameter should be within the range:

$$1 \leq q_s < 8$$

$\rho_F$  : Fillet radius at contact point of 30° tangent, in mm:

$$\frac{\rho_F}{m_{mn}} = \frac{\rho_{a0}}{m_{mn}} + \frac{2G^2}{\cos\theta \cdot (z_{vn} \cdot \cos^2\theta - 2G)}$$

### 3.5.5 Contact ratio factor $Y_\varepsilon$

The contact ratio factor  $Y_\varepsilon$  converts the load application at the tooth tip to the decisive point of load application.

$Y_\varepsilon$  is to be determined as follows:

- if  $\varepsilon_{v\beta} \leq 1$ :

$$Y_\varepsilon = 0,25 + \frac{0,75}{\varepsilon_{v\alpha}} - \varepsilon_{v\beta} \cdot \left( \frac{0,75}{\varepsilon_{v\alpha}} - 0,375 \right)$$

- if  $\varepsilon_{v\beta} > 1$ :

$$Y_\varepsilon = 0,625$$

Note 1: A minimum of 0,625 should always be taken for  $Y_\varepsilon$ .

### 3.5.6 Load sharing factor $Y_{LS}$

The load sharing factor  $Y_{LS}$  accounts for load sharing between two or more pairs of teeth.

$Y_{LS}$  is to be determined as follows:

$$Y_{LS} = Z_{LS}^2$$

### 3.5.7 Bevel gear factor $Y_K$

The bevel gear factor  $Y_K$  accounts for the difference between bevel and cylindrical gears loading.

$Y_K$  is to be determined as follows:

$$Y_K = \left( \frac{1}{2} + \frac{\ell'_{bm}}{2b} \right)^2 \cdot \frac{b}{\ell'_{bm}}$$

### 3.5.8 Permissible tooth root bending stress $\sigma_{FP}$

The permissible tooth root bending stress  $\sigma_{FP}$  is to be determined separately for pinion and for wheel, using the following formula:

$$\sigma_{FP} = \frac{\sigma_{FE}}{S_F} \cdot Y_d \cdot Y_{NT} \cdot Y_{\delta relT} \cdot Y_{RrelT} \cdot Y_X$$

where:

$\sigma_{FE}$  : Endurance limit for tooth root bending stress, defined in [3.5.9]

$\Psi_\delta$  : Design factor, defined in [3.5.10]

$\Psi_{NT}$  : Life factor for tooth root bending stress, defined in [3.5.11]

$\Psi_{\delta relT}$  : Relative notch sensitivity factor, defined in [3.5.12]

$\Psi_{PpeIT}$  : Relative surface factor, defined in [3.5.13]

$\Psi_\Sigma$  : Size factor for tooth root bending stress, defined in [3.5.14]

$\Sigma_\phi$  : Safety factor for tooth root bending stress, defined in [3.5.15].

### 3.5.9 Endurance limit for tooth root bending stress $\sigma_{FE}$

The endurance limit for tooth root bending stress  $\sigma_{FE}$  is the local tooth root stress which can be permanently endured.

The values to be adopted for  $\sigma_{FE}$  are given in [2.5.9] in relation to the type of steel employed and the heat treatment performed.

### 3.5.10 Design factor $Y_d$

The design factor  $Y_d$  takes into account the influence of load reversing and shrink fit pre-stressing on the tooth root strength.

$Y_d$  is defined in [2.5.10].

**3.5.11 Life factor  $Y_{NT}$**

The life factor  $Y_{NT}$  accounts for the influence of limited service life on the permissible tooth root bending stress.

Some values of  $Y_{NT}$  are given in Tab 20 for information.

The value  $Y_{NT}$  to be used will be given special consideration by the Society depending on the equipment's arrangement and use.

**3.5.12 Relative notch sensitivity factor  $\Psi_{\delta relT}$**

The relative notch sensitivity factor  $\Psi_{\delta relT}$  indicates the extent to which the theoretically concentrated stress lies above the fatigue endurance limit.

$\Psi_{\delta relT}$  is to be determined according to [2.5.12].

**3.5.13 Relative surface factor  $\Psi_{ppeIT}$**

The relative surface factor  $\Psi_{ppeIT}$  takes into account the dependence of the root strength on the surface condition on the tooth root fillet (roughness).

The values to be adopted for  $\Psi_{ppeIT}$  are given in Tab 22 in relation to the type of steel employed.

They are valid only when scratches or similar defects deeper than  $12 R_a$  are not present.

**3.5.14 Size factor  $Y_x$**

The size factor  $Y_x$  takes into account the decrease of the strength with increasing size.

The values to be adopted for  $Y_x$  are given in Tab 23 in relation to the type of steel employed and the value of normal module  $m_{mn}$ .

**3.5.15 Safety factor for tooth root bending stress  $S_F$**

The values to be adopted for the safety factor for tooth root bending stress  $S_F$  are given in Tab 24.

**3.6 Calculation of scuffing resistance**

**3.6.1 General**

The following calculations are requested for equipment running in supercritical domain i.e. when  $N > 1,5$  (see [3.3.4]).

The criterion for scuffing resistance is based on the calculation of the flash temperature method. According to this method, the risk of scuffing is assessed as a function of the properties of gear material, the lubricant characteristics, the surface roughness of tooth flanks, the sliding velocities and the load.

The interfacial contact temperatures are calculated as the sum of the interfacial bulk temperature of the moving interface and the fluctuating flash temperature of the moving faces in contact.

The maximum value of the interfacial contact temperature reduced by oil temperature is not to exceed 0,8 times the scuffing temperature reduced by oil temperature:

$$(\Theta_{B,Max} - \Theta_{oil}) \leq 0,8 (\Theta_{\Sigma} - \Theta_{oil})$$

where:

$\Theta_{B,Max}$  : Maximum contact temperature along the path of contact, in °C, defined in [3.6.2]

$\Theta_{oil}$  : Oil temperature, in °C

$\Theta_{\Sigma}$  : Scuffing temperature, in °C, defined in [3.6.11].

Additionally, the difference between the scuffing temperature and the contact temperature along the path is not to be below 30°C:

$$(\Theta_{\Sigma} - \Theta_{B,Max}) \geq 30^{\circ}C$$

Other methods of determination of the scuffing resistance could be accepted by the Society.

**3.6.2 Contact temperature  $\Theta_B$**

The maximum contact temperature  $\Theta_{B,Max}$  along the path of contact, in °C, is calculated as follows:

$$\Theta_{B,Max} = \Theta_{Mi} + \Theta_{fi,Max}$$

where:

$\Theta_{Mi}$  : Interfacial bulk temperature, in °C, defined in [3.6.10]

$\Theta_{fi,Max}$  : Maximum flash temperature along the path of contact, in °C, defined in [3.6.3].

The flash temperature is to be calculated on at least ten points along the path of contact and the maximum of these values has to be used for the calculation of maximum contact temperature.

**3.6.3 Flash temperature  $\Theta_{fi}$**

The flash temperature  $\Theta_{fi}$  at any point along the path of contact, in °C, is calculated with the following formula:

$$\Theta_{fi} = \mu_m \cdot X_M \cdot X_J \cdot X_G (X_F \cdot w_{Bl})^{0,75} \cdot \frac{V_{mt}^{0,5}}{r_m^{0,25}}$$

where:

- $\mu_m$  : Mean coefficient of friction, defined in [3.6.4]
- $\Xi_M$  : Thermo-elastic factor, in  $K \cdot N^{-3/4} \cdot s^{-1/2} \cdot m^{-1/2} \cdot mm$ , defined in [3.6.5]
- $\Xi_j$  : Approach factor, defined in [3.6.6]
- $\Xi_G$  : Geometry factor, defined in [3.6.7]
- $\Xi_T$  : Load sharing factor, defined in [3.6.8]
- $w_{Bt}$  : Transverse unit load, in N/mm, defined in [3.6.9].

**3.6.4 Mean coefficient of friction  $\mu_m$**

An estimation of the mean coefficient of friction  $\mu_m$  of common working conditions could be used with the following formula:

$$\mu_m = 0,06 \cdot \left( \frac{w_{Bt}}{v_{g\Sigma C} \cdot \rho_{relC}} \right)^{0,2} \cdot X_L \cdot X_R$$

where:

- $w_{Bt}$  : Transverse unit load, in N/mm (see [3.6.9])
- $v_{g\Sigma C}$  : Sum of tangential velocities in pitch point, in m/s:  
 $v_{g\Sigma C} = 2 v_{mt} \sin \alpha_{vt}$   
 with the maximum value of  $v_{mt}$  equal to 50 m/s
- $\rho_{relC}$  : Transverse relative radius of curvature, in mm:

$$\rho_{relC} = \frac{u \cdot \tan \delta_1 \cdot \tan \delta_2}{\tan \delta_1 + u \cdot \tan \delta_2} \cdot r_m \cdot \sin \alpha_{vt}$$

- $X_L$  : Lubricant factor, given in Tab 25
- $X_R$  : Roughness factor:

$$X_R = \left( \frac{R_{z1} + R_{z2}}{2} \right)^{0,25}$$

**3.6.5 Thermo-elastic factor  $X_M$**

The thermo-elastic factor  $X_M$  accounts for the influence of the material properties of pinion and wheel.

The values to be adopted for  $X_M$  are given in [2.6.5] in relation to the gear material characteristics.

**3.6.6 Approach factor  $X_j$**

The approach factor  $X_j$  takes empirically into account an increased scuffing risk in the beginning of the approach path, due to mesh starting without any previously built up oil film.

The values to be adopted for  $X_j$  are given in [2.6.6] in relation to the gear material characteristics.

**3.6.7 Geometry factor  $X_G$**

The geometry factor  $X_G$  is calculated according to the following formula:

$$X_G = 0,51 X_{\alpha\beta} \left( \frac{1}{\tan \delta_1} + \frac{1}{\tan \delta_2} \right)^{0,25} \frac{\left[ (1 + \Gamma)^{0,5} - \left( 1 + \Gamma \frac{\tan \delta_1}{\tan \delta_2} \right)^{0,5} \right]}{(1 + \Gamma)^{0,25} \cdot \left( 1 - \Gamma \frac{\tan \delta_1}{\tan \delta_2} \right)^{0,25}}$$

where:

- $X_{\alpha\beta}$  : Angle factor, equal to:  
 $X_{\alpha\beta} = 1,22 (\sin \alpha_{vt})^{0,25} \cdot (\cos \alpha_{vt})^{-0,5} \cdot (\cos \beta_{vb})^{0,25}$
- $\Gamma$  : Parameter of the point on the line of action, defined in Tab 32.

**3.6.8 Load sharing factor  $X_T$**

The load sharing factor  $X_T$  accounts for the load sharing of succeeding pairs of meshing teeth. It is defined as a function of the value of the parameter in the line of action, increasing at the approach path of transverse double contact.

The values to be adopted for  $X_T$  are given in [2.6.8].

The parameter of the line of action  $\Gamma$  to be used is given in Tab 32.

Table 32 : Parameter  $\Gamma$  on the line of action

Point	$\Gamma$
A : Lower end point of the path of contact	$\Gamma_A = -\frac{\tan \delta_2 \left( \frac{\tan \alpha_{a2}}{\tan \alpha_{vt}} - 1 \right)}{\tan \delta_1}$
AU : Lower end point of buttressing effect	$\Gamma_{AU} = \Gamma_A + 0,2 \sin \beta_{vb}$
AB : Intermediate point between A and B	$\Gamma_{AB} = 0,5 (\Gamma_A + \Gamma_B)$
B : Lower point of single pair tooth contact	$\Gamma_B = \frac{\tan \alpha_{a1}}{\tan \alpha_{vt}} - 1 - \frac{2\pi \cdot \cos \delta_1}{z_1 \tan \alpha_{vt}}$
C : Point with parameter equal to 0	$\Gamma_C = 0$
M : Intermediate point between A and E	$\Gamma_M = 0,5 (\Gamma_A + \Gamma_E)$
D : Upper point of single pair tooth contact	$\Gamma_D = -\frac{\tan \delta_2 \left( \frac{\tan \alpha_{a2}}{\tan \alpha_{vt}} - 1 \right)}{\tan \delta_1} + \frac{2\pi \cdot \cos \delta_1}{z_1 \tan \alpha_{vt}}$
DE : Intermediate point between D and E	$\Gamma_{DE} = 0,5 (\Gamma_D + \Gamma_E)$
EU : Upper end point of buttressing effect	$\Gamma_{EU} = \Gamma_E - 0,2 \sin \beta_{vb}$
E : Upper end point of the path of contact	$\Gamma_E = \frac{\tan \alpha_{a1}}{\tan \alpha_{vt}} - 1$
<b>Note 1:</b>	
$\alpha_{\alpha}$ : Transverse tip pressure angle of pinion and wheel, in rad:	
	$\cos \alpha_{ai} = \frac{\cos \alpha_{vt}}{1 + 2 h_{f0i} \cdot (\cos \delta_i) / d_{mi}}$

### 3.6.9 Transverse unit load $w_{Bt}$

The transverse unit load  $w_{Bt}$  is calculated according to the following formula:

$$w_{Bt} = K_A \cdot K_V \cdot K_{H\beta} \cdot K_{H\alpha} \cdot K_Y \cdot \frac{F_{mt}}{b}$$

where:

- $K_A$  : Application factor (see [3.3.2])
- $K_V$  : Dynamic factor (see [3.3.4])
- $K_{H\beta}$  : Face load distribution factor (see [3.3.5])
- $K_{H\alpha}$  : Transverse load distribution factor (see [3.3.6])
- $K_Y$  : Load sharing factor (see [3.3.3]).

### 3.6.10 Interfacial bulk temperature $\Theta_{Mi}$

The interfacial bulk temperature  $\Theta_{Mi}$  may be suitably averaged from the two overall bulk temperatures of the teeth in contact,  $\Theta_{M1}$  and  $\Theta_{M2}$ . An estimation of  $\Theta_{Mi}$ , given in [2.6.10], could be used in general configurations.

### 3.6.11 Scuffing temperature $\Theta_s$

The scuffing temperature  $\Theta_s$  may be determined according to the following formula:

$$\Theta_s = 80 + (0,85 + 1,4 X_W) \cdot X_L \cdot (S_{FZG} - 1)^2$$

where:

- $X_W$  : Structural factor given in Tab 27
- $X_L$  : Lubricant factor given in Tab 25
- $S_{FZG}$  : Load stage where scuffing occurs, according to gear tests, such as Ryder, FZG-Ryder, FZG L-42 or FZG A/8 3/90.

## 4 Design and construction - except tooth load capacity

### 4.1 Materials

#### 4.1.1 General

- a) Forged, rolled and cast materials used in the manufacturing of shafts, couplings, pinions and wheels are to comply with the requirements of NR216 Materials and Welding.
- b) Materials other than steels will be given special consideration by the Society.  
Requirements mentioned in Ch 1, Sec 1, [3.7.2] are to be applied when other materials than steel are used for components in contact with flammable fluids.

**4.1.2 Steels for pinions and wheel rims**

- a) Steels intended for pinions and wheels are to be selected considering their compatibility in service. In particular, for through-hardened pinion / wheel pairs, the hardness of the pinion teeth is to exceed that of the corresponding wheel. For this purpose, the minimum tensile strength of the pinion material is to exceed that of the wheel by at least 15%.
- b) The minimum tensile strength of the core is not to be less than:
  - 750 N/mm<sup>2</sup> for case-hardened teeth
  - 800 N/mm<sup>2</sup> for induction-hardened or nitrided teeth.

**4.2 Teeth**

**4.2.1 Manufacturing accuracy**

- a) Mean roughness (peak-to-valley) of shaved or ground teeth is not to exceed 4 µm.
- b) Wheels are to be cut by cutters with a method suitable for the expected type and quality. Whenever necessary, the cutting is to be carried out in a temperature-controlled environment.

**4.2.2 Tooth root**

Teeth are to be well faired and rounded at the root. The fillet radius at the root of the teeth, within a plane normal to the teeth, is to be not less than 0,25 m<sub>n</sub>.

Profile-grinding of gear teeth is to be performed in such a way that no notches are left in the fillet.

**4.2.3 Tooth tips and ends**

- a) All sharp edges on the tips and ends of gear teeth are to be removed after cutting and finishing of teeth.
- b) Where the ratio b/d exceeds 0,3, the ends of pinion and wheel are to be chamfered to an angle between 45 and 60 degrees. The chamfering depth is to be at least equal to 1,5 m<sub>n</sub>.

**4.2.4 Surface treatment**

- a) The hardened layer on surface-hardened gear teeth is to be uniform and extended over the whole tooth flank and fillet.
- b) Where the pinions and the toothed portions of the wheels are case-hardened and tempered, the teeth flanks are to be ground while the bottom lands of the teeth remain only case-hardened. The superficial hardness of the case-hardened zone is to be at least equal to 56 C Rockwell units.
- c) Where the pinions and the toothed portions of the wheels are nitrided, the hardened layer is to comply with Tab 33.
- d) The use of other processes of superficial hardening of the teeth, such as flame hardening, will be given special consideration, in particular as regards the values to be adopted for  $\sigma_{H,lim}$  and  $\sigma_{FE}$ .

**Table 33 : Characteristics of the hardened layer for nitrided gears**

Type of steel	Minimum thickness of hardened layer, in mm (1)	Minimum hardness (HV)
Nitrided steel	0,6	500 (at 0,25 mm depth)
Other steels	0,3	450 (surface)
(1) Depth of the hardened layer where the hardness is reduced to the core hardness. When the grinding of nitrided teeth is performed, the depth of the hardened layer to be taken into account is the depth after grinding.		

**4.3 Wheels and pinions**

**4.3.1 General**

Wheel bodies are to be so designed that radial deflexions and distortions under load are prevented, so as to ensure a satisfactory meshing of teeth.

**4.3.2 Welding**

- a) Where welding is employed for the construction of wheels, the welding procedure is to be submitted to the Society for approval. Welding processes and their qualification are to comply with NR216 Materials and Welding.
- b) Stress relieving treatment is to be performed after welding.
- c) Examination of the welded joints is to be performed by means of magnetic particle or dye penetrant tests to the satisfaction of the Surveyor. Suitable arrangements are to be made to permit the examination of the internal side of the welded joints.

**4.3.3 Shrink-fits**

a) The shrink-fit assembly of:

- rim and wheel body, and
- wheel body and shaft

is to be designed with a safety factor against slippage of not less than 2,8 c where c is a coefficient having the following values:

- c = 1 for gears driven by turbines or electric motors
- c = 1 for gears driven by diesel engines through a hydraulic, electromagnetic or high elasticity coupling
- c = 1,2 in the other cases.

Note 1: The manufacturer is to ensure that the maximum torque transmitted during the clutch engagement does not exceed the nominal torque by more than 20%.

b) The shrink-fit assembly is to take into account the thermal expansion differential between the shrunk-on parts in the service conditions.

**4.3.4 Bolting**

Where rims and hubs are joined together through bolted side plates or flanges, the assembly is to be secured:

- by tight fit bolts, or
- by bolts and tight fit pins.

The nuts are to be suitably locked by means other than welding.

**4.4 Shafts and bearings**

**4.4.1 General**

Shafts and their connections, in particular flange couplings and shrink-fits connections, are to comply with the provisions of Ch 1, Sec 7.

**4.4.2 Pinion and wheel shafts**

The minimum diameter of pinion and gear wheel shafts is not to be less than the value  $d_s$ , in mm, given by the following formula:

$$d_s = \left\{ \left[ \left( 10,2 + \frac{28000}{R_{s,min}} \right) T \right]^2 + \left[ \frac{170000}{412 + R_{s,min}} M \right]^2 \right\}^{\frac{1}{6}} \left( \frac{1}{1 - K_d^4} \right)^{\frac{1}{3}}$$

where:

$R_{s,min}$  : Minimum yield strength of the shaft material, in N/mm<sup>2</sup>

T : Nominal torque transmitted by the shaft, in Nm

M : Bending moment on the shaft, in Nm

$K_d$  : Coefficient having the following values:

- for solid shafts:  $K_d = 0$
- for hollow shafts,  $K_d$  is equal to the ratio of the hole diameter to the outer shaft diameter.

Where  $K_d \leq 0,3$ :  $K_d = 0$  may be taken.

Note 1: The values of  $d_s$ , T and M refer to the cross-section of the shaft concerned.

As an alternative to the above formula, the Society may accept direct strength calculations considering static and fatigue stresses occurring simultaneously and assuming safety factors for the material employed of at least:

- 1,5 in respect of the yield strength
- 2,0 in respect of the alternating bending fatigue limit.

**4.4.3 Quill shafts**

The minimum diameter of quill shafts subject to torque only is not to be less than the value  $d_{QS}$ , in mm, given by the following formula:

$$d_{QS} = \left[ \left( 7,65 + \frac{27000}{R_{s,min}} \right) \cdot \frac{T}{1 - K_d^4} \right]^{\frac{1}{3}}$$

$R_{s,min}$  and  $K_d$  being defined in [4.4.2].

**4.4.4 Bearings**

a) Thrust bearings and their supports are to be so designed as to avoid detrimental deflexions under load.

b) Life duration of bearings is not to be less than 40 000 hours. Shorter durations may be accepted on the basis of the actual load time distribution, and subject to the agreement of the owner.

**4.5 Casings**

**4.5.1 General**

Manufacturers are to build gear casings of sufficient stiffness such that misalignment, external loads and thermal effects in all service conditions do not adversely affect the overall tooth contact.

**4.5.2 Welded casings**

- a) Carbon content of steels used for the construction of welded casings is to comply with the provisions of NR216 Materials and Welding.
- b) The welded joints are to be so arranged that welding and inspection can be performed satisfactorily. They are to be of the full penetration type.
- c) Welded casings are to be stress-relieved after welding.

**4.5.3 Openings**

Access or inspection openings of sufficient size are to be provided to permit the examination of the teeth and the structure of the wheels.

**4.6 Lubrication**

**4.6.1 General**

- a) Manufacturers are to take care of the following points:
  - reliable lubrication of gear meshes and bearings is ensured:
    - over the whole speed range, including starting, stopping and, where applicable, manoeuvring
    - for all angles stated in Ch 1, Sec 1, [2.4]
  - in multi-propellers plants not fitted with shaft brakes, provision is to be made to ensure lubrication of gears likely to be affected by windmilling.
- b) Lubrication by means other than oil circulation under pressure will be given special consideration.

**4.6.2 Pumps**

- a) Gears intended for propulsion or other essential services are to be provided with:
  - one main lubricating pump, capable of maintaining a sufficient lubrication of the gearbox in the whole speed range
  - and one standby pump independently driven of at least the same capacity.
- b) In the case of:
  - gears having a transmitted power not exceeding 375 kW
  - or multi-engines plants
 one of the pumps mentioned in a) may be a spare pump ready to be connected to the reduction gear lubricating oil system, provided disassembling and reassembling operations can be carried out on board in a short time.

**4.6.3 Filtration**

- a) Forced lubrication systems are to be fitted with a device which efficiently filters the oil in the circuit.
- b) When fitted to gears intended for propulsion machinery or machinery driving electric propulsion generators, such filters are to be so arranged that they can be easily cleaned without stopping the lubrication of the machines.

**4.7 Control and monitoring**

**4.7.1** Gears are to be provided with the alarms and safeguards listed in Tab 34.

**Table 34 : Indications, alarms and safeguards for gears**

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Main Engine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Lubricating oil temperature at the oil cooler outlet		local					
Lubricating oil pressure	L (1)			X			
Oil tank level		local					

(1) May be omitted in case of restricted navigation notation.

## **5 Installation**

### **5.1 General**

**5.1.1** Manufacturers and shipyards are to take care directly that stiffness of gear seating and alignment conditions of gears are such as not to adversely affect the overall tooth contact and the bearing loads under all operating conditions of the ship.

### **5.2 Fitting of gears**

**5.2.1** Means such as stoppers or fitted bolts are to be arranged in the case of gears subject to propeller thrust. However, where the thrust is transmitted by friction and the relevant safety factor is not less than 2, such means may be omitted.

## **6 Certification, inspection and testing**

### **6.1 General**

#### **6.1.1**

- a) Inspection and testing of shafts and their connections (flange couplings, hubs, bolts, pins) are to be carried out in accordance with the provisions of Ch 1, Sec 7.
- b) For inspection of welded joints of wheels, refer to [4.3.2].

### **6.2 Workshop inspection and testing**

#### **6.2.1 Testing of materials**

Chemical composition and mechanical properties are to be tested in accordance with the applicable requirements of NR216 Materials and Welding, Chapter 5 for the following items:

- pinions and wheel bodies
- rims
- plates and other elements intended for propulsion gear casings of welded construction.

#### **6.2.2 Testing of pinion and wheel forgings**

- a) Mechanical tests of pinions and wheels are to be carried out in accordance with:
  - NR216 Materials and Welding, Ch 5, Sec 5, [1.6] for normalised and tempered or quenched and tempered forgings
  - NR216 Materials and Welding, Ch 5, Sec 5, [1.7] for surface-hardened forgings.
- b) Non-destructive examination of pinion and wheel forgings is to be performed in accordance with NR216 Materials and Welding, Ch 5, Sec 5, [1.8].

#### **6.2.3 Balancing test**

Rotating components, in particular gear wheel and pinion shaft assemblies with the coupling part attached, are to undergo a static balancing test.

Where  $n^2 \cdot d \geq 1,5 \cdot 10^9$ , gear wheel and pinion shaft assemblies are also to undergo a dynamic balancing test.

#### **6.2.4 Verification of cutting accuracy**

Examination of the accuracy of tooth cutting is to be performed in the presence of the Surveyor. Records of measurements of errors, tolerances and clearances of teeth are to be submitted at the request of the Surveyor.

#### **6.2.5 Meshing test**

- a) A tooth meshing test is to be performed in the presence of the Surveyor. This test is to be carried out at a load sufficient to ensure tooth contact, with the journals located in the bearings according to the normal running conditions. Before the test, the tooth surface is to be coated with a thin layer of suitable coloured compound.
- b) The results of such test are to demonstrate that the tooth contact is adequately distributed on the length of the teeth. Strong contact marks at the end of the teeth are not acceptable.
- c) A permanent record of the tooth contact is to be made for the purpose of subsequent checking of alignment following installation on board.
- d) For type approved cylindrical gears, with a power not greater than 375 kW and a cast casing, the above required workshop meshing test could be waived at the Surveyor satisfaction.

#### **6.2.6 Hydrostatic tests**

- a) Hydraulic or pneumatic clutches are to be hydrostatically tested before assembly to 1,5 times the maximum working pressure of the pumps.
- b) Pressure piping, pumps casings, valves and other fittings are to be hydrostatically tested in accordance with the requirements of Ch 1, Sec 10, [20].

# Section 7 Main Propulsion Shafting

## 1 General

### 1.1 Application

**1.1.1** This Section applies to shafts, couplings, clutches and other shafting components transmitting power for main propulsion. In addition, main propulsion machinery components are to comply with the requirements listed in Tab 1.

**Table 1 : Rule requirements for main propulsion components**

Item		Reference
Power transmission equipment	Diesel engines	Ch 1, Sec 2
	Turbines	Ch 1, Sec 4, Ch 1, Sec 5
	Gear	Ch 1, Sec 6
	Propellers	Ch 1, Sec 8
	Thrusters	Ch 1, Sec 15
Shaft line analysis	Shaft alignment	Ch 1, Sec 7
	Torsional vibration	Ch 1, Sec 9
Additional requirements	Navigation in ice	Pt F, Ch 8, Sec 3

### 1.2 Documentation to be submitted

**1.2.1** The Manufacturer is to submit to the Society the documents listed in Tab 2 for approval. Plans of power transmitting parts and shaft liners listed in Tab 2 are to include the relevant material specifications.

**Table 2 : Documentation to be submitted**

No.	Document (drawings, calculations, etc.)
1	Shafting arrangement (1)
2	Thrust shaft
3	Intermediate shafts
4	Propeller shaft
5	Shaft liners, relevant manufacture and welding procedures, if any
6	Couplings and coupling bolts
7	Flexible couplings (2)
8	Stern tube
9	Details of stern tube glands
10	Oil piping diagram for oil lubricated propeller shaft bearings
11	Shaft alignment calculation, see also [3.4]
<p>(1) This drawing is to show the entire shafting, from the main engine coupling flange to the propeller. The location of the thrust block, and the location and number of shafting bearings (type of material and length) are also to be shown.</p> <p>(2) The Manufacturer of the elastic coupling is also to submit the following data:</p> <ul style="list-style-type: none"> <li>• allowable mean transmitted torque (static) for continuous operation</li> <li>• maximum allowable shock torque</li> <li>• maximum allowable speed of rotation</li> <li>• maximum allowable values for radial, axial and angular misalignment</li> </ul> <p>In addition, when the torsional vibration calculation of main propulsion system is required (see Ch 1, Sec 9), the following data are also to be submitted:</p> <ul style="list-style-type: none"> <li>• allowable alternating torque amplitude and power loss for continuous operation, as a function of frequency and/or mean transmitted torque</li> <li>• static and dynamic stiffness, as a function of frequency and/or mean transmitted torque</li> <li>• moments of inertia of the primary and secondary halves of the coupling</li> <li>• damping coefficient or damping capability</li> <li>• properties of rubber components</li> <li>• for steel springs of couplings: chemical composition and mechanical properties of steel employed.</li> </ul>	

## 2 Design and construction

### 2.1 Materials

#### 2.1.1 General

The use of other materials or steels having values of tensile strength exceeding the limits given in [2.1.2], [2.1.3] and [2.1.4] will be considered by the Society in each case.

#### 2.1.2 Shaft materials

Where shafts may experience vibratory stresses close permissible stresses for transient operation (see Ch 1, Sec 9), the materials are to have a specified minimum ultimate tensile strength  $R_m$  of 500 N/mm<sup>2</sup>. Otherwise materials having a specified minimum ultimate tensile strength  $R_m$  of 400 N/mm<sup>2</sup> may be used.

For use in the following formulae in this Section,  $R_m$  is limited as follows:

- For carbon and carbon manganese steels,  $R_m$  is not exceed 760 N/mm<sup>2</sup>
- For alloy steels,  $R_m$  is not to exceed 800 N/mm<sup>2</sup>
- For propeller shafts,  $R_m$  is not to exceed 600 N/mm<sup>2</sup> (for carbon, carbon manganese and alloy steels).

Where materials with greater specified or actual tensile strengths than the limitations given above are used, reduced shaft dimensions are not acceptable when derived from the formulae given in this Section unless the Society verifies that the materials exhibit similar fatigue life as conventional steels (see Ch 1, App 6).

#### 2.1.3 Couplings, flexible couplings, hydraulic couplings

Non-solid forged couplings and stiff parts of elastic couplings subjected to torque are to be of forged or cast steel, or nodular cast iron.

Rotating parts of hydraulic couplings may be of grey cast iron, provided that the peripheral speed does not exceed 40m/s.

#### 2.1.4 Coupling bolts

Coupling bolts are to be of forged, rolled or drawn steel.

In general, the value of the tensile strength of the bolt material  $R_{mB}$  is to comply with the following requirements:

- $R_m \leq R_{mB} \leq 1,7 R_m$
- $R_{mB} \leq 1000 \text{ N/mm}^2$ .

#### 2.1.5 Shaft liners

Liners are to be of metallic corrosion resistant material complying with the applicable requirements of NR216 Materials and Welding and with the approved specification, if any; in the case of liners fabricated in welded lengths, the material is to be recognised as suitable for welding.

In general, they are to be manufactured from castings.

For small shafts, the use of liners manufactured from pipes instead of castings may be considered.

Where shafts are protected against contact with seawater not by metal liners but by other protective coatings, the coating procedure is to be approved by the Society.

#### 2.1.6 Sterntubes

Sterntubes are to comply with the requirements of Pt B, Ch 11, Sec 3, [4.5].

## 2.2 Shafts - Scantling

### 2.2.1 General

The provisions of this sub-article apply to propulsion shafts such as an intermediate and propeller shafts of traditional straight forged design and which are driven by rotating machines such as diesel engines, turbines or electric motors.

For shafts that are integral to equipment, such as for gear boxes, podded drives, electrical motors and/or generators, thrusters, turbines and which in general incorporate particular design features, additional criteria in relation to acceptable dimensions have to be taken into account. For the shafts in such equipment, the provisions of this sub-article apply only to shafts subject mainly to torsion and having traditional design features. Other shafts will be given special consideration by the Society.

### 2.2.2 Alternative calculation methods

Alternative calculation methods may be considered by the Society. Any alternative calculation method is to include all relevant loads on the complete dynamic shafting system under all permissible operating conditions. Consideration is to be given to the dimensions and arrangements of all shaft connections.

Moreover, an alternative calculation method is to take into account design criteria for continuous and transient operating loads (dimensioning for fatigue strength) and for peak operating loads (dimensioning for yield strength). The fatigue strength analysis may be carried out separately for different load assumptions

**2.2.3 Shafts diameters**

The diameter of intermediate shafts, thrust shafts and propellers shafts is not to be less than that determined from the following formula:

$$d = F \cdot k \cdot \left[ \frac{P}{n \cdot (1 - Q^4)} \cdot \frac{560}{R_m + 160} \right]^{1/3}$$

where:

- d : Minimum required diameter in mm
- Q : Factor equal to  $d_i / d_o$ , where:
  - $d_i$  : Actual diameter of the shaft bore, in mm (to be taken as 0 for solid shafts)
  - $d_o$  : Outside diameter of the shaft, in mm.

Note 1: Where  $d_i \leq 0,4 d_o$ , Q may be taken as 0.

- F : Factor for type of propulsion installation equal to:
  - 95 for intermediate and thrusts shafts in turbine installations, diesel installations with hydraulic (slip type) couplings and electric propulsion installations
  - 100 for all other diesel installation and all propeller shafts.
- k : Factor for the particular shaft design features, see Tab 3
- n : Speed of rotation of the shaft, in revolution per minute, corresponding to power P
- P : Maximum continuous power of the propulsion machinery for which the classification is requested, in kW
- $R_m$  : Specified minimum tensile strength of the shaft material, in N/mm<sup>2</sup>, see [2.1.2].

The diameter of the propeller shaft located forward of the inboard stern tube seal may be gradually reduced to the corresponding diameter required for the intermediate shaft using the minimum specified tensile strength of the propeller shaft in the formula and recognising any limitations given in [2.1.2].

Note 2: Transitions of diameters are to be designed with either a smooth taper or a blending radius equal to the change in diameter.

**Table 3 : Values of factor k**

straight sections and integral coupling flange (1)	shrink fit coupling (2)	keyway, tapered connection (3) (4)	keyway, cylindrical connection (3) (4)	radial hole (5)	longitudinal slots (6)	on both sides of thrust collar (1)	in way of bearing when a roller bearing is used	flange mounted or keyless taper fitted propellers (7)	key fitted propellers (7)	between forward end of aft most bearing and forward stern tube seal
1,00	1,00	1,10	1,10	1,10	1,20	1,10	1,10	1,22	1,26	1,15
<p>(1) The fillet radius is to be in accordance with the provisions of [2.5.1].</p> <p>(2) k values refer to the plain shaft section only. Where shafts may experience vibratory stresses close to permissible stresses for continuous operation, an increase in diameter to the shrink fit diameter is to be provided, e.g. a diameter increase of 1 to 2% and a blending radius as described in [2.2.3] Note 2.</p> <p>(3) At a distance of not less than 0,2 <math>d_o</math> from the end of the keyway the shaft diameter may be reduced to the diameter calculated with <math>k = 1,0</math>.</p> <p>(4) Keyways are to be in accordance with the provisions of [2.5.5].</p> <p>(5) Diameter of the radial bore is not to exceed 0,3 <math>d_o</math>.</p> <p>(6) Subject to limitations as <math>\ell/d_o &lt; 0,8</math> and <math>d_i/d_o &lt; 0,7</math> and <math>e/d_o &gt; 0,15</math>, where:  <math>\ell</math> : slot length in mm  <math>e</math> : slot width in mm                      The end rounding of the slot is not to be less than <math>e/2</math>. an edge rounding should preferably be avoided as this increases the stress concentration slightly.                      The k value is valid for 1, 2, 3 slots, i.e. with slots at 360 respectively 180 and respectively 120 degrees apart.</p> <p>(7) Applicable to the portion of the propeller shaft between the forward edge of the aftermost shaft bearing and the forward face of the propeller hub (or shaft flange), but not less than 2,5 times the required diameter.</p>										

## 2.3 Liners

### 2.3.1 General

Metal liners or other protective coatings approved by the Society are required where propeller shafts are not made of corrosion-resistant material.

Metal liners are generally to be continuous; however, discontinuous liners, i.e. liners consisting of two or more separate lengths, may be accepted by the Society on a case by case basis, provided that:

- they are fitted in way of all supports
- the shaft portion between liners, likely to come into contact with sea water, is protected with a coating of suitable material with characteristics, fitting method and thickness approved by the Society.

### 2.3.2 Scantling

The thickness of metal liners fitted on propeller shafts or on intermediate shafts inside sterntubes is to be not less than the value  $t$ , in mm, given by the following formula:

$$t = \frac{d + 230}{32}$$

where:

$d$  : Actual diameter of the shaft, in mm.

Between the sternbushes, the above thickness  $t$  may be reduced by 25%.

## 2.4 Stern tube bearings

### 2.4.1 Oil lubricated aft bearings of antifriction metal

- a) The length of bearings lined with white metal or other antifriction metal is to be not less than twice the rule diameter of the shaft in way of the bearing.
- b) The length of the bearing may be less than that given in (a) above, provided the nominal bearing pressure is not more than  $0,8 \text{ N/mm}^2$ , as determined by static bearing reaction calculations taking into account shaft and propeller weight, as exerting solely on the aft bearing, divided by the projected area of the shaft.

However, the minimum bearing length is to be not less than 1,5 times its actual inner diameter.

### 2.4.2 Oil lubricated aft bearings of synthetic rubber, reinforced resin or plastics material

- a) For bearings of synthetic rubber, reinforced resin or plastics material which are approved by the Society for use as oil lubricated sternbush bearings, the length of the bearing is to be not less than twice the rule diameter of the shaft in way of the bearing.
- b) The length of the bearing may be less than that given in (a) above provided the nominal bearing pressure is not more than  $0,6 \text{ N/mm}^2$ , as determined according to [2.4.1] b).

However, the minimum length of the bearing is to be not less than 1,5 times its actual inner diameter.

Where the material has proven satisfactory testing and operating experience, consideration may be given to an increased bearing pressure.

- c) Synthetic materials for application as oil lubricated stern tube bearings are to be of an approved type.

### 2.4.3 Water lubricated aft bearings

- a) The length of the bearing is to be not less than 4 times the rule diameter of the shaft in way of the bearing.
- b) For a bearing of synthetic material, consideration may be given to a bearing length less than 4 times, but in no case less than 2 times, the rule diameter of the shaft in way of the bearing, provided the bearing design and material is substantiated by experiments to the satisfaction of the Society.
- c) Synthetic materials for application as water lubricated stern tube bearings are to be Type Approved by the Society.

### 2.4.4 Grease lubricated bearings

The length of grease lubricated bearings is to be not less than 4 times the rule diameter of the shaft in way of the bearing.

### 2.4.5 Oil or grease lubrication system

- a) For oil lubricated bearings, provision for oil cooling is to be made.

A gravity tank is to be fitted to supply lubricating oil to the sterntube; the tank is to be located above the full load waterline.

Oil sealing glands are to be suitable for the various sea water temperatures which may be encountered in service.

- b) Grease lubricated bearings will be specially considered by the Society.

**2.4.6 Water circulation system**

For water lubricated bearings, means are to be provided to ensure efficient water circulation. In case of open loop systems, the sea water suction is normally to be from a sea chest.

The water grooves on the bearings are to be of ample section such as to ensure efficient water circulation and be scarcely affected by wear, particularly for bearings of the plastic type.

The shut-off valve or cock controlling the water supply is to be fitted direct to the stuffing box bulkhead or in way of the water inlet to the sterntube, when this is fitted forward of such bulkhead.

**2.5 Couplings**

**2.5.1 Flange couplings**

- a) Flange couplings of intermediate and thrust shafts and the flange of the forward coupling of the propeller shaft are to have a thickness not less than 0,2 times the rule diameter of the solid intermediate shaft and not less than the coupling bolt diameter calculated for a tensile strength equal to that of the corresponding shaft.

The fillet radius at the base of solid forged flanges is to be not less than 0,08 times the actual shaft diameter.

The fillet may be formed of multi-radii in such a way that the stress concentration factor will not be greater than that for a circular fillet with radius 0,08 times the actual shaft diameter.

For non-solid forged flange couplings, the above fillet radius is not to cause a stress in the fillet higher than that caused in the solid forged flange as above.

Filletts are to have a smooth finish and are not to be recessed in way of nuts and bolt heads.

- b) Where the propeller is connected to an integral propeller shaft flange, the thickness of the flange is to be not less than 0,25 times the rule diameter of the aft part of the propeller shaft. The fillet radius at the base of the flange is to be not less than 0,125 times the actual diameter.

The strength of coupling bolts of the propeller boss to the flange is to be equivalent to that of the aft part of the propeller shaft.

- c) Non-solid forged flange couplings and associated keys are to be of a strength equivalent to that of the shaft. They are to be carefully fitted and shrunk on to the shafts, and the connection is to be such as to reliably resist the vibratory torque and astern pull.
- d) For couplings of intermediate and thrust shafts and for the forward coupling of the propeller shaft having all fitted coupling bolts, the coupling bolt diameter in way of the joining faces of flanges is not to be less than the value  $d_B$ , in mm, given by the following formula:

$$d_B = 0,65 \cdot \left[ \frac{d^3 \cdot (R_m + 160)}{n_B \cdot D_C \cdot R_{mB}} \right]^{0,5}$$

where:

- d : Rule diameter of solid intermediate shaft, in mm, taking into account the ice strengthening requirements of Pt F, Ch 8, Sec 3, where applicable
- $n_B$  : Number of fitted coupling bolts
- $D_C$  : Pitch circle diameter of coupling bolts, in mm
- $R_m$  : Value of the minimum tensile strength of intermediate shaft material taken for calculation of d, in N/mm<sup>2</sup>
- $R_{mB}$  : Value of the minimum tensile strength of coupling bolt material, in N/mm<sup>2</sup>. Where, in compliance with [2.1.1], the use of a steel having  $R_{mB}$  in excess of the limits specified in [2.1.4] is allowed for coupling bolts, the value of  $R_{mB}$  to be introduced in the formula is not exceed the above limits.

- e) Flange couplings with non-fitted coupling bolts may be accepted on the basis of the calculation of bolt tightening, bolt stress due to tightening, and assembly instructions.

To this end, the torque based on friction between the mating surfaces of flanges is not to be less than 2,8 times the transmitted torque, assuming a friction coefficient for steel on steel of 0,18. In addition, the bolt stress due to tightening in way of the minimum cross-section is not to exceed 0,8 times the minimum yield strength ( $R_{eH}$ ), or 0,2 proof stress ( $R_{p0,2}$ ), of the bolt material.

Transmitted torque has the following meanings:

- For main propulsion systems powered by diesel engines fitted with slip type or high elasticity couplings, by turbines or by electric motors: the mean transmitted torque corresponding to the maximum continuous power P and the relevant speed of rotation n, as defined under [2.2.3].
- For main propulsion systems powered by diesel engines fitted with couplings other than those mentioned in (a): the mean torque above increased by 20% or by the torque due to torsional vibrations, whichever is the greater.

The value 2,8 above may be reduced to 2,5 in the following cases:

- ships having two or more main propulsion shafts
- when the transmitted torque is obtained, for the whole functioning rotational speed range, as the sum of the nominal torque and the alternate torque due to the torsional vibrations, calculated as required in Ch 1, Sec 9.

**2.5.2 Shrunken couplings**

Non-integral couplings which are shrunk on the shaft by means of the oil pressure injection method or by other means may be accepted on the basis of the calculation of shrinking and induced stresses, and assembly instructions.

To this end, the force due to friction between the mating surfaces is not to be less than 2,8 times the total force due to the transmitted torque and thrust.

The value 2,8 above may be reduced to 2,5 in the cases specified under item e) of [2.5.1].

The values of 0,14 and 0,18 will be taken for the friction coefficient in the case of shrinking under oil pressure and dry shrink fitting, respectively.

In addition, the equivalent stress due to shrinkage determined by means of the von Mises-Hencky criterion in the points of maximum stress of the coupling is not to exceed 0,8 times the minimum yield strength ( $R_{eH}$ ), or 0,2% proof stress ( $R_{p0,2}$ ), of the material of the part concerned.

The transmitted torque is that defined under item e) of [2.5.1].

For the determination of the thrust, see Ch 1, Sec 8, [3.1.2].

**2.5.3 Other couplings**

Types of couplings other than those mentioned in [2.5.1] and [2.5.2] will be specially considered by the Society.

**2.5.4 Flexible couplings**

- a) The scantlings of stiff parts of flexible couplings subjected to torque are to be in compliance with the requirements of Article [2].
- b) For flexible components, the limits specified by the Manufacturer relevant to static and dynamic torque, speed of rotation and dissipated power are not to be exceeded.
- c) Where all the engine power is transmitted through one flexible component only (ships with one propulsion engine and one shafting only), the flexible coupling is to be fitted with a torsional limit device or other suitable means to lock the coupling should the flexible component break.

In stiff transmission conditions with the above locking device, a sufficiently wide speed range is to be provided, free from excessive torsional vibrations, such as to enable safe navigation and steering of the ship. As an alternative, a spare flexible element is to be provided on board.

**2.5.5 Propeller shaft keys and keyways**

- a) Keyed connections are in general not to be used in installations with a barred speed range.
- b) Keyways

Keyways on the propeller shaft cone are to comply with the following requirements (see Fig 1).

Keyways are to have well rounded corners, with the forward end faired and preferably spooned, so as to minimize notch effects and stress concentrations.

The fillet radius at the bottom of the keyway is to be not less than 1,25% of the actual propeller shaft diameter at the large end of the cone.

The distance from the large end of the propeller shaft cone to the forward end of the key is to be not less than 20% of the actual propeller shaft diameter in way of the large end of the cone.

Key securing screws are not to be located within the first one-third of the cone length from its large end; the edges of the holes are to be carefully faired.

Note 1: Different scantlings may be accepted, provided that at least the same reduction in stress concentration is ensured.

- c) Keys

The sectional area of the key subject to shear stress is to be not less than the value A, in mm<sup>2</sup>, given by the following formula:

$$A = 0,4 \cdot \frac{d^3}{d_{PM}}$$

where:

d : Rule diameter, in mm, of the intermediate shaft calculated in compliance with the requirements of [2.2.3], assuming:

$$R_m = 400 \text{ N/mm}^2$$

d<sub>PM</sub> : Actual diameter of propeller shaft at mid-length of the key, in mm.

The edges of the key are to be rounded.

Figure 1 : Details of forward end of propeller shaft keyway

## 2.6 Design of oil control systems for clutches

2.6.1 Separate oil systems intended for the control of clutches are to include at least two power pumps, of such a capacity as to maintain normal control with any one pump out of action.

2.6.2 In the case of propulsion plants comprising:

- more than one shaft line with the clutches fitted with their own control system, or
- one engine with an output not exceeding 220 kW

one of the pumps mentioned in [2.6.1] may be a spare pump ready to be connected to the oil control system, provided disassembling and reassembling operations can be carried out on board in a short time.

2.6.3 However, when the propulsion plant comprises one or more engines, each with an output not exceeding 220 kW, the standby or spare pump may be omitted for the clutches provided that they are so designed as to be fixed mechanically in the "clutched" position and that the capacity of the starting means ensures the number of starts required in such conditions.

## 2.7 Monitoring

### 2.7.1 General

In addition to those given in this item, the requirements of Part C, Chapter 3 apply.

### 2.7.2 Propeller shaft monitoring

For the assignment of the propeller shaft monitoring system notation, see Pt F, Ch 5, Sec 2.

### 2.7.3 Indicators

The local indicators for main propulsion shafting to be installed on ships of 500 gross tonnage and upwards without automation notations are given in Tab 4. For monitoring of engines, turbines, gears, controllable pitch propellers and thrusters, see Ch 1, Sec 2, Ch 1, Sec 5, Ch 1, Sec 6, Ch 1, Sec 8 and Ch 1, Sec 15, respectively.

The indicators listed in Tab 4 are to be fitted at a normally attended position.

Table 4 : Shafting and clutches of propulsion machinery

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control					
			Main Engine			Auxiliary		
			Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start

Temperature of each shaft thrust bearing (non applicable for ball or roller bearings)	H		X					
Stern tube bush oil gravity tank level	L							
Clutches lubricating oil temperature	H		X					
Clutches oil tank level	L							

## 3 Arrangement and installation

### 3.1 General

**3.1.1** The installation is to be carried out according to the instructions of the component Manufacturer or approved documents, when required.

**3.1.2** The installation of sterntubes and/or associated non-shrunk bearings is subject to approval of procedures and materials used.

**3.1.3** The joints between liner parts are not to be located in way of supports and sealing glands.

Metal liners are to be shrunk on to the shafts by pre-heating or forced on by hydraulic pressure with adequate interference; dowels, screws or other means of securing the liners to the shafts are not acceptable.

### 3.2 Protection of propeller shaft against corrosion

**3.2.1** The propeller shaft surface between the propeller and the sterntube, and in way of propeller nut, is to be suitably protected in order to prevent any entry of sea water, unless the shaft is made of austenitic stainless steel.

### 3.3 Shaft alignment for ships granted with a notation ESA

#### 3.3.1 Application

Ships having the additional service feature or additional class notation **ESA**, as described respectively in Pt A, Ch 1, Sec 2, [4.1.5] and in Pt A, Ch 1, Sec 2, [6.25.8], are to comply with the requirements of Rule Note NR592 Elastic Shaft Alignment.

### 3.4 Shaft alignment for ships not granted with a notation ESA

#### 3.4.1 General

For ships to which the notation **ESA** is not assigned, shaft alignment calculations and shaft alignment procedures are to be submitted for review in the following cases:

- propulsion plants with a shaft diameter of 300 mm or greater in way of the aftermost bearing, whether or not they comprise a gearbox
- geared propulsion plants with power take-in (PTI) or power take-off (PTO), where the shaft diameter in way of the aftermost bearing is 150 mm or greater.

#### 3.4.2 Shaft alignment calculations

##### a) Scope of the calculations

The shaft alignment calculations are to be carried out in the following conditions:

- 1) alignment conditions during the shafting installation (ship in dry dock or afloat with propeller partly immersed)
- 2) cold, static, afloat conditions
- 3) hot, static, afloat conditions
- 4) hot, running conditions.

Note 1: Vertical and horizontal calculations are to be carried out, as deemed relevant.

##### b) Information to be submitted

The shaft alignment calculation report should contain the following information:

##### 1) Description of the shaftline model:

- length, diameters and density of material for each shaft
- definition of the reference line
- longitudinal, vertical and horizontal position of the bearing with respect to the reference line
- bearings characteristics: material, length, clearance.

##### 2) Input parameters

- hydrodynamic propeller loads (horizontal and vertical forces and moments)
- weight and buoyancy effect of the propeller, depending on the propeller immersion corresponding to the different loading cases of the ship
- engine power and rotational speed of the propeller (for calculations in running conditions)
- machining data of aft bush slope boring
- for slow speed engines, equivalent model of the crankshaft, with indication of the input loads
- for geared installation, gear tooth forces and moments
- thermal expansion of the gearbox or of the main engine between cold and hot conditions
- jack-up location.

3) Limits

- limits specified by engine or gearbox manufacturer (such as allowable bearing loads, allowable moments and forces at the shaft couplings)
- allowable loads specified by bearing manufacturer.

4) Results

- bearings influence coefficients table
- expected bearing reactions, for the different calculation conditions
- expected shaft deflections, shear forces and bending moments alongside the shaftline, for the different calculation conditions
- gap and sag values (depending on the alignment method)
- jack-up correction factors.

c) Acceptability criteria for the calculations

The results of the shaft alignment calculations are to comply with the following acceptability criteria:

- Relative slope between propeller shaft and aftermost boring axis is not to exceed 0,3 mm/m
- all bearings are to remain loaded
- loads on intermediate shaft bearings are not to exceed 80% of the maximum permissible load specified by the manufacturer
- stern tube bearing loads are not to exceed the limits started in [2.4].

### 3.4.3 Shaft alignment procedure

The shaft alignment procedure is to be submitted for review and is to be consistent with the shaft alignment calculations.

The shaft alignment procedure should include at least the following:

- Ship conditions in which the alignment is to be carried out (drafts, propeller immersion, engine room temperature)
- Method used for establishing the reference line (using laser or optical instruments or piano wire)
- Description of the different steps of the shafting installation:
  - bearing slope boring
  - setting of the bearing offset and installation of the temporary shaft support (where relevant) in accordance with the results of the shaft alignment calculation
  - flange coupling parameter setting (gap and sag)
  - bearing load test (jack-up test).

### 3.4.4 Verification of the alignment procedure

The purpose of the verification procedure is to ensure that the alignment measurements comply with the calculated values. The shaft alignment verification procedure is described in Ch 1, Sec 18, [3.11.1].

The shaft alignment verification is to be carried out by the shipyard in presence of the Surveyor and submitted to the Society.

The criteria for acceptability of the alignment conditions include the following:

- the position of the two aftermost bearings should not differ from the specified offsets by more than  $\pm 0,1$  mm.
- Gap and sag values should not differ from the calculated values by more than  $\pm 0,1$  mm.
- Bearing loads should not differ from the calculated values by more than  $\pm 20\%$ .

## 4 Material tests, workshop inspection and testing, certification

### 4.1 Material and non-destructive tests, workshop inspections and testing

#### 4.1.1 Material tests

Shafting components are to be tested by the Manufacturer in accordance with Tab 5 and in compliance with the requirements of NR216 Materials and Welding.

Magnetic particle or liquid penetrant tests are required for the parts listed in Tab 5 and are to be effected in positions agreed upon by the Surveyor, where Manufacturer's experience shows defects are most likely to occur.

Ultrasonic testing requires the Manufacturer's signed certificate.

#### 4.1.2 Hydrostatic tests

Parts of hydraulic couplings, clutches of hydraulic reverse gears and control units, hubs and hydraulic cylinders of controllable pitch propellers, including piping systems and associated fittings, are to be hydrostatically tested to 1,5 times the maximum working pressure.

Stern tubes, when machine-finished, and propeller shaft liners, when machine-finished on the inside and with an overthickness not exceeding 3 mm on the outside, are to be hydrostatically tested to 0,2 N/mm<sup>2</sup>.

**4.2 Certification**

**4.2.1 Testing certification**

Society’s certificates (C) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.1]) are required for material tests of components in items 1 to 5 of Tab 5.

Works’ certificates (W) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.3]) are required for hydrostatic tests of components indicated in [4.1.2] and for material and non-destructive tests of components in items of Tab 5 other than those for which Society’s certificates (C) are required.

**Table 5 : Material and non-destructive tests**

Shafting component	Material tests (Mechanical properties and chemical composition)	Non-destructive tests	
		Magnetic particle or liquid penetrant	Ultrasonic
1) Coupling (separate from shafts)	all	if diameter ≥ 100 mm <b>(1)</b>	if diameter ≥ 200 mm <b>(1)</b>
2) Propeller shafts	all	if diameter ≥ 100 mm <b>(1)</b>	if diameter ≥ 200 mm <b>(1)</b>
3) Intermediate shafts	all	if diameter ≥ 100 mm <b>(1)</b>	if diameter ≥ 200 mm <b>(1)</b>

# Section 8 Propellers

## 1 General

### 1.1 Application

#### 1.1.1 Propulsion propellers

The requirements of this Section apply to propellers of any size and type intended for propulsion. They include fixed and controllable pitch propellers, including those ducted in fixed nozzles.

#### 1.1.2 Exclusions

The requirements of this Section do not apply to propellers and impellers in bow and stern thrusters, which are covered in Ch 1, Sec 15, or to propellers for ships with ice strengthening, which are covered in Pt F, Ch 8, Sec 3.

### 1.2 Definitions

#### 1.2.1 Solid propeller

A solid propeller is a propeller (including hub and blades) cast in one piece.

#### 1.2.2 Built-up propeller

A built-up propeller is a propeller cast in more than one piece. In general, built up propellers have the blades cast separately and fixed to the hub by a system of bolts and studs.

#### 1.2.3 Controllable pitch propellers

Controllable pitch propellers are built-up propellers which include in the hub a mechanism to rotate the blades in order to have the possibility of controlling the propeller pitch in different service conditions.

#### 1.2.4 Nozzle

A nozzle is a circular structural casing enclosing the propeller.

#### 1.2.5 Ducted propeller

A ducted propeller is a propeller installed in a nozzle.

#### 1.2.6 Geometry of propeller

For all geometrical definitions (see Fig 1):

##### a) Blade area and area ratio

- $A_P$  : Projected blade area, i.e. projection of the blade area in the direction of the propeller shaft
- $A_D$  : Developed blade area, i.e. area enclosed by the connection line between the end points of the cylindrical profile sections turned in the propeller plane
- $A_E$  : Expanded blade area, i.e. area enclosed by the connection line between the end points of the developed and additionally straightened sections
- $A_O$  : Disc area calculated by means of the propeller diameter
- $B$  : Developed area ratio with  $B = A_D / A_O$

##### b) Rake and rake angle

- $h$  : Rake is the horizontal distance between the line connecting the blade tip to the blade root and the vertical line crossing the propeller axis in the same point where the prolongation of the first line crosses it, taken in correspondence of the blade tip. Aft rakes are considered positive, fore rakes are considered negative.

Rake angle is the angle at any point between the tangent to the generating line of the blade at that point and a vertical line passing at the same point. If the blade generating line is straight, there is only one rake angle; if it is curved there are an infinite number of rake angles.

##### c) Skew angle at tip of blade

- $\vartheta$  : Skew angle at the tip of blade, i.e. the angle on the projected blade plane between a line starting at the centre of the propeller axis and tangent to the blade midchord line and a line also starting at the centre of the propeller axis and passing at the outer end of this midchord line as measured.

##### d) Skewed propellers

Skewed propellers are propellers whose blades have a skew angle other than 0.

e) Leading and trailing edges

- LE : Leading edge of a propeller blade, i.e. the edge of the blade at side entering the water while the propeller rotates
- TE : Trailing edge of a propeller blade, i.e. the edge of the blade opposite to the leading edge.

**1.2.7 Rake angle**

Rake angle is the angle at any point between the tangent to the generating line of the blade at that point and a vertical line passing at the same point. If the blade generating line is straight, there is only one rake angle; if it is curved there are an infinite number of rake angles (see Fig 1).

**1.2.8 Skew angle**

Skew angle is the angle between a ray starting at the centre of the propeller axis and tangent to the blade midchord line and a ray also starting at the centre of the propeller axis and passing at the blade tip (see Fig 1).

**1.2.9 Skewed propellers**

Skewed propellers are propellers whose blades have a skew angle other than 0.

**1.2.10 Highly skewed propellers and very highly skewed propellers**

Highly skewed propellers are propellers having blades with skew angle exceeding 25°. Very highly skewed propellers are propellers having blades with skew angle exceeding 50°.

**Figure 1 : Description of propeller**

**1.2.11 Leading edge**

The leading edge of a propeller blade is the edge of the blade at side entering the water while the propeller rotates (see Fig 1).

**1.2.12 Trailing edge**

The trailing edge of a propeller blade is the edge of the blade opposite the leading edge (see Fig 1).

**1.2.13 Blade developed area**

Blade developed area is the area of the blade surface expanded in one plane.

**1.2.14 Developed area ratio**

Developed area ratio is the ratio of the total blade developed area to the area of the ring included between the propeller diameter and the hub diameter.

**1.3 Documentation to be submitted**

**1.3.1 Solid propellers**

The documents listed in Tab 1 are to be submitted for solid propellers intended for propulsion.

All listed plans are to be constructional plans complete with all dimensions and are to contain full indication of types of materials employed.

**Table 1 : Documents to be submitted for solid propellers**

No.	A/I (1)	ITEM
1	A	Sectional assembly
2	A	Blade and hub details
3	I	Rating (power, rpm, etc.)
4	A	Data and procedures for fitting propeller to the shaft
(1) A = to be submitted for approval ; I = to be submitted for information		

**1.3.2 Built-up and controllable pitch propellers**

The documents listed in Tab 2, as applicable, are to be submitted for built-up and controllable pitch propellers intended for propulsion.

**Table 2 : Documents to be submitted for built-up and controllable pitch propellers**

No.	A/I (1)	ITEM
1	A/I	Same documents requested for solid propellers
2	A	Blade bolts and pre-tensioning procedures
3	I	Pitch corresponding to maximum propeller thrust and to normal service condition
4	A	Pitch control mechanism
5	A	Pitch control hydraulic system
(1) A = to be submitted for approval ; I = to be submitted for information		

**1.3.3 Very highly skewed propellers and propellers of unusual design**

For very highly skewed propellers and propellers of unusual design, in addition to the documents listed in Tab 1 and Tab 2, as applicable, a detailed hydrodynamic load and stress analysis is to be submitted (see [2.4.3]).

**2 Design and construction**

**2.1 Materials**

**2.1.1 Normally used materials for propeller hubs and blades**

- a) Tab 3 indicates the minimum tensile strength  $R_m$  (in N/mm<sup>2</sup>), the density  $\delta$  (in kg/dm<sup>3</sup>) and the material factor  $f$  of normally used materials.
- b) Common bronze, special types of bronze and cast steel used for the construction of propeller hubs and blades are to have a minimum tensile strength of 400 N/mm<sup>2</sup>.
- c) Other materials are subject of special consideration by the Society following submission of full material specification.

Table 3 : Normally used materials for propeller blades and hub

Material	R <sub>m</sub>	δ	f
Common bronze	400	8,3	7,6
Manganese bronze	440	8,3	7,6
Nickel-manganese bronze	440	8,3	7,9
Aluminium bronze	590	7,6	8,3
Steel	440	7,9	9,0

2.1.2 Materials for studs

In general, steel (preferably nickel-steel) is to be used for manufacturing the studs connecting steel blades to the hub of built-up or controllable pitch propellers, and high tensile brass or stainless steel is to be used for studs connecting bronze blades.

2.2 Solid propellers - Blade thickness

2.2.1

- a) The maximum thickness t<sub>0,25</sub>, in mm, of the solid propeller blade at the section at 0,25 radius from the propeller axis is not to be less than that obtained from the following formula:

$$t_{0,25} = 3,2 \left[ f \cdot \frac{1,5 \cdot 10^6 \cdot \rho \cdot M_T + 51 \cdot \delta \cdot \left(\frac{D}{100}\right)^3 \cdot B \cdot l \cdot N^2 \cdot h}{l \cdot z \cdot R_m} \right]^{0,5}$$

where:

f : Material factor as indicated in Tab 3

ρ : ρ = D/H

H : Mean pitch of propeller, in m. When H is not known, the pitch at 0,7 radius from the propeller axis H<sub>0,7</sub> may be used instead of H

D : Propeller diameter, in m

M<sub>T</sub> : Continuous transmitted torque, in kN.m; where not indicated, the value given by the following formula may be assumed for M<sub>T</sub>:

$$M_T = 9,55 \cdot \left(\frac{P}{N}\right)$$

P : Maximum continuous power of propulsion machinery, in kW

N : Rotational speed of the propeller, in rev/min

δ : Density of blade material, in kg/dm<sup>3</sup>, as indicated in Tab 3

B : Developed area ratio

h : Rake, in mm

l : Expanded width of blade section at 0,25 radius from propeller axis, in mm

z : Number of blades

R<sub>m</sub> : Minimum tensile strength of blade material, in N/mm<sup>2</sup>.

- b) The maximum thickness t<sub>0,6</sub>, in mm, of the solid propeller blade at the section at 0,6 radius from the propeller axis is not to be less than that obtained from the following formula:

$$t_{0,6} = 1,9 \left[ f \cdot \frac{1,5 \cdot 10^6 \cdot \rho_{0,6} \cdot M_T + 18,4 \cdot \delta \cdot \left(\frac{D}{100}\right)^3 \cdot B \cdot l \cdot N^2 \cdot h}{l_{0,6} \cdot z \cdot R_m} \right]^{0,5}$$

where:

ρ<sub>0,6</sub> : D/H<sub>0,6</sub>

H<sub>0,6</sub> : Pitch at 0,6 radius from the propeller axis, in m

l<sub>0,6</sub> : Expanded width of blade section at 0,6 radius from propeller axis, in mm.

- c) The radius at the blade root is to be at least 3/4 of the minimum thickness required in that position. As an alternative, constant stress fillets may also be considered. When measuring the thickness of the blade, the increased thickness due to the radius of the fillet at the root of the blade is not to be taken into account. If the propeller hub extends over 0,25 radius, the thickness calculated by the formula in a) is to be compared with the thickness obtained by linear interpolation of the actual blade thickness up to 0,25 radius.

- d) As an alternative to the above formulae, a detailed hydrodynamic load and stress analysis carried out by the propeller designer may be considered by the Society, on a case by case basis. The safety factor to be used in this analysis is not to be less than 8 with respect to the ultimate tensile strength of the propeller material  $R_m$ .

### 2.3 Built-up propellers and controllable pitch propellers

#### 2.3.1 Blade thickness

- a) The maximum thickness  $t_{0,35}$ , in mm, of the blade at the section at 0,35 radius from the propeller axis is not to be less than that obtained from the following formula:

$$t_{0,35} = 2,7 \left[ f \frac{1,5 \cdot 10^6 \cdot \rho_{0,7} \cdot M_T + 41 \cdot \delta \left( \frac{D}{100} \right)^3 \cdot B \cdot l_{0,35} \cdot N^2 h}{l_{0,35} \cdot z \cdot R_m} \right]^{0,5}$$

where:

$$\rho_{0,7} = D / H_{0,7}$$

$H_{0,7}$  : Pitch at 0,7 radius from the propeller axis, in m. The pitch to be used in the formula is the actual pitch of the propeller when the propeller develops the maximum thrust

$l_{0,35}$  : Expanded width of blade section at 0,35 radius from propeller axis, in mm.

- b) The maximum thickness  $t_{0,6}$ , in mm, of the propeller blade at the section at 0,6 radius from the propeller axis is not to be less than that obtained from the formula in [2.2.1] b), using the value of  $l_{0,35}$  in lieu of  $l$ .
- c) The radius at the blade root is to be at least  $\frac{3}{4}$  of the minimum thickness required in that position. As an alternative, constant stress fillets may also be considered. When measuring the thickness of the blade, the increased thickness due to the radius of the fillet at the root of the blade is not to be taken into account.
- d) As an alternative to the above formulae, a detailed hydrodynamic load and stress analysis carried out by the propeller designer may be considered by the Society, on a case by case basis. The safety factor to be used in this analysis is not to be less than 8 with respect to the ultimate tensile strength of the propeller blade material  $R_m$ .

#### 2.3.2 Flanges for connection of blades to hubs

- a) The diameter  $D_F$ , in mm, of the flange for connection to the propeller hub is not to be less than that obtained from the following formula:

$$D_F = D_C + 1,8d_{PR}$$

where:

$D_C$  : Stud pitch circle diameter, in mm

$d_{PR}$  : Diameter of studs.

- b) The thickness of the flange is not to be less than 1/10 of the diameter  $D_F$ .

#### 2.3.3 Connecting studs

- a) The diameter  $d_{PR}$ , in mm, at the bottom of the thread of the studs is not to be less than obtained from the following formula:

$$d_{PR} = \left( \frac{4,6 \cdot 10^7 \cdot \rho_{0,7} \cdot M_T + 0,88 \cdot \delta \cdot \left( \frac{D}{10} \right)^3 \cdot B \cdot l_{0,35} \cdot N^2 \cdot h_1}{n_{PR} \cdot z \cdot D_C \cdot R_{m,PR}} \right)^{0,5}$$

where:

$h_1$  :  $h_1 = h + 1,125 D_C$

$n_{PR}$  : Total number of studs in each blade

$R_{m,PR}$  : Minimum tensile strength of stud material, in N/mm<sup>2</sup>.

- b) The studs are to be tightened in a controlled manner such that the tension on the studs is approximately 60-70% of their yield strength.
- c) The shank of studs may be designed with a minimum diameter equal to 0,9 times the root diameter of the thread.
- d) The studs are to be properly secured against unintentional loosening.

### 2.4 Skewed propellers

#### 2.4.1 Skewed propellers

The thickness of skewed propeller blades may be obtained by the formulae in [2.2] and [2.3.1], as applicable, provided the skew angle is less than 25°.

### 2.4.2 Highly skewed propellers

a) For solid and controllable pitch propellers having skew angles between 25° and 50°, the blade thickness, in mm, is not to be less than that obtained from the following formulae:

1) For solid propellers

$$t_{s-0,25} = t_{0,25} \cdot (0,92 + 0,0032\vartheta)$$

2) For built-up and controllable pitch propellers

$$t_{s-0,35} = t_{0,35} \cdot (0,9 + 0,004\vartheta)$$

3) For all propellers

$$t_{s-0,6} = t_{0,6} \cdot (0,74 + 0,0129\vartheta - 0,0001\vartheta^2)$$

$$t_{s-0,9} = t_{0,6} \cdot (0,35 + 0,0015\vartheta)$$

where:

$t_{s-0,25}$  : Maximum thickness, in mm, of skewed propeller blade at the section at 0,25 radius from the propeller axis

$t_{0,25}$  : Maximum thickness, in mm, of normal shape propeller blade at the section at 0,25 radius from the propeller axis, obtained by the formula in [2.2.1]

$t_{s-0,35}$  : Maximum thickness, in mm, of skewed propeller blade at the section at 0,35 radius from the propeller axis

$t_{0,35}$  : Maximum thickness, in mm, of normal shape propeller blade at the section at 0,35 radius from the propeller axis, obtained by the formula in [2.3.1]

$t_{s-0,6}$  : Maximum thickness, in mm, of skewed propeller blade at the section at 0,6 radius from the propeller axis

$t_{0,6}$  : Maximum thickness, in mm, of normal shape propeller blade at the section at 0,6 radius from the propeller axis, obtained by the formula in [2.2.1]

$t_{s-0,9}$  : Maximum thickness, in mm, of skewed propeller blade at the section at 0,9 radius from the propeller axis

$\vartheta$  : Skew angle.

b) As an alternative, highly skewed propellers may be accepted on the basis of a stress analysis, as stated in [2.4.3] for very highly skewed propellers.

### 2.4.3 Very highly skewed propellers

For very highly skewed propellers, the blade thickness is to be obtained by the Manufacturer, using a stress analysis according to a calculation criteria accepted by the Society. The safety factor to be used in this direct analysis is not to be less than 9 with respect to the ultimate tensile strength of the propeller blade material,  $R_m$ .

## 2.5 Ducted propellers

**2.5.1** The minimum blade thickness of propellers with wide tip blades running in nozzles is not to be less than the values obtained by the applicable formula in [2.2] or [2.3.1], increased by 10%.

## 2.6 Features

### 2.6.1 Blades and hubs

- All parts of propellers are to be free of defects and are to be built and installed with clearances and tolerances in accordance with sound marine practice.
- Particular care is to be taken with the surface finish of the blades.

### 2.6.2 Controllable pitch propellers pitch control system

- Where the pitch control mechanism is operated hydraulically, two independent, power-driven pump sets are to be fitted. For propulsion plants up to 220 kW, one power-driven pump set is sufficient provided that, in addition, a hand-operated pump is fitted for controlling the blade pitch.
- Pitch control systems are to be provided with an engine room indicator showing the actual setting of the blades. Further blade position indicators are to be mounted on the bridge and in the engine control room, if any.
- Suitable devices are to be fitted to ensure that an alteration of the blade setting cannot overload the propulsion plant or cause it to stall.
- Steps are to be taken to ensure that, in the event of failure of the control system, the setting of the blades
  - does not change, or
  - assumes a final position slowly enough to allow the emergency control system to be put into operation.
- Controllable pitch propeller systems are to be equipped with means of emergency control enabling the controllable pitch propeller to operate when the remote control system fails. This requirement may be complied with by means of a device which locks the propeller blades in the "ahead" setting.
- Tab 4 indicates the monitoring requirements to be displayed at the control console.

**Table 4 : Controllable pitch propeller**

Symbol convention H = High, HH = High high, L = Low, LL = Low low, X = function is required,	G = group alarm I = individual alarm R = remote	Automatic control					
		Main Engine			Auxiliary		
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Oil tank level	L						

### 3 Arrangement and installation

#### 3.1 Fitting of propeller on the propeller shaft

##### 3.1.1 General

- Screw propeller hubs are to be properly adjusted and fitted on the propeller shaft cone.
- The forward end of the hole in the hub is to have the edge rounded to a radius of approximately 6 mm.
- In order to prevent any entry of sea water under the liner and onto the end of the propeller shaft, the arrangement of Fig 2 is generally to be adopted for assembling the liner and propeller boss.
- The external stuffing gland is to be provided with a seawater resistant rubber ring preferably without joints. The clearance between the liner and the internal air space of the boss is to be as small as possible. The internal air space is to be filled with an appropriate protective material which is insoluble in sea water and non-corrodible or fitted with a rubber ring.
- All free spaces between the propeller shaft cone, propeller boss, nut and propeller cap are to be filled with a material which is insoluble in sea water and non-corrodible. Arrangements are to be made to allow any air present in these spaces to withdraw at the moment of filling. It is recommended that these spaces be tested under a pressure at least equal to that corresponding to the immersion of the propeller in order to check the tightness obtained after filling.
- For propeller keys and key area, see Ch 1, Sec 7, [2.5.5].

**Figure 2 : Example of sealing arrangement**

##### 3.1.2 Shrinkage of keyless propellers

In the case of keyless shrinking of propellers, the following requirements apply:

- The meaning of the symbols used in the subparagraphs below is as follows:
  - A : 100% theoretical contact area between propeller boss and shaft, as read from plans and disregarding oil grooves (i.e. oil grooves do not need to be subtracted), in mm<sup>2</sup>
  - C :
    - C = 1 for turbines, geared diesel engines, electrical drives and direct-drive reciprocating internal combustion engines with a hydraulic, electromagnetic or high elasticity coupling
    - C = 1,2 for diesel engines having couplings other than those specified above.
 The Society reserves the right to increase the value of C if the shrinkage needs to absorb an extremely high pulsating torque

$d_{PM}$	: Diameter of propeller shaft at the mid-point of the taper in the axial direction, in mm
$d_H$	: Mean outer diameter of propeller hub at the axial position corresponding to $d_{PM}$ , in mm
$d_{35}$	: Push-up length, in mm, at 35°C
$d_T$	: Push-up length, in mm, at temperature T
$d_{MAX}$	: Maximum permissible pull-up length, in mm, at 0°C
$E_P$	: Value of the modulus of elasticity of shaft material, in N/mm <sup>2</sup>
$E_M$	: Value of the modulus of elasticity of boss material, in N/mm <sup>2</sup>
F	: Tangential force at interface, in N
K	: $K = d_H/d_{PM}$
$M_T$	: Continuous torque transmitted, in N.m; where not indicated, $M_T$ may be assumed as indicated in [2.2.1]
$p_{35}$	: Surface pressure between mating surfaces, in N/mm <sup>2</sup> , at 35°C
$p_T$	: Surface pressure, in N/mm <sup>2</sup> , between mating surfaces at temperature T
$p_0$	: Surface pressure between mating surfaces, in N/mm <sup>2</sup> , at 0°C
$p_{MAX}$	: Maximum permissible surface pressure, in N/mm <sup>2</sup> , at 0°C
$R_{S,MIN}$	: Value of the minimum yield strength ( $R_{eH}$ ), or 0,2% proof stress ( $R_{p0,2}$ ), of propeller boss material, in N/mm <sup>2</sup>
$R_{m,B}$	: Value of the minimum tensile strength of the propeller boss material, in N/mm <sup>2</sup>
S	: Continuous thrust developed for free running ship, in N
$s_F$	: Safety factor against friction slip at 35°C
T	: Temperature of hub and propeller shaft material, in °C, assumed for calculation of pull-up length and push-up load
V	: Ship speed at P power, in knots
$W_T$	: Push-up load, in N, at temperature T
$\theta$	: Half taper of propeller shaft (for instance: taper = 1/15, $\theta = 1/30$ )
$\mu$	: Coefficient of friction between mating surfaces
$\sigma_{ID}$	: Equivalent uni-axial stress in the boss according to the von Mises-Hencky criterion, in N/mm <sup>2</sup>
$\alpha_P$	: Coefficient of linear expansion of shaft material, in mm/(mm°C)
$\alpha_M$	: Coefficient of linear expansion of boss material, in mm/(mm°C)
$\nu_P$	: Poisson's ratio for shaft material
$\nu_M$	: Poisson's ratio for boss material.

For other symbols not defined above, see [2.2].

- b) The manufacturer is to submit together with the required constructional plans specifications containing all elements necessary for verifying the shrinkage. Tests and checks deemed necessary for verifying the characteristics and integrity of the propeller material are also to be specified.
- c) Moreover, the manufacturer is to submit an instruction handbook, in which all operations and any precautions necessary for assembling and disassembling the propeller, as well as the values of all relevant parameters, are to be specified. A copy, endorsed by the Society, is to be kept on board each ship where the propeller is installed.
- d) The formulae and other provisions below do not apply to propellers where a sleeve is introduced between shaft and boss or in the case of hollow propeller shafts. In such cases, a direct shrinkage calculation is to be submitted to the Society.
- e) The taper of the propeller shaft cone is not to exceed 1/15.
- f) Prior to final pull-up, the contact area between the mating surfaces is to be checked and is not to be less than 70% of the theoretical contact area (100%). Non-contact bands extending circumferentially around the boss or over the full length of the boss are not acceptable.
- g) After final push-up, the propeller is to be secured by a nut on the propeller shaft. The nut is to be secured to the shaft.
- h) The safety factor  $s_F$  against friction slip at 35°C is not to be less than 2,8, under the combined action of torque and propeller thrust, based on the maximum continuous power P for which classification is requested at the corresponding speed of rotation N of the propeller, plus pulsating torque due to torsionals.
- i) For the oil injection method, the coefficient of friction  $\mu$  is to be 0,13 in the case of bosses made of bronze, brass or steel. For other methods, the coefficient of friction will be considered in each case by the Society.
- j) The maximum equivalent uni-axial stress in the boss at 0°C, based on the von Mises-Hencky criterion, is not to exceed 70% of the minimum yield strength ( $R_{eH}$ ), or 0,2% proof stress ( $R_{p0,2}$ ), of the propeller material, based on the test piece value. For cast iron, the value of the above stress is not to exceed 30% of the nominal tensile strength.
- k) For the formulae given below, the material properties indicated in the following items are to be assumed:
  - Modulus of elasticity, in N/mm<sup>2</sup>:
    - Cast and forged steel:  $E = 206000$
    - Cast iron:  $E = 98000$

Type Cu<sub>1</sub> and Cu<sub>2</sub> brass: E = 108000

Type Cu<sub>3</sub> and Cu<sub>4</sub> brass: E = 118000

- Poisson's ratio:

Cast and forged steel:  $\nu = 0,29$

Cast iron:  $\nu = 0,26$

All copper based alloys:  $\nu = 0,33$

- Coefficient of linear expansion in mm/(mm.°C)

Cast and forged steel and cast iron:  $\alpha = 12,0 \cdot 10^{-6}$

All copper based alloys:  $\alpha = 17,5 \cdot 10^{-6}$ .

- l) For shrinkage calculation the formulae in the following items, which are valid for the ahead condition, are to be applied. They will also provide a sufficient margin of safety in the astern condition.

- Minimum required surface pressure at 35°C:

$$p_{35} = \frac{s_F S}{AB} \cdot \left[ -s_F \theta + \left( \mu^2 + B \cdot \frac{F^2}{S^2} \right)^{0,5} \right]$$

where:

$$B = \mu^2 - s_F^2 \theta^2$$

- Corresponding minimum pull-up length at 35°C:

$$d_{35} = \frac{p_{35} d_{PM}}{2\theta} \cdot \left[ \frac{1}{E_M} \cdot \left( \frac{K^2 + 1}{K^2 - 1} + \nu_M \right) + \frac{1 - \nu_P}{E_P} \right]$$

- Minimum pull-up length at temperature T (T < 35°C):

$$d_T = d_{35} + \frac{d_{PM}}{2\theta} \cdot (\alpha_M - \alpha_P) \cdot (35 - T)$$

- Corresponding minimum surface pressure at temperature T:

$$p_T = p_{35} \cdot \frac{d_T}{d_{35}}$$

- Minimum push-up load at temperature T:

$$W_T = A p_T \cdot (\mu + \theta)$$

- Maximum permissible surface pressure at 0°C:

when the propeller boss is made of cast iron:

$$p_{MAX} = \frac{0,3 R_{m,B} \cdot (K^2 - 1)}{(3K^4 + 1)^{0,5}}$$

when the propeller boss is made of other materials:

$$p_{MAX} = \frac{0,7 R_{s,MIN} \cdot (K^2 - 1)}{(3K^4 + 1)^{0,5}}$$

- Corresponding maximum permissible pull-up length at 0°C:

$$d_{MAX} = d_{35} \cdot \frac{p_{MAX}}{p_{35}}$$

- Tangential force at interface:

$$F = \frac{2000 C M_T}{d_{PM}}$$

- Continuous thrust developed for free running ship; if the actual value is not given, the value, in N, calculated by one of the following formulae may be considered:

$$S = 1760 \cdot \frac{P}{V}$$

$$S = 57,3 \cdot 10^3 \cdot \frac{P}{H \cdot N}$$

### 3.1.3 Circulating currents

Means are to be provided to prevent circulating electric currents from developing between the propeller and the hull. A description of the type of protection provided and its maintenance is to be kept on board.

## 4 Testing and certification

### 4.1 Material tests

#### 4.1.1 Solid propellers

Material used for the construction of solid propellers is to be tested in accordance with the requirements of NR216 Materials and Welding in the presence of the Surveyor.

#### 4.1.2 Built-up propellers and controllable pitch propellers

In addition to the requirement in [4.1.1], materials for studs and for all other parts of the mechanism transmitting torque are to be tested in the presence of the Surveyor.

### 4.2 Testing and inspection

#### 4.2.1 Controllable pitch propellers

The complete hydraulic system for the control of the controllable pitch propeller mechanism is to be hydrotested at a pressure equal to 1,5 times the design pressure. The proper operation of the safety valve is to be tested in the presence of the Surveyor.

#### 4.2.2 Balancing

Finished propellers are to be statically balanced in accordance with the specified ISO 484 tolerance class. However, for built-up and controllable pitch propellers, the required static balancing of the complete propeller may be replaced by an individual check of blade weight and gravity centre position.

Refer also to:

- NR216 Materials and Welding, Ch 6, Sec 8, [1.9.3] for stainless steel propeller blades, and
- NR216 Materials and Welding, Ch 8, Sec 3, [1.9.4] for copper alloy propeller blades.

### 4.3 Certification

#### 4.3.1 Certification of propellers

Propellers having the characteristics indicated in [1.1.1] are to be individually tested and certified by the Society.

#### 4.3.2 Mass produced propellers

Mass produced propellers may be accepted within the framework of the type approval program of the Society.

## Section 9 Shaft Vibrations

### 1 General

#### 1.1 Application

1.1.1 The requirements of this Section apply to the shafting of the following installations:

- propulsion systems with prime movers developing 220 kW or more
- other systems with internal combustion engines developing 110 kW or more and driving auxiliary machinery intended for essential services.

#### 1.1.2 Exemptions

The requirements of this Section may be waived in cases where satisfactory service operation of similar installations is demonstrated.

### 2 Design of systems in respect of vibrations

#### 2.1 Principle

##### 2.1.1 General

- Special consideration shall be given by Manufacturers to the design, construction and installation of propulsion machinery systems so that any mode of their vibrations shall not cause undue stresses in these systems in the normal operating ranges.*
- Calculations are to be carried out for the configurations of the system likely to have influence on the torsional vibrations.
- Where deemed necessary by the Manufacturer, axial and/or bending vibrations are to be investigated.

##### 2.1.2 Vibration levels

Systems are to have torsional, bending and axial vibrations both in continuous and in transient running acceptable to the Manufacturers, and in accordance with the requirements of this Section.

Where vibrations are found to exceed the limits stated in this Section, the builder of the plant is to propose corrective actions, such as:

- operating restrictions, provided that the owner is informed, or
- modification of the plant.

##### 2.1.3 Condition of components

Systems are to be designed considering the following conditions, as deemed necessary by the Manufacturer:

- engine: cylinder malfunction
- flexible coupling: possible variation of the stiffness or damping characteristics due to heating or ageing
- vibration damper: possible variation of the damping coefficient.

#### 2.2 Modifications of existing plants

2.2.1 Where substantial modifications of existing plants, such as:

- change of the running speed or power of the engine
- replacement of an important component of the system (propeller, flexible coupling, damper) by one of different characteristics, or
- connection of a new component

are carried out, new vibration analysis is to be submitted for approval.

### 3 Torsional vibrations

#### 3.1 Documentation to be submitted

##### 3.1.1 Calculations

Torsional vibration calculations are to be submitted for the various configurations of the plants, showing:

- the equivalent dynamic system used for the modelling of the plant, with indication of:
  - inertia and stiffness values for all the components of the system
  - outer and inner diameters and material properties of the shafts

- the natural frequencies
- the values of the vibratory torques or stresses in the components of the system for the most significant critical speeds and their analysis in respect of the Rules and other acceptance criteria
- the possible restrictions of operation of the plant.

### **3.1.2 Particulars to be submitted**

The following particulars are to be submitted with the torsional vibration calculations:

- a) for turbines, multi-engine installations or installations with power take-off systems:
  - description of the operating configurations
  - load sharing law between the various components for each configuration
- b) for installations with controllable pitch propellers, the power/rotational speed values resulting from the combinator operation
- c) for prime movers, the service speed range and the minimum speed at no load
- d) for internal combustion engines:
  - manufacturer and type
  - nominal output and rotational speed
  - mean indicated pressure
  - number of cylinders
  - "V" angle
  - firing angles
  - bore and stroke
  - excitation data, such as the polynomial law of harmonic components of excitations
  - nominal alternating torsional stress considered for crankpin and journal

Note 1: The nominal alternating torsional stress is part of the basic data to be considered for the assessment of the crankshaft. It is defined in Ch 1, App 1.

- e) for turbines:
  - nominal output and rotational speed
  - power/speed curve and range of operation
  - number of stages, and load sharing between the stages
  - main excitation orders for each rotating disc
  - structural damping of shafts
  - external damping on discs (due to the fluid)
- f) for reduction or step-up gears, the speed ratio for each step
- g) for flexible couplings:
  - the maximum torque
  - the nominal torque
  - the permissible vibratory torque
  - the permissible heat dissipation
  - the relative damping
  - the torsional dynamic stiffness / transmitted torque relation where relevant
- h) for torsional vibration dampers:
  - the manufacturer and type
  - the permissible heat dissipation
  - the damping coefficient
  - the inertial and stiffness properties, as applicable
- i) for propellers:
  - the type of propeller: ducted or not ducted
  - the number of propellers of the ship
  - the number of blades
  - the excitation and damping data, if available
- j) for electric motors, generators and pumps, the drawing of the rotating parts, with their mass moment of inertia and main dimensions.

### 3.2 Definitions, symbols and units

#### 3.2.1 Definitions

- a) Torsional vibration stresses referred to in this Article are the stresses resulting from the alternating torque corresponding to the synthesis of the harmonic orders concerned.
- b) The misfiring condition of an engine is the malfunction of one cylinder due to the absence of fuel injection (which results in a pure compression or expansion in the cylinder).

#### 3.2.2 Symbols, units

The main symbols used in this Article are defined as follows:

- $\tau$  : Torsional vibration stress, as defined in [3.2.1], in N/mm<sup>2</sup>
- $\tau_1$  : Permissible stress due to torsional vibrations for continuous operation, in N/mm<sup>2</sup>
- $\tau_2$  : Permissible stress due to torsional vibrations for transient running, in N/mm<sup>2</sup>
- $R_m$  : Tensile strength of the shaft material, as defined in Ch 1, Sec 7, [2.1.2], in N/mm<sup>2</sup>
- $C_R$  : Material factor, equal to:
 
$$\frac{R_m + 160}{18}$$
- $d$  : Minimum diameter of the shaft, in mm
- $C_D$  : Size factor of the shaft, equal to:
 
$$0,35 + 0,93 d^{-0,2}$$
- $N$  : Speed of the shaft for which the check is carried out, in rev/min
- $N_n$  : Nominal speed of the shaft, in rev/min
- $N_c$  : Critical speed, in rev/min
- $\lambda$  : Speed ratio, equal to  $N/N_n$
- $C_\lambda$  : Speed ratio factor, equal to:
  - $3 - 2 \lambda^2$  for  $\lambda < 0,9$
  - $1,38$  for  $0,9 \leq \lambda < 1,05$
- $C_k$  : Factor depending on the stress concentration factor of the shaft design features given in Tab 1.

**Table 1 : Values of  $C_k$  factors**

Intermediate shafts with							Thrust shafts external to engines		Propeller shafts		
straight sections and integral coupling flanges	shrink-fit couplings (1)	keyways, tapered connection (2)	keyways, cylindrical connection (2)	radial hole	longitudinal slot (3)	splined shafts	on both sides of thrust collar	in way of axial bearing where a roller bearing is used as a thrust bearing	flange mounted or keyless fitted propellers (4)	key fitted propellers (4)	between forward end of aft most bearing and forward stern tube seal
1,00	1,00	0,60	0,45	0,50	0,30	0,80	0,85	0,85	0,55	0,55	0,80

(1)  $C_k$  values refer to the plain shaft section only. Where shafts may experience vibratory stresses close to the permissible stresses for continuous operation, an increase in diameter to the shrink fit diameter is to be provided, e.g. a diameter increase of 1 to 2% and a blending radius as described in Ch 1, Sec 7, [2.5.1]

(2) Keyways are to be in accordance with the provisions of Ch 1, Sec 7, [2.5.1].

(3) Subject to limitations as  $\ell/d_o < 0,8$  and  $d_i/d_o < 0,7$  and  $e/d_o > 0,15$ , where:  
 $\ell$  : Slot length in mm  
 $e$  : Slot width in mm  
 $d_i, d_o$  : As per Sec 7, [2.2.3]  
 The  $C_k$  value is valid for 1, 2 and 3 slots, i.e. with slots at 360 respectively 180 and respectively 120 degrees apart.

(4) Applicable to the portion of the propeller shaft between the forward edge of the aftermost shaft bearing and the forward face of the propeller hub (or shaft flange), but not less than 2.5 times the required diameter.

Note 1: Higher values of  $C_k$  factors based on direct calculations may also be considered.

Note 2: The determination of  $C_k$  factors for shafts other than those given in this table will be given special consideration by the Society.

### 3.3 Calculation principles

#### 3.3.1 Method

- a) Torsional vibration calculations are to be carried out using a recognised method.
- b) Where the calculation method does not include harmonic synthesis, attention is to be paid to the possible superimposition of two or more harmonic orders of different vibration modes which may be present in some restricted ranges.

#### 3.3.2 Scope of the calculations

- a) Torsional vibration calculations are to be carried out considering:
  - normal firing of all cylinders, and
  - misfiring of one cylinder.
- b) Where the torsional dynamic stiffness of the coupling depends on the transmitted torque, two calculations are to be carried out:
  - one at full load
  - one at the minimum load expected in service.
- c) For installations with controllable pitch propellers, two calculations are to be carried out:
  - one for full pitch condition
  - one for zero pitch condition.
- d) The calculations are to take into account other possible sources of excitation, as deemed necessary by the Manufacturer. Electrical sources of excitations, such as static frequency converters, are to be detailed. The same applies to transient conditions such as engine start up, reversing, clutching in, as necessary.
- e) The natural frequencies are to be considered up to a value corresponding to 15 times the maximum service speed. Therefore, the excitations are to include harmonic orders up to the fifteenth.

#### 3.3.3 Criteria for acceptance of the torsional vibration loads under normal firing conditions

- a) Torsional vibration stresses in the various shafts are not to exceed the limits defined in [3.4]. Higher limits calculated by an alternative method may be considered, subject to special examination by the Society.

The limit for continuous running  $\tau_1$  may be exceeded only in the case of transient running in restricted speed ranges, which are defined in [3.4.5]. In no case are the torsional vibration stresses to exceed the limit for transient running  $\tau_2$ .

Propulsion systems are to be capable of running continuously without restrictions at least within the speed range between  $0,8 N_n$  and  $1,05 N_n$ . Transient running may be considered only in restricted speed ranges for speed ratios  $\lambda \leq 0,8$ .

Auxiliary machinery is to be capable of running continuously without restrictions at least within the range between  $0,95 N_n$  and  $1,1 N_n$ . Transient running may be considered only in restricted speed ranges for speed ratios  $\lambda \leq 0,95$ .
- b) Torsional vibration levels in other components are to comply with the provisions of [3.5].
- c) The generating set is to show torsional vibration levels which are compatible with the allowable limits for the alternator, shafts, coupling and damper.

#### 3.3.4 Criteria for acceptance of torsional vibration loads under misfiring conditions

- a) The provisions of [3.3.3] related to normal firing conditions also apply to misfiring conditions.

Note 1: For propulsion systems operated at constant speed, restricted speed ranges related to misfiring conditions may be accepted for speed ratios  $\lambda > 0,8$ .

- b) Where calculations show that the limits imposed for certain components may be exceeded under misfiring conditions, a suitable device is to be fitted to indicate the occurrence of such conditions.

### 3.4 Permissible limits for torsional vibration stresses in crankshaft, propulsion shafting and other transmission shafting

#### 3.4.1 General

- a) The limits provided below apply to steel shafts. For shafts made of other material, the permissible limits for torsional vibration stresses will be determined by the Society after examination of the results of fatigue tests carried out on the material concerned.
- b) These limits apply to the torsional vibration stresses as defined in [3.2.1]. They relate to the shaft minimum section, without taking account of the possible stress concentrations.

#### 3.4.2 Crankshaft

- a) Where the crankshaft has been designed in accordance with Ch 1, App 1, the torsional vibration stresses in any point of the crankshaft are not to exceed the following limits:
  - $\tau_1 = \tau_N$  for continuous running
  - $\tau_2 = 1,7 \tau_N$  for transient running,where  $\tau_N$  is the nominal alternating torsional stress on which the crankshaft scantling is based (see Note 1 in [3.1.2]).

b) Where the crankshaft has not been designed in accordance with Ch 1, App 1, the torsional vibration stresses in any point of the crankshaft are not to exceed the following limits:

- $\tau_1 = 0,55 \cdot C_R \cdot C_D \cdot C_\lambda$  for continuous running
- $\tau_2 = 2,3 \tau_1$  for transient running.

**3.4.3 Intermediate shafts, thrust shafts and propeller shafts**

The torsional vibration stresses in any intermediate, thrust and propeller shafts are not to exceed the following limits:

- $\tau_1 = C_R \cdot C_k \cdot C_D \cdot C_\lambda$  for continuous running
- $\tau_2 = 1,7 \tau_1 \cdot C_k^{-0,5}$  for transient running.

**3.4.4 Transmission shafting for generating sets and other auxiliary machinery**

The torsional vibration stresses in the transmission shafting for generating sets and other auxiliary machinery, such as pumps or compressors, are not to exceed the following limits:

- $\tau_1 = 0,90 \cdot C_R \cdot C_D$  for continuous running
- $\tau_2 = 5,4 \tau_1$  for transient running.

**3.4.5 Restricted speed ranges**

- a) Where the torsional vibration stresses exceed the limit  $\tau_1$  for continuous running, restricted speed ranges are to be imposed which are to be passed through rapidly.
- b) The limits of the restricted speed range related to a critical speed  $N_c$  are to be calculated in accordance with the following formula:

$$\frac{16 \cdot N_c}{18 - \lambda} \leq N \leq \frac{(18 - \lambda) \cdot N_c}{16}$$

- c) Where the resonance curve of a critical speed is obtained from torsional vibration measurements, the restricted speed range may be established considering the speeds for which the stress limit for continuous running  $\tau_1$  is exceeded.
- d) Where restricted speed ranges are imposed, they are to be crossed out on the tachometers and an instruction plate is to be fitted at the control stations indicating that:
- the continuous operation of the engine within the considered speed range is not permitted
  - this speed range is to be passed through rapidly.
- e) When restricted speed ranges are imposed, the accuracy of the tachometers is to be checked in such ranges as well as in their vicinity.
- f) Restricted speed ranges in one-cylinder misfiring conditions of single propulsion engine ships are to enable safe navigation.

**3.5 Permissible vibration levels in components other than shafts**

**3.5.1 Gears**

- a) The torsional vibration torque in any gear step is not to exceed 30% of the torque corresponding to the approved rating throughout the service speed range.
- Where the torque transmitted at nominal speed is less than that corresponding to the approved rating, higher torsional vibration torques may be accepted, subject to special consideration by the Society.
- b) Gear hammering induced by torsional vibration torque reversal is not permitted throughout the service speed range, except during transient running at speed ratios  $\lambda \leq 0,3$ .
- Where calculations show the existence of torsional vibration torque reversals for speed ratios  $\lambda > 0,3$ , the corresponding speed ranges are to be identified by appropriate investigations during sea trials and considered as restricted speed ranges in accordance with [3.4.5].

**3.5.2 Generators**

- a) In the case of alternating current generators, the torsional vibration amplitude at the rotor is not to exceed  $\pm 2,5$  electrical degrees at service rotational speed under full load working conditions.
- b) Vibratory inertia torques due to torsional vibrations and imposed on the rotating parts of the generator are not to exceed the values  $M_A$ , in N.m, calculated by the following formulae, as appropriate:

- for  $0,95 \leq \lambda \leq 1,1$ :  $M_A = \pm 2,5 M_T$
- for  $\lambda \leq 0,95$ :  $M_A = \pm 6 M_T$

where:

$M_T$  : Mean torque transmitted by the engine under full load running conditions, in N.m

Note 1: In the case of two or more generators driven by the same engine, the portion of  $M_T$  transmitted to each generator is to be considered.

$\lambda$  : Speed ratio defined in [3.2.2].

### **3.5.3 Flexible couplings**

- a) Flexible couplings are to be capable of withstanding the mean transmitted torque and the torsional vibration torque throughout the service speed range, without exceeding the limits for continuous operation imposed by the manufacturer (permissible vibratory torque and power loss).  
Where such limits are exceeded under misfiring conditions, appropriate restrictions of power or speed are to be established.
- b) The coupling selection for the generating set is to take into account the stresses and torques imposed on it by the torsional vibration of the system.
- c) Flexible couplings fitted in generating sets are also to be capable of withstanding the torques and twist angles arising from transient criticals and short-circuit currents. Start up conditions are also to be checked.

### **3.5.4 Dampers**

- a) Torsional vibration dampers are to be such that the permissible power loss recommended by the manufacturer is not exceeded throughout the service speed range.
- b) Dampers for which a failure may lead to a significant vibration overload of the installation will be the subject of special consideration.

## **3.6 Torsional vibration measurements**

### **3.6.1 General**

- a) The Society may require torsional vibration measurements to be carried out under its attendance in the following cases:
- where the calculations indicate the possibility of dangerous critical speeds in the operating speed range
  - where doubts arise as to the actual stress amplitudes or critical speed location, or
  - where restricted speed ranges need to be verified.
- b) Where measurements are required, a comprehensive report including the analysis of the results is to be submitted to the Society.

### **3.6.2 Method of measurement**

When measurements are required, the method of measurement is to be submitted to the Society for approval. The type of measuring equipment and the location of the measurement points are to be specified.

## **4 Bending vibrations**

### **4.1 General**

**4.1.1** The provisions of this Article apply to the bending vibrations of propulsion systems having a transmitted power in excess of 1000 kW and:

- having a  $\ell/D$  ratio exceeding the following value:

$$\frac{\ell}{D} = 10 \left( \frac{\ln 2}{D} \right) + D^2$$

where:

- $\ell$  : Span between the aft bearings of the propeller shaft, in m  
 $D$  : Diameter of the propeller shaft, in m

or

- fitted with bearings located outboard the hull (brackets), or
- fitted with cardan shafts.

### **4.2 Documentation to be submitted**

#### **4.2.1 Particulars to be submitted**

The following particulars are to be submitted with the bending vibration calculations:

- shafting arrangement with indication of:
  - the diameter and length of the shafts
  - the position of the bearings
  - the mounting characteristics of the cardan shafts
  - detailed drawings of the bearings and their seating
  - details of the bearing lubrication, including the oil viscosity
  - the diametrical and polar moments of inertia of the propeller in air and water
  - propeller mass entrained water

- where vibratory amplitudes and bending moment calculations are required (see [4.2.2] item b)):
  - excitations values (bending moments and bending forces)
  - damping values.

#### **4.2.2 Calculations**

- a) Bending vibration calculations are to show:
- the equivalent dynamic system used for the modelling of the plant, with indication of the mass of the shafts, propeller and other rotating components, and the lateral stiffness of the bearings, including that of the oil film and that of the seating
  - the natural bending frequencies and associated mode shapes
  - the possible restrictions of operation of the plant.
- b) Where bending vibration calculations show a risk of vibration resonance, restrictions of operations of the plant are identified, or where deemed necessary by the Society or the manufacturer, additional calculations are to be provided showing the values of the vibratory amplitudes, bending moments and stresses in the shafting for the most significant critical speeds.

### **4.3 Calculation principles**

#### **4.3.1 Scope of the calculations**

Bending vibration calculations are to take into account:

- the stiffness of the bearings and their seatings and, where applicable, that of the lubricating oil film
- the excitations due to the propeller and cardan shafts.

Where data having a significant influence on the vibration levels cannot be determined with a sufficient degree of accuracy, parametric studies are to be carried out.

#### **4.3.2 Criteria for acceptance of the bending vibration levels**

- a) The first shafting vibration mode is not to be excited by the first propeller blade excitation order, in the speed range between 80% and 110% of nominal speed.
- b) Where bending vibration calculations show a risk of vibration resonance, vibration induced stresses are not to exceed 1,5 times the one indicated in [3.4.3] in the whole speed range. In case the shafting is checked by means of direct calculation the allowable stresses will be established on a case-by-case basis.

Additionally, vibratory amplitudes in way of aft stern tube bearing should not exceed bearing clearance value.

### **4.4 Bending vibration measurements**

#### **4.4.1 General**

The Society may require bending vibration measurements in the following cases:

- where the calculations indicate the possibility of dangerous critical speeds in or near the operating speed range
- where the accuracy of some data is not deemed sufficient
- where restricted speed ranges need to be verified.

Where measurements are required, a comprehensive report including the analysis of the results is to be submitted to the Society.

#### **4.4.2 Method of measurement**

When measurements are required, the method of measurement is to be submitted to the Society for approval. The type of measuring equipment and the location of the measurement points are to be specified.

## **5 Axial vibrations**

### **5.1 General**

**5.1.1** The provisions of this Article apply to the axial vibrations of propulsion systems fitted with:

- an internal combustion engine having a power exceeding 2000 kW and a running speed of less than 200 RPM, or
- a shaft line where the power transmitted exceeds 375 kW and the L/D ratio exceeds 50

where:

- L : Total length of the shaft line between the propeller and the thrust bearing
- D : Minimum diameter of the shaft line.

## **5.2 Documentation to be submitted**

### **5.2.1 Calculations**

Axial vibration calculations are to show:

- the equivalent dynamic system used for the modelling of the plant, with indication of the masses and axial stiffnesses for all the components of the system
- the natural frequencies
- the axial vibration amplitude in way of the sterntube sealing gland for the most significant critical speeds
- for engines directly connected to the shaftline, the axial vibration amplitude at the free end of the crankshaft for the most significant critical speeds
- the possible restrictions of operation of the plant.

### **5.2.2 Particulars to be submitted**

The following particulars are to be submitted with the axial vibration calculations:

- detailed drawing of the thrust bearing and its supporting structure with indication of their flexibility
- for the propeller:
  - the thrust
  - the excitations (axial forces)
  - the damping characteristics
- for the engine:
  - the axial excitations
  - the permissible axial amplitude at the free end of the crankshaft
  - the characteristics of the axial vibration damper or detuner.

## **5.3 Calculation principles**

### **5.3.1 Scope of the calculations**

Axial vibration calculations are to take into account:

- the flexibility of the thrust bearing and its supporting structure
- the excitations due to the engine and to the propeller.

Where data having a significant influence on the vibration levels cannot be determined with a sufficient degree of accuracy (e.g. the flexibility of the thrust bearing and its supporting structure), parametric studies are to be carried out.

Where the plant includes an axial vibration damper or detuner, a calculation is to be carried out assuming a malfunction of the damper or detuner.

### **5.3.2 Criteria for acceptance of the axial vibration levels**

The axial vibration force acting on the thrust bearing is not to exceed 30% of the nominal thrust.

The axial vibration amplitude is not to exceed:

- at the free end of the crankshaft, the limit recommended by the engine manufacturer
- in way of the sterntube sealing gland, the limit recommended by the sealing gland manufacturer, if any.

Where the calculations show that in the continuous operation speed range the above limits may be exceeded in the event of malfunction of the axial vibration damper or detuner, a suitable device is to be fitted to indicate the occurrence of such conditions.

Note 1: When detuners or dampers of satisfactorily proven design are used, this requirement may be waived.

## **5.4 Axial vibration measurements**

### **5.4.1 General**

The Society may require axial vibration measurements in the following cases:

- where the calculations indicate the possibility of dangerous critical speeds in the operating speed range
- where the accuracy of some data is not deemed sufficient
- where restricted speed ranges need to be verified.

Where measurements are required, a comprehensive report including the analysis of the results is to be submitted to the Society.

### **5.4.2 Method of measurement**

When measurements are required, the method of measurement is to be submitted to the Society for approval. The type of measuring equipment and the location of the measurement points are to be specified.

# Section 10 Piping Systems

## 1 General

### 1.1 Application

#### 1.1.1

- a) General requirements applying to all piping systems are contained in Articles:
- Article [2] for their design and construction
  - Article [3] for the welding of steel pipes
  - Article [4] for the bending of pipes
  - Article [5] for their arrangement and installation
  - Article [20] for their certification, inspection and testing.
- b) Specific requirements for ship piping systems and machinery piping systems are given in Articles [6] to [19].

### 1.2 Documentation to be submitted

#### 1.2.1 Documents

The documents listed in Tab 1 are to be submitted.

#### 1.2.2 Additional information

The information listed in Tab 2 is also to be submitted.

**Table 1 : Documents to be submitted**

No.	I/A (1)	Document (2)
1	A	Drawing showing the arrangement of the sea chests and ship side valves
2	A	Diagram of the bilge system (in and outside machinery spaces), including calculation for the bilge main, bilge branch lines and bilge pumps capacity as per Rule requirements
3	A	Specification of the central priming system intended for bilge pumps, when provided
4	A	Diagram of the ballast system (in and outside machinery spaces). See also Ch 1, Sec 13, [1.4] for the installation of ballast water treatment (BWTS) on board
5	A	Diagram of the scuppers and sanitary discharge systems
6	A	Diagram of the air, sounding and overflow systems
7	A	Diagram of cooling systems (sea water and fresh water)
8	A	Diagram of fuel oil system
9	A	Drawings of the fuel oil tanks not forming part of the ship's structure
10	A	Diagram of the lubricating oil system
11	A	Diagram of the thermal oil system
12	A	Diagram of the hydraulic systems intended for essential services or located in machinery spaces
13	A	Diagram of steam system, including safety valve exhaust and drain pipes
14	A I	For high temperature steam pipes: <ul style="list-style-type: none"> <li>• stress calculation note</li> <li>• drawing showing the actual arrangement of the piping in three dimensions</li> </ul>
15	A	Diagram of the boiler feed water and condensate system
16	A	Diagram of the compressed air system, including: <ul style="list-style-type: none"> <li>• starting air calculation as per Rule requirements</li> <li>• procedure and preliminary calculation showing that after "dead ship conditions" the propulsion may be restored within 30 min</li> </ul>
17	A	Diagram of the hydraulic and pneumatic remote control systems
<p>(1) A = to be submitted for approval I = to be submitted for information.</p> <p>(2) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.</p>		

No.	I/A (1)	Document (2)
18	A	Diagram of the remote level gauging system
19	A	Diagram of the exhaust gas system
20	A	Diagram of drip trays and gutterway draining system
21	A	Arrangement of the ventilation system
22	A	Diagram of the oxyacetylene welding system
23	A	Drawings and specification of valves and accessories, where required in [2.7]
<p>(1) A = to be submitted for approval I = to be submitted for information.</p> <p>(2) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.</p>		

**Table 2 : Information to be submitted**

No.	I/A (1)	Document
1	I	Nature, service temperature and pressure of the fluids
2	A	Material, external diameter and wall thickness of the pipes
3	A	Type of the connections between pipe lengths, including details of the welding, where provided
4	A	Material, type and size of the accessories
5	A	Capacity, prime mover and, when requested, location of the pumps
6	A	For plastic pipes: <ul style="list-style-type: none"> <li>• the chemical composition</li> <li>• the physical and mechanical characteristics in function of temperature</li> <li>• the characteristics of inflammability and fire resistance</li> <li>• the resistance to the products intended to be conveyed</li> </ul>
<p>(1) A = to be submitted for approval I = to be submitted for information.</p>		

### 1.3 Definitions

#### 1.3.1 Piping and piping systems

- a) Piping includes pipes and their connections, flexible hoses and expansion joints, valves and their actuating systems, other accessories (filters, level gauges, etc.) and pump casings.
- b) Piping systems include piping and all the interfacing equipment such as tanks, pressure vessels, heat exchangers, pumps and centrifugal purifiers, but do not include boilers, turbines, internal combustion engines and reduction gears.

Note 1: The equipment other than piping is to be designed in accordance with the relevant Sections of Part C, Chapter 1.

#### 1.3.2 Design pressure

- a) The design pressure of a piping system is the pressure considered by the manufacturer to determine the scantling of the system components. It is not to be taken less than the maximum working pressure expected in this system or the highest setting pressure of any safety valve or relief device, whichever is the greater.
- b) The design pressure of a boiler feed system is not to be less than 1,25 times the design pressure of the boiler or the maximum pressure expected in the feed piping, whichever is the greater.
- c) The design pressure of steam piping located upstream of pressure reducing valves (high pressure side) is not to be less than the setting pressure of the boiler or superheater safety valves.
- d) The design pressure of a piping system located on the low pressure side of a pressure reducing valve where no safety valve is provided is not to be less than the maximum pressure on the high pressure side of the pressure reducing valve.
- e) The design pressure of a piping system located on the delivery side of a pump or a compressor is not to be less than the setting pressure of the safety valve for displacement pumps or the maximum pressure resulting from the operating (head-capacity) curve for centrifugal pumps, whichever is the greater.

#### 1.3.3 Design temperature

The design temperature of a piping system is the maximum temperature of the medium inside the system.

#### 1.3.4 Flammable oils

Flammable oils include fuel oils, lubricating oils, thermal oils and hydraulic oils.

**1.4 Symbols and units**

**1.4.1** The following symbols and related units are commonly used in this Section. Additional symbols, related to some formulae indicated in this Section, are listed wherever it is necessary.

- p : Design pressure, in MPa
- T : Design temperature, in °C
- t : Rule required minimum thickness, in mm
- D : Pipe external diameter, in mm.

**1.5 Class of piping systems**

**1.5.1 Purpose of the classes of piping systems**

Piping systems are subdivided into three classes, denoted as class I, class II and class III, for the purpose of acceptance of materials, selection of joints, heat treatment, welding, pressure testing and the certification of fittings.

**1.5.2 Definitions of the classes of piping systems**

- a) Classes I, II and III are defined in Tab 3
- b) The following systems are not covered by Tab 3:
  - cargo piping for oil tankers, gas tankers and chemical tankers, and
  - fluids for refrigerating plants.

**Table 3 : Class of piping systems**

Media conveyed by the piping system	Class I	Class II (1) (4)	Class III (7)
Toxic media	without special safeguards (3)	not applicable	not applicable
Corrosive media	without special safeguards (3)	with special safeguards (3)	not applicable
Flammable media: • heated above flashpoint, or • having flashpoint < 60°C Liquefied gas	without special safeguards (3)	with special safeguards (3)	not applicable
Oxyacetylene	irrespective of p	not applicable	not applicable
Steam	p > 1,6 or T > 300	other (2)	p ≤ 0,7 and T ≤ 170
Thermal oil	p > 1,6 or T > 300	other (2)	p ≤ 0,7 and T ≤ 150
Fuel oil (8) Lubricating oil Flammable hydraulic oil (5)	p > 1,6 or T > 150	other (2)	p ≤ 0,7 and T ≤ 60
Other media (5) (6)	p > 4 or T > 300	other (2)	p ≤ 1,6 and T ≤ 200

(1) Valves under static pressure on oil fuel tanks or lubricating oil tanks belong to class II.  
 (2) Pressure and temperature conditions other than those required for class I and class III.  
 (3) Safeguards for reducing leakage possibility and limiting its consequences:  
 e.g. pipes led in positions where leakage of internal fluids will not cause a potential hazard or damage to surrounding areas which may include the use of pipe ducts, shielding, screening etc.  
 (4) Valves and fittings fitted on the ship side and collision bulkhead belong to class II. See also [20.5.3] b).  
 (5) Steering gear hydraulic piping system belongs to class I irrespective of p and T.  
 (6) Including water, air, gases, non-flammable hydraulic oil.  
 (7) The open ended pipes, irrespective of T, generally belong to class III (as drains, overflows, vents, exhaust gas lines, boiler escape pipes, etc.).  
 (8) Design pressure for fuel oil systems is to be determined in accordance with Tab 4.  
**Note 1:** p : Design pressure, as defined in [1.3.2], in MPa.  
**Note 2:** T : Design temperature, as defined in [1.3.3], in °C.  
**Note 3:** Flammable media generally include the flammable liquids as oil fuel, lubricating oil, thermal oil and flammable hydraulic oil.

**Table 4 : Definition of the design pressure for fuel oil systems**

Working pressure P, in bar	Working temperature T, in °C	
	T ≤ 60	T > 60
P ≤ 7	3 bar or max. working pressure, whichever is the greater	3 bar or max. working pressure, whichever is the greater
P > 7	max. working pressure	14 bar or max. working pressure, whichever is the greater

## 2 General requirements for design and construction

### 2.1 Materials

#### 2.1.1 General

Materials to be used in piping systems are to be suitable for the medium and the service for which the piping is intended.

For piping systems included in engine, turbine or gearbox installation in contact with flammable fluids, requirements mentioned in Ch 1, Sec 1, [3.7.2] are to be applied when other materials than steel are used.

#### 2.1.2 Use of metallic materials

- a) Metallic materials are to be used in accordance with Tab 5.
- b) Materials for class I and class II piping systems are to be manufactured and tested in accordance with the appropriate requirements of NR216 Materials and Welding.
- c) Materials for class III piping systems are to be manufactured and tested in accordance with the requirements of acceptable national or international standards or specifications.
- d) Mechanical characteristics required for metallic materials are specified in NR216 Materials and Welding.

#### 2.1.3 Use of plastics

- a) Plastics may be used for piping systems belonging to class III in accordance with Ch 1, App 3. The use of plastics for other systems or in other conditions will be given special consideration.
- b) Plastics intended for piping systems dealt with in this Section are to be of a type approved by the Society.

## 2.2 Thickness of pressure piping

### 2.2.1 Calculation of the thickness of pressure pipes

- a) The thickness  $t$ , in mm, of pressure pipes is to be determined by the following formula but, in any case, is not to be less than the minimum thickness given in Tab 6 to Tab 9.

$$t = \frac{t_0 + b + c}{1 - \frac{a}{100}}$$

where:

$t_0$  : Coefficient, in mm, equal to:

$$t_0 = \frac{p \cdot D}{2Ke + p}$$

with:

$p$  and  $D$  : as defined in [1.4.1],

$K$  : Permissible stress defined in [2.2.2]

$e$  : Weld efficiency factor to be:

- equal to 1 for seamless pipes and pipes fabricated according to a welding procedure approved by the Society,
- specially considered by the Society for other welded pipes, depending on the service and the manufacture procedure.

$b$  : Thickness reduction due to bending defined in [2.2.3], in mm

$c$  : Corrosion allowance defined in [2.2.4], in mm

$a$  : Negative manufacturing tolerance percentage:

- equal to 10 for copper and copper alloy pipes, cold drawn seamless steel pipes and steel pipes fabricated according to a welding procedure approved by the Society
- equal to 12,5 for hot laminated seamless steel pipes
- subject to special consideration by the Society in other cases.

- b) The thickness thus determined does not take into account the particular loads to which pipes may be subjected. Attention is to be drawn in particular to the case of high temperature and low temperature pipes.

**Table 5 : Conditions of use of metallic materials in piping systems**

Material	Allowable classes	Maximum design temperature (1)	Particular conditions of use
Carbon and carbon-manganese steels	III, II, I	400 (2)	Class I and II pipes are to be seamless drawn pipes (3)
Copper and aluminium brass	III, II, I	200	<ul style="list-style-type: none"> <li>Not to be used in fuel oil systems, except for class III pipes of a diameter not exceeding 25 mm not passing through fuel oil tanks</li> <li>Not to be used for boiler blow-down valves nor for associated pieces for connection to the shell plating</li> </ul> (4)
Copper-nickel	III, II, I	300	
Special high temperature resistant bronze	III, II, I	260	
Stainless steel	III, II, I	300	In general, austenitic stainless steel is not to be used for sea water systems (see Note (6))
Spheroidal graphite cast iron/Nodular cast iron	III, II (5)	350	<ul style="list-style-type: none"> <li>Minimum elongation is not to be less than 12% on a gauge length of <math>5,65.S^{0.5}</math>, where S is the actual cross-sectional area of the test piece</li> <li>Not to be used for boiler blow-down valves not for associated pieces for connection to the shell plating</li> </ul>
Grey cast iron/Ordinary cast iron	III, II	220	Grey cast iron/ordinary cast iron is not to be used for the following systems: <ul style="list-style-type: none"> <li>boiler blow-down systems and other piping systems subject to shocks, high stresses and vibrations</li> <li>bilge lines in tanks</li> <li>parts of scuppers and sanitary discharge systems located next to the hull below the freeboard deck or for passengers ships below the bulkhead deck</li> <li>ship side valves and fittings</li> <li>valves fitted on the collision bulkhead</li> <li>valves fitted to fuel oil and lubricating oil tanks under static pressure head</li> <li>class II fuel oil systems and thermal oil systems</li> </ul>
Aluminium and aluminium alloys	III, II	200	Aluminium and aluminium alloys are not to be used on the following systems: <ul style="list-style-type: none"> <li>flammable oil systems</li> <li>sounding and air pipes of fuel oil tanks</li> <li>fire-extinguishing systems</li> <li>bilge system in boiler or machinery spaces or in spaces containing fuel oil tanks or pumping units</li> <li>scuppers and overboard discharges except for pipes led to the bottoms or to the shell above the freeboard deck or fitted at their upper end with closing means operated from a position above the freeboard deck</li> <li>boiler blow-down valves and pieces for connection to the shell plating</li> </ul>
(1) Maximum design temperature is not to exceed that assigned to the class of piping. (2) Higher temperatures may be accepted if metallurgical behaviour and time dependent strength (ultimate tensile strength after 100 000 hours) are in accordance with national or international standards or specifications and if such values are guaranteed by the steel manufacturer. (3) Pipes fabricated by a welding procedure approved by the Society may also be used. (4) Pipes made of copper and copper alloys are to be seamless. (5) Use of spheroidal cast iron / nodular cast iron for class I piping systems will be given special consideration by the Society. (6) Austenitic stainless steels including grades 304, 304L, 316 and 316L are not considered suitable for use in seawater piping systems. Other types of stainless steel with higher contents of chromium, molybdenum and nitrogen may be considered if a technical justification considering critical factors (e.g. chemical composition, stagnant sea water, or low flow sea water piping, operational consideration, etc.) is provided. This includes austenitic stainless steels with at least 3% molybdenum and duplex ferritic-austenitic stainless steels such as grades UNS S31803 or UNS S2550.			

Table 6 : Minimum wall thickness for steel pipes

External diameter (mm)	Minimum nominal wall thickness (mm)			Minimum reinforced wall thickness (mm) (2)	Minimum extra-reinforced wall thickness (mm) (3)
	Pipes in general (1)	Vent, overflow and sounding pipes for integral tanks (1) (5)	Sea water pipes, bilge and ballast systems (1) (4)		
10,2 - 12,0	1,6	–	–	–	–
13,5 - 19,3	1,8	–	–	–	–
20,0	2,0	–	–	–	–
21,3 - 25,0	2,0	–	3,2	–	–
26,9 - 33,7	2,0	–	3,2	–	–
38,0 - 44,5	2,0	4,5	3,6	6,3	7,6
48,3	2,3	4,5	3,6	6,3	7,6
51,0 - 63,5	2,3	4,5	4,0	6,3	7,6
70,0	2,6	4,5	4,0	6,3	7,6
76,1 - 82,5	2,6	4,5	4,5	6,3	7,6
88,9 - 108,0	2,9	4,5	4,5	7,1	7,8
114,3 - 127,0	3,2	4,5	4,5	8,0	8,8
133,0 - 139,7	3,6	4,5	4,5	8,0	9,5
152,4 - 168,3	4,0	4,5	4,5	8,8	11,0
177,8	4,5	5,0	5,0	8,8	12,7
193,7	4,5	5,4	5,4	8,8	12,7
219,1	4,5	5,9	5,9	8,8	12,7
244,5 - 273,0	5,0	6,3	6,3	8,8	12,7
298,5 - 368,0	5,6	6,3	6,3	8,8	12,7
406,4 - 457,2	6,3	6,3	6,3	8,8	12,7

(1) Attention is drawn to the special requirements regarding:

- bilge and ballast systems
- scupper and discharge pipes
- sounding, air and overflow pipes
- ventilation systems
- oxyacetylene welding systems
- CO<sub>2</sub> fire-extinguishing systems (see Ch 4, Sec 15)
- cargo lines (see Pt D, Ch 10, Sec 3). The wall thickness is to be subject to special consideration by the Society.

(2) Reinforced wall thickness applies to pipes passing through tanks containing a fluid distinct from that conveyed by the pipe and to pipe connections fitted to the tanks.

(3) Extra-reinforced wall thickness applies to pipes connected to the shell below the freeboard deck.

(4) The minimum wall thickness for bilge lines and ballast lines through deep tanks is to be subject to special consideration by the Society. The ballast lines within oil cargo tanks (where permitted) is to be subject to special consideration by the Society (see Pt D, Ch 7, Sec 4, [2.1.3]).

(5) For sounding pipes, except those for flammable cargoes, the minimum wall thickness is intended to apply only to the part outside the tank.

**Note 1:** A different thickness may be considered by the Society on a case by case basis, provided that it complies with recognised standards.

**Note 2:** For pipes efficiently protected against corrosion, the thickness may be reduced by an amount up to 1 mm.

**Note 3:** The thickness of threaded pipes is to be measured at the bottom of the thread.

**Note 4:** The minimum thickness listed in this table is the nominal wall thickness and no allowance is required for negative tolerance and reduction in thickness due to bending.

**Note 5:** For nominal diameters ND > 450 mm, the minimum wall thickness is to be in accordance with a national or an international standard, but is not to be less than the minimum wall thickness of the appropriate column indicated for 450 mm pipe size.

**Note 6:** Exhaust gas pipe minimum wall thickness is to be subject to special consideration by the Society.

**Table 7 : Minimum wall thickness for copper and copper alloy pipes**

External diameter (mm)	Minimum wall thickness (mm)	
	Copper	Copper alloy
8 - 10	1,0	0,8
12 - 20	1,2	1,0
25 - 44,5	1,5	1,2
50 - 76,1	2,0	1,5
88,9 - 108	2,5	2,0
133 - 159	3,0	2,5
193,7 - 267	3,5	3,0
273 - 457,2	4,0	3,5
470	4,0	3,5
508	4,5	4,0

**Note 1:** A different thickness may be considered by the Society on a case by case basis, provided that it complies with recognised standards.

**Table 8 : Minimum wall thickness for austenitic stainless steel pipes**

External diameter (mm)	Minimum wall thickness (mm)
10,2 to 17,2	1,0
21,3 to 48,3	1,6
60,3 to 88,9	2,0
114,3 to 168,3	2,3
219,1	2,6
273,0	2,9
323,9 to 406,4	3,6
over 406,4	4,0

**Note 1:** Diameters and thicknesses according to national or international standards may be accepted.

**Table 9 : Minimum wall thickness for aluminium and aluminium alloy pipes**

External diameter (mm)	Minimum wall thickness (mm)
0 - 10	1,5
12 - 38	2,0
43 - 57	2,5
76 - 89	3,0
108 - 133	4,0
159 - 194	4,5
219 - 273	5,0
above 273	5,5

**Note 1:** A different thickness may be considered by the Society on a case by case basis, provided that it complies with recognised standards.

**Note 2:** For sea water pipes, the minimum thickness is not to be less than 5 mm.

**2.2.2 Permissible stress**

- a) The permissible stress K is given:
- in Tab 10 for carbon and carbon-manganese steel pipes
  - in Tab 11 for alloy steel pipes, and
  - in Tab 12 for copper and copper alloy pipes,
- as a function of the temperature. Intermediate values may be obtained by interpolation.
- b) Where, for carbon steel and alloy steel pipes, the value of the permissible stress K is not given in Tab 10 or Tab 11, it is to be taken equal to the lowest of the following values:

$$\frac{R_{m,20}}{2,7} \quad \frac{R_e}{A} \quad \frac{S_R}{A} \quad S$$

where:

$R_{m,20}$  : Minimum tensile strength of the material at ambient temperature (20°C), in N/mm<sup>2</sup>

$R_e$  : Minimum yield strength or 0,2% proof stress at the design temperature, in N/mm<sup>2</sup>

$S_R$  : Average stress to produce rupture in 100000 h at design temperature, in N/mm<sup>2</sup>

$S$  : Average stress to produce 1% creep in 100000 h at design temperature, in N/mm<sup>2</sup>

$A$  : Safety factor to be taken equal to:

- 1,6 when  $R_e$  and  $S_R$  values result from tests attended by the Society
- 1,8 otherwise.

- c) The permissible stress values adopted for materials other than carbon steel, alloy steel, copper and copper alloy will be specially considered by the Society.

**Table 10 : Permissible stresses for carbon and carbon-manganese steel pipes**

Specified minimum tensile strength (N/mm <sup>2</sup> )	Design temperature (°C)												
	≤50	100	150	200	250	300	350	400	410	420	430	440	450
320	107	105	99	92	78	62	57	55	55	54	54	54	49
360	120	117	110	103	91	76	69	68	68	68	64	56	49
410	136	131	124	117	106	93	86	84	79	71	64	56	49
460	151	146	139	132	122	111	101	99	98	85	73	62	53
490	160	156	148	141	131	121	111	109	98	85	73	62	53

**Table 11 : Permissible stresses for alloy steel pipes**

Type of steel	Specified minimum tensile strength (N/mm <sup>2</sup> )	Design temperature (°C)											
		≤50	100	200	300	350	400	440	450	460	470		
1Cr1/2Mo	440	159	150	137	114	106	102	101	101	100	99		
2 1/4Cr1Mo annealed	410	76	67	57	50	47	45	44	43	43	44		
2 1/4Cr1Mo normalised and tempered below 750°C	490	167	163	153	144	140	136	130	128	127	116		
2 1/4Cr1Mo normalised and tempered above 750°C	490	167	163	153	144	140	136	130	122	114	105		
1/2Cr 1/2Mo 1/4V	460	166	162	147	120	115	111	106	105	103	102		

Type of steel	Specified minimum tensile strength (N/mm <sup>2</sup> )	Design temperature (°C)											
		480	490	500	510	520	530	540	550	560	570		
1Cr1/2Mo	440	98	97	91	76	62	51	42	34	27	22		
2 1/4Cr1Mo annealed	410	42	42	41	41	41	40	40	40	37	32		
2 1/4Cr1Mo normalised and tempered below 750°C	490	106	96	86	79	67	58	49	43	37	32		
2 1/4Cr1Mo normalised and tempered above 750°C	490	96	88	79	72	64	56	49	43	37	32		
1/2Cr 1/2Mo 1/4V	460	101	99	97	94	82	72	62	53	45	37		

**Table 12 : Permissible stresses for copper and copper alloy pipes**

Material (annealed)	Specified minimum tensile strength (N/mm <sup>2</sup> )	Design temperature (°C)										
		≤50	75	100	125	150	175	200	225	250	275	300
Copper	215	41	41	40	40	34	27,5	18,5				
Aluminium brass	325	78	78	78	78	78	51	24,5				
Copper-nickel 95/5 and 90/10	275	68	68	67	65,5	64	62	59	56	52	48	44
Copper-nickel 70/30	365	81	79	77	75	73	71	69	67	65,5	64	62

**2.2.3 Thickness reduction due to bending**

a) Unless otherwise justified, the thickness reduction *b* due to bending is to be determined by the following formula:

$$b = \frac{Dt_0}{2,5\rho}$$

where:

$\rho$  : Bending radius measured on the centre line of the pipe, in mm

*D* : as defined in [1.4.1]

*t*<sub>0</sub> : as defined in [2.2.1].

b) When the bending radius is not given, the thickness reduction is to be taken equal to:

$$\frac{t_0}{10}$$

c) For straight pipes, the thickness reduction is to be taken equal to 0.

**2.2.4 Corrosion allowance**

The values of corrosion allowance *c* are given for steel pipes in Tab 13 and for non-ferrous metallic pipes in Tab 14.

**Table 13 : Corrosion allowance for steel pipes**

Piping system	Corrosion allowance (mm)
Superheated steam	0,3
Saturated steam	0,8
Steam coils in cargo tanks and liquid fuel tanks	2,0
Feed water for boilers in open circuit systems	1,5
Feed water for boilers in closed circuit systems	0,5
Blow-down systems for boilers	1,5
Compressed air	1,0
Hydraulic oil	0,3
Lubricating oil	0,3
Fuel oil	1,0
Thermal oil	1,0
Fresh water	0,8
Sea water	3,0
Refrigerants referred to in Ch 1, Sec 16	0,3
Cargo systems for oil tankers	2,0
Cargo systems for ships carrying liquefied gases	0,3

**Note 1:** For pipes passing through tanks, an additional corrosion allowance is to be considered in order to account for the external corrosion.

**Note 2:** The corrosion allowance of pipes efficiently protected against corrosion may be reduced by no more than 50%.

**Note 3:** When the corrosion resistance of alloy steels is adequately demonstrated, the corrosion allowance may be disregarded.

**Table 14 : Corrosion allowance for non-ferrous metal pipes**

Piping material (1)	Corrosion allowance (mm) (2)
Copper	0,8
Brass	0,8
Copper-tin alloys	0,8
Copper-nickel alloys with less than 10% of Ni	0,8
Copper-nickel alloys with at least 10% of Ni	0,5
Aluminium and aluminium alloys	0,5
(1) The corrosion allowance for other materials will be specially considered by the Society. Where their resistance to corrosion is adequately demonstrated, the corrosion allowance may be disregarded.	
(2) In cases of media with high corrosive action, a higher corrosion allowance may be required by the Society.	

### 2.2.5 Tees

As well as complying with the provisions of [2.2.1] to [2.2.4], the thickness  $t_T$  of pipes on which a branch is welded to form a Tee is not to be less than that given by the following formula:

$$t_T = \left(1 + \frac{D_1}{D}\right) \cdot t_0$$

where:

$D_1$  : External diameter of the branch pipe

$D$  : As defined in [1.4.1]

$t_0$  : As defined in [2.2.1].

Note 1: This requirement may be dispensed with for Tees provided with a reinforcement or extruded.

## 2.3 Calculation of high temperature pipes

### 2.3.1 General

For main steam piping having a design temperature exceeding 400°C, calculations are to be submitted to the Society concerning the stresses due to internal pressure, piping weight and any other external load, and to thermal expansion, for all cases of actual operation and for all lengths of piping.

The calculations are to include, in particular:

- the components, along the three principal axes, of the forces and moments acting on each branch of piping
- the components of the displacements and rotations causing the above forces and moments
- all parameters necessary for the computation of forces, moments and stresses.

In way of bends, the calculations are to be carried out taking into account, where necessary, the pipe ovalisation and its effects on flexibility and stress increase.

A certain amount of cold springing, calculated on the basis of expected thermal expansion, is to be applied to the piping during installation. Such springing is to be neglected in stress calculations; it may, however, be taken into account in terms of its effect on thrusts on turbines and other parts.

### 2.3.2 Thermal stress

The combined stress  $\sigma_{ID}$ , in N/mm<sup>2</sup>, due to thermal expansion, calculated by the following formula:

$$\sigma_{ID} = (\sigma^2 + 4 \tau^2)^{0,5}$$

is to be such as to satisfy the following equation:

$$\sigma_{ID} \leq 0,75 K_{20} + 0,25 K_T$$

where:

$\sigma$  : Value of the longitudinal stress due to bending moments caused by thermal expansion, increased, if necessary, by adequate factors for bends, in N/mm<sup>2</sup>; in general it is not necessary to take account of the effect of axial force

$\tau$  : Value of the tangential stress due to torque caused by thermal expansion, in N/mm<sup>2</sup>; in general it is not necessary to take account of the effect of shear force

$K_{20}$  : Value of the permissible stress for the material employed, calculated according to [2.2.2], for a temperature of 20°C, in N/mm<sup>2</sup>

$K_T$  : Value of the permissible stress for the material employed, calculated according to [2.2.2], for the design temperature  $T$ , in N/mm<sup>2</sup>.

**2.3.3 Longitudinal stresses**

The sum of longitudinal stresses  $\sigma_L$ , in N/mm<sup>2</sup>, due to pressure, piping weight and any other external loads is to be such as to satisfy the following equation:

$$\sigma_L \leq K_T$$

where  $K_T$  is defined in [2.3.2].

**2.3.4 Alternative limits for permissible stresses**

Alternative limits for permissible stresses may be considered by the Society in special cases or when calculations have been carried out following a procedure based on hypotheses other than those considered above.

**2.4 Junction of pipes**

**2.4.1 General**

- a) The junctions between metallic pipe lengths or between metallic pipe lengths and fittings are to be made by:
  - direct welding (butt-weld, socket-weld)
  - bolted flanges (welded-on or screwed-on)
  - threaded sleeve joints, or
  - mechanical joints (see [2.4.5]).

The joints are to comply with a recognised standard or to be of a design proven to be suitable for the intended purpose and acceptable to the Society. See also [2.1.2].

The expression “mechanical joints” means devices intended for direct connection of pipe lengths other than by welding, flanges or threaded joints described in [2.4.2], [2.4.3], [2.4.4].

- b) The number of joints in flammable oil piping systems is to be kept to the minimum necessary for mounting and dismantling purposes.
- c) The gaskets and packings used for the joints are to suit the design pressure, the design temperature and the nature of the fluids conveyed.
- d) The junction between plastic pipes is to comply with Ch 1, App 3.

**2.4.2 Welded metallic joints**

- a) Welded joints are to be used in accordance with Tab 15. Welding and non destructive testing of welds are to be carried out in accordance with Article [3].
- b) Butt-welded joints are to be of full penetration type, with or without special provision for a high quality of root side. The expression "special provision for a high quality of root side" means that butt welds were accomplished as double welded or by use of a backing ring or inert gas back-up on first pass, or other similar methods accepted by the Society.
- c) Slip-on sleeve and socket welded joints are to have sleeves, sockets and weldments of adequate dimensions in compliance with a standard recognised by the Society.

**Table 15 : Use of welded and threaded metallic joints in piping systems**

Joints	Permitted classes of piping	Restrictions of use
Butt-welded, with special provision for a high quality of root side (1)	III, II, I	no restrictions
Butt-welded, without special provision for a high quality of root side (1)	III, II	no restrictions
Slip-on sleeve and socket welded (2)	III	no restrictions
Threaded sleeve joints with tapered thread (3)	I	not allowed for: <ul style="list-style-type: none"> <li>• pipes with outside diameter of more than 33,7 mm</li> <li>• pipes inside tanks</li> <li>• piping systems conveying toxic or flammable media or services where fatigue, severe erosion or crevice corrosion is expected to occur (4).</li> </ul>
	III, II	not allowed for: <ul style="list-style-type: none"> <li>• pipes with outside diameter of more than 60,3 mm</li> <li>• pipes inside tanks</li> <li>• piping systems conveying toxic or flammable media or services where fatigue, severe erosion or crevice corrosion is expected to occur (4).</li> </ul>

Joints	Permitted classes of piping	Restrictions of use
Threaded sleeve joints with parallel thread and tightening suitable for intended design conditions (3)	III	not allowed for: <ul style="list-style-type: none"> <li>• pipes with outside diameter of more than 60,3 mm</li> <li>• pipes inside tanks</li> <li>• piping systems conveying toxic or flammable media or services where fatigue, severe erosion or crevice corrosion is expected to occur (4).</li> </ul>
<p>(1) For expression “special provision for a high quality of root side” see [2.4.2] b).</p> <p>(2) Particular cases may be allowed by the Society for piping systems of Class I and II having outside diameter ≤ 88,9 mm except for piping systems conveying toxic media or services where fatigue, severe erosion or crevice corrosion is expected to occur.</p> <p>(3) In particular cases, sizes in excess of those mentioned above may be accepted by the Society if found in compliance with a recognised national and/or international standard.</p> <p>(4) May be accepted for accessory lines and instrumentation lines with external diameters up to 25 mm.</p> <p><b>Note 1:</b> Other applications will be specially considered by the Society.</p>		

**2.4.3 Metallic flange connections**

- a) In general, the metallic flange connections used for piping systems are to be in compliance with a standard recognised by the Society.
- b) The material used for flanges and gaskets is to be suitable for the nature and temperature of the fluid, as well as pipes on which the flanges are to be fitted.
- c) The dimensions and configuration of flanges and bolts are to be chosen in accordance with recognised standard intended for design pressure and design temperature of the piping system. Otherwise, the flange connections are subject to special consideration.
- d) Flanges are to be attached to the pipes by welding or screwing. Examples of acceptable metallic flange connections are shown in Fig 1. However, other types of flange connections may be also considered by the Society in each particular case, provided that they are in accordance with national or international standards applicable to the piping system and recognise the boundary fluids, design pressure and temperature conditions, external or cyclic loading and location.
- e) Permitted applications are indicated in Tab 16.

**Table 16 : Use of metallic flange connections in piping systems (types as shown in Fig 1)**

Type of media conveyed	Class of piping (see Tab 3)		
	I	II	III
Toxic or corrosive media Flammable liquids (where heated above flashpoint or having flashpoint < 60°C) Liquefied gases	A1, A2, B1, B2, B3 (1) (2) (4)	A1, A2, B1, B2, B3, C1, C2, C3 (1) (4)	not applicable
Fuel oil Lubricating oil	A1, A2, B1, B2, B3	A1, A2, B1, B2, B3, C1, C2, C3	A1, A2, B1, B2, B3, C1, C2, C3, E2
Steam Thermal oil	A1, A2, B1, B2, B3 (2) (3)	A1, A2, B1, B2, B3, C1, C2, C3, D, E2 (6)	A1, A2, B1, B2, B3, C1, C2, C3, D, E2
Other media as water, air, gases (refrigerants), non-flammable hydraulic oil, etc.	A1, A2, B1, B2, B3 (3)	A1, A2, B1, B2, B3, C1, C2, C3, D, E2 (6)	A1, A2, B1, B2, B3, C1, C2, C3, D, E1, E2 (5) (6) (7)
<p>(1) When design pressure p (see [1.3.2]) exceeds 1 MPa, types A1 and A2 only.</p> <p>(2) For nominal diameter ND ≥ 150 mm, types A1 and A2 only.</p> <p>(3) When design temperature T (see [1.3.3] exceeds 400°C, types A1 and A2 only.</p> <p>(4) For cargo piping of ships having the service notation <b>chemical tanker</b>, IBC Code Ch. 5, 5.3 and Pt D, Ch 8, Sec 5, [3.1.4] are to be applied. For cargo piping of ships having the service notation <b>liquefied gas carrier</b>, Pt D, Ch 9, Sec 5, [8.3] is to be applied.</p> <p>(5) Type E2: only for design pressure p ≤ 1,6 MPa and design temperature T ≤ 150°C.</p> <p>(6) Types D and E2: only for design temperature T ≤ 250°C.</p> <p>(7) Type E1: only for water pipelines and for open ended lines (e.g. drain, overflow, air vent piping, etc.).</p>			

Figure 1 : Examples of metallic flange connections

Note 1: For type D, the pipe and flange are to be screwed with a tapered thread and the diameter of the screw portion of the pipe over the thread is not to be appreciably less than the outside diameter of the unthreaded pipe. For certain types of thread, after the flange has been screwed hard home, the pipe is to be expanded into the flange.

Note 2: The leg length of the fillet weld, as well as the dimension of the groove penetration in the flange, is to be in general equal to 1,5 times the pipe thickness but not less than 5 mm.

#### **2.4.4 Slip-on threaded joints**

- a) Slip-on threaded joints having pipe threads where pressure-tight joints are made on the threads with parallel or tapered threads are to comply with requirements of a recognised national or international standard and are to be acceptable to the Society.
- b) Slip-on threaded joints may be used for piping systems in accordance with Tab 15.
- c) Threaded joints may be accepted also in CO<sub>2</sub> piping systems, provided that they are used only inside protected spaces and in CO<sub>2</sub> cylinder rooms.

#### **2.4.5 Mechanical joints**

Due to the great variations in design and configuration of mechanical joints, specific recommendation regarding calculation method for theoretical strength calculations is not specified. The Type Approval is to be based on the results of testing of the actual joints.

Below specified requirements are applicable to pipe unions, compression couplings, slip-on joints as shown in Fig 2. Similar joints complying with these requirements may be acceptable.

- a) The application and pressure ratings of different mechanical joints are to be approved by the Society. The approval is to be based on the Type Approval procedure provided in Ch 1, App 5. Mechanical joints including pipe unions, compression couplings, slip-on joints and similar joints are to be of approved type for the service conditions and the intended application.
- b) Where the application of mechanical joints results in reduction in pipe wall thickness due to the use of bite type rings or other structural elements, this is to be taken into account in determining the minimum wall thickness of the pipe to withstand the design pressure.
- c) Material of mechanical joints is to be compatible with the piping material and internal and external media.
- d) As far as applicable, the mechanical joints are to be tested to a burst pressure of 4 times the design pressure. For design pressures above 200 bar the required burst pressure is to be specially considered by the Society.
- e) Where appropriate, mechanical joints are to be of fire resistant type as required by Tab 17.
- f) Mechanical joints, which in the event of damage could cause fire or flooding, are not to be used in piping sections directly connected to the ship's side below the bulkhead deck of passenger ships and freeboard deck of cargo ships or tanks containing flammable fluids.
- g) The number of mechanical joints in flammable liquid systems is to be kept to a minimum. In general, flanged joints conforming to recognised standards are to be used.
- h) Piping in which a mechanical joint is fitted is to be adequately adjusted, aligned and supported. Supports or hangers are not to be used to force alignment of piping at the point of connection.
- i) Slip-on joints are not to be used in pipelines in cargo holds, tanks and other spaces which are not easily accessible (refer to IMO MSC/Circ.734), except that these joints may be permitted in tanks that contain the same media as the pipe where the joint is fitted. Usage of slip type slip-on joints as the main means of pipe connection is not permitted except for cases where compensation of axial pipe deformation is necessary.
- j) Application of mechanical joints and their acceptable use for each service is indicated in Tab 17; dependence upon the class of piping, pipe dimensions, working pressure and temperature is indicated in Tab 18.
- k) In some particular cases, sizes in excess of those mentioned above may be accepted by the Society if they are in compliance with a recognised national and/or international standard.
- l) Application of various mechanical joints may be accepted as indicated by Tab 17. However, in all cases, acceptance of the joint type is to be subject to approval for the intended application, and subject to conditions of the approval and applicable Rules.
- m) Mechanical joints are to be tested in accordance with a program approved by the Society, which is to include at least the following:
  - 1) leakage test
  - 2) vacuum test (where necessary)
  - 3) vibration (fatigue) test
  - 4) fire endurance test (where necessary)
  - 5) burst pressure test
  - 6) pressure pulsation test (where necessary)
  - 7) assembly test (where necessary)
  - 8) pull out test (where necessary).
- n) The installation of mechanical joints is to be in accordance with the manufacturer's assembly instructions. Where special tools and gauges are required for installation of the joints, these are to be supplied by the manufacturer.

Figure 2 : Examples of mechanical joints

Table 17 : Application of mechanical joints

Systems	Kind of connections			Classification of pipe system	Fire endurance test condition (7)	
	Pipe unions	Compression couplings	Slip-on joints			
FLAMMABLE FLUIDS (FLASHPOINT ≤ 60°C)						
1	Cargo oil lines (1)	+	+	+	dry	30 min dry (*)
2	Crude oil washing lines (1)	+	+	+	dry	30 min dry (*)
3	Vent lines (3)	+	+	+	dry	30 min dry (*)
INERT GAS						
4	Water seal effluent lines	+	+	+	wet	30 min wet (*)
5	Scrubber effluent lines	+	+	+	wet	30 min wet (*)
6	Main lines (1) (2)	+	+	+	dry	30 min dry (*)
7	Distribution lines (1)	+	+	+	dry	30 min dry (*)
FLAMMABLE FLUIDS (FLASHPOINT > 60°C)						
8	Cargo oil lines (1)	+	+	+	dry	30 min dry (*)
9	Fuel oil lines (2) (3)	+	+	+	wet	30 min wet (*)
10	Lubricating oil lines (2) (3)	+	+	+	wet	30 min wet (*)
11	Hydraulic oil (2) (3)	+	+	+	wet	30 min wet (*)
12	Thermal oil (2) (3)	+	+	+	wet	30 min wet (*)

Systems		Kind of connections			Classification of pipe system	Fire endurance test condition (7)
		Pipe unions	Compression couplings	Slip-on joints		
<b>SEA WATER</b>						
13	Bilge lines (4)	+	+	+	dry / wet	8 min dry + 22 min wet (*)
14	Permanent water filled fire extinguishing systems, e.g. fire main, sprinkler systems (3)	+	+	+	wet	30 min wet (*)
15	Non-permanent water filled fire extinguishing systems, e.g. foam, drencher systems and fire main (3)	+	+	+	dry / wet	8 min dry + 22 min wet (*) For foam systems, Ch 4, Sec 15, [5] to be observed
16	Ballast system (4)	+	+	+	wet	30 min wet (*)
17	Cooling water system (4)	+	+	+	wet	30 min wet (*)
18	Tank cleaning services	+	+	+	dry	Fire endurance test not required
19	Non-essential systems	+	+	+	dry dry / wet wet	Fire endurance test not required
<b>FRESH WATER</b>						
20	Cooling water system (4)	+	+	+	wet	30 min wet (*)
21	Condensate return (4)	+	+	+	wet	30 min wet (*)
22	Non-essential systems	+	+	+	dry dry / wet wet	Fire endurance test not required
<b>SANITARY / DRAINS / SCUPPERS</b>						
23	Deck drains (internal) (5)	+	+	+	dry	Fire endurance test not required
24	Sanitary drains	+	+	+	dry	
25	Scuppers and discharge (overboard)	+	+	-	dry	
<b>SOUNDING / VENT</b>						
26	Water tanks / Dry spaces	+	+	+	dry / wet	Fire endurance test not required
27	Oil tanks (flashpoint > 60°C) (2) (3)	+	+	+	dry	
<b>MISCELLANEOUS</b>						
28	Starting/Control air (4)	+	+	-	dry	30 min dry (*)
29	Service air (non-essential)	+	+	+	dry	Fire endurance test not required
30	Brine	+	+	+	wet	
31	CO <sub>2</sub> system (outside protected space)	+	+	-	dry	30 min dry (*)
32	CO <sub>2</sub> system (inside protected space)	+	+	-	dry	Mechanical joints are to be constructed of materials with melting point above 925°C Refer to Ch 4, Sec 15, [4]
33	Steam	+	+	+ (6)	wet	Fire endurance test not required

**Note 1:** + : Application is allowed ; - : Application is not allowed.

(\*) Fire test as specified in Ch 1, App 5, [2.7.6].

Footnotes - Fire resistance capability

If mechanical joints include any components which readily deteriorate in case of fire, the following footnotes are to be observed:

- (1) Fire endurance test is to be applied when mechanical joints are installed in pump rooms and open decks.
- (2) Slip on joints are not accepted inside machinery spaces of category A or accommodation spaces. May be accepted in other machinery spaces provided the joints are located in easily visible and accessible positions (refer to IMO Circular MSC/Circ.734).
- (3) Approved fire-resistant types except in cases where such mechanical joints are installed on open decks, as defined in Ch 4, Sec 5, [1.4.3] item b) 2) (10), and not used for fuel oil lines.
- (4) Fire endurance test is to be applied when mechanical joints are installed inside machinery spaces of category A.

Footnotes - General

- (5) Only above bulkhead deck of passenger ships and freeboard deck of cargo ships.
- (6) Slip type slip-on joints as shown in Fig 2. May be used for pipes on deck with a design pressure of 10 bar or less.
- (7) In cases exposure time ( $t_f$ ) is greater than 30 minutes the dry-wet test conditions are 8 minutes dry and, accordingly, the wet period  $t_f - 8$  min

If a connection has passed the "30 min dry" test, it is considered suitable also for applications for which the "8 min dry+22 min wet" and/or "30 min wet" tests are required. If a connection has passed the "8 min dry+22 min wet" test, it is considered suitable also for applications for which the "30 min wet" test is required.

Table 18 : Application of mechanical joints depending upon the class of piping

Types of joints	Classes of piping systems		
	Class I	Class II	Class III
Pipe Unions			
Welded and brazed types	+ (OD ≤ 60,3 mm)	+ (OD ≤ 60,3 mm)	+

Grip type	–	+	+
Slip type	–	+	+
<b>Note 1:</b> + : Application is allowed ; – : Application is not allowed.			

## 2.5 Protection against overpressure

### 2.5.1 General

- These requirements deal with the protection of piping systems against overpressure, with the exception of heat exchangers and pressure vessels, which are dealt with in Ch 1, Sec 3, [3.5.1].
- Safety valves are to be sealed after setting.

### 2.5.2 Protection of flammable oil systems

Provisions shall be made to prevent overpressure in any flammable oil tank or in any part of the flammable oil systems, including the filling lines served by pumps on board.

### 2.5.3 Protection of pump and compressor discharges

- Provisions are to be made so that the discharge pressure of pumps and compressors cannot exceed the pressure for which the pipes located on the discharge of these pumps and compressors are designed.
- When provided on the pump discharge for this purpose, safety valves are to lead back to the pump suction or to any other suitable place.
- The discharge capacity of the safety valves installed on pumps and compressors is to be such that the pressure at the discharge side cannot exceed by more than 10% the design pressure of the discharge pipe in the event of operation with closed discharge.

### 2.5.4 Protection of pipes

- Pipes likely to be subjected to a pressure exceeding their normal working pressure are to be provided with safety valves or equivalent overpressure protecting devices.
- In particular, pipes located on the low pressure side of pressure reducing valves are to be provided with safety valves unless they are designed for the maximum pressure on the high pressure side of the pressure reducing valve. See also [1.3.2] and [2.9.1].
- The discharge capacity of the devices fitted on pipes for preventing overpressure is to be such that the pressure in these pipes cannot exceed the design pressure by more than 10%.

## 2.6 Flexible hoses and expansion joints

### 2.6.1 General

- Definitions:
  - Flexible hose assembly: short length of metallic or non-metallic hose normally with prefabricated end fittings ready for installation
  - Expansion joint: an assembly designed to safely absorb the heat-induced expansion and contraction, mainly to allow axial relative movement between pipes and the ship's structure as required in [5.6].
- Flexible hoses and expansion joints are to be of a type approved by the Society. Unless otherwise specified, they are to comply with the requirements of this sub-article.
- The requirements of this sub-article apply to flexible hoses and expansion joints of metallic or non-metallic material intended for a permanent connection between a fixed piping system and items of machinery. The requirements may also be applied to temporarily connected flexible hoses or hoses of portable equipment.

- d) Unless otherwise specified, the requirements of this sub-article do not apply for flexible hose assemblies and expansion joints intended to be used in fire extinguishing systems.
- e) Flexible hose assemblies and expansion joints intended for piping systems with a design temperature below the ambient temperature are subject to special consideration by the Society.
- f) Specific requirements for flexible hoses and expansion joints intended for cargo pipe lines are given in:
  - Part D, Chapter 7 for oil tankers
  - Part D, Chapter 8 for chemical tankers
  - Part D, Chapter 9 for liquefied gas carriers
  - NR 620 for flexible hoses intended for LNG bunkering.

**2.6.2 General conditions of use applicable to flexible hoses and expansion joints**

- a) Unless otherwise specified, the Society may permit the use of flexible hoses and expansion joints, made of both metallic and non-metallic materials, provided they are approved for the intended service. They may be accepted for use in oil fuel, lubricating, hydraulic and thermal oil systems, fresh water and sea water cooling systems, compressed air systems, bilge and ballast systems, Class III steam systems and exhaust gas systems where they comply with the requirements of this sub-article.
- b) For steam systems, the flexible hose assemblies and expansion joints are to be of metallic construction.
- c) The position of flexible hose assemblies and expansion joints is to be clearly shown on the drawings listed in [1.2.1] and [1.2.2] when submitted to the Society.
- d) Flexible hose assembly or an expansion joint is to be selected for the intended location and application taking into consideration ambient conditions, compatibility with fluids under working pressure and temperature conditions consistent with the manufacturer's instructions and any requirements of the Society.
- e) The arrangement and installation of the flexible hose assemblies and expansion joints are also to comply with [5.9.3].

**2.6.3 Specific conditions of use applicable to flexible hoses**

- a) Flexible hose assembly is not accepted in high pressure fuel oil injection systems.
- b) Flexible hose assemblies for essential services or containing either flammable or toxic media are not to exceed 1,5 m in length.

**2.6.4 General requirements for the design of flexible hoses and expansion joints**

- a) Flexible hoses and expansion joints are to be designed and constructed in accordance with recognised National or International standards acceptable to the Society.
- b) Acceptance of a flexible hose assembly or an expansion joint is subject to satisfactory prototype testing in accordance with the provisions of [20.2].
- c) The material, design and construction are to be at least suitable for:
  - marine environment and external contact with hydrocarbons
  - internal contact and resistance to the fluid they are to convey
  - maximal pressure and temperature of fluid they are to convey
  - maximum expected forces due to vibrations
  - maximum expected impulse peak pressure.

The metallic materials are to comply with [2.1.2].

- d) Where rubber materials are intended for use in bilge, ballast, compressed air, oil fuel, lubricating, hydraulic and thermal oil systems, the construction is to incorporate a single, double or more, closely woven integral wire braid or other suitable material reinforcement acceptable to the Society.

Flexible hoses and expansion joints of plastic materials for the same purposes, such as Teflon or Nylon, which are unable to be reinforced by incorporating closely woven integral wire braid, are to have suitable material reinforcement, as far as practicable.

Rubber or plastic material hoses and expansion joints used in oil supply lines to burners are to have external wire braid protection in addition to the reinforcement mentioned above.

- e) Flexible hose assemblies and expansion joints constructed of non-metallic materials, which are intended for installation in piping systems for flammable media or in sea water systems where failure may result in flooding, are to be of fire-resistant type except in cases where such hoses are installed on open decks as defined in Ch 4, Sec 5, [1.5.2], item b), (10) and not used for fuel oil lines.

Fire resistance is to be demonstrated by testing in accordance with the standards specified in Tab 36 and Tab 38.

- f) Flexible hoses and expansion joints are to be complete with approved end fittings in accordance with manufacturer's specification. The end connections that do not have a flange are to comply with [2.4.5] as applicable and each type of hose/ fitting combination is to be subject to prototype testing to the same standard as that required by the hose or expansion joint with particular reference to pressure and impulse tests.

### **2.6.5 Specific requirements for the design of flexible hoses**

The hose clamps and similar types of end attachments are not acceptable for use in piping systems for steam, flammable media, starting air systems or for sea water systems where failure may result in flooding. In other piping systems, the use of hose clamps may be accepted where the working pressure is less than 0,5 MPa and provided that there are double clamps at each end connection.

### **2.6.6 Marking**

Flexible hoses or expansion joints are to be permanently marked by the manufacturer with the following details:

- manufacturer's name or trademark
- date of manufacture (month/year)
- designation type reference
- nominal diameter
- pressure rating
- temperature rating.

Where a flexible hose assembly or an expansion joint is made up of items from different manufacturers, the components are to be clearly identified and traceable to evidence of prototype testing.

## **2.7 Valves and accessories**

### **2.7.1 General**

- a) Valves and accessories are normally to be built in accordance with a recognised standard. Otherwise, they are subject to special consideration for approval by the Society.

Valves and fittings in piping systems are to be compatible with the pipes to which they are attached in respect of their strength (see [1.3.2] for design pressure) and are to be suitable for effective operation at the maximum working pressure they will experience in service.

Valves and accessories which are fitted:

- in a class I piping system, or
- in a class II piping system, or
- on the ship side, on the collision bulkhead, on fuel oil tanks or on lubricating oil tanks under static pressure, are to be subject to the applicable testing and inspection required by the Rules. See [20.7.1].

- b) Shut-off valves are to be provided where necessary to isolate pumps, heat exchangers, pressure vessels, etc., from the rest of the piping system when necessary, and in particular:
- to allow the isolation of duplicate components without interrupting the fluid circulation
  - for survey or repair purposes.

### **2.7.2 Design of valves and accessories**

- a) Materials of valve and accessory bodies are to comply with the provisions of [2.1].
- b) Connections of valves and accessories with pipes are to comply with the provisions of [2.4].
- c) All valves and accessories are to be so designed as to prevent the loosening of covers and glands when they are operated.
- d) Valves are to be so designed as to shut with a right-hand (clockwise) motion of the wheels.
- e) Valves are to be provided with local indicators showing whether they are open or shut, unless this is readily apparent.

### **2.7.3 Valves with remote control**

- a) Unless otherwise specified, the valves and cocks which can not be fitted in places where they are at all times readily accessible are to be provided with remote control.

All valves which are provided with remote control are also to be designed for local manual operation.

- b) The remote control system and means of local operation are to be independent. For shipside valves and valves on the collision bulkhead, the means for local manual operation are to be permanently attached.
- c) For submerged valves in ballast, cargo, or other tanks where accepted by the Society, local manual operation may be by extended spindle or portable hand pump.

The manual operation by hand pump is to have the control lines to each submerged valve provided with the quick coupling connections, as close to the valve actuator as practicable, to allow easy connection of the hand pump. For shipside valves and valves on the collision bulkhead, the hand pump is to be permanently attached and fitted to the quick coupling connection. For other valves, not less than two portable hand pumps are to be provided.

- d) In the case of valves which are to be provided with remote control in accordance with the Rules, opening and/or closing of the valves by local manual means is not to render the remote control system inoperable.
- e) Power failure of the remote control system is not to cause an undesired change of the valve position.

- f) Unless otherwise specified, indicators are to be provided on the remote controls to show whether the valves are open or closed.

The indicators for local manual control are to comply with [2.7.2], item e).

## **2.8 Sea inlets and overboard discharges**

### **2.8.1 General**

- a) Except where expressly stated in Article [8], the requirements of this sub-article do not apply to scuppers and sanitary discharges.
- b) Unless otherwise specified, the number of sea inlets is to be as stated in [10.7].
- c) The sea inlets are to comply also with the requirements specified for particular service notations or additional class notations, such as:
- Pt D, Ch 7, Sec 4, [2.3.6] for oil tankers and FLS tankers
  - Pt E, Ch 4, Sec 3, [3.3.2] for fire fighting ships
  - Pt D, Ch 15, Sec 4, [1.8] for fishing vessels
  - Pt F, Ch 8, Sec 3, [3.2] for navigation in ice
  - Pt F, Ch 8, Sec 4, [6.2.2] for navigation in cold weather conditions.

### **2.8.2 Design of sea inlets and overboard discharges**

- a) All inlets and discharges in the shell plating are to be fitted with efficient and accessible arrangements for preventing the accidental admission of water into the ship.
- b) Sea inlets and overboard discharges are to be fitted with valves complying with [2.7] and [2.8.3].
- c) Machinery space main and auxiliary sea inlets and discharges in connection with the operation of machinery are to be fitted with readily accessible valves between the pipes and the shell plating or between the pipes and fabricated boxes attached to the shell plating. The valves may be controlled locally and are to be provided with indicators showing whether they are open or closed.
- d) Sea inlets are to be so designed and arranged as to limit turbulence and to avoid the admission of air due to motion of the ship.
- e) Sea inlets are to be fitted with gratings complying with [2.8.4].
- f) Provisions are to be made for clearing sea inlet gratings.
- g) Sea chests are to be suitably protected against corrosion.
- h) Sea water suction lines are to be fitted with strainers having a free passage area of at least twice that of the sea suction valve.

### **2.8.3 Valves**

- a) Sea inlet and overboard discharge valves are to be secured:
- directly on the shell plating, or
  - on sea chests built on the shell plating, with scantlings in compliance with Part B of the Rules, or
  - on extra-reinforced and short distance pieces attached to the shell (see Tab 6).
- b) The bodies of the valves and distance pieces are to have a spigot passing through the plating without projecting beyond the external surface of such plating or of the doubling plates and stiffening rings, if any.
- c) Valves are to be secured by means of:
- bolts screwed through the plating with a countersunk head, or
  - studs screwed in heavy pads themselves secured to the hull or chest plating, without penetration of the plating by the stud holes.
- d) The use of butterfly valves will be specially considered by the Society. In any event, butterfly valves not fitted with flanges are not to be used for water inlets or overboard discharges unless provisions are made to allow disassembling at sea of the pipes served by these valves without any risk of flooding.
- e) The materials of the valve bodies and connecting pieces are to comply with Tab 5.
- f) Ship side valves serving piping systems made of plastics are to comply with following requirements:
- the ship side valves required in [2.8.2] and, where provided, the connecting pipes to the shell are to be made of metal in accordance with [2.1], and
  - Ship side valves are to be provided with remote control from outside the space concerned. See Ch 1, App 3, Tab 1
- g) In manned machinery spaces, the valves may be controlled locally and shall be provided with indicators showing whether they are open or closed. Location of controls shall comply with [5.5.4].

### **2.8.4 Gratings**

- a) Gratings are to have a free flow area not less than twice the total section of the pipes connected to the inlet.
- b) When gratings are secured by means of screws with a countersunk head, the tapped holes provided for such screws are not to pass through the plating or doubling plates outside distance pieces or chests.
- c) Screws used for fixing gratings are not to be located in the corners of openings in the hull or of doubling plates.
- d) In the case of large sea inlets, the screws used for fixing the gratings are to be locked and protected from corrosion.
- e) When gratings are cleared by use of compressed air or steam devices, the chests, distance pieces and valves of sea inlets and outlets thus arranged are to be so constructed as to withstand the maximum pressure to which they may be subjected when such devices are operating.
- f) For additional class notation **INWATERSURVEY**, see Pt F, Ch 15, Sec 3.

### **2.8.5 Ship side connections for blow-down of boilers**

- a) Blow-down pipes of boilers are to be provided with cocks or valves placed as near the end of the pipes as possible, while remaining readily accessible and located above the engine room floor.
- b) Blow-down valves are to be so designed that it is easy to ascertain whether they are open or shut. Where cocks are used, the control keys are to be such that they cannot be taken off unless the cocks are shut. Where valves are used, the control-wheels are to be permanently fixed to the spindle.
- c) A protection ring is to be fitted on the shell plating, outside, at the end of the blow-down pipes. The spigot of the valve referred to in [2.8.3], item b), is to pass through this ring.

## **2.9 Control and monitoring**

### **2.9.1 General**

- a) Local indicators are to be provided for at least the following parameters:
  - pressure, in pressure vessels, at pump or compressor discharge, at the inlet of the equipment served, on the low pressure side of pressure reducing valves
  - temperatures, in tanks and vessels, at heat exchanger inlet and outlet
  - levels, in tanks and vessels containing liquids.
- b) Safeguards are to be provided where an automatic action is necessary to restore acceptable values for a faulty parameter.
- c) Automatic controls are to be provided where it is necessary to maintain parameters related to piping systems at a pre-set value.

### **2.9.2 Level gauges**

Level gauges used in flammable oil systems are to be of a type approved by the Society and are subject to the following conditions:

- in passenger ships, they are not to require penetration below the top of the tank and their failure or overfilling of the tanks is not to permit release of fuel
- in cargo ships, their failure or overfilling of the tank is not to permit release of fuel into the space. The use of cylindrical gauges is prohibited. The Society may permit the use of oil-level gauges with flat glasses and self-closing valves between the gauges and fuel tanks.
- their glasses are to be made of heat-resistant material and efficiently protected against shocks.

On cargo ships of less than 500 gross tonnage and non-propelled ships:

- cylindrical gauges may be used provided they are fitted with self-closing valves at their lower end as well as at their upper end if the latter is below the maximum liquid level
- in the case of tanks not subject to filling by power pumps, with the exception of fuel oil service tanks, the valves need not be of the self-closing type. Such valves are, however, to be readily accessible and instruction plates are to be fitted adjacent to them specifying that they are to be kept closed.

## **3 Welding of steel piping**

### **3.1 Application**

#### **3.1.1**

- a) The following requirements apply to welded joints belonging to class I or II piping systems.  
They may also be applied to class III piping systems, at the discretion of the Society.
- b) This article does not apply to refrigerated cargo installation piping systems operating at temperatures lower than minus 40°C.
- c) The requirements for qualification of welding procedures are given in NR216 Materials and Welding.

**3.2 General**

**3.2.1 Welding processes**

- a) Welded joints of pipes are to be made by means of electric arc or oxyacetylene welding, or any other previously approved process.
- b) When the design pressure exceeds 0,7 MPa, oxyacetylene welding is not permitted for pipes with an external diameter greater than 100 mm or a thickness exceeding 6 mm.

**3.2.2 Location of joints**

The location of welded joints is to be such that as many as possible can be made in a workshop. The location of welded joints to be made on board is to be so determined as to permit their joining and inspection in satisfactory conditions.

**3.3 Design of welded joints**

**3.3.1 Types of joints**

- a) Except for the fixing of flanges on pipes in the cases mentioned in Fig 1 and for the fixing of branch pipes, joints between pipes and between pipes and fittings are to be of the butt-welded type. Other type of connections might be accepted by the Society according to Tab 15.
- b) For butt-welded joints between pipes or between pipes and flanges or other fittings, correctly adjusted backing rings may be used; such rings are to be either of the same grade of steel as the elements to be welded or of such a grade as not to adversely influence the weld; if the backing ring cannot be removed after welding, it is to be correctly profiled.

**3.3.2 Assembly of pipes of unequal thickness**

If the difference of thickness between pipes to be butt-welded exceeds 10% of the thickness of the thinner pipe plus 1 mm, subject to a maximum of 4 mm, the thicker pipe is to be thinned down to the thickness of the thinner pipe on a length at least equal to 4 times the offset, including the width of the weld if so desired.

**3.3.3 Accessories**

- a) When accessories such as valves are connected by welding to pipes, they are to be provided with necks of sufficient length to prevent abnormal deformations during the execution of welding or heat treatment.
- b) For the fixing by welding of branch pipes on pipes, it is necessary to provide either a thickness increase as indicated in [2.2.5] or a reinforcement by doubling plate or equivalent.

**3.4 Preparation of elements to be welded and execution of welding**

**3.4.1 General**

Attention is drawn to the provisions of Ch 1, Sec 3, which apply to the welding of pressure pipes.

**3.4.2 Edge preparation for welded joints**

The preparation of the edges is preferably to be carried out by mechanical means. When flame cutting is used, care is to be taken to remove the oxide scales and any notch due to irregular cutting by matching, grinding or chipping back to sound metal.

**3.4.3 Abutting of parts to be welded**

- a) The elements to be welded are to be so abutted that surface misalignments are as small as possible.
- b) As a general rule, for elements which are butt-welded without a backing ring the misalignment between internal walls is not to exceed the lesser of:
  - the value given in Tab 19 as a function of thickness  $t$  and internal diameter  $d$  of these elements, and
  - $t/4$ .

Where necessary, the pipe ends are to be bored or slightly expanded so as to comply with these values; the thickness obtained is not to be less than the Rule thickness.

- c) In the case of welding with a backing ring, smaller values of misalignment are to be obtained so that the space between the backing ring and the internal walls of the two elements to be assembled is as small as possible; normally this space is not to exceed 0,5 mm.
- d) The elements to be welded are to be adequately secured so as to prevent modifications of their relative position and deformations during welding.

**Table 19 : Maximum value of misalignment**

d (mm)	t (mm)		
	$t \leq 6$	$6 < t \leq 10$	$10 < t$
$d < 150$	1,0	1,0	1,0
$150 \leq d < 300$	1,0	1,5	1,5
$300 \leq d$	1,0	1,5	2,0

**3.4.4 Protection against adverse weather conditions**

- a) Pressure pipes are to be welded, both on board and in the shop, away from draughts and sudden temperature variations.
- b) Unless special justification is given, no welding is to be performed if the temperature of the base metal is lower than 0°C.

**3.4.5 Preheating**

- a) Preheating is to be performed as indicated in Tab 20, depending on the type of steel, the chemical composition and the pipe thickness.
- b) The temperatures given in Tab 20 are based on the use of low hydrogen processes. Where low hydrogen processes are not used, the Society reserves the right to require higher preheating temperatures.

**Table 20 : Preheating temperature**

Type of steel		Thickness of thicker part (mm)	Minimum preheating temperature (°C)
C and C-Mn steels	$C + \frac{Mn}{6} \leq 0,40$	$t \geq 20$ (2)	50
	$C + \frac{Mn}{6} > 0,40$	$t \geq 20$ (2)	100
0,3 Mo		$t \geq 13$ (2)	100
1 Cr 0,5 Mo		$t < 13$	100
		$t \geq 13$	150
2,25 Cr 1 Mo (1)		$t < 13$	150
		$t \geq 13$	200
0,5 Cr 0,5 Mo V (1)		$t < 13$	150
		$t \geq 13$	200

(1) For 2,25 Cr 1 Mo and 0,5 Cr 0,5 Mo V grades with thicknesses up to 6 mm, preheating may be omitted if the results of hardness tests carried out on welding procedure qualification are considered acceptable by the Society.

(2) For welding in ambient temperature below 0°C, the minimum preheating temperature is required independent of the thickness unless specially approved by the Society.

**3.5 Post-weld heat treatment**

**3.5.1 General**

- a) As far as practicable, the heat treatment is to be carried out in a furnace. Where this is impracticable, and more particularly in the case of welding on board, the treatment is to be performed locally by heating uniformly a circular strip, extending on at least 75 mm on both sides of the welded joint; all precautions are to be taken to permit accurate checking of the temperature and slow cooling after treatment.
- b) For austenitic and austenitic ferritic steels, post-weld heat treatment is generally not required.

**3.5.2 Heat treatment after welding other than oxyacetylene welding**

- a) Stress relieving heat treatment after welding other than oxyacetylene welding is to be performed as indicated in Tab 21, depending on the type of steel and thickness of the pipes.
- b) The stress relieving heat treatment is to consist in heating slowly and uniformly to a temperature within the range indicated in Tab 21, soaking at this temperature for a suitable period, normally one hour per 25 mm of thickness with a minimum of half an hour, cooling slowly and uniformly in the furnace to a temperature not exceeding 400°C and subsequently cooling in still atmosphere.
- c) In any event, the heat treatment temperature is not to be higher than  $(T_T - 20)^\circ\text{C}$ , where  $T_T$  is the temperature of the final tempering treatment of the material.

**3.5.3 Heat treatment after oxyacetylene welding**

Stress relieving heat treatment after oxyacetylene welding is to be performed as indicated in Tab 22, depending on the type of steel.

**Table 21 : Heat treatment temperature**

Type of steel	Thickness of thicker part (mm)	Stress relief treatment temperature (°C)
C and C-Mn steels	$t \geq 15$ (1) (3)	550 to 620
0,3 Mo	$t \geq 15$ (1)	580 to 640
1 Cr 0,5 Mo	$t \geq 8$	620 to 680
2,25 Cr 1 Mo 0,5 Cr 0,5 Mo V	any (2)	650 to 720

(1) Where steels with specified Charpy V notch impact properties at low temperature are used, the thickness above which post-weld heat treatment is to be applied may be increased, subject to the special agreement of the Society.

(2) For 2,25Cr 1Mo and 0,5Cr 0,5Mo V grade steels, heat treatment may be omitted for pipes having thickness lower than 8 mm, diameter not exceeding 100 mm and service temperature not exceeding 450°C.

(3) For C and C-Mn steels, stress relieving heat treatment may be omitted up to 30 mm thickness, subject to the special agreement of the Society.

**Table 22 : Heat treatment after oxyacetylene welding**

Type of steel	Heat treatment and temperature (°C)
C and C-Mn	Normalising 880 to 940
0,3 Mo	Normalising 900 to 940
1Cr-0,5Mo	Normalising 900 to 960 Tempering 640 to 720
2,25Cr-1Mo	Normalising 900 to 960 Tempering 650 to 780
0,5Cr-0,5Mo-0,25V	Normalising 930 to 980 Tempering 670 to 720

### 3.6 Inspection of welded joints

#### 3.6.1 General

- The inspection of pressure pipe welded joints is to be performed at the various stages of the fabrication further to the qualifications defined in [3.1.1], item c).
- The examination mainly concerns those parts to be welded further to their preparation, the welded joints once they have been made and the conditions for carrying out possible heat treatments.
- The required examinations are to be carried out by qualified operators in accordance with procedures and techniques to the Surveyor's satisfaction.

#### 3.6.2 Visual examination

Welded joints, including the inside wherever possible, are to be visually examined.

#### 3.6.3 Non-destructive examinations

Non-destructive tests required are given in:

- Tab 23 for class I pipes
- Tab 24 for class II pipes.

**Table 23 : Class I pipe - Type of welded joints**

Class I pipe outer diameter D	Butt welded joint	Fillet weld for flange connection	Other welded joint which cannot be radiographed
Frequency of testing	every weld for $D > 75$ mm minimum 10% of welds selected in agreement with the Surveyor for $D \leq 75$ mm	every weld for $D > 75$ mm minimum 10% of welds selected in agreement with the Surveyor for $D \leq 75$ mm	every weld for $D > 75$ mm minimum 10% of welds selected in agreement with the Surveyor for $D \leq 75$ mm
Extent of testing	full length	full length	full length
Type of testing	radiographic or equivalent accepted by the Society	magnetic particle or liquid penetrant	magnetic particle or liquid penetrant

Table 24 : Class II pipe - Type of welded joints

Class II pipe outer diameter D	Butt welded joint	Fillet weld for flange connection	Other welded joint which cannot be radiographed
Frequency of testing	minimum 10% of welds selected in agreement with the Surveyor for D > 100 mm	minimum 10% of welds selected in agreement with the Surveyor for D > 100 mm	minimum 10% of welds selected in agreement with the Surveyor for D > 100 mm
Extent of testing	full length	full length	full length
Type of testing	radiographic or equivalent accepted by the Society	magnetic particle or liquid penetrant	magnetic particle or liquid penetrant

### 3.6.4 Defects and acceptance criteria

- a) Joints for which non-destructive examinations reveal unacceptable defects are to be re-welded and subsequently to undergo a new non-destructive examination. The Surveyor may require that the number of joints to be subjected to non-destructive examination is larger than that resulting from the provisions of [3.6.3].
- b) Acceptance criteria and repairs
  - Indications evaluated to be crack, lack of fusion or lack of penetration for class I pipes are not acceptable. Indications evaluated to be crack or lack of fusion in welds for class II pipes are not acceptable. Other types of imperfection are to be assessed in accordance with a recognised standard accepted by the Society.
  - Unacceptable indications are to be eliminated and repaired where necessary. The repair welds are to be examined on their full length using magnetic particle or liquid penetrant test and ultrasonic or radiographic testing.

When unacceptable indications are found, additional area of the same weld length are to be examined unless the indication is judged isolated without any doubt. In case of automatic welded joints, additional NDE is to be extended to all areas of the same weld length.

The extent of examination can be increased at the surveyor's discretion when repeated non-acceptable indications are found.

## 4 Bending of pipes

### 4.1 Application

4.1.1 This Article applies to pipes made of:

- alloy or non-alloy steels,
- copper and copper alloys.

### 4.2 Bending process

#### 4.2.1 General

The bending process is to be such as not to have a detrimental influence on the characteristics of the materials or on the strength of the pipes.

#### 4.2.2 Bending radius

Unless otherwise justified, the bending radius measured on the centreline of the pipe is not to be less than:

- twice the external diameter for copper and copper alloy pipes,
- 3 times the external diameter for cold bent steel pipes.

#### 4.2.3 Acceptance criteria

- a) The pipes are to be bent in such a way that, in each transverse section, the difference between the maximum and minimum diameters after bending does not exceed 10% of the mean diameter; higher values, but not exceeding 15%, may be allowed in the case of pipes which are not subjected in service to appreciable bending stresses due to thermal expansion or contraction.
- b) The bending is to be such that the depth of the corrugations is as small as possible and does not exceed 5% of their length.

#### 4.2.4 Hot bending

- a) In the case of hot bending, all arrangements are to be made to permit careful checking of the metal temperature and to prevent rapid cooling, especially for alloy steels.
- b) Hot bending is to be generally carried out in the temperature range 850°C - 1000°C for all steel grades; however, a decreased temperature down to 750°C may be accepted during the forming process.

### **4.3 Heat treatment after bending**

#### **4.3.1 Copper and copper alloy**

Copper and copper alloy pipes are to be suitably annealed after cold bending if their external diameter exceeds 50 mm.

#### **4.3.2 Steel**

- a) After hot bending carried out within the temperature range specified in [4.2.4], the following applies:
  - for C, C-Mn and C-Mo steels, no subsequent heat treatment is required,
  - for Cr-Mo and C-Mo-V steels, a subsequent stress relieving heat treatment in accordance with Tab 21 is required.
- b) After hot bending performed outside the temperature range specified in [4.2.4], a subsequent new heat treatment in accordance with Tab 22 is required for all grades.
- c) After cold bending at a radius lower than 4 times the external diameter of the pipe, a heat treatment in accordance with Tab 22 is required.

## **5 Arrangement and installation of piping systems**

### **5.1 General**

**5.1.1** Unless otherwise specified, piping and pumping systems covered by the Rules are to be permanently fixed on board ship.

### **5.2 Location of tanks and piping system components**

#### **5.2.1 Flammable oil systems**

Location of tanks and piping system components conveying flammable fluids under pressure is to comply with [5.10].

#### **5.2.2 Piping systems with open ends**

Attention is to be paid to the requirements for the location of open-ended pipes on board ships having to comply with the provisions of [5.5].

#### **5.2.3 Pipe lines located inside tanks**

- a) The passage of pipes through tanks, when permitted, normally requires special arrangements such as reinforced thickness or tunnels, in particular for:
  - bilge pipes
  - ballast pipes
  - scuppers and sanitary discharges
  - air, sounding and overflow pipes
  - fuel oil pipes.
- b) Junctions of pipes inside tanks are to be made by welding or flange connections. See also [2.4.3].

#### **5.2.4 Overboard discharges**

- a) All discharges in the shell plating below the freeboard deck shall be fitted with efficient and accessible arrangements for preventing the accidental admission of water into the ship.
- b) In manned machinery spaces, the valves may be controlled locally and shall be provided with indicators showing whether they are open or closed. For control of discharge valves fitted below the waterline, see [5.5.4].
- c) Overboard discharges are to be so located as to prevent any discharge of water into the lifeboats while they are being lowered.

#### **5.2.5 Piping and electrical apparatus**

As far as possible, pipes are not to pass near switchboards or other electrical apparatus. If this requirement is impossible to satisfy, gutterways or masks are to be provided wherever deemed necessary to prevent projections of liquid or steam on live parts.

### **5.3 Passage through bulkheads or decks**

#### **5.3.1 General**

For ships other than cargo ships, see also the additional requirements for the relevant service notations.

#### **5.3.2 Penetration of watertight bulkheads or decks and fire divisions**

- a) Where penetrations of watertight bulkheads or decks and fire divisions are necessary for piping and ventilation, arrangements are to be made to maintain the watertight integrity and fire integrity. See also Ch 4, Sec 5, [2].

Note 1: In cargo ships, the Society may permit relaxation in the watertightness of opening above the freeboard deck, provided that it is demonstrated that any progressive flooding can be easily controlled and that the safety of the ship is not impaired

- b) Lead or other heat sensitive materials are not to be used in piping systems which penetrate watertight subdivision bulkheads or decks, where deterioration of such systems in the event of fire would impair the watertight integrity of the bulkhead or decks.

This applies in particular to the following systems:

- bilge system
  - ballast system
  - scuppers and sanitary discharge systems.
- c) Where bolted connections are used when passing through watertight bulkheads or decks, the bolts are not to be screwed through the plating. Where welded connections are used, they are to be welded on both sides of the bulkhead or deck.
- d) Penetrations of watertight bulkheads or decks and fire divisions by plastic pipes are to comply with Ch 1, App 3, [4.7.2].

### **5.3.3 Passage through the collision bulkhead**

- a) *Except as provided in b) the collision bulkhead may be pierced below the bulkhead deck of passenger ships and the freeboard deck of cargo ships by not more than one pipe for dealing with fluid in the forepeak tank, provided that the pipe is fitted with a screw-down valve capable of being operated from above the bulkhead deck of passenger ships and the freeboard deck of cargo ships, the valve being located inside the forepeak at the collision bulkhead. The Society may, however, authorize the fitting of this valve on the after side of the collision bulkhead provided that the valve is readily accessible under all service conditions and the space in which it is located is not a cargo space. Alternatively, for cargo ships, the pipe may be fitted with a butterfly valve suitably supported by a seat or flanges and capable of being operated from above the freeboard deck. All valves shall be of steel, bronze or other approved ductile material. Valves of ordinary cast iron or similar material are not acceptable.*
- b) *If the forepeak is divided to hold two different kinds of liquids the Society may allow the collision bulkhead to be pierced below the bulkhead deck of passenger ships and the freeboard deck of cargo ships by two pipes, each of which is fitted as required by a), provided the Society is satisfied that there is no practical alternative to the fitting of such a second pipe and that, having regard to the additional subdivision provided in the forepeak, the safety of the ship is maintained*
- c) The remote operation device of the valve referred to in a) is to include an indicator to show whether the valve is open or shut.

## **5.4 Independence of lines**

### **5.4.1 Independence between bilge and ballast lines**

These lines are to be independent. This requirement does not need to be fulfilled for:

- pipes located between collecting boxes and pump suction
- pipes located between pumps and overboard discharges

### **5.4.2 Liquid cargo, lubricating oil and fuel oil**

These lines are not to be connected to bilge and ballast lines.

### **5.4.3 Pipe lines connected to tanks used alternatively as ballast, fuel oil, liquid or dry cargo when permitted**

Such pipes shall be fitted with blind flanges or other appropriate change over-devices in order to avoid any mishandling.

## **5.5 Prevention of progressive flooding**

### **5.5.1 Principle**

- a) In order to comply with the subdivision and damage stability requirements of Pt B, Ch 3, Sec 3, provision is to be made to prevent any progressive flooding of a dry compartment served by any open-ended pipe, in the event that such pipe is damaged or broken in any other compartment by collision or grounding.
- b) For this purpose, if pipes are situated within assumed flooded compartments, arrangements are to be made to ensure that progressive flooding cannot thereby extend to compartments other than those assumed to be flooded for each case of damage. However, the Society may permit minor progressive flooding if it is demonstrated that its effects can be easily controlled and the safety of the ship is not impaired. Refer to Pt B, Ch 3, Sec 3.

### **5.5.2 Extent of damage**

For the definition of the assumed transverse extent of damage, reference is to be made to Pt B, Ch 3, Sec 3.

### **5.5.3 Piping arrangement**

- a) The assumed transverse extent of damage is not to contain any pipe with an open end in a compartment located outside this extent, except where the section of such pipe does not exceed 710 mm<sup>2</sup>.

Note 1: Where several pipes are considered, the limit of 710 mm<sup>2</sup> applies to their total section.

- b) Where the provisions of item a) cannot be fulfilled, and after special examination by the Society, pipes may be situated within the assumed transverse extent of damage penetration provided that:
- either a closable valve operable from above the bulkhead deck is fitted at each penetration of a watertight subdivision and secured directly on the bulkhead, or
  - a closable valve operable from above the bulkhead deck is fitted at each end of the pipe concerned, the valves and their control system being inboard of the assumed extent of damage, or
  - the tanks to which the pipe concerned leads are regarded in the damage stability calculations as being flooded when damage occurs in a compartment through which the pipe passes.
- c) Valves required to be operable from above the bulkhead deck are to be fitted with an indicator to show whether the valve is open or shut.
- Where the valve is remote controlled by other than mechanical means, and where the remote control system is located, even partly, within the assumed extent of damage penetration, this system is to be such that the valve is automatically closed by loss of power.
- d) Air and overflow pipes are to be so arranged as to prevent the possibility of flooding of other tanks in other watertight compartments in the event of any one tank being flooded.
- This arrangement is to be such that in the range of positive residual righting levers beyond the angle of equilibrium stage of flooding, the progressive flooding of tanks or watertight compartments other than that flooded does not occur.

#### **5.5.4 Suction and discharge valves below the waterline**

- a) *The location of the controls of any valve serving a sea inlet, a discharge below the waterline or a bilge injection system shall be so sited as to allow adequate time for operation in case of influx of water to the space, having regard to the time likely to be required in order to reach and operate such controls. If the level to which the space could become flooded with the ship in the fully loaded condition so requires, arrangements shall be made to operate the controls from a position above such level.*

A calculation is to be carried out to show that the time taken from alarm activation plus the time to reach and fully close manually operated or powered valves is less than the time taken for the influx of water to reach the control without submergence of the platform on which the person is operating the valves. If necessary a remote control device is to be fitted above the level.

*Note 1:* The time it takes for the influx of water to reach the control of valves should be based on a breach in the largest diameter seawater line in the lowest location in the engine room when the ship is fully loaded.

*Note 2:* The time it takes to reach the sea valves should be determined based on the distance between the navigation bridge and the platform from where the valves associated with the aforementioned seawater line are manually operated (or the actuator for valves controlled by stored mechanical energy).

*Note 3:* In the event calculations are not available, 10 minutes shall be regarded as adequate time for operation unless other requirements are specified by the flag Administration.

- b) When the Administration of the State whose flag the ship is entitled to fly has issued specific rules covering flooding protection, the Society may accept such rules for classification purposes in lieu of those given in item a).

### **5.6 Provision for expansion**

#### **5.6.1 General**

Piping systems are to be so designed and pipes so fixed as to allow for relative movement between pipes and the ship's structure, having due regard to the:

- temperature of the fluid conveyed
- coefficient of thermal expansion of the pipes material
- deformation of the ship's hull.

#### **5.6.2 Fitting of expansion devices**

All pipes subject to thermal expansion and those which, due to their length, may be affected by deformation of the hull, are to be fitted with expansion pieces or loops.

### **5.7 Supporting of the pipes**

#### **5.7.1 General**

Unless otherwise specified, the fluid lines referred to in this Section are to consist of pipes connected to the ship's structure by means of collars or similar devices.

#### **5.7.2 Arrangement of supports**

Shipyards are to take care that:

- a) The arrangement of supports and collars is to be such that pipes and flanges are not subjected to abnormal bending stresses, taking into account their own mass, the metal they are made of, and the nature and characteristics of the fluid they convey, as well as the contractions and expansions to which they are subjected.
- b) Heavy components in the piping system, such as valves, are to be independently supported.

## **5.8 Protection of pipes**

### **5.8.1 Protection against shocks**

Pipes passing through cargo holds and 'tweendecks are to be protected against shocks by means of strong casings.

### **5.8.2 Protection of sea water pipes from mechanical damage**

Seawater pipes in cargo holds for dry cargoes, including cargo spaces of ships having the service notation **ro-ro passenger ship, PCTC, PCC, ro-ro cargo ship, container ship** or of ships having the additional service feature **equipped for the carriage of containers**, are to be protected from impact of cargo where they are liable to be damaged.

### **5.8.3 Protection against corrosion and erosion**

- a) Pipes are to be efficiently protected against corrosion, particularly in their most exposed parts, either by selection of their constituent materials, or by an appropriate coating or treatment.
- b) The layout and arrangement of sea water pipes are to be such as to prevent sharp bends and abrupt changes in section as well as zones where water may stagnate. The inner surface of pipes is to be as smooth as possible, especially in way of joints. Where pipes are protected against corrosion by means of galvanising or other inner coating, arrangements are to be made so that this coating is continuous, as far as possible, in particular in way of joints.
- c) If galvanised steel pipes are used for sea water systems, the water velocity is not to exceed 3 m/s.
- d) If copper pipes are used for sea water systems, the water velocity is not to exceed 2 m/s.
- e) Arrangements are to be made to avoid galvanic corrosion.
- f) If aluminium brass pipes are used for sea water systems, the water velocity is not to exceed 3 m/s
- g) If 90/10 copper-nickel-iron pipes are used for sea water systems, the water velocity is not to exceed 3,5 m/s
- h) If 70/30 copper-nickel pipes are used for sea water systems, the water velocity is not to exceed 5 m/s
- i) If GRP pipes are used for sea water systems, the water velocity is not to exceed 5 m/s.

### **5.8.4 Protection against frosting**

Pipes are to be adequately insulated against cold wherever deemed necessary to prevent frost.

This applies specifically to pipes passing through refrigerated spaces and which are not intended to ensure the refrigeration of such spaces.

### **5.8.5 Protection of high temperature pipes and components**

- a) All pipes and other components where the temperature may exceed 220°C are to be efficiently insulated. Where necessary, precautions are to be taken to protect the insulation from being impregnated with flammable oils.
- b) Particular attention is to be paid to lagging in way of flanges.

## **5.9 Valves, accessories and fittings**

### **5.9.1 General**

Cocks, valves and other accessories are generally to be arranged so that they are easily visible and accessible for manoeuvring, control and maintenance. They are to be installed in such a way as to operate properly.

### **5.9.2 Valves and accessories**

- a) In machinery spaces and tunnels, the cocks, valves and other accessories of the fluid lines referred to in this Section are to be placed:
  - above the floor, or
  - when this is not possible, immediately under the floor, provided provision is made for their easy access and control in service.
- b) Control-wheels of low inlet valves are to rise at least 0,45 m above the lowest floor.

### **5.9.3 Flexible hoses and expansion joints**

- a) Flexible hoses and expansion joints are to be in compliance with [2.6]. They are to be installed in clearly visible and readily accessible locations.
- b) The number of flexible hoses and expansion joints is to be kept to minimum and limited for the purpose stated in [2.6.1], item c).
- c) In general, flexible hoses and expansion joints are to be limited to a length necessary to provide for relative movement between fixed and flexibly mounted items of machinery/equipment or systems.

- d) The installation of a flexible hose assembly or an expansion joint is to be in accordance with the manufacturer's instructions and use limitations, with particular attention to the following:
- orientation
  - end connection support (where necessary)
  - avoidance of hose contact that could cause rubbing and abrasion
  - minimum bend radii.
- e) Flexible hose assemblies or expansion joints are not to be installed where they may be subjected to torsion deformation (twisting) under normal operating conditions.
- f) Where flexible hoses or an expansion joint are intended to be used in piping systems conveying flammable fluids that are in close proximity of heated surfaces, the risk of ignition due to failure of the hose assembly and subsequent release of fluids is to be mitigated, as far as practicable, by the use of screens or other similar protection, to the satisfaction of the Society.
- g) The adjoining pipes are to be suitably aligned, supported, guided and anchored.
- h) Isolating valves are to be provided permitting the isolation of flexible hoses intended to convey flammable oil or compressed air.
- i) Expansion joints are to be protected against over extension or over compression.
- j) Where they are likely to suffer external damage, flexible hoses and expansion joints are to be provided with adequate protection.

#### **5.9.4 Thermometers**

Thermometers and other temperature-detecting elements in fluid systems under pressure are to be provided with pockets built and secured so that the thermometers and detecting elements can be removed while keeping the piping under pressure.

#### **5.9.5 Pressure gauges**

Pressure gauges and other similar instruments are to be fitted with an isolating valve or cock at the connection with the main pipe.

#### **5.9.6 Nameplates**

- a) Accessories such as cocks and valves on the fluid lines referred to in this Section are to be provided with nameplates indicating the apparatus and lines they serve except where, due to their location on board, there is no doubt as to their purpose.
- b) Nameplates are to be fitted at the upper part of air and sounding pipes.

### **5.10 Additional arrangements for flammable fluids**

#### **5.10.1 General**

All necessary precautions are to be taken to reduce fire risks from flammable liquids, such as:

- drips
- leaks under pressure
- overflow
- hydrocarbon accumulation in particular under lower floors
- discharges of oil vapours during heating
- soot or unburnt residue in smoke stacks or exhaust pipes.

Unless otherwise specified, the requirements in [5.10.3] apply to:

- fuel oil systems, in all spaces
- lubricating oil systems, in machinery spaces
- other flammable oil systems, in locations where means of ignition are present.

#### **5.10.2 Prohibition of carriage of flammable oils in forepeak tanks**

In cargo ships of more than 400 gross tonnage and in passenger ships, fuel oil, lubricating oil and other flammable oils are not to be carried in forepeak tanks or tanks forward of the collision bulkhead.

### **5.10.3 Prevention of flammable oil leakage ignition**

- a) As far as practicable, the piping arrangement in the flammable oil systems shall comply generally with the following:
- The conveying of flammable oils through accommodation and service spaces is to be avoided. Where it is not possible, the arrangement may be subject to special consideration by the Society, provided that the pipes are of a material approved having regard to the fire risk.
  - The pipes are not to be located immediately above or close to the hot surfaces (exhaust manifolds, silencers, steam pipelines, boilers, etc.), electrical installations or other sources of ignition. Otherwise, suitable protection (screening and effective drainage to the safe position) is to be provided to prevent of spraying or leakage onto the sources of ignition.
  - Parts of the piping systems conveying heated flammable oils under pressure exceeding 0,18 MPa are to be placed above the platform or in any other position where defects and leakage can readily be observed. The machinery spaces in way of such parts are to be adequately illuminated.
- b) No flammable oil tanks are to be situated where spillage or leakage therefrom can constitute a hazard by falling on:
- hot surfaces, including those of boilers, heaters, steam pipes, exhaust manifolds and silencers
  - electrical equipment
  - air intakes
  - other sources of ignition.
- c) Parts of flammable oil systems under pressure exceeding 0,18 MPa such as pumps, filters and heaters are to comply with the provisions of b) above.
- d) Pipe connections, expansion joints and flexible parts of flammable oil lines are to be screened or otherwise suitably protected to avoid, as far as practicable, oil spray or oil leakages onto hot surfaces, into machinery air intakes, or on other sources of ignition. In case of additional class notation **AUT-IMS**, see also Pt F, Ch 3, Sec 4, [3.1.2]. The fastening of connections (nuts, screws, etc.) of lubricating oil or fuel oil pipes above 1,8 bar pressure is to be locked.
- e) Any relief valve or air vent cock fitted within the flammable liquid systems is to discharge to a safe position, such as an appropriate tank.
- f) Appropriate means are to be provided to prevent undue opening (due to vibrations) of air venting cocks fitted on equipment or piping containing flammable liquid under pressure.

### **5.10.4 Provisions for flammable oil leakage containment**

- a) Tanks used for the storage of flammable oils together with their fittings are to be so arranged as to prevent spillages due to leakage or overfilling.
- b) Drip trays with adequate drainage to contain possible leakage from flammable fluid systems are to be fitted:
- under independent tanks
  - under burners
  - under purifiers and any other oil processing equipment
  - under pumps, heat exchangers and filters
  - under valves and all accessories subject to oil leakage
  - surrounding internal combustion engines.
- c) The coaming height of drip trays is to be appropriate for the service and not less than 75 mm. In case of additional class notation **AUT-IMS**, see also Pt F, Ch 3, Sec 4, [3.1.1].
- d) Where boilers are located in machinery spaces on 'tweendecks and the boiler rooms are not separated from the machinery spaces by watertight bulkheads, the 'tweendecks are to be provided with oil-tight coamings at least 200 mm in height.
- e) Where drain pipes are provided for collecting leakages, they are to be led to an appropriate drain tank.
- f) The draining system of the room where thermal fluid heaters are fitted, as well as the save all of the latter, are not to allow any fire extension outside this room. See also [13.3.2].

### **5.10.5 Drain tank**

- a) The drain tank is not to form part of an overflow system and is to be fitted with an overflow alarm device.
- b) In ships required to be fitted with a double bottom, appropriate precautions are to be taken when the drain tank is constructed in the double bottom, in order to avoid flooding of the machinery space where drip trays are located, in the event of accidentally running aground.

### **5.10.6 Valves**

All valves and cocks forming part of flammable oil systems are to be capable of being operated from readily accessible positions and, in machinery spaces, from above the working platform.

### **5.10.7 Level switches**

Level switches fitted to flammable oil tanks are to be contained in a steel or other fire-resisting enclosure.

## 6 Bilge systems

### 6.1 Application

6.1.1 This Article does not apply to bilge systems of non-propelled ships. See Part D, Chapter 14.

#### 6.1.2 Application to ships having the additional service feature SPxxx or SPxxx-capable

Ships having the additional service feature **SPxxx** or **SPxxx-capable** are to comply, in addition to the applicable requirements of this Article, with the requirements of Pt D, Ch 11, Sec 4, [1], considering special personnel as passengers.

### 6.2 Principle

#### 6.2.1 General

*An efficient bilge pumping system shall be provided, capable of pumping from and draining any watertight compartment other than a space permanently appropriated for the carriage of fresh water, water ballast, fuel oil or liquid cargo and for which other efficient means of pumping are provided, under all practical conditions. Efficient means shall be provided for draining water from insulated holds.*

Bilge pumping system is not intended at coping with water ingress resulting from structural or main sea water piping damage.

#### 6.2.2 Availability of the bilge system

The bilge system is to be able to work while the other essential installations of the ship, especially the fire-fighting installations, are in service.

#### 6.2.3 Bilge and ballast systems

*The arrangement of the bilge and ballast pumping system shall be such as to prevent the possibility of water passing from the sea and from water ballast spaces into the cargo and machinery spaces, or from one compartment to another.*

*Provisions shall be made to prevent any deep tank having bilge and ballast connections being inadvertently flooded from the sea when containing cargo, or being discharged through a bilge pump when containing water ballast.*

### 6.3 Design of bilge systems

#### 6.3.1 General

- a) The bilge pumping system is to consist of pumps connected to a bilge main line so arranged as to allow the draining of all spaces mentioned in [6.2.1] through bilge branches, distribution boxes and bilge suction, except for some small spaces where individual suction by means of hand pumps may be accepted as stated in [6.6.3] and [6.6.4].
- b) If deemed acceptable by the Society, bilge pumping arrangements may be dispensed with in specific compartments provided the safety of the ship is not impaired.

#### 6.3.2 Number and distribution of bilge suction

- a) Draining of watertight spaces is to be possible, when the ship is on an even keel and either is upright or has a list of up to 5°, by means of at least:
  - two suction in machinery spaces, including one branch bilge suction and one direct suction and, in addition, for spaces containing propulsion machinery, one emergency bilge suction
  - one suction in other spaces.See also [6.5.5].
- b) Bilge suction are to be arranged as follows:
  - wing suction are generally to be provided except in the case of short and narrow compartments when a single suction ensures effective draining in the above conditions
  - in the case of compartments of unusual form, additional suction may be required to ensure effective draining under the conditions mentioned in item a).
- c) In all cases, arrangements are to be made such as to allow a free and easy flow of water to bilge suction.

#### 6.3.3 Prevention of communication between spaces Independence of the lines

- a) Bilge lines are to be so arranged as to avoid inadvertent flooding of any dry compartment.
- b) Bilge lines are to be entirely independent and distinct from other lines except where permitted in [5.4].
- c) In ships designed for the carriage of flammable or toxic liquids in enclosed cargo spaces, the bilge pumping system is to be designed to prevent the inadvertent pumping of such liquids through machinery space piping or pumps. See also Ch 4, Sec 12, [2.6].

## **6.4 Draining of cargo spaces**

### **6.4.1 General**

- a) Cargo holds are to be fitted with bilge suctions connected to the bilge main.
- b) Drainage arrangements for cargo holds likely to be used alternatively for ballast, fuel oil or liquid or dry cargoes are to comply with [7.1].
- c) Drainage of enclosed cargo spaces situated on the freeboard deck of a cargo ship and on the bulkhead deck of a passenger ship shall comply with [8.5].
- d) Drainage of enclosed cargo spaces intended to carry dangerous goods (see Ch 4, Sec 12) shall be provided in accordance with Ch 4, Sec 12, [2.6].

### **6.4.2 Ships without double bottom**

- a) In ships without double bottom, bilge suctions are to be provided in the holds:
  - at the aft end in the centreline where the rise of floor exceeds 5°
  - at the aft end on each side in other cases.
- b) Additional suctions may be required if, due to the particular shape of the floor, the water within the compartment cannot be entirely drained by means of the suctions mentioned in a) above.

### **6.4.3 Ships with double bottom**

- a) In ships with double bottom, bilge suctions are to be provided in the holds on each side aft. Where the double bottom plating extends from side to side, the bilge suctions are to be led to wells located at the wings. Where the double bottom plating slopes down to the centreline by more than 5°, a centreline well with a suction is also to be provided.
- b) If the inner bottom is of a particular design, shows discontinuity or is provided with longitudinal wells, the number and position of bilge suctions will be given special consideration by the Society.

### **6.4.4 Ships with holds over 30 m in length**

In holds greater than 30 m in length, bilge suctions are to be provided in the fore and aft ends.

### **6.4.5 Additional suctions**

Additional suctions may be required in the forward part of holds in ships which are likely to navigate normally with a trim by the head.

### **6.4.6 Drainage of cargo spaces, other than ro-ro spaces, intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion**

In cargo spaces, other than ro-ro spaces, intended for the carriage of motor vehicles with fuel in their tanks for their own propulsion and fitted with a fixed pressure water-spraying fire-extinguishing system, the pumping arrangement is to be such as to prevent the build-up of free surfaces. If this is not possible, the adverse effect upon stability of the added weight and free surface of water is to be taken into account to the extent deemed necessary by the Society in its approval of the stability information. See Part B, Chapter 3.

See also [8.7].

### **6.4.7 Drainage of cargo spaces intended for the carriage of flammable or toxic liquids**

In ships designed for the carriage of flammable or toxic liquids in enclosed cargo spaces, and where large quantities of such liquids are carried, consideration is to be given to the provision of additional means of draining such spaces. See also Ch 4, Sec 12, [2.6].

## **6.5 Draining of machinery spaces**

### **6.5.1 General**

Where all the propulsion machinery, boilers and main auxiliaries are located in a single watertight space, the bilge suctions are to be distributed and arranged in accordance with the provisions of [6.5.5].

### **6.5.2 Branch bilge suction**

The branch bilge suction is to be connected to the bilge main.

### **6.5.3 Direct suction**

The direct suction is to be led direct to an independent power bilge pump and so arranged that it can be used independently of the main bilge line.

The use of ejectors for pumping through the direct suction will be given special consideration.

#### **6.5.4 Emergency bilge suction**

- a) The emergency bilge suction is to be led directly from the drainage level of the machinery space to a main circulating (or cooling) pump and fitted with a non-return valve.
- b) In ships where, in the opinion of the Society, the main circulating (or cooling) pump is not suitable for this purpose, the emergency bilge suction is to be led from the largest available independent power driven pump to the drainage level of the machinery space. Such a pump is not to be a bilge pump. Its capacity when the emergency suction is operating is to be at least equal to the required capacity of each bilge pump as determined in [6.7.4].
- c) The emergency bilge suction is to be located at the lowest possible level in the machinery spaces.

#### **6.5.5 Number and distribution of suctions in propulsion machinery spaces**

- a) In propulsion machinery spaces, bilge suctions are to include:
  - where the bottom of the space, bottom plating or top of the double bottom slope down to the centreline by more than 5°, at least two centreline suctions, i.e. one branch bilge suction and one direct suction, or
  - where the bottom of the space is horizontal or slopes down to the sides and in all passenger ships, at least two suctions, i.e. one branch bilge suction and one direct suction, on each side, and
  - one emergency bilge suction.

Note 1: In cargo ships, if an emergency bilge suction is arranged in accordance with [6.5] and connected to a self-priming pump, the direct bilge suction may be omitted on the side where the emergency suction is fitted.

- b) If the tank top is of a particular design or shows discontinuity, additional suctions may be required.
- c) Where the propulsion machinery space is located aft, suctions are normally to be provided on each side at the fore end and, except where not practicable due to the shape of the space, on each side at the aft end of the space.
- d) In electrically propelled ships, provision is to be made to prevent accumulation of water under electric generators and motors.

#### **6.5.6 Number and distribution of suctions in boiler and auxiliary machinery spaces**

In boiler and auxiliary compartments, bilge suctions are to include:

- bilge branch suctions distributed as required in [6.4.2] to [6.4.5] for cargo holds
- one direct suction.

### **6.6 Draining of dry spaces other than cargo holds and machinery spaces**

#### **6.6.1 General**

- a) Except where otherwise specified, bilge suctions are to be branch bilge suctions, i.e. suctions connected to a bilge main.
- b) Draining arrangements of tanks are to comply with the provisions of [7].

#### **6.6.2 Draining of cofferdams**

- a) All cofferdams are to be provided with suction pipes led to the bilge main.
- b) Where cofferdams are divided by longitudinal watertight bulkheads or girders into two or more parts, a single suction pipe led to the aft end of each part is acceptable.

#### **6.6.3 Draining of fore and aft peaks**

- a) Where the peaks are not used as tanks and bilge suctions are not fitted, drainage of both peaks may be effected by hand pump suction provided that the suction lift is well within the capacity of the pump and in no case exceeds 7,3 m.
- b) Except where permitted in [5.3.3], the collision bulkhead is not to be pierced below the freeboard deck.
- c) For tankers, see Pt D, Ch 7, Sec 4, [2.1.4].
- d) For ships intended primarily to carry dry cargo in bulk, see [6.6.7].

#### **6.6.4 Draining of spaces above fore and aft peaks**

- a) Provision is to be made for the drainage of the chain lockers and watertight compartments above the fore peak tank by hand or power pump suctions.
- b) Steering gear compartments or other small enclosed spaces situated above the aft peak tank are to be provided with suitable means of drainage, either by hand or power pump bilge suctions. However, in the case of rudder stock glands located below the summer load line, the bilge suctions of the steering gear compartment are to be connected to the main bilge system.
- c) If the compartments referred to in b) are adequately isolated from the adjacent 'tweendecks, they may be drained by scuppers discharging to the tunnel (or machinery space in the case of ships with machinery aft) and fitted with self-closing cocks situated in well-lighted and visible positions.

Note 1: This arrangement is not applicable to ships required to comply with [5.5], and in particular to passenger ships, unless they are specially approved in relation to subdivision.

- d) For ships intended primarily to carry dry cargo in bulk, see [6.6.7].

**6.6.5 Draining of tunnels**

- a) Tunnels are to be drained by means of suction connected to the main bilge system. Such suction is generally to be located in wells at the aft end of the tunnels.
- b) Where the top of the double bottom, in the tunnel, slopes down from aft to forward, an additional suction is to be provided at the forward end of this space.

**6.6.6 Draining of refrigerated spaces**

Provision is to be made for the continuous drainage of condensate in refrigerated and air cooler spaces. To this end, valves capable of blanking off the water draining lines of such spaces are not to be fitted, unless they are operable from an easily accessible place located above the load waterline.

**6.6.7 Specific requirements for drainage of forward spaces of bulk, ore and combination carriers ("dewatering system")**

Unless otherwise specified, this requirement applies to ships with service notation **bulk carrier**, **ore carrier** or **combination carrier**, as described in Pt A, Ch 1, Sec 2, [4.3].

- a) The bilge of dry spaces any part of which extends forward of the foremost cargo hold, as well as the means for draining and pumping ballast tanks forward of the collision bulkhead, is to be capable of being brought into operation from a readily accessible enclosed space, the location of which is accessible from the navigation bridge or propulsion machinery control position without traversing exposed freeboard or superstructure decks. The following criteria are to govern the application of the requirement:
  - a position which is accessible via an under deck passage, a pipe trunk or other similar means of access is not to be taken as being in the accessible enclosed space.
  - the requirement does not apply to the enclosed spaces the volume of which does not exceed 0,1% of the ship maximum displacement volume and to the chain locker.
- b) The water level detectors, giving an audible and visual alarm located on the navigation bridge, are to be fitted:
  - in any ballast tank forward of the collision bulkhead, indicating when the liquid in the tank reaches a level not exceeding 10% of the tank capacity. An alarm overriding device may be installed to be activated when the tank is in use.
  - in any dry or void space which is to comply with the requirements in item a), giving the alarm at a water level of 0,1 m above the deck.
- c) The capacity of the dewatering system is to be designed to remove water from the forward spaces at a rate of not less than  $(320 \cdot A) \text{ m}^3/\text{h}$ , where A is the cross-sectional area, in  $\text{m}^2$ , of the largest air pipe or ventilator pipe connected from the exposed deck to a closed forward space that is required to be dewatered by these arrangements.
- d) When dewatering systems are in operation, the following is to be fulfilled:
  - other systems essential for the safety of the ship, including fire-fighting and bilge systems, are to remain available and ready for immediate use
  - it is to be possible to start fire pumps immediately and to have a ready available supply of fire-fighting water
  - the systems for normal operation of electric power supplies, propulsion and steering are not to be affected by this operation.
- e) The drainage arrangements are to be such that:
  - any accumulated water can be drained directly by a pump or an eductor
  - it may be possible to configure and use bilge system for any compartment when the drainage system is in operation
  - remotely operated valves within the system comply with [2.7.3]
  - bilge wells are protected by gratings or strainers to prevent blockage of the drainage system with debris.
- f) Where pipes serving such tanks or bilge pierce the collision bulkhead, valve operation by means of remotely operated actuators may be accepted as an alternative to the valve control required in [5.3.3], provided that the location of such valve controls complies with [5.3.3]. For that purpose, the following is to be fulfilled:
  - the valve required in [5.3.3] is to be capable of being controlled from the position as required in item a)
  - the valve is not to move from the demanded position in the case of failure of the control system power or actuator power
  - positive indication is to be provided at the remote control station to show that the valve is fully open or closed
  - in addition, the local hand powered valve operation from above the freeboard deck is also to be provided.
- g) The piping arrangements for drainage of closed dry spaces may be connected to the piping arrangements for drainage of water ballast tanks, provided that:
  - two non-return valves are provided to prevent the ingress of water into dry spaces from those intended for the carriage of water ballast
  - the non-return valves are located in readily accessible positions
  - one of these non-return valves is fitted with shut-off isolation arrangement
  - the shut-off isolation arrangement is capable of being controlled from the position as required in item a).
- h) The enclosures of electrical equipment for the dewatering system installed in any of the forward dry spaces are to be in accordance with requirements given in Ch 2, Sec 3, [4.1.5].

## **6.7 Bilge pumps**

### **6.7.1 Number and arrangement of pumps**

- a) For cargo ships, at least two power pumps connected to the main bilge system are to be provided, one of which may be driven by the propulsion machinery.
- b) Additional requirements for passenger ships are given in Part D.
- c) Each pump may be replaced by a group of pumps connected to the bilge main, provided their total capacity meets the requirements specified in [6.7.4].
- d) Alternative arrangements, such as the use of a hand pump in lieu of a power pump, will be given special consideration by the Society.

### **6.7.2 Use of ejectors**

One of the pumps may be replaced by a hydraulic ejector connected to a high pressure water pump and capable of ensuring the drainage under similar conditions to those obtained with the other pump.

On passenger ships, the pump supplying the ejector is not to be used for other services.

### **6.7.3 Use of other pumps for bilge duties**

- a) Other pumps may be used for bilge duties, such as fire, general service, sanitary service or ballast pumps, provided that:
  - they meet the capacity requirements
  - suitable piping arrangements are made
  - pumps are available for bilge duty when necessary.
- b) The use of bilge pumps for fire duty is to comply with the provisions of Ch 4, Sec 6.

### **6.7.4 Capacity of the pumps**

- a) Each power bilge pump is to be capable of pumping water through the required main bilge pipe at a speed of not less than 2 m/s.
- b) The capacity of each pump or group of pumps is not to be less than:  
 $Q = 0,00565 d^2$   
where:  
Q : Minimum capacity of each pump or group of pumps, in m<sup>3</sup>/h  
d : Internal diameter, in mm, of the bilge main as defined in [6.8.1].

Note 1: For cargo ships of less than 35 m in length:

- the speed of water to be considered for calculating the capacity may be reduced to 1,22 m/s
  - the capacity of each pump or group of pumps is not to be less than  $Q = 0,00345 d^2$ .
- c) If the capacity of one of the pumps or one of the groups of pumps is less than the Rule capacity, the deficiency may be compensated by an excess capacity of the other pump or group of pumps; as a rule, such deficiency is not permitted to exceed 30% of the Rule capacity.

Note 2: This provision does not apply to passenger ships.

- d) The capacity of hand pumps is to be based on one movement once a second.
- e) Where an ejector is used in lieu of a driven pump, its suction capacity is not to be less than the required capacity of the pump it replaces.

### **6.7.5 Choice of the pumps**

- a) Bilge pumps are to be of the self-priming type. Centrifugal pumps are to be fitted with efficient priming means, unless an approved priming system is provided to ensure the priming of pumps under normal operating conditions.
- b) Circulating or cooling water pumps connected to an emergency bilge suction need not be of the self-priming type.
- c) Sanitary, ballast and general service pumps may be accepted as independent power bilge pumps if fitted with the necessary connections to the bilge pumping system.
- d) Hand pumps are to have a maximum suction height not exceeding 7,30 m and to be operable from a position located above the load waterline.

### **6.7.6 Connection of power pumps**

- a) Bilge pumps and other power pumps serving essential services which have common suction or discharge are to be connected to the pipes in such a way that:
  - compartments and piping lines remain segregated in order to prevent possible intercommunication
  - the operation of any pump is not affected by the simultaneous operation of other pumps.
- b) The isolation of any bilge pump for examination, repair or maintenance is to be made possible without impeding the operation of the remaining bilge pumps.

### **6.7.7 Electrical supply of submersible pump motors**

- a) Where submersible bilge pumps are provided, arrangements are to be made to start their motors from a convenient position above the bulkhead deck.
- b) Where an additional local-starting device is provided at the motor of a permanently installed submersible bilge pump, the circuit is to be arranged to provide for the disconnection of all control wires therefrom at a position adjacent to the starter installed on the deck.

## **6.8 Size of bilge pipes**

### **6.8.1 Bilge main line**

- a) The diameter of the bilge main is to be calculated according to the following formula:

$$d = 25 + 1,68\sqrt{L(B + D)}$$

where:

d : Internal diameter of the bilge main, in mm

L and B : Length and breadth of the ship as defined in Pt B, Ch 1, Sec 3, in m

D : Moulded depth of the ship to the bulkhead deck, in m, provided that, in a ship having an enclosed cargo space on the bulkhead deck which is internally drained in accordance with the requirements of [8.5.3] and which extends for the full length of the ship, D is measured to the next deck above the bulkhead deck. Where the enclosed cargo spaces cover a lesser length, D is to be taken as the moulded depth to the bulkhead deck plus  $l \cdot h / L$  where l and h are the aggregate length and height, respectively, of the enclosed cargo spaces, in m.

Note 1: In cargo ships fitted with side ballast tanks forming a double hull on the whole length of the holds, the diameter of the bilge main may be determined by introducing the actual breadth of the holds amidships as B in the above formula. For the part of bilge main serving the suction to machinery spaces, the cross-section is not to be less than twice the cross-sections resulting from [6.8.3], item a) for branch bilge suction to those machinery spaces and need not exceed that of the bilge main resulting from the above formula.

- b) In no case is the actual internal diameter to be:
  - more than 5 mm smaller than that obtained from the formula given in a), or
  - less than 60 mm, or
  - less than that obtained from the formula given in [6.8.3] for branch bilge suction.
- c) For tankers, the internal diameter d of the bilge main in engine room shall be determined in accordance with Pt D, Ch 7, Sec 4, [2.2.2].
- d) For cargo ships where  $L < 20$  m and assigned with a restricted navigation notation, as well as for sailing ships with or without auxiliary engine, the bilge system will be specially considered by the Society in each particular case.

### **6.8.2 Distribution box branch pipes**

The cross-section of any branch pipe connecting the bilge main to a bilge distribution box is not to be less than the sum of the cross-sections required for the two largest branch suction connected to this box. However, this cross-section need not exceed that of the bilge main.

### **6.8.3 Branch bilge suction pipes**

- a) The internal diameter, in mm, of pipes situated between distribution boxes and suction in holds and machinery spaces is not to be less than the diameter given by the following formula:

$$d_1 = 25 + 2,16\sqrt{L_1(B + D)}$$

where:

B and D : as defined in [6.8.1]

$L_1$  : Length of the compartment, in m.

$d_1$  is not to be less than 50 mm and need not exceed 100 mm.

- b) For ships other than passenger ships, which have side ballast tanks forming a double hull, the diameter of suction pipes in holds may be determined by introducing as B the actual breadth of the holds amidships.

### **6.8.4 Direct suction other than emergency suction**

- a) Direct suction are to be suitably arranged and those in a machinery space are to be of a diameter not less than that required for the bilge main.
- b) In cargo ships having separate machinery spaces of small dimensions, the size of the direct suction need not exceed that given in [6.8.3] for branch bilge suction.

### **6.8.5 Emergency suction in machinery spaces**

- a) The diameter of emergency bilge suction pipes is to be:
  - at least two thirds of the diameter of the pump inlet in the case of steamships
  - the same as the diameter of the pump inlet in the case of motorships.
- b) Where the emergency suction is connected to a pump other than a main circulating or cooling pump, the suction is to be the same diameter as the main inlet of the pump.

### **6.8.6 Bilge suction from tunnels**

Bilge suction pipes to tunnel wells are not to be less than 65 mm in diameter. In ships up to 60 metres in length, this diameter may be reduced to 50 mm.

### **6.8.7 Scuppers in aft spaces**

Any scupper provided for draining aft spaces and discharging to the tunnel is to have an internal diameter not less than 35 mm.

### **6.8.8 Bilge for small ships**

For cargo ships of a length  $L$ , as defined in [6.8.1], less than 20 m and assigned with a restricted navigation notation, as well as for sailing ships with or without auxiliary engine, the bilge system will be specially considered by the Society in each single case.

### **6.8.9 Bilge main for tankers**

In tankers and other ships where the bilge pumps are designed to pump from the machinery space only, the internal diameter  $d$ , in mm, of the bilge main may be less than that required by the formula in [6.8.1] above, but it is to be not less than that obtained from the formula specified in Pt D, Ch 7, Sec 4.

## **6.9 Bilge accessories**

### **6.9.1 Drain valves on watertight bulkheads**

- a) The fitting of drain valves or similar devices is not allowed on the collision bulkhead.
- b) On other watertight bulkheads, the fitting of drain valves or similar devices is allowed unless practical alternative draining means exist. Such valves are to be easily accessible at all times and operable from above the freeboard deck. Means indicating whether the valves are open or closed are to be provided.

### **6.9.2 Screw-down non-return valves**

- a) Accessories are to be provided to prevent intercommunication of compartments or lines which are to remain segregated from one another. For this purpose, non-return devices are to be fitted:
  - on the pipe connections to bilge distribution boxes or to the alternative valves, if any
  - on direct and emergency suction in machinery spaces
  - on the suction of pumps which also have connections from the sea or from compartments normally intended to contain liquid
  - on flexible bilge hose connections
  - on the suction of water bilge ejectors
  - at the open end of bilge pipes passing through deep tanks
  - in compliance with the provisions for the prevention of progressive flooding, if applicable.
- b) Screw-down and other non-return valves are to be of a recognised type which does not offer undue obstruction to the flow of water.

### **6.9.3 Mud boxes**

In machinery spaces and shaft tunnels, termination pipes of bilge suction are to be straight and vertical and are to be led to mud boxes so arranged as to be easily inspected and cleaned.

The lower end of the termination pipe is not to be fitted with a strum box.

### **6.9.4 Strum boxes**

- a) In compartments other than machinery spaces and shaft tunnels, the open ends of bilge suction pipes are to be fitted with strum boxes or strainers having holes not more than 10 mm in diameter. The total area of such holes is to be not less than twice the required cross-sectional area of the suction pipe.
- b) Strum boxes are to be so designed that they can be cleaned without having to remove any joint of the suction pipe.

### **6.9.5 Bilge wells**

- a) The wells provided for draining the various compartments are to be of a capacity not less than 0,15 m<sup>3</sup>. In small compartments, smaller cylindrical wells may be fitted.
- b) Bilge wells are to comply with the relevant provisions of Part B.

### **6.9.6 Liquid sealed traps**

- a) The bilge line of refrigerated spaces is to be provided with liquid sealed traps of adequate size arranged for easy cleaning and refilling with brine. These traps are to be fitted with removable grids intended to hold back waste products when defrosting.
- b) Where drain pipes from separate refrigerated rooms join a common main, each of these pipes is to be provided with a liquid sealed trap.
- c) As a general rule, liquid sealed traps are to be fitted with non-return valves. However, for refrigerated spaces not situated in the ship bottom, non-return valves may be omitted, provided this arrangement does not impair the integrity of the watertight subdivision.

### **6.10 Materials**

**6.10.1** *All bilge pipes used in or under coal bunkers or fuel storage tanks or in boiler or machinery spaces, including spaces in which oil-settling tanks or fuel oil pumping units are situated, shall be of steel or other suitable material non-sensitive to heat.*

### **6.11 Bilge piping arrangement**

#### **6.11.1 Passage through double bottom compartments**

Bilge pipes are not to pass through double bottom compartments. If such arrangement is unavoidable, the parts of bilge pipes passing through double bottom compartments are to have reinforced thickness, as per Tab 6 for steel pipes.

#### **6.11.2 Passage through deep tanks**

The parts of bilge pipes passing through deep tanks intended to contain water ballast, fresh water, liquid cargo or fuel oil are normally to be contained within pipe tunnels. Alternatively, such parts are to have reinforced thickness, as per Tab 6 for steel pipes, and are to be made either of one piece or several pieces assembled by welding, by reinforced flanges or by devices deemed equivalent for the application considered; the number of joints is to be as small as possible. These pipes are to be provided at their ends in the holds with non-return valves.

#### **6.11.3 Provision for expansion**

Where necessary, bilge pipes inside tanks are to be fitted with expansion bends. Sliding joints are not permitted for this purpose.

#### **6.11.4 Connections**

Connections used for bilge pipes passing through tanks are to be welded joints or reinforced flange connections.

#### **6.11.5 Access to valves and distribution boxes**

*All distribution boxes and manually operated valves in connection with the bilge pumping arrangement shall be in positions which are accessible under ordinary circumstances*

Hand-wheels of valves controlling emergency bilge suction are to rise at least 0,45 m above the manoeuvring floor.

### **6.12 Water ingress detection**

#### **6.12.1 Specific requirements for bulk, ore and combination carriers**

Unless otherwise specified, the provisions of [6.12.1] apply to ships having one of the following service notations:

- **bulk carrier ESP, bulk carrier CSR ESP, bulk carrier CSR BC-A ESP, bulk carrier CSR BC-B ESP, bulk carrier CSR BC-C ESP, bulk carrier, self-unloading bulk carrier ESP**
- **ore carrier ESP**
- **combination carrier/OBO ESP or combination carrier/OOC ESP.**

- a) Each cargo hold is to be fitted with the water level detectors, giving audible and visual alarms located on the navigation bridge, one when the water level above the inner bottom in any hold reaches a height of 0,5 m and another at a height not less than 15% of the depth of the cargo hold but not more than 2 m.
- b) The water level detectors (see Note 1) are to be fitted in the aft end of the cargo holds. For cargo holds which are used for water ballast, an alarm overriding device may be installed. The visual alarms are to clearly discriminate between the two different water levels detected in each hold.

Note 1: Refer to the Performance standards for water level detectors on bulk carriers and single hold cargo ships other than bulk carriers (IMO Resolution MSC.188(79) Rev.1).

- c) Relevant documentation and drawings are to be submitted for review, including at least:
  - type approval of Water Ingress Detection System, i.e. sensors/detectors wiring and control panel
  - general arrangement of sensors and cables
  - power supply electrical diagram
  - detailed installation drawing of a sensor
  - copy of the DOC of compliance for the carriage of dangerous goods and BC Code attestation, if any.

### **6.12.2 Specific requirements for single hold cargo ships other than bulk carriers**

Unless otherwise specified, the provisions of [6.12.2] apply to ships having a length L of less than 80 m and 500 GT and over, with the service notation **general cargo ship** (see Note 1), **container ship, ro-ro cargo ship, PCTC** (see Note 2), **PCC** (see Note 2), **refrigerated cargo ship, livestock carrier, deck ship** (see Note 2), **liquefied gas carrier** (with independent tanks) (see Note 2) or **supply** (see Note 2).

- a) Ships with a single cargo hold below the freeboard deck, or with cargo holds below the freeboard deck which are not separated by at least one bulkhead made watertight up to the freeboard deck, are to be fitted with water level detectors, giving audible and visual alarms located on the navigation bridge, one when the water level above the inner bottom reaches a height of not less than 0,3 m and another at a height not more than 15% of the mean depth of the cargo hold.
- b) The water level detectors (see [6.12.1], Note 1) are to be fitted in the aft end of the cargo hold or above its lowest part where the inner bottom is not parallel to the designed waterline. Where webs or partial watertight bulkheads are fitted above the inner bottom, the Society may require the fitting of additional detectors. The visual alarms are to clearly discriminate between the two different water level detectors in hold.
- c) The water level detectors need not to be fitted in ships complying with the requirements in [6.12.1] or in ships having watertight side compartments each side of the cargo hold length extending vertically at least from the inner bottom to the freeboard deck.
- d) Relevant documentation and drawings are to be submitted for review, including at least:
  - type approval of Water Ingress Detection System, i.e. sensors/detectors wiring and control panel
  - general arrangement of sensors and cables
  - power supply electrical diagram
  - detailed installation drawing of a sensor
  - copy of the DOC of compliance for the carriage of dangerous goods and BC Code attestation, if any.

Note 1: The requirements also apply to dedicated cement carriers, dedicated forest product carriers, dedicated woodchip carriers, timber and log carriers, with the same conditions.

Note 2: The scope of application for this type of ships is subject to special consideration.

### **6.12.3 Specific requirements for multiple hold cargo ships other than bulk carriers and tankers**

Unless otherwise specified, the provisions of [6.12.3] apply to multiple hold cargo ships of 500 GT and over having the service notation **general cargo ship** (see Note 1), **container ship, ro-ro cargo ship, PCTC** (see Note 2), **PCC** (see Note 2), **refrigerated cargo ship, livestock carrier, deck ship** (see Note 2) or **supply** (see Note 2).

- a) Water level detectors (see [6.12.1], Note 1) are to be fitted in each cargo hold intended for dry cargoes. Water level detectors are not required for cargo holds located entirely above the freeboard deck.
- b) The water level detectors required by item a) are to:
  - 1) give audible and visual alarms at the navigation bridge, one when the water level above the bottom of the cargo hold reaches a height of not less than 0.3 m, and another at a height not less than 15% of the depth of the cargo hold but not more than 2 m; and
  - 2) be fitted at the aft end of the cargo holds. For cargo holds which are occasionally used for water ballast, an alarm overriding device may be installed. The visual alarms shall clearly discriminate between the two different water levels detected in each hold.
- c) As an alternative to the water level detector at a height of not less than 0.3 m as per item b)1), a bilge level sensor (see [6.12.1], Note 1) serving the bilge pumping arrangements required by [6.2] to [6.11] and installed in the cargo hold bilge wells or other suitable location is considered acceptable, subject to:
  - 1) the fitting of the bilge level sensor at a height of not less than 0,3 m at the aft end of the cargo hold; and
  - 2) the bilge level sensor giving audible and visual alarm at the navigation bridge which is clearly distinctive from the alarm given by the other water level detector fitted in the cargo hold.
- d) Relevant documentation and drawings are to be submitted for review, including at least:
  - type approval of water detectors, including sensor wiring and control panel
  - general arrangement of sensors and cables
  - power supply electrical diagram
  - detailed installation drawing of sensors
  - copy of the document of compliance for the carriage of dangerous goods (DoC) and BC Code attestation, if any.

Note 1: The requirements also apply to dedicated cement carriers, dedicated forest product carriers, dedicated woodchip carriers, timber and log carriers, with the same conditions.

Note 2: The scope of application for this type of ships is subject to special consideration.

## 7 Ballast systems

### 7.1 Principles

#### 7.1.1 Independence of ballast lines

Ballast lines are to be entirely independent and distinct from other lines except where permitted in [5.4].

#### 7.1.2 Prevention of undesirable communication between spaces or with the sea

Ballast systems in connection with bilge systems are to be so designed as to avoid any risk of undesirable communication between spaces or with the sea. See [6.2.3].

#### 7.1.3 Alternative carriage of ballast water or other liquids and dry cargo

Holds and deep tanks designed for the alternative carriage of water ballast, fuel oil or dry cargo are to have their filling and suction lines provided with blind flanges or appropriate change-over devices to prevent any mishandling.

#### 7.1.4 Ballast water management systems

In addition to the requirements contained in BWM Convention (2004) and the Code for Approval of Ballast Water Management Systems (BWMS Code), ballast water management systems (BWMS), where fitted, are to comply with the requirements of Ch 1, Sec 13.

### 7.2 Ballast pumping arrangement

#### 7.2.1 Filling and suction pipes

- a) All tanks including aft and fore peak and double bottom tanks intended for ballast water are to be provided with suitable filling and suction pipes connected to special power driven pumps of adequate capacity.
- b) Small tanks used for the carriage of domestic fresh water may be served by hand pumps.
- c) Suctions are to be so positioned that the transfer of sea water can be suitably carried out in the normal operating conditions of the ship. In particular, two suction may be required in long compartments.
- d) On bulk carriers, the means for draining and pumping ballast tanks forward of the collision bulkhead are to comply with [6.6.7].

#### 7.2.2 Pumps

At least two power driven ballast pumps are to be provided, one of which may be driven by the propulsion unit. Sanitary and general service pumps may be accepted as independent power ballast pumps.

Bilge pumps may be used for ballast water transfer provided the provisions of [6.7.3] are fulfilled.

Alternative means of deballasting, such as an eductor, may be accepted in lieu of a second ballast pump, subject to special consideration in each particular case.

#### 7.2.3 Passage of ballast pipes through tanks

If not contained in pipe tunnels, the ballast steel pipes passing through tanks intended to contain fresh water, fuel oil or liquid cargo are:

- to have reinforced thickness, as per Tab 6
- to consist either of a single piece or of several pieces assembled by welding, by reinforced flanges or by devices deemed equivalent for the application considered
- to have a minimal number of joints in these lines
- to have expansion bends in these lines within the tank, where needed
- not to have slip joints.

For ballast lines passing through oil cargo tanks, where permitted, see Pt D, Ch 7, Sec 4, [2.1.3].

#### 7.2.4 Ballast valves and piping arrangements

##### a) Ballast tank valves

Valves controlling flow to ballast tanks are to be arranged so that they remain closed at all times except when ballasting. Where butterfly valves are used, they are to be of a type able to prevent movement of the valve position due to vibration or flow of fluids.

##### b) Remote control valves

Remote control valves, where fitted, are to be arranged so that they close and remain closed in the event of loss of control power. The valves may remain in the last ordered position upon loss of power, provided that there is a readily accessible manual means to close the valves upon loss of power.

Remote control valves are to be clearly identified as to the tanks they serve and are to be provided with position indicators at the ballast control station.

c) Ballast piping arrangements

For ships which are subject to damage stability, the piping arrangements are to comply with the requirements of [5.5] concerning the prevention of progressive flooding. The pipes, if damaged, which are located within the extent of assumed damage, are not to affect damage stability considerations.

### **7.3 Ballast water exchange at sea**

#### **7.3.1 General**

Unless otherwise specified, this sub-article applies to ships assigned with additional class notation **BWE**.

#### **7.3.2 Definitions**

- a) A Ballast Water Exchange (BWE) plan contains procedures and advice to safely and efficiently exchange of ballast water in accordance with applicable structural and stability requirements and taking into account the precautions contained in Appendix 2 of IMO Res. A. 868(20).
- b) Sequential method - a process by which a ballast tank or hold intended for the carriage of water ballast is emptied of at least 95% or more of its volume and then refilled with replacement ballast water.
- c) Flow-through method - a process by which replacement ballast water is pumped into a ballast tank or hold intended for the carriage of water ballast allowing water to flow through overflow or other arrangements. At least three times the tank or hold volume is to be pumped through the tank or hold.
- d) Dilution method - a process by which replacement ballast water is filled through the top of the ballast tank or hold intended for the carriage of water ballast with simultaneous discharge from the bottom at the same flow rate and maintaining a constant level in the tank or hold. At least three times the tank or hold volume is to be pumped through the tank or hold.

#### **7.3.3 Ballast water pumping and piping arrangement**

- a) Ballast water pumping and piping arrangements are to be capable of filling and pumping out any ballast tank and hold intended for the carriage of water ballast under any environmental conditions permitted by the Ballast Water Exchange (BWE) plan.
- b) Where the flow-through method of water ballast exchange is used, the design of water ballast exit arrangements is to be such that, when the tank or hold is overflowing at the maximum pumping capacity available to the tank or hold, it is not subject to a pressure greater than that for which it has been designed.
- c) Every ballast tank and hold intended for the carriage of water ballast is to be provided with isolating valves for filling and /or emptying purposes.
- d) On ships classed for navigation in ice, ship side ballast discharge valves placed above the assigned lightest load line are to be arranged with adequate heating arrangements.

#### **7.3.4 Sea chests and shipside openings intended for ballast water exchange**

The relative positions of ballast water intake and discharge openings are to be such as to preclude as far as practicable the possibility of contamination of replacement ballast water by water which is being pumped out.

#### **7.3.5 Pumps**

- a) The ballast system is to be served by at least two pumps.
- b) The complete ballast water exchange of cargo holds, where used for the carriage of water ballast, is to be possible by one pump within not more than twenty four hours.

#### **7.3.6 System arrangement**

- a) The design of ballast water systems is to allow the ballast water exchange operations with the minimum number of operational procedures.
- b) The internal arrangements of ballast tanks, as well as ballast water piping inlet and outlet arrangements, are to allow, as far as practical, the complete ballast water exchange and the clearing of any sediments.
- c) The design of sea suction line strainers is to be such as to permit cleaning of strainers without interrupting ballast water exchange procedures.

#### **7.3.7 Control features**

- a) Remote control, local control, emergency control
  - Remote control - ballast pumps, and all valves which may be operated during ballast water exchange are to be provided with a means of remote control from a central ballast control station.
  - Local control - a means of local control is to be provided at each ballast pump operated during ballast water exchange.
  - Emergency control - a readily accessible manual means for control of any valve required for ballast water exchange is to be also provided to enable the emergency operation in the event of main control system failure (see also [7.2.4], item b)).

- b) The central ballast control station is to include the following:
- a valve position indicating system,
  - a tank level indicating system,
  - a draft indicating system,
  - a means of communication between the central ballast control station and those spaces containing the means of local control for the ballast pumps and the manually operated independent means of control for the valves.
- c) The ballast pump and ballast valve control systems are to be so arranged that the failure of any component within the control system is not to cause the loss of operation to the pumps or valves of other systems.

### **7.3.8 Tanks**

- a) For ships with an **ICE** or **COLD** class notation (as defined in Pt A, Ch 1, Sec 2, [6.10]) and, generally, where a risk of water ballast freezing exists, water ballast tanks are to be provided with means to prevent the water from freezing. See Pt F, Ch 8, Sec 1, [2.2.2] and Pt F, Ch 8, Sec 4, [6.2.3].
- b) The design of ballast tanks is to allow ready sampling of ballast water and sediments, as far as practical. Providing safe access to the tanks by the fitting of tank hatches as an alternative to manholes is recommended. The area immediately below any tank opening is to be free in order to enable the use of sampling equipment or free access.

### **7.3.9 Special provisions depending on the method of ballast water exchange**

- a) Flow-through method
- The capability of the ballast water system to provide ballast water exchange by the flow-through method without the risk of the tank being subject to a pressure greater than that for which it has been designed is to be demonstrated by water flow calculations and by testing on board. Subject to consideration in each particular case, the calculation may be omitted where justified that total cross-sectional area of all vent pipes fitted to the tank is not less than twice the sectional area of the related filling pipes.
  - The flow-through method with water flowing over the deck is not permitted. The use of collecting pipes, internal overflow pipes or interconnecting pipe/trunk arrangements between tanks may be accepted to avoid water flowing over the deck.
- b) Dilution method
- Where the dilution method is accepted, arrangements are to be made to automatically maintain the ballast water level in the tanks at a constant level. These arrangements are to include the provision of a manual emergency stop for any operating ballast pump, in case of valve malfunction or incorrect control actions.
  - High and low water level alarms are to be provided where maintaining a constant level in a tank is essential to the safety of the ship during ballast water exchange.

## **8 Scuppers and sanitary discharges**

### **8.1 Application**

#### **8.1.1**

- a) This Article applies to:
- scuppers and sanitary discharge systems, and
  - discharges from sewage tanks.
- b) Discharges in connection with machinery operation are dealt with in [2.8].
