(1) NA means that the requirements referred to in the second column of the table are not applicable.

**Table 2 : Documents to be submitted**

No.	Description of the document (1)
1	General layout of cargo pump room with details of: <ul style="list-style-type: none"> <li>bulkhead penetrations</li> <li>gas detection system</li> <li>other alarms and safety arrangements</li> </ul>
2	Diagram of cargo piping system
3	Diagram of the cargo tank venting system with: <ul style="list-style-type: none"> <li>indication of the outlet position</li> <li>details of the pressure/vacuum valves and flame arrestors</li> <li>details of the draining arrangements, if any</li> </ul>
4	Diagram of the cargo tank level gauging system with overfill safety arrangements
5	Diagram of the cargo tank cleaning system
6	Diagram of the bilge and ballast systems serving the spaces located in the cargo area
7	Diagram of the cargo heating systems
8	Diagram of inert gas system with details of the inert gas plant
9	Diagram of gas measurement system for double hull and double bottom spaces

(1) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems

## 2 Piping systems other than cargo piping system

### 2.1 General

#### 2.1.1 Materials

- a) Materials are to comply with the provisions of Pt C, Ch 1, Sec 10.
- b) Spheroidal graphite cast iron may be accepted for bilge and ballast piping within double bottom or cargo tanks.
- c) Grey cast iron may be accepted for ballast lines within cargo tanks, except for ballast lines to forward tanks through cargo tanks.

#### 2.1.2 Independence of piping systems

- a) Unless otherwise specified in this Chapter, bilge, ballast and scupper systems serving spaces located within the cargo area:
  - are to be independent from any piping system serving spaces located outside the cargo area
  - are not to lead outside the cargo area.
- b) Fuel oil systems are to:
  - be independent from the cargo piping system
  - have no connections with pipelines serving cargo or slop tanks.

#### 2.1.3 Passage through cargo tanks and slop tanks

- a) Unless otherwise specified, bilge, ballast and fuel oil systems serving spaces located outside the cargo area are not to pass through cargo tanks or slop tanks. They may pass through ballast tanks or void spaces located within the cargo area.
- b) Where expressly permitted, ballast pipes passing through cargo tanks are to fulfil the following provisions:
  - they are to have welded or heavy flanged joints the number of which is kept to a minimum
  - they are to be of extra-reinforced wall thickness as per Tab 3
  - they are to be adequately supported and protected against mechanical damage.
- c) Where required by Ch 7, Sec 2, [3.4.1], lines of piping which run through cargo tanks are to be fitted with closing devices.

**Table 3 : Minimum wall thickness for carbon steel pipes**

Nominal diameter (mm)	Minimum wall thickness (mm)
50	6,3
100	8,6
125	9,5
150	11,0
200 and above	12,5

#### 2.1.4 Pumps forward of cargo tank area

One or more driven pumps are to be fitted, in a suitable space forward of cargo tanks, for bilge, ballast and, where relevant, fuel oil services.

Note 1: On ships of less than 500 gross tonnage, such pumps may be omitted provided that the above services are ensured by means of equivalent arrangements, subject to the approval of the Society.

## 2.2 Bilge system

### 2.2.1 Bilge pumps

- a) At least one bilge pump is to be provided for draining the spaces located within the cargo area. Cargo pumps or stripping pumps may be used for this purpose.
- b) Bilge pumps serving spaces located within the cargo area are to be located in the cargo pump room or in another suitable space within the cargo area.

### 2.2.2 Draining of spaces located outside the cargo area

For bilge draining of spaces located outside the cargo area, refer to Pt C, Ch 1, Sec 10, [6].

Note 1: Where the bilge pumps are designed to pump from the machinery space only, the internal diameter  $d$ , in mm, of the bilge main may be less than that required in Pt C, Ch 1, Sec 10, [6.8.1] but it is not to be less than that obtained from the following formula:

$$d = 35 + 3\sqrt{L_0(B+D)}$$

where:

$L_0$  : Length of the engine room, in m

- B : Breadth of the ship, in m  
D : Moulded depth of the ship to the bulkhead deck, in m.

In any case, the internal section of the bilge main is not to be less than twice that of the bilge suction pipes determined from Pt C, Ch 1, Sec 10, [6.8.3].

Attention is drawn to the requirements stated in Part C, Chapter 4 as regards the diameter to be adopted for the determination of fire pump capacity.

### 2.2.3 Draining of pump rooms

- a) Arrangements are to be provided to drain the pump rooms by means of power pumps or bilge ejectors.

Note 1: On tankers of less than 500 gross tonnage, the pump rooms may be drained by means of hand pumps with a suction diameter of not less than 50 mm.

- b) Cargo pumps or stripping pumps may be used for draining cargo pump rooms provided that:
- a screw-down non-return valve is fitted on the bilge suction, and
  - a remote control valve is fitted between the pump suction and the bilge distribution box.
- c) Bilge pipe diameter is not to be less than 50 mm.
- d) The bilge system of cargo pump rooms is to be capable of being controlled from outside.
- e) A high level alarm is to be provided. Refer to item d) of [3.5.2].

### 2.2.4 Draining of tunnels and pump rooms other than cargo pump rooms

Arrangements are to be provided to drain tunnels and pump rooms other than cargo pump rooms. Cargo pumps may be used for this service under the provisions of [2.2.3], item b).

### 2.2.5 Draining of cofferdams located at the fore and aft ends of the cargo spaces

- a) When they are not intended to be filled with water ballast, cofferdams located at the fore and aft ends of the cargo spaces are to be fitted with drainage arrangements.
- b) Aft cofferdams adjacent to the cargo pump room may be drained by a cargo pump in accordance with the provisions of [2.2.3], items b) and c), or by bilge ejectors.
- c) Cofferdams located at the fore end of the cargo spaces may be drained by the bilge or ballast pumps required in [2.1.4], or by bilge ejectors.
- d) Drainage of the after cofferdam from the engine room bilge system is not permitted.

Note 1: On tankers of less than 500 gross tonnage, cofferdams may be drained by means of hand pumps with a suction diameter of not less than 50 mm.

### 2.2.6 Drainage of other cofferdams and void spaces located within the cargo area

Other cofferdams and void spaces located within the cargo area and not intended to be filled with water ballast are to be fitted with suitable means of drainage.

## 2.3 Ballast system

### 2.3.1 General

- a) Every crude oil tanker of 20 000 tons deadweight and above and every product carrier of 30 000 tons deadweight and above is to be provided with segregated ballast tanks.
- b) Except where expressly permitted, ballast systems serving segregated ballast tanks are to be completely separated from the cargo oil and fuel oil systems.
- c) In oil tankers of 150 gross tonnage and above, no ballast water is normally to be carried in any fuel oil tank; see Pt C, Ch 1, Sec 10, [7.1.3].
- d) In:
- crude oil tankers of 20 000 tons deadweight and above
  - product carriers of 30 000 tons deadweight and above,
- no ballast water is to be carried in cargo tanks, except in exceptional cases.

### 2.3.2 Ballast pumps

- a) Ballast pumps are to be located in the cargo pump room, or a similar space within the cargo area not containing any source of ignition.
- b) Where installed in the cargo pump room, ballast pumps are to comply with the applicable provisions of [3.2.3].

Note 1: The above provisions do not apply to tankers having one of the following service notations:

- oil tanker, flash point > 60°C
- oil tanker, asphalt carrier
- FLS tanker, flash point > 60°C.

**2.3.3 Pumping arrangements for ballast tanks within the cargo area**

- a) Segregated ballast tanks located within the cargo area are to be served by two different means. At least one of these means is to be a pump or an eductor used exclusively for dealing with ballast.
- b) Pumps, ballast lines, vent lines and other similar equipment serving permanent ballast tanks shall be independent of similar equipment serving cargo tanks and of cargo tanks themselves. Discharge arrangements for permanent ballast tanks sited immediately adjacent to cargo tanks shall be outside machinery spaces and accommodation spaces. Filling arrangements may be in the machinery spaces provided that such arrangements ensure filling from tank deck level and a non-return valve and removable spool piece are fitted in the supply line outside the machinery space.
- c) An eductor situated in the cargo area using water power from pumps in the machinery spaces may be accepted as a means to discharge permanent ballast from tanks and/or double bottoms adjacent to cargo tanks, provided the supply line is above deck level and a non-return valve and removable spool piece are fitted in the supply line outside the machinery space (See Fig 1).

**Figure 1 : Discharge arrangement**

**2.3.4 Pumping arrangement for cofferdams located at the fore and aft ends of the cargo spaces**

Where they are intended to be filled with water ballast, the cofferdams located at the fore and aft ends of the cargo spaces may be emptied by a ballast pump located inside the machinery compartment or the forward space mentioned in [2.1.4], whichever is the case, provided that:

- the suction is directly connected to the pump and not to a piping system serving machinery spaces
- the delivery is directly connected to the ship side.

**2.3.5 Emergency discharge of segregated ballast**

Provisions may be made for emergency discharge of the segregated ballast by means of a connection to a cargo pump through a detachable spool piece provided that:

- non-return valves are fitted on the segregated ballast connections to prevent the passage of oil to the ballast tank, and
- shut-off valves are fitted to shut off the cargo and ballast lines before the spool piece is removed.

The detachable spool piece is to be placed in a conspicuous position in the pump room and a permanent warning notice restricting its use is to be permanently displayed adjacent to it.

**2.3.6 Carriage of ballast water in cargo tanks**

- a) Provisions are to be made for filling cargo tanks with sea water, where permitted. Such ballast water is to be processed and discharged using the equipment referred to in [5].
- b) The sea water inlets and overboard discharges serving cargo tanks for the purpose of a) are not to have any connection with the ballast system of segregated ballast tanks.
- c) Cargo pumps may be used for pumping ballast water to or from the cargo tanks, provided two shut-off valves are fitted to isolate the cargo piping system from the sea inlets and overboard discharges.
- d) Ballast pumps serving segregated ballast tanks may be used for filling the cargo tanks with sea water provided that the connection is made on the top of the tanks and consists of a detachable spool piece and a screw-down non-return valve to avoid siphon effects.

**2.3.7 Ballast pipes passing through tanks**

- a) In oil tankers of 600 tons deadweight and above, ballast piping is not to pass through cargo tanks except in the case of short lengths of piping complying with [2.1.3], item b).
- b) Sliding type couplings are not to be used for expansion purposes where ballast lines pass through cargo tanks. Expansion bends only are permitted.

### **2.3.8 Fore peak ballast system**

The fore peak tank may be ballasted with the system serving other ballast tanks within the cargo area, provided:

- the fore peak tank is considered as a hazardous area, and the hazardous area classification is defined in accordance with Ch 7, Sec 5
- the vent pipe openings are located on open deck at an appropriate distance from sources of ignition. In this respect, the hazardous zones distances are to be defined in accordance with Ch 7, Sec 5
- means are provided, on the open deck, to allow measurement of flammable gas concentrations within the tank by a suitable portable instrument
- the access to the fore peak tank is direct from open deck. Alternatively, indirect access from the open deck to the fore peak tank through an enclosed space may be accepted provided that:
  - In case the enclosed space is separated from the cargo tanks by cofferdams, the access is through a gas tight bolted manhole located in the enclosed space and a warning sign is provided at the manhole stating that the fore peak tank may only be opened after:
    - it has been proven to be gas free; or
    - any electrical equipment which is not certified safe in the enclosed space is isolated.
  - In case the enclosed space has a common boundary with the cargo tanks and is therefore a hazardous area, the enclosed space can be well ventilated.

## **2.4 Air and sounding pipes of spaces other than cargo tanks**

### **2.4.1 Application**

The provisions of [2.4] do not apply to ships having one of the following service notations:

- **oil tanker, flash point > 60°C**
- **oil tanker, asphalt carrier**
- **FLS tanker, flash point > 60°C.**

### **2.4.2 General**

The air and sounding pipes fitted to the following spaces:

- cofferdams located at the fore and aft ends of the cargo spaces
- tanks and cofferdams located within the cargo area and not intended for cargo

are to be led to the open.

### **2.4.3 Air pipes**

The air pipes referred to in [2.4.2] are to be arranged as per Pt C, Ch 1, Sec 10, [9] and are to be fitted with easily removable flame screens at their outlets.

### **2.4.4 Passage through cargo tanks**

In oil tankers of 600 tons deadweight and above, the air and sounding pipes referred to in [2.4.2] are not to pass through cargo tanks except in the following cases:

- short lengths of piping serving ballast tanks
- lines serving double bottom tanks located within the cargo area, except in the case of oil tankers of 5 000 tons deadweight and above

where the provisions of [2.1.3], item b) are complied with.

## **2.5 Scupper pipes**

**2.5.1** Scupper pipes are not to pass through cargo tanks except, where this is impracticable, in the case of short lengths of piping complying with the following provisions:

- they are of steel
- they have only welded or heavy flanged joints the number of which is kept to a minimum
- they are of substantial wall thickness as per Pt C, Ch 1, Sec 10, Tab 25, column 1.

## **2.6 Heating systems intended for cargo**

### **2.6.1 General**

- a) Heating systems intended for cargo are to comply with the relevant requirements of Pt C, Ch 1, Sec 10.
- b) No part of the heating system is normally to exceed 220°C.
- c) Blind flanges or similar devices are to be provided on the heating circuits fitted to tanks carrying cargoes which are not to be heated.

- d) Heating systems are to be so designed that the pressure maintained in the heating circuits is higher than that exerted by the cargo oil. This need not be applied to heating circuits which are not in service provided they are drained and blanked-off.
  - e) Isolating valves are to be provided at the inlet and outlet connections of the tank heating circuits. Arrangements are to be made to allow manual adjustment of the flow.
- Heating pipes and coils inside tanks are to be built of a material suitable for the heated fluid and of reinforced thickness as per Pt C, Ch 1, Sec 10, Tab 6. They are to have welded connections only.

### 2.6.2 Steam heating

To reduce the risk of liquid or gaseous cargo returns inside the engine or boiler rooms, steam heating systems of cargo tanks are to satisfy either of the following provisions:

- they are to be independent of other ship services, except cargo heating or cooling systems, and are not to enter machinery spaces, or
- they are to be provided with an observation tank on the water return system located within the cargo area. However, this tank may be placed inside the engine room in a well-ventilated position remote from boilers and other sources of ignition. Its air pipe is to be led to the open and fitted with a flame arrester.

### 2.6.3 Hot water heating

Hot water systems serving cargo tanks are to be independent of other systems. They are not to enter machinery spaces unless the expansion tank is fitted with:

- means for detection of flammable vapours
- a vent pipe led to the open and provided with a flame arrester.

### 2.6.4 Thermal oil heating

Thermal oil heating systems serving cargo tanks are to be arranged by means of a separate secondary system, located completely within the cargo area. However, a single circuit system may be accepted provided that:

- the system is so arranged as to ensure a positive pressure in the coil of at least 3 m water column above the static head of the cargo when the circulating pump is not in operation
- the thermal oil system expansion tank is to be fitted with high and low level alarms
- means are provided in the expansion tank for detection of flammable cargo vapours. Portable equipment may be accepted
- valves for the individual heating coils are provided with a locking arrangement to ensure that the coils are under static pressure at all times.

## 3 Cargo pumping and piping systems

### 3.1 General

3.1.1 A complete system of pumps and piping is to be fitted for handling the cargo oil. Except where expressly permitted, and namely for the bow and stern cargo loading and unloading stations, this system is not to extend outside the cargo area and is to be independent of any other piping system on board.

### 3.2 Cargo pumping system

#### 3.2.1 Number and location of cargo pumps

- a) Each cargo tank is to be served by at least two separate fixed means of discharging and stripping. However, for tanks fitted with an individual submerged pump, the second means may be portable.
- b) Cargo pumps are to be located:
  - in a dedicated pump room, or
  - on deck, or
  - when designed for this purpose, within the cargo tanks.

#### 3.2.2 Use of cargo pumps

- Except where expressly permitted in [2.2] and [2.3], cargo pumps are to be used exclusively for handling the liquid cargo and are not to have any connections to compartments other than cargo tanks.
- Subject to their performance, cargo pumps may be used for tank stripping.
- Cargo pumps may be used, where necessary, for the washing of cargo tanks.

**3.2.3 Cargo pumps drive**

- a) Prime movers of cargo pumps are not to be located in the cargo area, except in the following cases:
  - steam driven machine supplied with steam having a temperature not exceeding 220°C
  - hydraulic motors
  - electric motors in accordance with Ch 7, Sec 5, [2].
- b) Pumps with a submerged electric motor are not permitted in cargo tanks.
- c) Where cargo pumps are driven by a machine which is located outside the cargo pump room, the provisions of item a) of [3.5.2] are to be complied with.

**3.2.4 Design of cargo pumps**

- a) Materials of cargo pumps are to be suitable for the products carried.
- b) The delivery side of cargo pumps is to be fitted with relief valves discharging back to the suction side of the pumps (bypass) in closed circuit. Such relief valves may be omitted in the case of centrifugal pumps with a maximum delivery pressure not exceeding the design pressure of the piping, with the delivery valve closed.
- c) Pump casings are to be fitted with temperature sensing devices; see Tab 4.

Note 1: The provisions of item c) above do not apply to ships having one of the following service notations:

- **oil tanker, flash point > 60°C**
- **oil tanker, asphalt carrier**
- **FLS tanker, flash point > 60°C.**

**3.2.5 Monitoring of cargo pumps**

Cargo pumps are to be monitored as required in Tab 4.

**Table 4 : Monitoring of cargo pumps**

Equipment, parameter	Alarm	Indication	Comments
pump, discharge pressure	L	Local	<ul style="list-style-type: none"> <li>• on the pump (1), or</li> <li>• next to the unloading control station</li> </ul>
pump casing, temperature (2)	H (2)		visual and audible, in cargo control room or pump control station
bearings, temperature (2)	H (2)		visual and audible, in cargo control room or pump control station
bulkhead shaft gland, temperature (2)	H (2)		visual and audible, in cargo control room or pump control station
(1) and next to the driving machine if located in a separate compartment (2) not required for tankers having one of the following service notations: <ul style="list-style-type: none"> <li>• <b>oil tanker, flash point &gt; 60°C</b></li> <li>• <b>oil tanker, asphalt carrier</b></li> <li>• <b>FLS tanker, flash point &gt; 60°C.</b></li> </ul>			

**3.2.6 Control of cargo pumps**

Cargo pumps are to be capable of being stopped from:

- a position outside the pump room, and
- a position next to the pumps.

**3.3 Cargo piping design**

**3.3.1 General**

- a) Unless otherwise specified, cargo piping is to be designed and constructed according to the requirements of Pt C, Ch 1, Sec 10 applicable to piping systems of:
  - class III, in the case of ships having the service notation **oil tanker**
  - class II, in the case of ships having the service notation **FLS tanker**, with the exception of cargo pipes and accessories having an open end or situated inside cargo tanks, for which class III may be accepted.
- b) For tests, refer to [6].

**3.3.2 Materials**

- a) *For the protection of cargo tanks carrying crude oil and petroleum products having a flash point not exceeding 60°C, materials readily rendered ineffective by heat are not to be used for valves, fittings, cargo vent piping and cargo piping so as to prevent the spread of fire to the cargo.*
- b) Cargo piping is, in general, to be made of steel or cast iron.
- c) Valves, couplings and other end fittings of cargo pipe lines for connection to hoses are to be of steel or other suitable ductile material.

- d) Spheroidal graphite cast iron may be used for cargo oil piping within the double bottom or cargo tanks.
- e) Grey cast iron may be accepted for cargo oil lines:
- within cargo tanks, and
  - on the weather deck for pressure up to 1,6 Mpa.
- It is not to be used for manifolds and their valves or fittings connected to cargo handling hoses.
- f) Plastic pipes may be used in the conditions specified in Pt C, Ch 1, App 3. Arrangements are to be made to avoid the generation of static electricity.

### **3.3.3 Connection of cargo pipe lengths**

Cargo pipe lengths may be connected either by means of welded joints or, unless otherwise specified, by means of flange connections.

### **3.3.4 Expansion joints**

- a) Where necessary, cargo piping is to be fitted with expansion joints or bends.
- b) Expansion joints including bellows are to be of a type approved by the Society.
- c) Expansion joints made of non-metallic material may be accepted only inside tanks and provided they are:
- of an approved type
  - designed to withstand the maximum internal and external pressure
  - electrically conductive.
- d) In ships having the service notation **oil tanker**, sliding type couplings are not to be used for expansion purposes where lines for cargo oil pass through tanks for segregated ballast.
- e) In ships having the service notation **FLS tanker**, slip joints are not to be used for cargo piping systems with the exception of pipe sections inside cargo tanks served by such sections.

### **3.3.5 Valves with remote control**

- a) Valves with remote control are to comply with Pt C, Ch 1, Sec 10, [2.7.3].
- b) Submerged valves are to be remote controlled. In the case of a hydraulic remote control system, control boxes are to be provided outside the tank, in order to permit the emergency control of valves.
- c) Valve actuators located inside cargo tanks are not to be operated by means of compressed air.

### **3.3.6 Cargo hoses**

- a) Cargo hoses are to be of a type approved by the Society for the intended conditions of use.
- b) Hoses subject to tank pressure or pump discharge pressure are to be designed for a bursting pressure not less than 5 times the maximum pressure under cargo transfer conditions.
- c) Unless bonding arrangements complying with Section 6 are provided, the ohmic electrical resistance of cargo hoses is not to exceed  $10^6 \Omega$ .

## **3.4 Cargo piping arrangement and installation**

### **3.4.1 Cargo pipes passing through tanks or compartments**

- a) Cargo piping is not to pass through tanks or compartments located outside the cargo area.
- b) Cargo piping and similar piping to cargo tanks is not to pass through ballast tanks except in the case of short lengths of piping complying with [2.1.3], item b).
- c) Cargo piping may pass through vertical fuel oil tanks adjacent to cargo tanks on condition that the provisions of [2.1.3], item b) are complied with.
- d) Cargo piping passing through cargo tanks is to comply with the provisions of Ch 7, Sec 2, [3.4.1].

### **3.4.2 Cargo piping passing through bulkheads**

Cargo piping passing through bulkheads is to be so arranged as to preclude excessive stresses at the bulkhead. Bolted flanges are not to be used in the bulkhead.

### **3.4.3 Valves**

- a) Stop valves are to be provided to isolate each tank.
- b) A stop valve is to be fitted at each end of the cargo manifold.
- c) When a cargo pump in the cargo pump room serves more than one cargo tank, a stop valve is to be fitted in the cargo pump room on the line leading to each tank.

- d) Main cargo oil valves located in the cargo pump room below the floor gratings are to be remote controlled from a position above the floor.
- e) Valves are also to be provided where required by Ch 7, Sec 2, [3.4.1].

**3.4.4 Prevention of the generation of static electricity**

- a) In order to avoid the generation of static electricity, the loading pipes are to be led as low as practicable in the tank.
- b) Cargo pipe sections and their accessories are to be electrically bonded together and to the ship’s hull.

Note 1: The provisions of [3.4.4] do not apply to ships having one of the following service notations:

- oil tanker / flash point > 60°C
- oil tanker / asphalt carrier
- FLS tanker, flash point > 60°C.

**3.4.5 Bow or stern cargo loading and unloading arrangements**

Where the ship is arranged for loading and unloading outside the cargo area, the following provisions are to be complied with:

- a) the piping outside the cargo area is to be fitted with a shut-off valve at its connection with the piping system within the cargo area and separating means such as blank flanges or removable spool pieces are to be provided when the piping is not in use, irrespective of the number and type of valves in the line
- b) the shore connection is to be fitted with a shut-off valve and a blank flange
- c) pipe connections outside the cargo area are to be of welded type only
- d) arrangements are made to allow the piping outside the cargo area to be efficiently drained and purged.

Note 1: The provisions of [3.4.5] do not apply to ships having one of the following service notations:

- oil tanker / flash point > 60°C
- oil tanker / asphalt carrier
- FLS tanker, flash point > 60°C.

**3.4.6 Draining of cargo pumps and oil lines**

Every oil tanker required to be provided with segregated ballast tanks or fitted with a crude oil washing system is to comply with the following requirements:

- a) it is to be equipped with oil piping so designed and installed that oil retention in the lines is minimised, and
- b) means are to be provided to drain all cargo pumps and all oil lines at the completion of cargo discharge, where necessary by connection to a stripping device. The line and pump drainings are to be capable of being discharged both ashore and to a cargo tank or slop tank. For discharge ashore, a special small diameter line having a cross-sectional area not exceeding 10% of the main cargo discharge line is to be provided and is to be connected on the downstream side of the tanker’s deck manifold valves, both port and starboard, when the cargo is being discharged; see Fig 2.

For oil tankers fitted with a crude oil washing system, refer also to Ch 7, App 2, [2.4.5].

**Figure 2 : Connection of small diameter line to the manifold valve**

**3.4.7 Cleaning and gas-freeing**

- a) The cargo piping system is to be so designed and arranged as to permit its efficient cleaning and gas-freeing.
- b) Requirements for inert gas systems are given in Ch 7, Sec 6, [5].

**3.5 Arrangement of cargo pump rooms**

**3.5.1 Pump room ventilation**

In addition to the provisions of Ch 7, Sec 2, [2.3.3], the ventilation of the cargo pump room is to comply with the following provisions:

- a) *Cargo pump rooms are to be mechanically ventilated and discharges from exhaust fans are to be led to a safe place on the open deck. The ventilation of these rooms is to have sufficient capacity to minimize the possibility of accumulation of flammable vapours. The number of changes of air is to be at least 20 per hour, based upon the gross volume of the space. The air ducts are to be arranged so that all of the space is effectively ventilated. The ventilation is to be of the suction type using fans of the non-sparking type.*
- b) The ventilation ducts are to be so arranged that their suction is just above the transverse floor plates or bottom longitudinals in the vicinity of bilges.
- c) An emergency intake located about 2 m above the pump room lower grating is to be provided. It is to be fitted with a damper capable of being opened or closed from the exposed main deck and lower grating level.  
Ventilation through the emergency intake is to be effective when the lower intakes are sealed off due to flooding in the bilges.
- d) The foregoing exhaust system is in association with open grating floor plates to allow the free flow of air.
- e) Arrangements involving a specific ratio of areas of upper emergency and lower main ventilator openings, which can be shown to result in at least the required 20 air changes per hour through the lower inlets, can be adopted without the use of dampers. When the lower access inlets are closed then at least 15 air changes per hour should be obtained through the upper inlets.

### **3.5.2 Measures to prevent explosions**

The provisions of [3.5.2] do not apply to ships having one of the following service notations:

- **oil tanker, flash point > 60°C**
- **oil tanker, asphalt carrier**
- **FLS tanker, flash point > 60°C,**

except where the cargo is carried at a temperature within 15°C of its flash point.

- a) Where cargo pumps, ballast pumps and stripping pumps are driven by a machine which is located outside the cargo pump room, the following arrangements are to be made:
  - 1) drive shafts are to be fitted with flexible couplings or other means suitable to compensate for any misalignment
  - 2) the shaft bulkhead or deck penetration is to be fitted with a gas-tight gland of a type approved by the Society. The gland is to be efficiently lubricated from outside the pump room and so designed as to prevent overheating. The seal parts of the gland are to be of a material that cannot initiate sparks. The glands are to be constructed and fitted in accordance with the relative rules for fittings attached to watertight bulkheads, and if a bellows piece is incorporated in the design, it should be pressure tested before fitting.
  - 3) *Temperature sensing devices are to be fitted for bulkhead shaft glands, bearings and pump casings. A continuous audible and visual alarm signal shall be automatically effected in the cargo control room or the pump control station.*
- b) To discourage personnel from entering the cargo pump room when the ventilation is not in operation, the *lighting in the cargo pump room is to be interlocked with ventilation such that ventilation is to be in operation to energise the lighting.*  
*Failure of the ventilation system is not to cause the lighting to go out.*

Where the lighting in cargo pump rooms can be commonly used as the emergency lighting, this lighting should be interlocked with the ventilation systems. However, this interlock should not prevent operation of the emergency lighting in case of loss of the main source of electrical power.

- c) *A system for continuously monitoring the concentration of hydrocarbon gases is to be fitted. Sampling points or detector heads are to be located in suitable positions in order that potentially dangerous leakages are readily detected. Sequential sampling is acceptable as long as it is dedicated for the pump room only, including exhaust ducts, and the sampling time is reasonably short. Detection positions are the zones where air circulation is reduced (e.g. recessed corners). When the hydrocarbon gas concentration reaches a pre-set level, which shall not be higher than 10 per cent of the lower flammable limit (LFL), a continuous audible and visual alarm signal shall be automatically effected in the pump room, engine control room, cargo control room and navigation bridge to alert personnel to the potential hazard.*
- d) *All pump rooms are to be provided with bilge level monitoring devices together with appropriately located alarms or bilge high level alarms.*  
High liquid level in the bilges is to activate an audible and visual alarm in the cargo control room and on the navigation bridge.

## **3.6 Design of integrated cargo and ballast systems on tankers**

### **3.6.1 Application**

The following requirements are applicable to integrated cargo and ballast systems installed on tankers (i.e. cargo ships constructed or adapted for the carriage of liquid cargoes in bulk), irrespective of the size or type of the tanker.

Within the scope of these requirements, integrated cargo and ballast system means any integrated hydraulic and/or electric system used to drive both cargo and ballast pumps (including active control and safety systems and excluding passive components, e.g. piping).

**3.6.2 Functional requirements**

The operation of cargo and/or ballast systems may be necessary, under certain emergency circumstances or during the course of navigation, to enhance the safety of tankers.

As such, measures are to be taken to prevent cargo and ballast pumps becoming inoperative simultaneously due to a single failure in the integrated cargo and ballast system, including its control and safety systems.

**3.6.3 Design features**

The following design features are, inter alia, to be fitted:

- a) The emergency stop circuits of the cargo and ballast systems are to be independent from the circuits for the control systems. A single failure in the control system circuits or the emergency stop circuits are not to render the integrated cargo and ballast system inoperative.
- b) Manual emergency stops of the cargo pumps are to be arranged in a way that they are not to cause the stop of the power pack making ballast pumps inoperable.
- c) The control systems are to be provided with backup power supply, which may be satisfied by a duplicate power supply from the main switch board. The failure of any power supply is to provide audible and visible alarm activation at each location where the control panel is fitted.
- d) In the event of failure of the automatic or remote control systems, a secondary means of control is to be made available for the operation of the integrated cargo and ballast system. This is to be achieved by manual overriding and/or redundant arrangements within the control systems.

**4 Cargo tanks and fittings**

**4.1 Application**

**4.1.1**

- a) The provisions of Article [4] apply to cargo tanks and slop tanks.
- b) The provisions of Article [4] apply for the various service notations in accordance with Tab 5.

**Table 5 : Requirements applicable to cargo tanks according to the service notations**

Reference of item	Subject	Service notations to which the item applies	Substitutive requirements for service notations to which the item does not apply
[4.2]	tank venting	<ul style="list-style-type: none"> <li>• <b>oil tanker</b></li> <li>• <b>FLS tanker</b></li> </ul>	<ul style="list-style-type: none"> <li>• The relevant provisions of Pt C, Ch 1, Sec 10, [9] and Pt C, Ch 1, Sec 10, [11] are to be complied with.</li> <li>• Tank venting systems are to open to the atmosphere at a height of at least 760 mm above the weather deck <b>(1)</b>.</li> <li>• Tanks may be fitted with venting systems of the open type provided with a flame screen.</li> </ul>
[4.3]	tank purging/gas-freeing	<ul style="list-style-type: none"> <li>• <b>oil tanker</b></li> <li>• <b>FLS tanker</b></li> </ul>	No requirement
[4.4]	tank level gauging	<ul style="list-style-type: none"> <li>• <b>oil tanker</b></li> <li>• <b>FLS tanker</b></li> </ul>	<ul style="list-style-type: none"> <li>• The relevant provisions of Pt C, Ch 1, Sec 10, [9] and Pt C, Ch 1, Sec 10, [11] are to be complied with.</li> <li>• Tanks may be fitted with gauging systems of the open type, such as a hand sounding pipe or other portable gauging devices.</li> </ul>
[4.5]	protection against tank overload	<ul style="list-style-type: none"> <li>• <b>oil tanker</b></li> <li>• <b>oil tanker, flash point &gt; 60°C</b></li> <li>• <b>oil tanker, asphalt carrier</b></li> <li>• <b>FLS tanker</b></li> <li>• <b>FLS tanker, flash point &gt; 60°C</b></li> </ul>	
[4.6]	tank washing	<ul style="list-style-type: none"> <li>• <b>oil tanker</b></li> <li>• <b>oil tanker, flash point &gt; 60°C</b></li> <li>• <b>oil tanker, asphalt carrier</b></li> </ul>	
<b>(1)</b> For ships having the notation <b>oil tanker, flash point &gt; 60°C</b> and carrying bulk cargoes at a temperature exceeding flash point-15°C, this height is to be increased to 2,4 m.			

## 4.2 Cargo tank venting

### 4.2.1 Principle

Cargo tanks are to be provided with venting systems *entirely distinct from the air pipes of the other compartments of the ship. The arrangements and position of openings in the cargo tank deck from which emission of flammable vapours can occur are to be such as to minimise the possibility of flammable vapours being admitted to enclosed spaces containing a source of ignition, or collecting in the vicinity of deck machinery and equipment which may constitute an ignition hazard.*

### 4.2.2 Design of venting arrangements

*The venting arrangements are to be so designed and operated as to ensure that neither pressure nor vacuum in cargo tanks exceeds design parameters and be such as to provide for:*

- a) *the flow of the small volumes of vapour, air or inert gas mixtures caused by thermal variations in a cargo tank in all cases through pressure/vacuum valves, and*
- b) *the passage of large volumes of vapour, air or inert gas mixtures during cargo loading and ballasting, or during discharging,*
- c) *a secondary means of allowing full flow relief of vapour, air or inert gas mixtures to prevent overpressure or underpressure in the event of failure of the arrangements in b). In addition, the secondary means shall be capable of preventing over-pressure or under-pressure in the event of damage to, or inadvertent closing of, the means of isolation required in [4.2.3] item b). Alternatively, pressure sensors may be fitted in each tank protected by the arrangement required in b), with a monitoring system in the ship's cargo control room or the position from which cargo operations are normally carried out. Such monitoring equipment is also to provide an alarm facility which is activated by detection of overpressure or underpressure conditions within a tank.*

*Note 1: Note 1: For ships that apply pressure sensors in each tank as an alternative secondary means of venting as allowed above, the setting of the over-pressure alarm shall be above the pressure setting of the P/V valve and the setting of the under-pressure alarm shall be below the vacuum setting of the P/V valve. The alarm settings are to be within the design pressures of the cargo tanks. The settings are to be fixed and not arranged for blocking or adjustment in operation. However, for ships that carry different types of cargo and use P/V valves with different settings (one setting for each type of cargo), the settings may be adjusted to account for the different types of cargo.*

### 4.2.3 Combination of venting arrangements

- a) *The venting arrangements in each cargo tank may be independent or combined with other cargo tanks and may be incorporated into the inert gas piping.*
- b) *Where the arrangements are combined with other cargo tanks, either stop valves or other acceptable means are to be provided to isolate each cargo tank. Where stop valves are fitted, they are to be provided with locking arrangements which are to be under the control of the responsible ship's officer. There is to be a clear visual indication of the operational status of the valves or other acceptable means. Where tanks have been isolated, it is to be ensured that relevant isolating valves are opened before cargo loading or ballasting or discharging of those tanks is commenced. Any isolation must continue to permit the flow caused by thermal variations in a cargo tank in accordance with [4.2.2].  
Any isolation shall also continue to permit the passage of large volumes of vapour, air or inert gas mixtures during cargo loading and ballasting, or during discharging in accordance with [4.2.2].*
- c) *If cargo loading and ballasting or discharging of a cargo tank or cargo tank group is intended, which is isolated from a common venting system, that cargo tank or cargo tank group is to be fitted with a means for overpressure or underpressure protection as required in [4.2.2].*

### 4.2.4 Arrangement of vent lines

*The venting arrangements are to be connected to the top of each cargo tank and are to be self-draining to the cargo tanks under all normal conditions of trim and list of the ship. Where it may not be possible to provide self-draining lines, permanent arrangements are to be provided to drain the vent lines to a cargo tank.*

Plugs or equivalent means are to be provided on the lines after the safety relief valves.

### 4.2.5 Pressure/vacuum valves

- a) *Pressure/vacuum valves are to be set at a positive pressure not exceeding 0,021 N/mm<sup>2</sup> and at a negative pressure not exceeding 0,007 N/mm<sup>2</sup>.*

*Note 1: Higher setting values not exceeding 0,07 N/mm<sup>2</sup> may be accepted in positive pressure if the scantlings of the tanks are appropriate.*

- b) *Pressure/vacuum valves required by [4.2.2] may be provided with a bypass when they are located in a vent main or masthead riser. Where such an arrangement is provided, there are to be suitable indicators to show whether the bypass is open or closed.*
- c) *Pressure/vacuum valves are to be of a type approved by the Society in accordance with Ch 7, App 1.*
- d) *Pressure/vacuum valves are to be readily accessible.*
- e) *Pressure/vacuum valves are to be provided with a manual opening device so that valves can be locked on open position. Locking means on closed position are not permitted.*

#### **4.2.6 Vent outlets**

Openings for pressure release required by [4.2.2] item a) and vent outlets for cargo loading, discharging and ballasting required by [4.2.2] item b) are to:

- a) permit:
  - the free flow of vapour mixtures, or
  - the throttling of the discharge of the vapour mixtures to achieve a velocity of not less than 30 m/s,
- b) be so arranged that the vapour mixture is discharged vertically upwards,
- c) where the method is by free flow of vapour mixtures, be such that the outlet is not less than 6 m above the cargo tank deck or fore and aft gangway if situated within 4 m of the gangway and located not less than 10 m measured horizontally from the nearest air intakes and openings to enclosed spaces containing a source of ignition and from deck machinery, which may include anchor windlass and chain locker openings, and equipment which may constitute an ignition hazard,
- d) where the method is by high velocity discharge, be located at a height not less than 2 m above the cargo tank deck and not less than 10 m measured horizontally from the nearest air intakes and openings to enclosed spaces containing a source of ignition and from deck machinery, which may include anchor windlass and chain locker openings, and equipment which may constitute an ignition hazard. These outlets are to be provided with high velocity devices of a type approved by the Society,
- e) be designed on the basis of the maximum designed loading rate multiplied by a factor of at least 1,25 to take account of gas evolution, in order to prevent the pressure in any cargo tank from exceeding the design pressure. The Master is to be provided with information regarding the maximum permissible loading rate for each cargo tank and in the case of combined venting systems, for each group of cargo tanks.

#### **4.2.7 High velocity valves**

- a) High velocity valves are to be readily accessible.
- b) High velocity valves not required to be fitted with flame arresters (see [4.2.8]) are not to be capable of being locked on open position.

#### **4.2.8 Prevention of the passage of flame into the tanks**

- a) The venting system is to be provided with devices to prevent the passage of flame into the cargo tanks. The design, testing and locating of these devices are to comply with Ch 7, App 1.
- b) A flame arresting device integral to the venting system may be accepted.
- c) Flame screens and flame arresters are to be designed for easy overhauling and cleaning.
- d) Ullage openings shall not be used for pressure equalization. They shall be provided with self-closing and tightly sealing covers. Flame arresters and screens are not permitted in these openings.

#### **4.2.9 Prevention of liquid rising in the venting system**

- a) Provisions are to be made to prevent liquid rising in the venting system; refer to [4.5].
- b) Cargo tanks gas venting systems are not to be used for overflow purposes.
- c) Spill valves are not considered equivalent to an overflow system.

#### **4.2.10 Additional provisions for ships fitted with an inert gas system**

- a) On ships fitted with an inert gas system, one or more pressure/vacuum-breaking devices are to be provided to prevent the cargo tanks from being subject to:
  - 1) a positive pressure in excess of the test pressure of the cargo tank if the cargo were to be loaded at the maximum rated capacity and all other outlets are left shut, and
  - 2) a negative pressure in excess of 700 mm water gauge if cargo were to be discharged at the maximum rated capacity of the cargo pumps and the inert gas blowers were to fail.Such devices are to be installed on the inert gas main unless they are installed in the venting system required by [4.2.1] or on individual cargo tanks.
- b) The location and design of the devices referred to in paragraph a) above are to be in accordance with requirements [4.2.1] to [4.2.9].

### **4.3 Cargo tank inerting, purging and/or gas-freeing**

#### **4.3.1 General**

- a) Arrangements are to be made for purging and/or gas-freeing of cargo tanks. The arrangements are to be such as to minimise the hazards due to the dispersal of flammable vapours in the atmosphere and to flammable mixtures in a cargo tank. Accordingly, the provisions of [4.3.2] and [4.3.3], as applicable, are to be complied with.

- b) *The arrangements for inerting, purging or gas-freeing of empty tanks as required in Pt C, Ch 4, Sec 15, [13.2.1], item b), are to be to the satisfaction of the Society and are to be such that the accumulation of hydrocarbon vapours in pockets formed by the internal structural members in a tank is minimized.*
- c) Ventilation/gas-freeing lines between fans and cargo tanks are to be fitted with means, such as detachable spool pieces, to prevent any back-flow of hydrocarbon gases through the fans when they are not used.
- d) Discharge outlets are to be located at least 10 m measured horizontally from the nearest air intake and openings to enclosed spaces with a source of ignition and from deck machinery equipment which may constitute an ignition hazard.

#### **4.3.2 Ships provided with an inert gas system**

The following provisions apply to ships provided with an inert gas system:

- a) *On individual cargo tanks the gas outlet pipe, if fitted, is to be positioned as far as practicable from the inert gas / air inlet and in accordance with [4.2]. The inlet of such outlet pipes may be located either at the deck level or at not more than 1 m above the bottom of the tank.*
- b) *The cross-sectional area of such gas outlet pipe referred to in a) above is to be such that an exit velocity of at least 20 m/s can be maintained when any three tanks are being simultaneously supplied with inert gas. Their outlets are to extend not less than 2 m above deck level.*
- c) *Each gas outlet referred to in b) above is to be fitted with suitable blanking arrangements.*
- d) The arrangement of inert gas and cargo piping systems is to comply with the provisions of Pt C, Ch 4, Sec 15, [13.2.3], item b) 7).
- e) *The cargo tanks are first to be purged in accordance with the provisions of a) to d) above until the concentration of hydrocarbon vapours in the cargo tanks has been reduced to less than 2% by volume. Thereafter, gas-freeing may take place at the cargo tank deck level.*

#### **4.3.3 Ships not provided with an inert gas system**

*When the ship is not provided with an inert gas system, the operation is to be such that the flammable vapour is discharged initially:*

- a) *through the vent outlets as specified in [4.2.6], or*
- b) *through outlets at least 2 m above the cargo tank deck level with a vertical efflux velocity of at least 30 m/s maintained during the gas-freeing operation, or*
- c) *through outlets at least 2 m above the cargo tank deck level with a vertical efflux velocity of at least 20 m/s and which are protected by suitable devices to prevent the passage of flame.*

*When the flammable vapour concentration at the outlet has been reduced to 30% of the lower flammable limit, gas-freeing may thereafter be continued at cargo tank deck level.*

### **4.4 Cargo tank level gauging systems**

#### **4.4.1 General**

- a) Each cargo or slop tank is to be fitted with a level gauging system indicating the liquid level along the entire height of the tank. Unless otherwise specified, the gauge may be portable or fixed with local reading.
- b) Gauging devices and their remote reading systems are to be type approved.
- c) Ullage openings and other gauging devices likely to release cargo vapour to the atmosphere are not to be arranged in enclosed spaces.

#### **4.4.2 Definitions**

- a) A “restricted gauging device” means a device which penetrates the tank and which, when in use, permits a small quantity of vapour or liquid to be exposed to the atmosphere. When not in use, the device is completely closed. Examples are sounding pipes.
- b) A “closed gauging device” means a device which is separated from the tank atmosphere and keeps tank contents from being released. It may:
  - penetrate the tank, such as float-type systems, electric probe, magnetic probe or protected sight glass,
  - not penetrate the tank, such as ultrasonic or radar devices.
- c) An “indirect gauging device” means a device which determines the level of liquid, for instance by means of weighing or pipe flow meter.

#### **4.4.3 Tankers fitted with an inert gas system**

- a) In tankers fitted with an inert gas system, the gauging devices are to be of the closed type.
- b) Use of indirect gauging devices will be given special consideration.

#### **4.4.4 Tankers not fitted with an inert gas system**

- a) In tankers not fitted with an inert gas system, the gauging devices are to be of the closed or restricted types. Ullage openings may be used only as a reserve sounding means and are to be fitted with a watertight closing appliance.
- b) Where restricted gauging devices are used, provisions are to be made to:
  - avoid dangerous escape of liquid or vapour under pressure when using the device
  - relieve the pressure in the tank before the device is operated.
- c) Where used, sounding pipes are to be fitted with a self-closing blanking device.

### **4.5 Protection against tank overfilling**

#### **4.5.1 General**

- a) Provisions are to be made to guard against liquid rising in the venting system of cargo or slop tanks to a height which would exceed the design head of the tanks. This is to be accomplished by high level alarms or overflow control systems or other equivalent means, together with gauging devices and cargo tank filling procedures.

Note 1: For ships having the service notation **FLS tanker**, only high level alarms are permitted.

- b) Sufficient ullage is to be left at the end of tank filling to permit free expansion of liquid during carriage.
- c) High level alarms, overflow control systems and other means referred to in a) are to be independent of the gauging systems referred to in [4.4].

#### **4.5.2 High level alarms**

- a) High level alarms are to be type approved.
- b) High level alarms are to give an audible and visual signal at the control station, where provided.

#### **4.5.3 Other protection systems**

- a) Where the tank level gauging systems, cargo and ballast pump control systems and valve control systems are centralised in a single location, the provisions of [4.5.1] may be complied with by the fitting of a level gauge for the indication of the end of loading, in addition to that required for each tank under [4.4]. The readings of both gauges for each tank are to be as near as possible to each other and so arranged that any discrepancy between them can be easily detected.
- b) Where a tank can be filled only from other tanks, the provisions of [4.5.1] are considered as complied with.

### **4.6 Tank washing systems**

#### **4.6.1 General**

- a) Adequate means are to be provided for cleaning the cargo tanks.
- b) Every crude oil tanker of 20 000 tons deadweight and above is to be fitted with a cargo tank cleaning system using crude oil washing and complying with Ch 7, App 2.
- c) Crude oil washing systems fitted on oil tankers other than crude oil tankers of 20 000 tons deadweight or above are to comply with the provisions of Ch 7, App 2 related to safety.

#### **4.6.2 Washing machines**

- a) Tank washing machines are to be of a type approved by the Society.
- b) Washing machines are to be made of steel or other electricity conducting materials with a limited propensity to produce sparks on contact.

#### **4.6.3 Washing pipes**

- a) Washing pipes are to be built, fitted, inspected and tested in accordance with the applicable requirements of Pt C, Ch 1, Sec 10, depending on the kind of washing fluid, water or crude oil.
- b) Crude oil washing pipes are also to satisfy the requirements of Article [3.3].

#### **4.6.4 Use of crude oil washing machines for water washing operations**

Crude oil washing machines may be connected to water washing pipes, provided that isolating arrangements, such as a valve and a detachable pipe section, are fitted to isolate water pipes.

#### **4.6.5 Installation of washing systems**

- a) Tank cleaning openings are not to be arranged in enclosed spaces.
- b) The complete installation is to be permanently earthed to the hull.

## 5 Prevention of pollution by cargo oil

### 5.1 General

#### 5.1.1 Application

- a) Unless otherwise specified, the provisions of [5.3] apply only to ships having the service notations **oil tanker** or **oil tanker, flash point > 60°C** and of 150 gross tonnage and above.
- b) The provisions of Ch 7, Sec 2, [3.6] are to be complied with.

#### 5.1.2 Provisions for oil tankers of less than 150 gross tonnage

The control of discharge for ships having the service notations **oil tanker** or **oil tanker, flash point > 60°C** and of less than 150 gross tonnage is to be effected by the retention of oil on board with subsequent discharge of all contaminated washings to reception facilities unless adequate arrangements are made to ensure that the discharge of any effluent which is allowed to be discharged into the sea is effectively monitored to ensure that the total quantity of oil discharged into the sea does not exceed 1/30 000 of the total quantity of the particular cargo of which the residue formed a part.

#### 5.1.3 Exemptions

- a) The provisions of [5.3] may be waived in the following cases:
  - oil tankers which engage exclusively on both voyages of 72 hours or less in duration and within 50 miles from the nearest land, provided that the oil tanker is engaged exclusively in trades between ports or terminals within a State Party to MARPOL 73/78 Convention. Any such waiver is to be subject to the requirements that the oil tanker is to retain on board all oily mixtures for subsequent discharge to reception facilities and to the determination by the Administration that facilities available to receive such oily mixtures are adequate,
  - oil tankers carrying products which through their physical properties inhibit effective product/water separation and monitoring, for which the control of discharge is to be effected by the retention of residues on board with discharge of all contaminated washings to reception facilities.
- b) Where, in the view of the Society, the equipment referred to in [5.3.1] and [5.3.2] is not obtainable for the monitoring of discharge of oil refined products (white oils), compliance with such requirements may be waived provided that discharge is performed only in compliance with the applicable procedures.

## 5.2 Discharge into the sea of cargo oil or oily mixtures

**5.2.1** Any discharge into the sea of cargo oil or oily mixtures is to be prohibited except when all the following conditions are satisfied:

- a) the tanker is not within a special area,  
*Note 1:* Special areas are defined in MARPOL Annex I, regulation (9).
- b) the tanker is more than 50 nautical miles from the nearest land.
- c) the tanker is proceeding on route.
- d) the instantaneous rate of discharge of oil content does not exceed 30 litres per nautical mile.
- e) the total quantity of oil discharged into the sea does not exceed 1/30000 of the total quantity of the particular cargo of which the residue formed a part.
- f) the tanker has in operation an oil discharge and monitoring system complying with the provisions of [5.3] and a slop tank arrangement as required by Ch 7, Sec 2, [3.6].

**5.2.2** The provisions of [5.2.1] are not to apply to the discharge of segregated ballast.

**5.2.3** The cargo oil residues which cannot be discharged into the sea in compliance with [5.2.1] above are to be retained on board or discharged to reception facilities.

## 5.3 Oil discharge monitoring and control system

### 5.3.1 General

- a) An oil discharge monitoring and control system is to be fitted.
- b) A manually operated alternative method is to be provided.

### 5.3.2 Design of the discharge monitoring and control system

- a) The discharge monitoring and control system is to be of a type approved in compliance with the provisions of IMO Resolution MEPC 108(49), as amended.
- b) The discharge monitoring and control system is to be fitted with a recording device to provide a continuous record of the discharge in litres per nautical mile and total quantity discharged, or the oil content and rate of discharge. This record is to be identifiable as regards time and date.

- c) The oil discharge monitoring and control system is to come into operation when there is any discharge of effluent into the sea and is to be such as will ensure that any discharge of oily mixture is automatically stopped when the instantaneous rate of discharge of oil content exceeds 30 litres per nautical mile.
- d) Any failure of the monitoring and control system is to stop the discharge.

### **5.3.3 Oil/water interface detectors**

Effective oil/water interface detectors approved by the Society are to be provided for a rapid and accurate determination of the oil/water interface in slop tanks and are to be available for use in other tanks where the separation of oil and water is effected and from which it is intended to discharge effluent directly to the sea.

## **5.4 Pumping, piping and discharge arrangements**

### **5.4.1 Discharge manifold**

In every oil tanker, a discharge manifold for connection to reception facilities for the discharge of dirty ballast water or oil contaminated water is to be located on the open deck on both sides of the ship.

### **5.4.2 Discharge pipelines**

In every oil tanker, pipelines for the discharge of ballast water or oil contaminated water from cargo tank areas to the sea, where permitted, are to be led to the open deck or to the ship side above the waterline in the deepest ballast condition, except that:

- a) segregated ballast and clean ballast may be discharged below the waterline:
  - in ports or at offshore terminals, or
  - at sea by gravity,provided that the surface of the ballast water has been examined immediately before the discharge to ensure that no contamination with oil has taken place.
- b) on every oil tanker at sea, dirty ballast water or oil contaminated water from tanks in the cargo area, other than slop tanks, may be discharged by gravity below the waterline, provided that sufficient time has elapsed in order to allow oil/water separation to have taken place and the water ballast has been examined immediately before the discharge with an oil/water interface detector referred to in [5.3.3], in order to ensure that the height of the interface is such that the discharge does not involve any increased risk of harm to the marine environment.

### **5.4.3 Discharge stopping**

Means are to be provided for stopping the discharge into the sea of ballast water or oil contaminated water from cargo tank areas, other than those discharges below the waterline permitted under [5.4.2], from a position on the upper deck or above located so that the manifold in use referred to in [5.4.1] and the discharge to the sea from the pipelines referred to in [5.4.2] may be visually observed. Means for stopping the discharge need not be provided at the observation position if a positive communication system such as a telephone or radio system is provided between the observation position and the discharge control position.

## **6 Certification, inspection and testing**

### **6.1 Application**

**6.1.1** The provisions of this Article are related to cargo piping and other equipment fitted in the cargo area. They supplement those given in Pt C, Ch 1, Sec 10, [20] for piping systems.

### **6.2 Workshop tests**

#### **6.2.1 Tests for materials**

Where required in Tab 6, materials used for pipes, valves and fittings are to be subjected to the tests specified in Pt C, Ch 1, Sec 10, [20.4.2].

#### **6.2.2 Inspection of welded joints**

Where required in Tab 6, welded joints are to be subjected to the examinations specified in Pt C, Ch 1, Sec 10, [3.6] for class II pipes.

#### **6.2.3 Hydrostatic testing**

- a) Where required in Tab 6, cargo pipes, valves, fittings and pump casings are to be submitted to hydrostatic tests in accordance with the relevant provisions of Pt C, Ch 1, Sec 10, [20.5].
- b) Expansion joints and cargo hoses are to be submitted to hydrostatic tests in accordance with the relevant provisions of Pt C, Ch 1, Sec 10, [20.5].
- c) Where fitted, bellow pieces of gas-tight penetration glands are to be pressure tested.

**6.2.4 Tightness tests**

Tightness of the following devices is to be checked:

- gas-tight penetration glands
- cargo tank P/V and high velocity valves.

Note 1: These tests may be carried out in the workshops or on board.

**6.2.5 Check of the safety valves setting**

The setting pressure of the pressure/vacuum valves is to be checked in particular with regard to [4.2.5].

**6.2.6 Summarising table**

Inspections and tests required for cargo piping and other equipment fitted in the cargo area are summarised in Tab 6.

**6.3 Shipboard tests**

**6.3.1 Pressure test**

- After installation on board, the cargo piping system is to be checked for leakage under operational conditions.
- The piping system used in crude oil washing systems is to be submitted to hydrostatic tests in accordance with Ch 7, App 2, [3.2.1].

**Table 6 : Inspection and testing at works**

No	Item	Tests for materials		Inspections and tests for the products			References to the Rules
		Y/N (1)	Type of material certificate (2)	during manufacturing (1)	after completion (1) (3)	Type of product certificate (2)	
1	pipes, valves and fittings of class II (see [3.3.1])	Y	<ul style="list-style-type: none"> <li>• C where ND &gt; 100mm</li> <li>• W where ND ≤ 100mm</li> </ul>	Y (4)	Y	C	[6.2.1] [6.2.1] [6.2.2] [6.2.3]
2	expansion joints and cargo hoses	Y (5)	W	N	Y	C	[6.2.1]  [6.2.3]
3	cargo pumps	Y	<ul style="list-style-type: none"> <li>• C for cast body</li> <li>• W for welded construction</li> </ul>	Y (6)	Y	C	see note (6) [6.2.3]
4	gas-tight penetration glands	N		N	Y	C	[6.2.3], [6.2.4]

- (1) Y = required, N = not required.  
 (2) C = class certificate, W = works' certificate.  
 (3) includes the checking of the rule characteristics according to the approved drawings.  
 (4) only in the case of welded construction.  
 (5) if metallic.  
 (6) inspection during manufacturing is to be carried out according to a program approved by the Society.  
 (7) may also be carried out on board.

No	Item	Tests for materials		Inspections and tests for the products			References to the Rules

(5) if metallic.                      (6) inspection during manufacturing is to be carried out according to a program approved by the Society.                      (7) may also be carried out on board.</p>							

**6.3.2 Survey of pollution prevention equipment**

Every ship having the service notations **oil tanker** or **oil tanker, flash point > 60°C** and of 150 gross tonnage and above is to be subjected to an initial survey before the ship is put in service, to ensure that the equipment, systems, fittings, arrangements and materials fully comply with the relevant provisions of [4.6] and [5].

**7 Steering gear**

**7.1 General**

**7.1.1** In addition to the provisions of Pt C, Ch 1, Sec 14, the steering gear of ships having the service notation **oil tanker** or **FLS tanker** and of 10000 gross tonnage and above is to comply with the requirements of [7].

**7.2 Design of the steering gear**

**7.2.1** *In every tanker of 10 000 gross tonnage and upwards, the main steering gear shall comprise two or more identical power units complying with the provisions of Pt C, Ch 1, Sec 14, [2.4.2].*

**7.2.2** *Every tanker of 10 000 gross tonnage and upwards is, subject to the provisions of [7.3], to comply with the following:*

- a) *the main steering gear is to be so arranged that in the event of loss of steering capability due to a single failure in any part of one of the power actuating systems of the main steering gear, excluding the tiller, quadrant or components serving the same purpose, or seizure of the rudder actuators, steering capability is to be regained in not more than 45 s after the loss of one power actuating system.*

b) the main steering gear is to comprise either:

- 1) two independent and separate power actuating systems, each capable of meeting the requirements of Pt C, Ch 1, Sec 14, [2.2.1]; The two independent power actuating systems are to be so arranged that a mechanical or electrical failure in one of them will not render the other one inoperative, and be in accordance with Pt C, Ch 1, Sec 14, [2.3.3]; or
- 2) at least two identical power actuating systems which, acting simultaneously in normal operation, are to be capable of meeting the requirements of Pt C, Ch 1, Sec 14, [2.2.1]. Where necessary to comply with this requirement, interconnection of hydraulic power actuating systems is to be provided. Loss of hydraulic fluid from one system is to be capable of being detected and the defective system automatically isolated so that the other actuating system or systems remain(s) fully operational

c) steering gear other than that of the hydraulic type is to achieve equivalent standards.

### **7.3 Alternative design for ships of less than 100 000 tonnes deadweight**

#### **7.3.1 General**

For tankers of 10 000 gross tonnage and upwards, but of less than 100 000 tons deadweight, solutions other than those set out in [7.2], which need not apply the single failure criterion to the rudder actuator or actuators, may be permitted provided that an equivalent safety standard is achieved and that:

- a) following loss of steering capability due to a single failure of any part of the piping system or in one of the power units, steering capability is regained within 45 s; and
- b) where the steering gear includes only a single rudder actuator, special consideration is given to stress analysis for the design including fatigue analysis and fracture mechanics analysis, as appropriate, to the material used, to the installation of sealing arrangements and to testing and inspection and to the provision of effective maintenance.

#### **7.3.2 Materials**

Parts subject to internal hydraulic pressure or transmitting mechanical forces to the rudder stock are to be made of duly tested ductile materials complying with recognised standards. Materials for pressure retaining components are to be in accordance with recognised pressure vessel standards. These materials are not to have an elongation of less than 12% or a tensile strength in excess of 650 N/mm<sup>2</sup>.

#### **7.3.3 Design**

a) Design pressure

The design pressure is assumed to be at least equal to the greater of the following:

- 1) 1,25 times the maximum working pressure to be expected under the operating conditions required in Pt C, Ch 1, Sec 14, [2.2.1]
- 2) the relief valve setting.

b) Analysis

- 1) the manufacturers of rudder actuators are to submit detailed calculations showing the suitability of the design for the intended service
- 2) a detailed stress analysis of the pressure retaining parts of the actuator is to be carried out to determine the stress at the design pressure
- 3) where considered necessary because of the design complexity or manufacturing procedures, a fatigue analysis and fracture mechanics analysis may be required. In connection with the analyses, all foreseen dynamic loads are to be taken into account. Experimental stress analysis may be required in addition to, or in lieu of, theoretical calculations depending on the complexity of the design.

c) Allowable stresses

For the purpose of determining the general scantlings of parts of rudder actuators subject to internal hydraulic pressure, the allowable stresses are not to exceed:

- $\sigma_m \leq f$
- $\sigma_l \leq 1,5 f$
- $\sigma_b \leq 1,5 f$
- $\sigma_l + \sigma_b \leq 1,5 f$
- $\sigma_m + \sigma_b \leq 1,5 f$

where:

$\sigma_m$  : Equivalent primary general membrane stress

$\sigma_l$  : Equivalent primary local membrane stress

$\sigma_b$  : Equivalent primary bending stress

$f$  : The lesser of  $\sigma_B/A$  or  $\sigma_y/B$

$\sigma_B$  : Specified minimum tensile strength of material at ambient temperature

$\sigma_y$  : Specified minimum yield stress or 0,2% proof stress of material at ambient temperature

- A : Equal to:
- 4,0 for steel
  - 4,6 for cast steel
  - 5,8 for nodular cast iron
- B : Equal to:
- 2,0 for steel
  - 2,3 for cast steel
  - 3,5 for nodular cast iron

d) Burst test

- 1) Pressure retaining parts not requiring fatigue analysis and fracture mechanics analysis may be accepted on the basis of a certified burst test at the discretion of the Society and the detailed stress analysis required by [7.3.3], item b), need not be provided.
- 2) The minimum bursting pressure is to be calculated as follows:

$$P_b = P \cdot A \cdot \frac{\sigma_{Ba}}{\sigma_B}$$

where:

- $P_b$  : Minimum bursting pressure  
 $P$  : Design pressure as defined in [7.3.3], item a)  
 $A$  : As from [7.3.3], item c)  
 $\sigma_{Ba}$  : Actual tensile strength  
 $\sigma_B$  : Tensile strength as defined in [7.3.3], item c).

### 7.3.4 Construction details

a) General

The construction is to be such as to minimise the local concentration of stress.

b) Welds

- 1) The welding details and welding procedures are to be approved.
- 2) All welded joints within the pressure boundary of a rudder actuator or connecting parts transmitting mechanical loads are to be full penetration type or of equivalent strength.

c) Oil seals

- 1) Oil seals between non-moving parts, forming part of the external pressure boundary, are to be of the metal upon metal type or of an equivalent type.
- 2) Oil seals between moving parts, forming part of the external pressure boundary, are to be duplicated, so that the failure of one seal does not render the actuator inoperative. Alternative arrangements providing equivalent protection against leakage may be accepted at the discretion of the Society.

d) Isolating valves

Isolating valves are to be fitted at the connection of pipes to the actuator, and are to be directly mounted on the actuator.

e) Relief valves

Relief valves for protecting the rudder actuator against overpressure as required in Pt C, Ch 1, Sec 14, [2.6.5] are to comply with the following:

- 1) the setting pressure is not to be less than 1,25 times the maximum working pressure expected under operating conditions required in Pt C, Ch 1, Sec 14, [2.2.1], item b)
- 2) the minimum discharge capacity of the relief valves is not to be less than the total capacity of all pumps which provide power for the actuator, increased by 10 per cent. Under such conditions, the rise in pressure is not to exceed 10 per cent of the setting pressure. In this regard, due consideration is to be given to extreme foreseen ambient conditions in respect of oil viscosity.

### 7.3.5 Inspection and testing

a) Non-destructive testing

The rudder actuator is to be subjected to suitable and complete non-destructive testing to detect both surface flaws and volumetric flaws. The procedure and acceptance criteria for non-destructive testing is to be in accordance with requirements of recognised standards. If found necessary, fracture mechanics analysis may be used for determining maximum allowable flaw size.

b) Other testing

- 1) Tests, including hydrostatic tests, of all pressure parts at 1,5 times the design pressure are to be carried out.
- 2) When installed on board the ship, the rudder actuator is to be subjected to a hydrostatic test and a running test.

## 8 Additional requirements for ships having the additional service feature asphalt carrier

### 8.1 Application

8.1.1 The provisions of this Article apply, in addition to those contained in Articles [1] to [7] above, to oil tankers having the additional service feature **asphalt carrier**.

### 8.2 Additional requirements

#### 8.2.1 Heating systems

- Cargo tanks intended for the carriage of asphalt solutions are to be equipped with a heating system capable of preserving the asphalt solutions in their liquid state. Valves are to be fitted on the heating system inlet and outlet.
- Cargo piping and associated fittings outside tanks are to be provided with suitable heating devices. For heating of piping and fittings, refer to [2.6].

#### 8.2.2 Thermometers

Each tank is to be equipped with at least two thermometers in order to ascertain the temperature of the asphalt solution.

#### 8.2.3 Insulation

Cargo piping and associated fittings outside tanks are to be suitably insulated, where necessary.

## 9 Specific requirements for ships having the notations “FLS tanker” or “FLS tanker, flash point > 60°C”

### 9.1 Application

9.1.1 The provisions of this Article, derived from Appendix II of the MARPOL 73/78 Convention, are related to the prevention of pollution by noxious liquid substances. They apply as follows:

- Where the ship is granted only the service notation **FLS tanker** or **FLS tanker, flash point > 60°C**, these provisions replace those of [5] related to the prevention of pollution by cargo oil.
- Where the ship is granted both service notations **oil tanker-FLS tanker**, or **oil tanker-FLS tanker, flash point > 60°C**, these provisions are additional to those of [5].

### 9.2 Design requirements

#### 9.2.1 General

The requirements of [9.2] apply to ships carrying category Z substances (see Ch 7, App 3, Tab 2).

#### 9.2.2 Underwater discharge

The underwater discharge outlet arrangement is to be such that the residue/water mixture discharged into the sea will not pass through the ship's boundary layer. To this end, when the discharge is made normal to the ship's shell plating, the minimum diameter of the discharge outlet is governed by the following equation:

$$D = \frac{Q_D}{5L}$$

where:

D : Minimum diameter of the discharge outlet, in m

L : Distance from the forward perpendicular to the discharge outlet, in m

$Q_D$  : The maximum rate selected at which the ship may discharge a residue/water mixture through the outlet, in m<sup>3</sup>/h.

When the discharge is directed at an angle to the ship's shell plating, the above relationship is to be modified by substituting for  $Q_D$  the component of  $Q_D$  which is normal to the ship's shell plating.

#### 9.2.3 Ventilation equipment

- If residues from cargo tanks are removed by means of ventilation, ventilation equipment meeting the following provisions is to be provided.

Note 1: Ventilation procedures may be applied only to those substances having a vapour pressure greater than  $5 \cdot 10^3$  Pa at 20°C.

- The ventilation equipment is to be capable of producing an air jet which can reach the tank bottom. Fig 3 may be used to evaluate the adequacy of ventilation equipment used for ventilating a tank of given depth.
- The ventilation equipment is to be placed in the tank opening closest to the tank sump or suction point.

- d) When practicable, the ventilation equipment is to be positioned so that the air jet is directed at the tank sump or suction point and impingement of the air jet on tank structural members is to be avoided as far as possible.

**Figure 3 : Minimum flow rate as a function of jet penetration depth**

Jet penetration depth is to be compared against tank height.

# Section 5 Electrical Installations

## 1 General

### 1.1 Application

**1.1.1** The requirements in this Section apply, in addition to those contained in Part C, Chapter 2 to ships with the service notation **oil tanker** or **FLS tanker**.

**1.1.2** The design is to be in accordance with IEC publication 60092-502.

However, where the prescriptive requirements in the present Rules and IEC 60092-502 are not aligned, the prescriptive requirements in the present Rules take precedence and are to be applied.

### 1.2 Documentation to be submitted

**1.2.1** In addition to the documentation requested in Pt C, Ch 2, Sec 1, Tab 1, the following are to be submitted for approval:

- a) plan of hazardous areas
- b) document giving details of types of cables and safety characteristics of the equipment installed in hazardous areas
- c) diagrams of tank level indicator systems, high level alarm systems and overflow control systems where requested.

### 1.3 System of supply

**1.3.1** The following systems of generation and distribution of electrical energy are acceptable:

- a) direct current:
  - two-wire insulated
- b) alternating current:
  - single-phase, two-wire insulated
  - three-phase, three-wire insulated.

**1.3.2** Earthed systems with hull return are not permitted, with the following exceptions to the satisfaction of the Society:

- a) impressed current cathodic protective systems
- b) limited and locally earthed systems, such as starting and ignition systems of internal combustion engines, provided that any possible resulting current does not flow directly through any hazardous area
- c) insulation level monitoring devices, provided that the circulation current of the device does not exceed 30 mA under the most unfavourable conditions.

**1.3.3** Earthed systems without hull return are not permitted, with the following exceptions:

- a) earthed intrinsically safe circuits and the following other systems to the satisfaction of the Society
- b) power supplies, control circuits and instrumentation circuits in non-hazardous areas where technical or safety reasons preclude the use of a system with no connection to earth, provided the current in the hull is limited to not more than 5 A in both normal and fault conditions, or
- c) limited and locally earthed systems, such as power distribution systems in galleys and laundries to be fed through isolating transformers with the secondary windings earthed, provided that any possible resulting hull current does not flow directly through any hazardous area, or
- d) alternating current power networks of 1,000 V root mean square (line to line) and over, provided that any possible resulting current does not flow directly through any hazardous area; to this end, if the distribution system is extended to areas remote from the machinery space, isolating transformers or other adequate means are to be provided.

**1.3.4** In insulated distribution systems, no current carrying part is to be earthed, other than:

- a) through an insulation level monitoring device
- b) through components used for the suppression of interference in radio circuits.

### 1.4 Earth detection

**1.4.1** The devices intended to continuously monitor the insulation level of all distribution systems are also to monitor all circuits, other than intrinsically safe circuits, connected to apparatus in hazardous areas or passing through such areas. An audible and visual alarm is to be given, at a manned position, in the event of an abnormally low level of insulation.

## **1.5 Mechanical ventilation of hazardous spaces**

**1.5.1** Electric motors driving fans of the ventilating systems of hazardous spaces are to be located outside the ventilation ducting.

**1.5.2** Motors driving ventilating fans may be located within the ducting provided that they are of a certified safe type.

**1.5.3** The materials used for the fans and their housing are to be in compliance with Pt C, Ch 4, Sec 1, [2.32].

**1.5.4** Cargo pump-rooms and other enclosed spaces which contain cargo-handling equipment and similar spaces in which work is performed on the cargo should be fitted with mechanical ventilation systems, capable of being controlled from outside such spaces.

**1.5.5** Provisions are to be made to ventilate the spaces defined in [1.5.4] prior to entering the compartment and operating the equipment.

## **1.6 Electrical installation precautions**

### **1.6.1 Precautions against inlet of gases or vapours**

Suitable arrangements are to be provided, to the satisfaction of the Society, so as to prevent the possibility of gases or vapours passing from a gas-dangerous space to another space through runs of cables or their conduits.

## **2 Hazardous locations and types of equipment**

### **2.1 Special requirements for oil tankers carrying flammable liquids having a flash point not exceeding 60°C and for oil tankers carrying flammable liquids having a flash point exceeding 60°C heated to a temperature within 15°C of their flash point or above their flash point**

**2.1.1** In order to facilitate the selection of appropriate electrical apparatus and the design of suitable electrical installations, hazardous areas are divided into zone 0, 1 and 2 according to Pt C, Ch 2, Sec 1, [3.25.3]. The different spaces are to be classified according to Tab 1.

The types of electrical equipment admitted, depending on the zone where they are installed, are specified in Pt C, Ch 2, Sec 3, [10].

**2.1.2** The explosion group and temperature class of electrical equipment of a certified safe type are to be at least IIA and T3 in the case of ships arranged for the carriage of crude oil or other petroleum products.

Other characteristics may be required for dangerous products other than those above.

**2.1.3** A space separated by a gastight boundaries from a hazardous area may be classified as zone 0, 1, 2 or considered as non hazardous, taking into account the sources of release inside that space and its conditions of ventilation.

**2.1.4** Access door and other openings are not to be provided between an area intended to be considered as non-hazardous and a hazardous area or between a space intended to be considered as zone 2 and a zone 1, except where required for operational reasons.

**2.1.5** In enclosed or semi-enclosed spaces having a direct opening into any hazardous space or area, electrical installations are to comply with the requirements for the space or area to which the opening leads.

**2.1.6** Where a space has an opening into an adjacent, more hazardous space or area, it may be made into a less hazardous space or non-hazardous space, taking into account the type of separation and the ventilation system.

**2.1.7** A differential pressure monitoring device or a flow monitoring device, or both, are to be provided for monitoring the satisfactory functioning of pressurisation of spaces having an opening into a more hazardous zone.

In the event of loss of the protection by the over-pressure or loss of ventilation in spaces classified as zone 1 or zone 2, protective measures are to be taken.

### **2.2 Special requirements for oil tankers carrying flammable liquids having a flash point exceeding 60°C unheated or heated to a temperature below and not within 15°C of their flash point**

**2.2.1** For systems of supply and earth detection, the requirements under [1.3] and [1.4] apply.

**2.2.2** Cargo tanks, slop tanks, any pipe work of pressure-relief or other venting systems for cargo and slop tanks, pipes and equipment containing the cargo are to be classified as zone 2.

### **2.3 Special requirements for FLS tankers**

**2.3.1** The requirements under Ch 8, Sec 10 apply.

**Table 1 : Space descriptions and hazardous area zones for oil tankers carrying flammable liquids having a flash point not exceeding 60°C and for oil tankers carrying flammable liquids heated to a temperature within 15°C of their flash point or above their flash point**

No.	Description of spaces	Hazardous area
1	The interior of cargo tanks, slop tanks, any pipework of pressure-relief or other venting systems for cargo and slop tanks, pipes and equipment containing the cargo or developing flammable gases and vapours	Zone 0
2	Void space adjacent to, above or below integral cargo tanks	Zone 1
3	Hold spaces	Zone 1
4	Cofferdams and permanent (for example, segregated) ballast tanks adjacent to cargo tanks	Zone 1
5	Cargo pump rooms	Zone 1
6	Enclosed or semi-enclosed spaces, immediately above cargo tanks (for example, between decks) or having bulkheads above and in line with cargo tank bulkheads, unless protected by a diagonal plate acceptable to the Society	Zone 1
7	Spaces, other than cofferdam, adjacent to and below the top of a cargo tank (for example, trunks, passageways and hold)	Zone 1
8	Areas on open deck, or semi-enclosed spaces on open deck, within 3 m of any cargo tank outlet, gas or vapour outlet, cargo manifold valve, cargo valve, cargo pipe flange and cargo pump-room ventilation outlets.	Zone 1
9	Areas on open deck, or semi-enclosed spaces on open deck above and in the vicinity of any cargo gas outlet intended for the passage of large volumes of gas or vapour mixture during cargo loading and ballasting or during discharging or of small volumes of gas or vapour mixtures caused by thermal variation, within a vertical cylinder of unlimited height and 6 m radius centred upon the centre of the outlet, and within a hemisphere of 6 m radius below the outlet	Zone 1
10	Areas on open deck, or semi-enclosed spaces on open deck, within 1,5 m of cargo pump entrances, cargo pump room ventilation inlet, openings into cofferdams, or other zone 1 spaces	Zone 1
11	Areas on open deck within spillage coamings surrounding cargo manifold valves and 3 m beyond these, up to a height of 2,4 m above the deck	Zone 1
12	Areas on open deck over the cargo area where structures are restricting the natural ventilation and to the full breadth of the ship plus 3 m fore and aft of the forward-most and aft-most cargo tank bulkhead, up to a height of 2,4 m above the deck	Zone 1
13	Compartments for cargo hoses	Zone 1
14	Enclosed or semi-enclosed spaces in which pipes containing cargoes are located	Zone 1
15	Areas of 1,5 m surrounding a space of zone 1	Zone 2
16	Spaces 4 m beyond the cylinder and 4 m beyond the sphere defined in item 9	Zone 2
17	Fore peak ballast tank not adjacent to cargo tanks, when ballasted with the system serving ballast tanks in the cargo area according to Ch 7, Sec 4, [2.3.8]	Zone 2
18	Areas on open deck extending to the coamings fitted to keep any spills on deck and away from the accommodation and service area and 3 m beyond these up to a height of 2,4 m above the deck	Zone 2
19	Areas on open deck over the cargo area where unrestricted natural ventilation is guaranteed and to the full breadth of the ship plus 3 m fore and aft of the forward-most and aft-most cargo tank bulkhead, up to a height of 2,4 m above the deck surrounding open or semi-enclosed spaces of zone 1	Zone 2
20	Spaces forward of the open deck areas to which reference is made in 12 and 18, below the level of the main deck, and having an opening on to the main deck or at a level less than 0,5 m above the main deck, unless: <ul style="list-style-type: none"> <li>the doors and all openings are in non-hazardous area; and</li> <li>the spaces are mechanically ventilated</li> </ul>	Zone 2

# Section 6 Fire Protection

## 1 General

### 1.1 Application

1.1.1 Unless otherwise specified, the provisions of this Section apply to the ships having one of the following service notations:

- oil tanker
- oil tanker, flash point > 60°C
- oil tanker, asphalt carrier
- FLS tanker
- FLS tanker, flash point > 60°C.

### 1.2 Documents to be submitted

1.2.1 The documents listed in Ch 7, Sec 2, Tab 1 are to be submitted for approval in addition to those listed in Tab 1.

**Table 1 : Documents to be submitted**

No.	Description of the document (1)
1	General arrangement drawing
2	Specification of the fire integrity of bulkheads and decks
3	Specification of the instruments for measuring oxygen and flammable vapour concentrations
4	Diagram of the pressure water system within the cargo area
5	For the foam extinguishing system within the cargo area: <ul style="list-style-type: none"> <li>• diagrammatic arrangement drawing</li> <li>• calculation note</li> <li>• foam agent specification</li> <li>• characteristics of foam monitors and hoses</li> </ul>
6	For the fire-extinguishing system in cargo pump rooms: <ul style="list-style-type: none"> <li>• general arrangement drawing</li> <li>• calculation note</li> </ul>
7	For the inert gas installation: <ul style="list-style-type: none"> <li>• single-wire diagram of the installation together with the main characteristics: capacity, pressure, temperature, oxygen content, water content,</li> <li>• list of the components with their characteristics: pipes, scrubber, blowers, non-return devices, valves, pumps, protective devices for over-pressure and vacuum,</li> <li>• drawing of arrangement of installation on board,</li> <li>• diagram of instrumentation, alarm and safeguard systems,</li> <li>• specification of oxygen analyser, recorder and portable instrumentation,</li> <li>• operational manual containing instructions relative to the operation of the inert gas system and to safety.</li> </ul>
(1) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.	

## 2 General requirements

### 2.1 Sources of ignition

2.1.1 Dangerous zones or spaces are not to contain:

- internal combustion engines
- steam turbines and steam piping with a steam temperature in excess of 220°C
- other piping systems and heat exchangers with a fluid temperature in excess of 220°C
- any other source of ignition.

Note 1: Dangerous zones and spaces correspond to hazardous areas defined in Pt C, Ch 2, Sec 1, [3.25].

## 2.2 Electrical equipment

2.2.1 For the installation of electrical equipment, refer to Ch 7, Sec 5.

## 3 Fixed deck foam system

### 3.1 Application

#### 3.1.1 Service notation oil tanker

Ships having the service notation **oil tanker** are to be provided with a fixed deck foam system complying with the provisions of [3.2] and [3.3] or with an equivalent fixed installation.

Note 1: To be considered equivalent, the system proposed in lieu of the deck foam system is to:

- be capable of extinguishing spill fires and also preclude ignition of spilled oil not yet ignited, and
- be capable of combating fires in ruptured tanks.

#### 3.1.2 Service notation FLS tanker

Ships having the service notation **FLS tanker** are to be provided with a fixed deck foam system complying with [11.3] of the IBC Code. The type of foam to be used is specified in Ch 7, App 4, Tab 1. Where ordinary foam is considered suitable, foam fire-extinguishing systems complying with the provisions of [3.2] and [3.3] are acceptable.

#### 3.1.3 Service notations oil tanker, flash point > 60°C or oil tanker, asphalt carrier

Ships having the service notations **oil tanker, flash point > 60°C** or **oil tanker, asphalt carrier** are to be provided with a fixed deck foam system complying with the provisions of [3.2] and [3.3] or with an equivalent fixed installation. However, such a system is not required in the case of ships of less than 2000 gross tonnage.

Note 1: For the definition of "equivalent installation", refer to [3.1.1].

### 3.2 System design

#### 3.2.1 Principles

- a) The arrangements for providing foam are to be capable of delivering foam to the entire cargo tank deck area as well as into any cargo tank the deck of which has been ruptured.
- b) The deck foam system is to be capable of simple and rapid operation.
- c) Operation of a deck foam system at its required output shall permit the simultaneous use of the minimum required number of jets of water at the required pressure from the fire main. Where the deck foam system is supplied by a common line from the fire main, additional foam concentrate shall be provided for operation of two nozzles for the same period of time required for the foam system.

The simultaneous use of the minimum required jets of water shall be possible on deck over the full length of the ship, in the accommodation spaces, service spaces, control stations and machinery spaces.

- d) Foam from the fixed foam system is to be supplied by means of monitors and foam applicators.

Note 1: On tankers of less than 4000 tonnes deadweight, the Society may not require installation of monitors but only applicators.

- e) Applicators are to be provided to ensure flexibility of action during fire-fighting operations and to cover areas screened from the monitors.

#### 3.2.2 Foam solution - Foam concentrate

- a) The rate of supply of foam solution is not to be less than the greatest of the following:

- 1) 0,6 l/min per square metre of cargo tanks deck area, where cargo tanks deck area means the maximum breadth of the ship multiplied by the total longitudinal extent of the cargo tank spaces,
- 2) 6 l/min per square metre of the horizontal sectional area of the single tank having the largest such area, or
- 3) 3 l/min per square metre of the area protected by the largest monitor, such area being entirely forward of the monitor, but in no case should the output of any monitor be less than 1,250 l/min.

- b) Sufficient foam concentrate shall be supplied to ensure at least 20 minutes of foam generation in tankers fitted with an inert gas installation or 30 minutes of foam generation in tankers not fitted with an inert gas installation or not required to use an inert gas system.

- c) The foam concentrate supplied on board shall be approved by the Society based on IMO Circular MSC.1/Circ.1312 for the cargoes intended to be carried. Type B foam concentrates shall be supplied for the protection of crude oil, petroleum products and non-polar solvent cargoes. Type A foam concentrates shall be supplied for polar solvent cargoes, as listed in the table of chapter 17 of the IBC Code. Only one type of foam concentrate shall be supplied, and it shall be effective for the maximum possible number of cargoes intended to be carried. For cargoes for which foam is not effective or is incompatible, additional arrangements to the satisfaction of the Society shall be provided.

- d) *Liquid cargoes with a flashpoint not exceeding 60°C for which a regular foam fire-fighting system is not effective shall comply with the following provisions:*
- 1) *The foam shall be of alcohol-resistant type;*
  - 2) *The type of foam concentrates for use in chemical tankers shall be approved by the Society based on IMO Circular MSC.1/Circ.1312; and*
  - 3) *The capacity and application rates of the foam extinguishing system shall comply with chapter 11 of the IBC Code, except that lower application rates may be accepted based on performance tests. For tankers fitted with inert gas systems, a quantity of foam concentrate sufficient for 20 min of foam generation may be accepted.*

### **3.2.3 Monitors and foam applicators**

- a) *Prototype tests of the monitors and foam applicators shall be performed to ensure the foam expansion and drainage time of the foam produced does not differ more than 10 per cent of that determined in [3.2.2], item c). When medium expansion ratio foam (between 21 to 1 and 200 to 1 expansion ratio) is employed, the application rate of the foam and the capacity of a monitor installation shall be to the satisfaction of the Society. At least 50 per cent of the foam solution supply rate required shall be delivered from each monitor.*
- b) *The capacity of any applicator is to be not less than 400 l/min and the applicator throw in still air conditions is to be not less than 15 m.*

*Note 1: Where, in pursuance of [3.2.1], the installation of monitors is not required on tankers of less 4000 tonnes deadweight, the capacity of each applicator is to be at least 25% of the foam solution supply rate required in [3.2.2], items a) 1) and a) 2).*

## **3.3 Arrangement and installation**

### **3.3.1 Monitors**

- a) *The number and position of monitors are to be such as to comply with item a) of [3.2.1].*
- b) *The distance from the monitor to the farthest extremity of the protected area forward of that monitor is not to be more than 75 per cent of the monitor throw in still air conditions.*
- c) *A monitor and hose connection for a foam applicator shall be situated both port and starboard at the front of the poop or accommodation spaces facing the cargo tank deck. The monitors and hose connections shall be aft of any cargo tanks, but may be located in the cargo area above pump-rooms, cofferdams, ballast tanks, oil bunker tanks, and void spaces adjacent to cargo tanks if capable of protecting the deck below and aft of each other.*

*Note 1: On tankers of less than 4000 tonnes deadweight a hose connection for a foam applicator is to be situated both port and starboard at the front of the poop or accommodation spaces facing the cargo tank deck.*

### **3.3.2 Applicators**

- a) *At least four foam applicators shall be provided on all tankers. The number and disposition of foam main outlets shall be such that foam from at least two applicators can be directed on to any part of the cargo tank deck area.*
- b) *Where the ship is provided with a stern or aft cargo loading or unloading arrangement, the deck foam system is to be so arranged as to permit the protection of the shore connection by at least two foam applicators.*

### **3.3.3 Isolation valves**

*Valves are to be provided in the foam main, and in the fire main when this is an integral part of the deck foam system, immediately forward of any monitor position to isolate damaged sections of those mains.*

### **3.3.4 Main control station**

*The main control station for the system is to be suitably located outside the cargo area, adjacent to the accommodation spaces and readily accessible and operable in the event of fire in the areas protected.*

## **4 Fire-extinguishing systems except deck foam system**

### **4.1 Pressure water fire-extinguishing systems**

**4.1.1** *The pressure water fire-fighting systems provided on ships having the service notations **oil tanker, oil tanker, flash point > 60°C, oil tanker, asphalt carrier, FLS tanker or FLS tanker, flash point > 60°C** are subject to the provisions of Pt C, Ch 4, Sec 6, [1], except that:*

- a) *The capacity of the fire pumps is to be calculated without taking into account the reduction permitted in Ch 7, Sec 4, [2.2.2].*
- b) *Isolation valves are to be fitted in the fire main at poop front in a protected position and on the tank deck at intervals of not more than 40 m to preserve the integrity of the fire main system in the event of fire or explosion.*

**4.1.2** *Attention is drawn to the provisions of item c) of [3.2.1].*

## 4.2 Fire-extinguishing systems for cargo pump rooms

### 4.2.1 Application

- a) Cargo pump rooms of ships having the service notations **oil tanker** or **FLS tanker** are to be provided with a fixed fire-extinguishing system complying with [4.2.2].
- b) Cargo pump rooms of ships having the service notations **oil tanker, flash point > 60°C** or **oil tanker, asphalt carrier** are to be provided with a fixed fire-extinguishing system complying with [4.2.2], except where the cargo is carried at a temperature below and not within 15°C of the flash point.

### 4.2.2 Design and arrangement of the fire-extinguishing system

- a) Where required by [4.2.1], each cargo pump-room is to be provided with one of the following fixed fire-extinguishing systems operated from a readily accessible position outside the pump-room. Cargo pump-rooms are to be provided with a system suitable for machinery spaces of category A.
  - 1) Carbon dioxide fire-extinguishing system complying with the provisions of Pt C, Ch 4, Sec 15, [4] and with the following:
    - the alarms giving audible warning of the release of fire-extinguishing medium are to be safe for use in a flammable cargo vapour/air mixture,
    - a notice is to be exhibited at the controls stating that due to the electrostatic ignition hazard, the system is to be used only for fire extinguishing and not for inerting purposes.
  - 2) A high-expansion foam system complying with the provisions of Pt C, Ch 4, Sec 15, [5.2], provided that the foam concentrate supply is suitable for extinguishing fires involving the cargoes carried.
  - 3) A fixed pressure water-spraying system complying with the provisions of Pt C, Ch 4, Sec 15, [6].
- b) Where the extinguishing medium used in the cargo pump-room system is also used in systems serving other spaces, the quantity of medium provided or its delivery rate need not be more than the maximum required for the largest compartment.

## 5 Inert gas systems

### 5.1 Application

#### 5.1.1 Ships where an inert gas system is required

- a) Ships having the service notation **oil tanker** or **FLS tanker** and of 8 000 tonnes deadweight and upwards are to be fitted with an inert gas system complying with the provisions of this Article, or with equivalent systems or arrangements in accordance with [5.1.2].
- b) All tankers operating with a cargo tank cleaning procedure using crude oil washing are to be fitted with an inert gas system complying with the requirements of this Article.
- c) Such system is to be provided in every cargo tank and slop tank.
- d) Tankers required to be fitted with inert gas systems shall comply with the following provisions:
  - double hull spaces shall be fitted with suitable connections for the supply of inert gas. This includes all ballast tanks and void spaces of double hull and double bottom spaces adjacent to the cargo tanks, including the forepeak tank and any other tanks and spaces under the bulkhead deck adjacent to cargo tanks, except cargo pump-rooms and ballast pump-rooms
  - where hull spaces are connected to a permanently fitted inert gas distribution system, means shall be provided to prevent hydrocarbon gases from the cargo tanks entering the double hull spaces through the system; and
  - where such spaces are not permanently connected to an inert gas distribution system, appropriate means shall be provided to allow connection to the inert gas main.

#### 5.1.2 Requirements for equivalent systems

- a) For ships having the service notations **oil tanker** or **FLS tanker** and of 8 000 tonnes deadweight and upwards but less than 20 000 tonnes deadweight, the Society may accept other equivalent arrangements in accordance with item a) of [5.1.1] and following item b)
- b) Equivalent systems or arrangements shall:
  - be capable of preventing dangerous accumulation of explosive mixtures in intact cargo tanks during normal service throughout the ballast voyage and necessary in-tank operations, and
  - be so designed as to minimize the risk of ignition from the generation of static electricity by the system itself.

#### 5.1.3 Ships where an inert gas system is fitted but not required

Inert gas systems provided on ships where such systems are not required by [5.1.1] are to comply with the provisions of [5.4].

## 5.2 General requirements

5.2.1 The inert gas system is to comply with the applicable requirements of Pt C, Ch 4, Sec 15, [13].

**5.2.2** Plans in diagrammatic form are to be submitted for appraisal and are to include the following:

- details and arrangement of inert gas generating plant including all control monitoring devices
- arrangement of piping system for distribution of the inert gas.

**5.2.3** An automatic control capable of producing suitable inert gas under all service conditions is to be fitted.

### **5.3 Additional requirements for nitrogen generator systems**

**5.3.1** The following requirements apply where a nitrogen generator system is fitted on board as required by [5.1.1]. For the purpose, the inert gas is to be produced by separating air into its component gases by passing compressed air through a bundle of hollow fibres, semi-permeable membranes or adsorber materials.

**5.3.2** In addition to the applicable requirements of Pt C, Ch 4, Sec 15, [13], the nitrogen generator system is to comply with Ch 7, Sec 4, [4.3.2] and Ch 7, Sec 4, [4.2.10].

**5.3.3** A nitrogen generator is to consist of a feed air treatment system and any number of membrane or adsorber modules in parallel necessary to meet the requirements of Pt C, Ch 4, Sec 15, [13.2.1], item b) 4).

**5.3.4** The nitrogen generator is to be capable of delivering high purity nitrogen in accordance with Pt C, Ch 4, Sec 15, [13.2.1], item b) 5). In addition to Pt C, Ch 4, Sec 15, [13.2.2], item d), the system is to be fitted with automatic means to discharge “off-spec” gas to the atmosphere during start-up and abnormal operation.

**5.3.5** The system is to be provided with one or more compressors to generate enough positive pressure to be capable of delivering the total volume of gas required by Pt C, Ch 4, Sec 15, [13.2.1], item b). Where two compressors are provided, the total required capacity of the system is preferably to be divided equally between the two compressors, and in no case is one compressor to have a capacity less than 1/3 of the total capacity required.

**5.3.6** The feed air treatment system fitted to remove free water, particles and traces of oil from the compressed air as required by Pt C, Ch 4, Sec 15, [13.4.2], item b), is also to preserve the specification temperature.

**5.3.7** The oxygen-enriched air from the nitrogen generator and the nitrogen-product enriched gas from the protective devices of the nitrogen receiver are to be discharged to a safe location on the open deck.

Note 1: “safe location” needs to address the two types of discharges separately:

- oxygen-enriched air from the nitrogen generator - safe locations on the open deck are:
  - outside of hazardous area;
  - not within 3m of areas traversed by personnel; and
  - not within 6m of air intakes for machinery (engines and boilers) and all ventilation inlets
- nitrogen-product enriched gas from the protective devices of the nitrogen receiver - safe locations on the open deck are:
  - not within 3m of areas traversed by personnel; and
  - not within 6m of air intakes for machinery (engines and boilers) and all ventilation inlets/outlets.

**5.3.8** In order to permit maintenance, means of isolation are to be fitted between the generator and the receiver.

### **5.4 Nitrogen/inert gas systems fitted for purposes other than inerting required by [5.1.1]**

**5.4.1** Nitrogen/inert gas systems fitted on oil tankers of less than 8 000 tonnes deadweight and for which an inert gas system is not required by [5.1.1] are to comply with the following requirements.

**5.4.2** Requirements of:

- Pt C, Ch 4, Sec 15, [13.2.2], item b)
- Pt C, Ch 4, Sec 15, [13.2.2], item d)
- Pt C, Ch 4, Sec 15, [13.2.4], item b)
- Pt C, Ch 4, Sec 15, [13.2.4], item c)
- Pt C, Ch 4, Sec 15, [13.2.4], item e) 1) regarding oxygen content and power supply to the indicating devices
- Pt C, Ch 4, Sec 15, [13.2.4], item e) 4)
- Pt C, Ch 4, Sec 15, [13.4.2] and
- Pt C, Ch 4, Sec 15, [13.4.3],

apply to the systems.

**5.4.3** The requirements of [5.3] apply except requirements [5.3.1] to [5.3.3] and [5.3.5]

**5.4.4** The two non-return devices as required by Pt C, Ch 4, Sec 15, [13.2.3], item a) 1) are to be fitted in the inert gas main. The non-return devices are to comply with Pt C, Ch 4, Sec 15, [13.2.3], item a) 2) and Pt C, Ch 4, Sec 15, [13.2.3], item a) 3); however, where the connections to the cargo tanks, to the hold spaces or to cargo piping are not permanent, the non-return devices required by Pt C, Ch 4, Sec 15, [13.2.3], item a) 1) may be substituted by two non-return valves.

## 6 Fixed hydrocarbon gas detection systems

### 6.1 Engineering specifications

#### 6.1.1 General

- a) The fixed hydrocarbon gas detection system is to be designed, constructed and tested to the satisfaction of the Society based on IMO Circular MSC.1/Circ.1370.
- b) The system is to be comprised of a central unit for gas measurement and analysis and gas sampling pipes in all ballast tanks and void spaces of double-hull and double-bottom spaces adjacent to the cargo tanks, including the forepeak tank and any other tanks and spaces under the bulkhead deck adjacent to cargo tanks.
- c) The system may be integrated with the cargo pump-room gas detection system, provided that the spaces referred to in item b) above are sampled at the rate required in [6.1.2], item c) 1). Continuous sampling from other locations may also be considered provided the sampling rate is complied with.

#### 6.1.2 Component requirements

- a) Gas sampling lines
  - 1) Common sampling lines to the detection equipment shall not be fitted, except the lines serving each pair of sampling points as required in item 3) below.
  - 2) The materials of construction and the dimensions of gas sampling lines are to be such as to prevent restriction. Where non-metallic materials are used, they shall be electrically conductive. The gas sampling lines shall not be made of aluminium.
  - 3) The configuration of gas sampling lines is to be adapted to the design and size of each space. Except as provided in items 4) and 5) below, the sampling system shall allow for a minimum of two hydrocarbon gas sampling points, one located on the lower and one on the upper part where sampling is required. When required, the upper gas sampling point shall not be located lower than 1 m from the tank top. The position of the lower located gas sampling point shall be above the height of the girder of bottom shell plating but at least 0,5 m from the bottom of the tank and it shall be provided with means to be closed when clogged. In positioning the fixed sampling points, due regard should also be given to the density of vapours of the oil products intended to be transported and the dilution from space purging or ventilation.
  - 4) For ships with deadweight of less than 50000 tonnes, the Society may allow the installation of one sampling location for each tank for practical and/or operational reasons.
  - 5) For ballast tanks in the double-bottom, ballast tanks not intended to be partially filled and void spaces, the upper gas sampling point is not required.
  - 6) Means are to be provided to prevent gas sampling lines from clogging when tanks are ballasted by using compressed air flushing to clean the line after switching from ballast to cargo loaded mode. The system shall have an alarm to indicate if the gas sampling lines are clogged.

#### b) Gas analysis unit

The gas analysis unit shall be located in a safe space and may be located in areas outside the ship's cargo area; for example, in the cargo control room and/or navigation bridge in addition to the hydraulic room when mounted on the forward bulkhead, provided the following requirements are observed:

- 1) Sampling lines shall not run through gas safe spaces, except where permitted under item 5) below;
- 2) The hydrocarbon gas sampling pipes shall be equipped with flame arresters. Sample hydrocarbon gas is to be led to the atmosphere with outlets arranged in a safe location, not close to a source of ignitions and not close to the accommodation area air intakes;
- 3) A manual isolating valve, which shall be easily accessible for operation and maintenance, shall be fitted in each of the sampling lines at the bulkhead on the gas safe side;
- 4) The hydrocarbon gas detection equipment including sample piping, sample pumps, solenoids, analysing units etc., shall be located in a reasonably gas-tight cabinet (e.g., fully enclosed steel cabinet with a door with gaskets) which is to be monitored by its own sampling point. At a gas concentration above 30% of the lower flammable limit inside the steel enclosure the entire gas analysing unit is to be automatically shut down; and
- 5) Where the enclosure cannot be arranged directly on the bulkhead, sample pipes shall be of steel or other equivalent material and without detachable connections, except for the connection points for isolating valves at the bulkhead and analysing unit, and are to be routed on their shortest ways.

c) Gas detection equipment

- 1) The gas detection equipment is to be designed to sample and analyse from each sampling line of each protected space, sequentially at intervals not exceeding 30 min.
- 2) Means are to be provided to enable measurements with portable instruments, in case the fixed system is out of order or for system calibration. In case the system is out of order, procedures shall be in place to continue to monitor the atmosphere with portable instruments and to record the measurement results.
- 3) Audible and visual alarms are to be initiated in the cargo control room, navigation bridge and at the analysing unit when the vapour concentration in a given space reaches a pre-set value, which shall not be higher than the equivalent of 30% of the lower flammable limit.
- 4) The gas detection equipment shall be so designed that it may readily be tested and calibrated.

## 7 Gas measurement and detection

### 7.1 Provisions applicable to all ships

**7.1.1** All ships are to be provided with at least two portable gas detectors capable of measuring flammable vapour concentrations in air (%LEL) and at least two portable oxygen analysers. Alternatively, at least two gas detectors, each capable of measuring both oxygen and flammable vapour concentrations in air (%LEL), are to be provided.

Note 1: The number of portable detection instruments required above is considered equivalent to one portable instrument for measuring flammable vapour concentration, one portable instrument for measuring oxygen and sufficient spares.

**7.1.2** The gas detectors required in [7.1.1] are to be type approved by the Society.

### 7.2 Additional provisions for ships having the service notation oil tanker or FLS tanker

#### 7.2.1 Gas measurement

Ships having the service notation **oil tanker** or **FLS tanker** are to comply with the following provisions:

- a) *Suitable means are to be provided for the calibration of portable instruments for measuring oxygen and/or flammable vapour concentrations.*
- b) *Suitable portable instruments for measuring oxygen and flammable vapour concentrations in double hull spaces and double-bottom spaces are to be provided. In selecting these instruments, due attention is to be given to their use in combination with the fixed gas sampling line systems referred to in item c).*
- c) *Where the atmosphere in double hull spaces cannot be reliably measured using flexible gas sampling hoses, such spaces are to be fitted with permanent gas sampling lines. The configuration of gas sampling lines is to be adapted to the design of such spaces.*
- d) *The materials of construction and the dimensions of gas sampling lines are to be such as to prevent restriction. Where plastic materials are used, they are to be electrically conductive.*

#### 7.2.2 Fixed hydrocarbon gas detection systems

Ships having the service notation **oil tanker** or **FLS tanker** are to comply with the following provisions:

- a) *In addition to the requirements in [7.2.1], ships having the service notation **oil tanker** or **FLS tanker** of 20000 tonnes deadweight and above, are to be provided with a fixed hydrocarbon gas detection system complying with [6] for measuring hydrocarbon gas concentrations in all ballast tanks and void spaces of double-hull and double-bottom spaces adjacent to the cargo tanks, including the forepeak tank and any other tanks and spaces under the bulkhead deck adjacent to cargo tanks.*

Note 1: The term "cargo tanks" in the phrase "spaces adjacent to the cargo tanks" includes slop tanks except those arranged for the storage of oily water only.

The term "spaces" in the phrase "spaces under the bulkhead deck adjacent to cargo tanks" includes dry compartments such as ballast pump-rooms and bow thruster rooms and any tanks such as freshwater tanks, but excludes fuel oil tanks.

The term "adjacent" in the phrase "adjacent to the cargo tanks" includes ballast tanks, void spaces, other tanks or compartments located below the bulkhead deck located adjacent to cargo tanks and includes any spaces or tanks located below the bulkhead deck which form a cruciform (corner to corner) contact with the cargo tanks.

- b) *Ships having the service notation **oil tanker** or **FLS tanker** provided with constant operative inerting systems for such spaces need not be equipped with fixed hydrocarbon gas detection equipment.*
- c) *Notwithstanding the above, cargo pump-rooms subject to the provisions of Ch 7, Sec 4, [3.5] need not comply with the present requirement.*

### 7.3 Additional provisions for ships fitted with an inert gas system

**7.3.1** In addition to the provisions of [7.1], for ships fitted with inert gas systems, at least two portable gas detectors are to be capable of measuring concentrations of flammable vapours in inerted atmosphere.

Gas detectors are to be capable of measuring any gas content from 0 to 100% in volume.

## **7.4 Provisions for installation of gas analysing units**

**7.4.1** The following provisions apply to gas analysing units of the sampling type located outside gas dangerous zones.

**7.4.2** Gas analysing units with non-explosion proof measuring equipment may be located in areas outside cargo areas, e.g. in cargo control room, navigation bridge or engine room when mounted on the forward bulkhead provided the following requirements are observed:

- a) Sampling lines are not to run through gas safe spaces, except where permitted under e).
- b) The gas sampling pipes are to be equipped with flame arresters. Sample gas is to be led to the atmosphere with outlets arranged in a safe location.
- c) Bulkhead penetrations of sample pipes between safe and dangerous areas are to be of approved type and have same fire integrity as the division penetrated. A manual isolating valve is to be fitted in each of the sampling lines at the bulkhead on the gas safe side.
- d) The gas detection equipment including sample piping, sample pumps, solenoids, analysing units etc. is to be located in a reasonably gas tight (e.g. a fully enclosed steel cabinet with a gasketed door) which is to be monitored by its own sampling point. At gas concentrations above 30% LFL inside the steel cabinet the entire gas analysing unit is to be automatically shut down.
- e) Where the cabinet cannot be arranged directly on the bulkhead, sample pipes are to be of steel or other equivalent material and without detachable connections, except for the connection points for isolating valves at the bulkhead and analysing units, and are to be routed on their shortest ways.

# Appendix 1      Devices to Prevent the Passage of Flame into the Cargo Tanks

## 1 General

### 1.1 Application

**1.1.1** This Appendix reproduces the text of MSC Circ. 677. It is intended to cover the design, testing, location and maintenance of "devices to prevent the passage of flame into cargo tanks" (hereafter called "devices") of ships having the service notations **oil tanker** or **combination carrier** carrying crude oil, petroleum products having a flash point of 60°C (closed cup test) or less and a Reid vapour pressure below atmospheric pressure, and other liquids with similar fire hazard. It also applies to ships having the service notation **FLS tanker** carrying flammable products having such a flash point.

**1.1.2** Ships having the service notations **oil tanker**, **combination carrier** or **FLS tanker** and fitted with an inert gas system in accordance with Ch 7, Sec 6, [5] are to be fitted with devices which comply with this Appendix, except that the tests specified in [4.2.3] and [4.3.3] are not required. Such devices are only to be fitted at openings unless they are tested in accordance with [4.4].

**1.1.3** This Appendix is intended for devices protecting cargo tanks containing crude oil, petroleum products and flammable chemicals. In the case of the carriage of chemicals, the test media referred to in [4] can be used. However, devices for chemical tankers dedicated to the carriage of products with MESH less than 0,9 mm are to be tested with appropriate media.

Note 1: For MESH (Maximum Experimental Safe Gap) reference should be made to IEC 60079-1.

**1.1.4** Devices are to be tested and located in accordance with this Appendix.

**1.1.5** Devices are installed to protect:

- a) openings designed to relieve pressure or vacuum caused by thermal variations (see Ch 7, Sec 4, [4.2.2], item a));
- b) openings designed to relieve pressure or vacuum during cargo loading, ballasting or discharging (see Ch 7, Sec 4, [4.2.2], item b));
- c) outlets designed for gas-freeing (see Ch 7, Sec 4, [4.3.3]).

**1.1.6** Devices are not to be capable of being bypassed or blocked open unless they are tested in the bypassed or blocked open position in accordance with [4].

**1.1.7** This Appendix does not include consideration of sources of ignition such as lightning discharges, since insufficient information is available to formulate equipment recommendations. All cargo handling, tank cleaning and ballasting operations are to be suspended on the approach of an electrical storm.

**1.1.8** This Appendix is not intended to deal with the possibility of the passage of flame from one cargo tank to another on tankers with common venting systems.

**1.1.9** When outlet openings of gas-freeing systems on tankers not fitted with inert gas systems are required to be protected with devices, they are to comply with this Appendix except that the tests specified in [4.2.3] and [4.3.3] are not required.

**1.1.10** Certain of the tests prescribed in [4] of this Appendix are potentially hazardous, but no attempt is made in this Appendix to specify safety requirements for these tests.

### 1.2 Definitions

#### 1.2.1 Premise

For the purpose of this Appendix, the definitions given in the following paragraphs are applicable.

#### 1.2.2 Flame arrester

A flame arrester is a device to prevent the passage of flame in accordance with a specified performance standard. Its flame arresting element is based on the principle of quenching.

#### 1.2.3 Flame screen

A flame screen is a device utilising wire mesh to prevent the passage of unconfined flames in accordance with a specified performance standard.

### 1.2.4 Flame speed

The flame speed is the speed at which a flame propagates along a pipe or other system.

### 1.2.5 Flashback

Flashback is the transmission of a flame through a device.

### 1.2.6 High velocity vent

A high velocity vent is a device to prevent the passage of flame consisting of a mechanical valve which adjusts the opening available for flow in accordance with the pressure at the inlet of the valve in such a way that the efflux velocity cannot be less than 30 m/s.

### 1.2.7 Pressure/vacuum valve

A pressure/vacuum valve is a device designed to maintain pressure and vacuum in a closed container within preset limits.

Note 1: Pressure/vacuum valves are devices to prevent the passage of flame when designed and tested in accordance with this Appendix.

## 1.3 Instruction manual

**1.3.1** The manufacturer is to supply a copy of the instruction manual, which is to be kept on board the tanker and which is to include:

- a) installation instructions
- b) operating instructions
- c) maintenance requirements, including cleaning (see [2.3.3])
- d) a copy of the laboratory report referred to in [4.6]
- e) flow test data, including flow rates under both positive and negative pressures, operating sensitivity, flow resistance and velocity.

## 2 Design of the devices

### 2.1 Principles

**2.1.1** Depending on their service and location, devices are required to protect against the propagation of:

- a) moving flames, and/or
- b) stationary flames from pre-mixed gases after ignition of gases resulting from any cause.

**2.1.2** When flammable gases from outlets ignite, the following four situations may occur:

- a) at low gas velocities the flame may:
  - 1) flashback, or
  - 2) stabilise itself as if the outlet were a burner.
- b) at high gas velocities, the flame may:
  - 1) burn at a distance above the outlet, or
  - 2) be blown out.

**2.1.3** In order to prevent the passage of flame into a cargo tank, devices are to be capable of performing one or more of the following functions:

- a) permitting the gas to pass through passages without flashback and without ignition of the gases on the protected side when the device is subjected to heating for a specified period
- b) maintaining an efflux velocity in excess of the flame speed for the gas irrespective of the geometric configuration of the device and without the ignition of gases on the protected side, when the device is subjected to heating for a specified period; and
- c) preventing an influx of flame when conditions of vacuum occur within the cargo tanks.

### 2.2 Mechanical design

**2.2.1** The casing or housing of devices is to meet similar standards of strength, heat resistance and corrosion resistance as the pipe to which it is attached.

**2.2.2** The design of devices is to allow for ease of inspection and removal of internal elements for replacement, cleaning or repair.

**2.2.3** All flat joints of the housing are to be machined true and are to provide an adequate metal-to-metal contact.

**2.2.4** Flame arrester elements are to fit in the housing in such a way that flame cannot pass between the element and the housing.

- 2.2.5** Resilient seals may be installed only if their design is such that if the seals are partially or completely damaged or burned, the device is still capable of effectively preventing the passage of flame.
- 2.2.6** Devices are to allow for efficient drainage of moisture without impairing their efficiency to prevent the passage of flame.
- 2.2.7** The casing, flame arrester element and gasket materials are to be capable of withstanding the highest pressure and temperature to which the device may be exposed under both normal and specified fire test conditions.
- 2.2.8** End-of-line devices are to be so constructed as to direct the efflux vertically upwards.
- 2.2.9** Fastenings essential to the operation of the device, i.e. screws, etc., are to be protected against loosening.
- 2.2.10** Means are to be provided to check that any valve lifts easily without remaining in the open position.
- 2.2.11** Devices in which the flame arresting effect is achieved by the valve function and which are not equipped with flame arrester elements (e.g. high velocity valves) are to have a width of the contact area of the valve seat of at least 5 mm.
- 2.2.12** Devices are to be resistant to corrosion in accordance with [4.5.1].
- 2.2.13** Elements, gaskets and seals are to be of material resistant to both seawater and the cargoes carried.
- 2.2.14** The casing of the housing is to be capable of passing a hydrostatic pressure test, as required in [4.5.2].
- 2.2.15** In-line devices are to be able to withstand without damage or permanent deformation the internal pressure resulting from detonation when tested in accordance with [4.4].
- 2.2.16** A flame arrester element is to be designed to ensure quality control of manufacture to meet the characteristics of the prototype tested, in accordance with this Appendix.

## **2.3 Performance**

**2.3.1** Devices are to be tested in accordance with [4.5] and thereafter shown to meet the test requirements of [4.2] to [4.4], as appropriate.

Note 1: End-of-line devices which are intended for exclusive use at openings of inerted cargo tanks need not be tested against endurance burning as specified in [4.2.3].

Note 2: Where end-of-line devices are fitted with cowls, weather hoods and deflectors, etc., these attachments are to be fitted for the tests described in [4.2].

Note 3: When venting to atmosphere is not performed through an end-of-line device according to Note 2, or a detonation flame arrester according to [3.2.2], the in-line device is to be specifically tested with the inclusion of all pipes, tees, bends, cowls, weather hoods, etc., which may be fitted between the device and atmosphere. The testing is to consist of the flashback test in [4.2.2] and, if for the given installation it is possible for a stationary flame to rest on the device, the testing is also to include the endurance burning test in [4.2.3].

**2.3.2** Performance characteristics such as the flow rates under both positive and negative pressure, operating sensitivity, flow resistance and velocity are to be demonstrated by appropriate tests.

**2.3.3** Devices are to be designed and constructed to minimise the effect of fouling under normal operating conditions. Instructions on how to determine when cleaning is required and the method of cleaning are to be provided for each device in the manufacturer's instruction manual.

**2.3.4** Devices are to be capable of operating in freezing conditions and if any device is provided with heating arrangements so that its surface temperature exceeds 85°C, then it is to be tested at the highest operating temperature.

**2.3.5** Devices based upon maintaining a minimum velocity are to be capable of opening in such a way that a velocity of 30 m/s is immediately initiated, maintaining an efflux velocity of at least 30 m/s at all flow rates and, when the gas flow is interrupted, closing in such a way that this minimum velocity is maintained until the valve is fully closed.

**2.3.6** In the case of high velocity vents, the possibility of inadvertent detrimental hammering leading to damage and/or failure is to be considered, with a view to eliminating it.

Note 1: Hammering is intended to mean a rapid full stroke opening/ closing, not foreseen by the manufacturer during normal operations.

## **2.4 Flame screens**

**2.4.1** Flame screens are to be:

- a) designed in such a manner that they cannot be inserted improperly in the opening
- b) securely fitted in openings so that flames cannot circumvent the screen
- c) able to meet the requirements of this Appendix. For flame screens fitted at vacuum inlets through which vapours cannot be vented, the test specified in [4.2.3] need not be complied with
- d) protected against mechanical damage.

## **2.5 Marking of devices**

**2.5.1** Each device is to be permanently marked, or have a permanently fixed tag made of stainless steel or other corrosion-resistant material, to indicate:

- a) the manufacturer's name or trade mark
- b) the style, type, model or other manufacturer's designation for the device
- c) the size of the outlet for which the device is approved
- d) the approved location for installation, including maximum or minimum length of pipe, if any, between the device and the atmosphere
- e) the direction of flow through the device
- f) the test laboratory and report number, and
- g) compliance with the requirements of this Appendix.

## **3 Sizing, location and installation of devices**

### **3.1 Sizing of devices**

**3.1.1** To determine the size of devices to avoid inadmissible pressure or vacuum in cargo tanks during loading or discharging, calculations of pressure losses are to be carried out.

The following parameters are to be taken into account:

- a) loading/discharge rates
- b) gas evolution
- c) pressure loss through devices, taking into account the resistance coefficient
- d) pressure loss in the vent piping system
- e) pressure at which the vent opens if a high velocity valve is used
- f) density of the saturated vapour/air mixture
- g) possible fouling of a flame arrester; 70% of its rated performance is to be used in the pressure drop calculation of the installation.

### **3.2 Location and installation of devices**

#### **3.2.1 General**

- a) Devices are to be located at the vent outlets to atmosphere unless tested and approved for in-line installation.
- b) Devices for in-line installation may not be fitted at the outlets to atmosphere unless they have also been tested and approved for that position.

#### **3.2.2 Detonation flame arresters**

Where detonation flame arresters are installed as in-line devices venting to atmosphere, they are to be located at a sufficient distance from the open end of the pipeline so as to preclude the possibility of a stationary flame resting on the arrester.

#### **3.2.3 Access to the devices**

Means are to be provided to enable personnel to reach devices situated more than 2 m above deck to facilitate maintenance, repair and inspection.

## **4 Type test procedures**

### **4.1 Principles**

**4.1.1** Tests are to be conducted by a laboratory acceptable to the Society.

**4.1.2** Each size of each model is to be submitted for type testing. However, for flame arresters, testing may be limited to the smallest and the largest sizes and one additional size in between to be chosen by the Society. Devices are to have the same dimensions and most unfavourable clearances expected in the production model. If a test device is modified during the test program, the testing is to be restarted.

**4.1.3** Tests described in this Article using gasoline vapours (a non-leaded petroleum distillate consisting essentially of aliphatic hydrocarbon compounds with a boiling range approximating  $65^{\circ}\text{C} \pm 75^{\circ}\text{C}$ ), technical hexane vapours or technical propane, as appropriate, are suitable for all devices protecting tanks containing a flammable atmosphere of the cargoes referred to in Ch 7, Sec 1, [1.1.3]. This does not preclude the use of gasoline vapours or technical hexane vapours for all tests referred to in this Article.

**4.1.4** After the relevant tests, the device is not to show mechanical damage that affects its original performance.

4.1.5 Before the tests the following equipment, as appropriate, is to be properly calibrated:

- a) gas concentration meters
- b) thermometers
- c) flow meters
- d) pressure meters, and
- e) time recording devices.

4.1.6 The following characteristics are to be recorded, as appropriate, throughout the tests:

- a) concentration of fuel in the gas mixture
- b) temperature of the test gas mixture at inflow of the device, and
- c) flow rates of the test gas mixtures when applicable.

4.1.7 Flame passage is to be observed by recording, e.g. temperature, pressure, or light emission, by suitable sensors on the protected side of the device; alternatively, flame passage may be recorded on video tape.

## 4.2 Test procedure for flame arresters located at openings to the atmosphere

### 4.2.1 Test rig

The test rig is to consist of an apparatus producing an explosive mixture, a small tank with a diaphragm, a flanged prototype of the flame arrester, a plastic bag and a firing source in three positions (see Fig 1). Other test rigs may be used, provided the tests referred to in this Article are carried out to the satisfaction of the Society.

Note 1: The dimensions of the plastic bag are dependent on those of the flame arrester, but for flame arresters normally used on tankers the plastic bag may have a circumference of 2 m, a length of 2,5 m and a wall thickness of 0,05 mm.

Note 2: In order to avoid remnants of the plastic bag from falling back on to the device being tested after ignition of the fuel/air mixture, it may be useful to mount a coarse wire frame across the device within the plastic bag. The frame is to be so constructed as not to interfere with the test result.

Figure 1 : Test rig for flashback test

- (1): Plastic bursting diaphragm
- (2): Explosive mixture inlet
- (3): Tank
- (4): Flame arresting device
- (5): Plastic bag
- (6): Ignition source

### 4.2.2 Flashback test

A flashback test is to be carried out as follows:

- a) The tank, flame arrester assembly and the plastic bag (see [4.2.1]) enveloping the prototype flame arrester are to be filled so that this volume contains the most easily ignitable propane/air mixture (see IEC 60079-1). The concentration of the mixture is to be verified by appropriate testing of the gas composition in the plastic bag. Where devices referred to in [2.3.1], Note 3 are tested, the plastic bag is to be fitted at the outlet to atmosphere. Three ignition sources are to be installed along the axis of the bag, one close to the flame arrester, another as far away as possible therefrom, and the third at the mid-point between these two. These three sources are to be fired in succession, twice in each of the three positions. The temperature of the test gas is to be within the range of 15°C to 40°C.
- b) If a flashback occurs, the tank diaphragm will burst and this will be audible and visible to the operator by the emission of a flame. Flame, heat and pressure sensors may be used as an alternative to a bursting diaphragm.

### **4.2.3 Endurance burning test**

An endurance burning test is to be carried out, in addition to the flashback test, for flame arresters at outlets where flows of explosive vapour are foreseeable:

- a) The test rig as referred to in [4.2.1] may be used, without the plastic bag. The flame arrester is to be so installed that the mixture emission is vertical. In this position the mixture is to be ignited. Where devices referred to in [2.3.1] Note 3, are tested, the flame arrester is to be so installed as to reflect its final orientation.
- b) Endurance burning is to be achieved by using the most easily ignitable gasoline vapour/air mixture or the most easily ignitable technical hexane vapour/air mixture with the aid of a continuously operated pilot flame or a continuously operated spark igniter at the outlet. The test gas is to be introduced upstream of the tank shown in Fig 1. Maintaining the concentration of the mixture as specified above, by varying the flow rate, the flame arrester is to be heated until the highest obtainable temperature on the cargo tank side of the arrester is reached. Temperatures are to be measured, for example, at the protected side of the flame quenching matrix of the arrester (or at the seat of the valve in the case of testing high velocity vents according to [4.3]). The highest obtainable temperature may be considered to have been reached when the rate of rise of temperature does not exceed 0,5°C per minute over a ten-minute period. This temperature is to be maintained for a period of ten minutes, after which the flow is to be stopped and the conditions observed. The temperature of the test gas is to be within the range of 15°C to 40°C.

If no temperature rise occurs at all, the arrester is to be inspected for a more adequate position of the temperature sensor, taking account of the visually registered position of the stabilised flame during the first test sequence. Positions which require the drilling of small holes into fixed parts of the arrester are to be taken into account. If all this is not successful, the temperature sensor is to be affixed at the unprotected side of the arrester in a position near to the stabilised flame.

If difficulties arise in establishing stationary temperature conditions (at elevated temperatures), the following criteria is to apply: using the flow rate which produced the maximum temperature during the foregoing test sequence, endurance burning is to be continued for a period of two hours from the time the above-mentioned flow rate has been established. After that period the flow is to be stopped and the conditions observed. Flashback is not to occur during this test.

### **4.2.4 Pressure/vacuum valve integrated to a flame arresting device**

When a pressure/vacuum valve is integrated to a flame arresting device, the flashback test is to be performed with the pressure/vacuum valve blocked open. If there are no additional flame quenching elements integrated in a pressure valve, this valve is to be considered and tested as a high velocity vent valve according to [4.3].

## **4.3 Test procedures for high velocity vents**

### **4.3.1 Test rig**

The test rig is to be capable of producing the required volume flow rate. In Fig 2 and Fig 3 drawings of suitable test rigs are shown. Other test rigs may be used provided the tests are performed to the satisfaction of the Society.

### **4.3.2 Flow condition test**

A flow condition test is to be carried out with high velocity vents using compressed air or gas at agreed flow rates. The following are to be recorded:

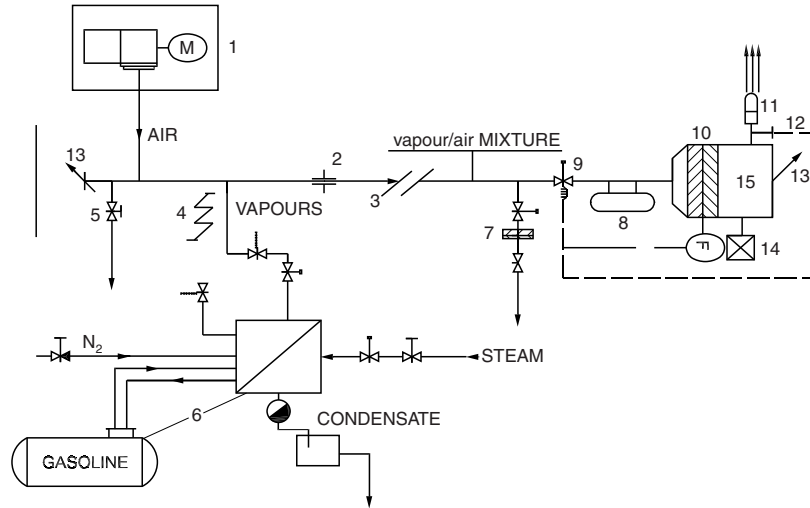

- a) the flow rate; where air or a gas other than vapours of cargoes with which the vent is to be used is employed in the test, the flow rates achieved are to be corrected to reflect the vapour density of such cargoes
- b) the pressure before the vent opens; the pressure in the test tank on which the device is located is not to rise at a rate greater than 0,01 N/mm<sup>2</sup>/min
- c) the pressure at which the vent opens
- d) the pressure at which the vent closes
- e) the efflux velocity at the outlet which is not to be less than 30 m/s at any time when the valve is open.

### **4.3.3 Fire safety tests**

The following fire safety tests are to be conducted while adhering to [2.3.6] using a mixture of gasoline vapour and air or technical hexane vapour and air, which produces the most easily ignitable mixture at the point of ignition. This mixture is to be ignited with the aid of a permanent pilot flame or a spark igniter at the outlet.

- a) Flashback tests in which propane may be used instead of gasoline or hexane are to be carried out with the vent in the upright position and then inclined at 10° from the vertical. For some vent designs further tests with the vent inclined in more than one direction may be necessary. In each of these tests the flow is to be reduced until the vent closes and the flame is extinguished, and each is to be carried out at least 50 times. The vacuum side of combined valves is to be tested in accordance with [4.2.2] with the vacuum valve maintained in the open position for the duration of this test, in order to verify the efficiency of the device which is to be fitted.
- b) An endurance burning test, as described in [4.2.3], is to be carried out. Following this test, the main flame is to be extinguished and then, with the pilot flame burning or the spark igniter discharging, small quantities of the most easily ignitable mixture are to be allowed to escape for a period of ten minutes maintaining a pressure below the valve of 90% of the valve opening setting, during which time flashback is not to occur. For the purpose of this test the soft seals or seats are to be removed.

#### 4.4 Test rig and test procedures for detonation flame arresters located in-line

4.4.1 A flame arrester is to be installed at one end of a pipe of suitable length and of the same diameter as the flange of the flame arrester. On the opposed flange a pipe of a length corresponding to 10 pipe diameters is to be affixed and closed by a plastic bag or diaphragm. The pipe is to be filled with the most easily ignitable mixture of propane and air, which is then to be ignited. The velocity of the flame near the flame arrester is to be measured and is to have the same value as that for stable detonations.

Note 1: The dimensions of the plastic bag are to be at least 4 m circumference, 4 m length and a material wall thickness of 0,05 mm.

Figure 4 : Test rig for arresters located in-line

- (1): Explosive mixture inlet
- (2): Ignition source; ignition within non-streaming mixture
- (3): Tank
- (4): Measuring system for flame speed of a stable detonation
- (5): Flame arrester located in-line; (5.1): Flame arrester element; (5.2): Shock wave absorber
- (6): Plastic bag
- (7):  $l/d = 100$

4.4.2 Three detonation tests are to be conducted, no flashback is to occur through the device and no part of the flame arrester is to be damaged or show permanent deformation.

4.4.3 Other test rigs may be used provided the tests are carried out to the satisfaction of the Society. A drawing of the test rig is shown in Fig 4.

#### 4.5 Operational test procedure

##### 4.5.1 Corrosion test

A corrosion test is to be carried out. In this test a complete device, including a section of the pipe to which it is fitted, is to be exposed to a 5% sodium chloride solution spray at a temperature of 25°C for a period of 240 hours, and allowed to dry for 48 hours. An equivalent test may be conducted to the satisfaction of the Society. Following this test, all movable parts are to operate properly and there are to be no corrosion deposits which cannot be washed off.

##### 4.5.2 Hydraulic pressure test

A hydraulic pressure test is to be carried out in the casing or housing of a sample device, in accordance with [2.2.15].

#### 4.6 Laboratory report

4.6.1 The laboratory report is to include:

- a) detailed drawings of the device
- b) types of tests conducted; where in-line devices are tested, this information is to include the maximum pressures and velocities observed in the test
- c) specific advice on approved attachments
- d) types of cargo for which the device is approved
- e) drawings of the test rig
- f) in the case of high velocity vents, the pressures at which the device opens and closes and the efflux velocity, and
- g) all the information marked on the device in [2.5].

# Appendix 2      Design of Crude Oil Washing Systems

## 1 General

### 1.1 Application

**1.1.1** This Appendix reproduces the text of IMO Resolution A.446. It applies to ships having the notation **oil tanker** in the conditions stated in Ch 7, Sec 4, [4.6.1].

### 1.2 Definitions

#### 1.2.1 Arrival ballast

For the purpose of this Appendix, "arrival ballast" means clean ballast as defined in Ch 7, Sec 1, [1.2.5].

#### 1.2.2 Departure ballast

For the purpose of this Appendix, "departure ballast" means ballast other than arrival ballast.

### 1.3 Operations and Equipment Manual

**1.3.1** The Operations and Equipment Manual of the crude oil washing system is to be submitted to the Society for information. It is to contain at least the following information:

- a) line drawing of the crude oil washing system showing the respective position of pumps, lines and washing machines which relate to the crude oil washing system
- b) a description of the system and a listing of procedures for checking that equipment is working properly during crude oil washing operations. This is to include a listing of the system and equipment parameters to be monitored, such as line pressure, oxygen level, machine revolutions, duration of cycles, etc. The established values for these parameters are to be included. The results of the tests carried out in accordance with [3.3] and the values of all parameters monitored during such tests are also to be included.
- c) other information referred to in [2.1.8], [2.2.2], [2.3.2], [2.3.5], [2.4.3] and [3.3.1].

## 2 Design and installation

### 2.1 Piping

**2.1.1** The crude oil washing pipes and all valves incorporated in the supply piping system are to be of steel or other equivalent material, of adequate strength having regard to the pressure to which they may be subjected, and properly jointed and supported.

Note 1: Grey cast iron may be permitted in the supply system for crude oil washing systems when complying with nationally approved standards.

**2.1.2** The crude oil washing system is to consist of permanent pipework and is to be independent of the fire mains and of any system other than for tank washing except that sections of the ship's cargo system may be incorporated into the crude oil washing system provided that they meet the requirements applicable to crude oil pipework. Notwithstanding the above requirements, in combination carriers the following arrangements may be allowed:

- a) the removal of the equipment, if necessary, when carrying cargoes other than crude oil, provided that, when reinstated, the system is as originally fitted and tested for oil-tightness
- b) the use of flexible hose pipes to connect the crude oil washing system to tank washing machines if it is necessary to locate these machines in a cargo tank hatch cover. Such flexible hose pipes are to be provided with flanged connections, manufactured and tested in accordance with standards acceptable to the Society, and consistent with the duties the hoses are required to perform. The length of these hoses is not to be greater than necessary to connect the tank washing machines to an adjacent point just outside the hatch coaming. The hoses are to be removed to a suitably prepared and protected stowage location when not in use.

**2.1.3** Provisions are to be made to prevent overpressure in the tank washing supply piping. Any relief device fitted to prevent overpressure is to discharge into the suction side of the supply pump. Alternative methods to the satisfaction of the Society may be accepted provided an equivalent degree of safety and environmental protection is provided.

Note 1: Where the system is served only by centrifugal pumps so designed that the pressure derived cannot exceed that for which the piping is designed, a temperature sensing device located in the pump casing is required to stop the pump in the case of overheating.

**2.1.4** Where hydrant valves are fitted for water washing purposes on tank washing lines, all such valves are to be of adequate strength and provisions are to be made for such connections to be blanked off by blank flanges when washing lines may contain crude oil. Alternatively, hydrant valves are to be isolated from the crude oil washing system by spade blanks.

**2.1.5** All connections for pressure gauges or other instrumentation are to be provided with isolating valves adjacent to the lines unless the fitting is of the sealed type.

**2.1.6** No part of the crude oil washing system is to enter machinery spaces. Where the tank washing system is fitted with a steam heater for use when water washing, the heater is to be located outside machinery spaces and effectively isolated during crude oil washing by double shut-off valves or by clearly identifiable blanks.

**2.1.7** Where combined crude oil-water washing supply piping is provided, the piping is to be so designed that it can be drained so far as practicable of crude oil, before water washing is commenced, into designated spaces. These spaces may be the slop tank or other cargo spaces.

**2.1.8** The piping system is to be of such diameter that the greatest number of tank cleaning machines required, as specified in the Operations and Equipment Manual, can be operated simultaneously at the designed pressure and throughput. The arrangement of the piping is to be such that the required number of tank cleaning machines for each cargo compartment as specified in the Operations and Equipment Manual can be operated simultaneously.

**2.1.9** The crude oil washing supply piping is to be anchored (firmly attached) to the ship's structure at appropriate locations, and means are to be provided to permit freedom of movement elsewhere to accommodate thermal expansion and flexing of the ship. The anchoring is to be such that any hydraulic shock can be absorbed without undue movement of the supply piping. The anchors are normally to be situated at the ends furthest from the entry of the crude oil supply to the supply piping. If tank washing machines are used to anchor the ends of branch pipes then special arrangements are necessary to anchor these sections when the machines are removed for any reason.

## **2.2 Tank washing machines**

**2.2.1** Tank washing machines for crude oil washing are to be permanently mounted and of a design acceptable to the Society.

**2.2.2** The performance characteristic of a tank washing machine is governed by nozzle diameter, working pressure and the movement pattern and timing. Each tank cleaning machine fitted is to have a characteristic such that the sections of the cargo tank covered by that machine will be effectively cleaned within the time specified in the Operations and Equipment Manual.

**2.2.3** Tank washing machines are to be mounted in each cargo tank and the method of support is to be to the satisfaction of the Society. Where a machine is positioned well below the deck level to cater for protuberances in the tank, consideration may need to be given to additional support for the machine and its supply piping.

**2.2.4** Each machine is to be capable of being isolated by means of stop valves in the supply line. If a deck mounted tank washing machine is removed for any reason, provision is to be made to blank off the oil supply line to the machine for the period the machine is removed. Similarly, provision is to be made to close the tank opening with a plate or equivalent means.

Note 1: Where more than one submerged machine is connected to the same supply line, a single isolating stop valve in the supply line may be acceptable provided the rotation of the submerged machine can be verified in accordance with [2.2.10]

**2.2.5** The number and location of tank washing machines are to be to the satisfaction of the Society.

**2.2.6** The location of the machines is dependent upon the characteristics detailed in [2.2.2] and upon the configuration of the internal structure of the tank.

**2.2.7** The number and location of the machines in each cargo tank are to be such that all horizontal and vertical areas are washed by direct impingement or effectively by deflection or splashing of the impinging jet. In assessing an acceptable degree of jet deflection and splashing, particular attention is to be paid to the washing of upward facing horizontal areas and the following parameters are to be used:

- a) For horizontal areas of a tank bottom and the upper surfaces of a tank's stringers and other large primary structural members, the total area shielded from direct impingement by deck or bottom transverses, main girders, stringers or similar large primary structural members is not to exceed 10 per cent of the horizontal area of the tank bottom, the upper surface of stringers, and other large primary structural members.
- b) For vertical areas of the sides of a tank, the total area of the tank's sides shielded from direct impingement by deck or bottom transverses, main girders, stringers or similar large primary structural members is not to exceed 15 per cent of the total area of the tank's sides.

In some installations, it may be necessary to consider the fitting of more than one type of tank washing machine in order to effect adequate coverage.

Note 1: With regard to the application of this requirement, a slop tank is considered as a cargo tank.

**2.2.8** At the design stage the following minimum procedures are to be used to determine the area of the tank surface covered by direct impingement:

- a) Using suitable structural plans, lines are set out from the tips of each machine to those parts of the tank within the range of the jets.
- b) Where the configuration of the tanks is considered by the Society to be complicated, a pinpoint of light simulating the tip of the tank washing machine in a scale model of the tank is to be used.

**2.2.9** The design of the deck mounted tank washing machines is to be such that means are provided external to cargo tanks which, when crude oil washing is in progress, would indicate the rotation and arc of the movement of the machine. Where the deck mounted machine is of the non-programmable, dual nozzle type, alternative methods to the satisfaction of the Society may be accepted provided an equivalent degree of verification is attained.

**2.2.10** Where submerged machines are required, they are to be non-programmable and, in order to comply with the requirements of [2.2.7], it is to be possible to verify their rotation by one of the following methods:

- a) by indicators external to the tanks
- b) by checking the characteristic sound pattern of the machine, in which case the operation of the machine is to be verified towards the end of each wash cycle. Where two or more submerged machines are installed on the same supply line, valves are to be provided and arranged so that the operation of each machine can be verified independently of other machines on the same supply line.
- c) by gas freeing the tank and checking the operation of the machine with water during ballast voyages.

## **2.3 Pumps**

**2.3.1** Pumps supplying crude oil to tank cleaning machines are to be either the cargo pumps or pumps specifically provided for the purpose.

**2.3.2** The capacity of the pumps is to be sufficient to provide the necessary throughput at the required pressure for the maximum number of tank cleaning machines required to be operated simultaneously as specified in the Operations and Equipment Manual. In addition to the above requirement, if an eductor system is fitted for tank stripping, the pumps are to be capable of supplying the eductor driving fluid to meet the provisions of [2.4.2].

**2.3.3** The capacity of the pumps is to be such that the requirements of [2.3.2] can be met with any one pump inoperative. The pumping and piping arrangements are to be such that the crude oil washing system can be effectively operated with any one pump out of use.

**2.3.4** The carriage of more than one grade of cargo is not to prevent crude oil washing of tanks.

**2.3.5** To permit crude oil washing to be effectively carried out where the back pressure presented by the shore terminal is below the pressure required for crude oil washing, provision is to be made such that an adequate pressure to the washing machines can be maintained in accordance with [2.3.2]. This requirement is to be met with any one cargo pump out of action. The minimum supply pressure required for crude oil washing is to be specified in the Operations and Equipment Manual. Should this minimum supply pressure not be obtainable, crude oil washing operations are not to be carried out.

## **2.4 Stripping system**

**2.4.1** The design of the system for stripping crude oil from the bottom of every cargo tank is to be to the satisfaction of the Society.

**2.4.2** The design and capacity of the tank stripping system are to be such that the bottom of the tank being cleaned is kept free of accumulations of oil and sediment towards completion of the tank washing process.

**2.4.3** The stripping system is to be at least 1,25 times the total throughput of all the tank cleaning machines to be operated simultaneously when washing the bottom of the cargo tanks as described in the ship's Operations and Equipment Manual.

**2.4.4** Means such as level gauges, hand dipping and stripping system performance gauges as referred to in [2.4.8] are to be provided for checking that the bottom of every cargo tank is dry after crude oil washing. Suitable arrangements for hand dipping are to be provided at the aftermost portion of a cargo tank and in three other suitable locations unless other approved means are fitted for efficiently ascertaining that the bottom of every cargo tank is dry. For the purpose of this paragraph, the cargo tank bottom is to be considered "dry" if there is no more than a small quantity of oil near the stripping suction with no accumulation of oil elsewhere in the tank.

**2.4.5** Means are to be provided to drain all cargo pumps and lines at the completion of cargo discharge, where necessary, by connection to a stripping device. The line and pump draining is to be capable of being discharged both to a cargo tank and ashore. For discharge ashore, a special small diameter line is to be provided for this purpose and connected outboard of the ship's manifold valve. The cross-sectional area of this line is not to exceed 10 per cent of that of a main cargo discharge line.

Note 1: In crude oil tankers having individual cargo pumps in each tank, each pump having an individual piping system, dispensation from the required special small diameter line may be granted in cases where the combined amount of oil left in the tank after stripping and the volume

of oil in the piping system from the manifold to the tank is less than 0,00085 times the volume of the cargo tank. The above consideration is also to apply if a deepwell cargo pump system is provided with an evacuating system for retained oil.

**2.4.6** The means for stripping oil from cargo tanks are to be a positive displacement pump, self-priming centrifugal pump or eductor or other methods to the satisfaction of the Society. Where a stripping line is connected to a number of tanks, means are to be provided for isolating each tank not being stripped at that particular time.

**2.4.7** The carriage of more than one grade of cargo is not to prevent crude oil washing of tanks.

**2.4.8** Equipment is to be provided for monitoring the efficiency of the stripping system. All such equipment is to have remote read out facilities in the cargo control room or in some other safe and convenient place easily accessible to the officer in charge of cargo and crude oil washing operations. Where a stripping pump is provided, the monitoring equipment is to include either a flow indicator, or a stroke counter or revolution counter as appropriate, and pressure gauges at the inlet and discharge connections of the pump or equivalent. Where eductors are provided, the monitoring equipment is to include pressure gauges at the driving fluid intake and at the discharge and a pressure/vacuum gauge at the suction intake.

**2.4.9** The internal structure of the tank is to be such that drainage of oil to the tank suction of the stripping system is adequate to meet the requirements of [2.4.2] and [2.4.4].

## 2.5 Ballast lines

**2.5.1** Where a separate ballast water system for ballasting cargo tanks is not provided, the arrangement is to be such that the cargo pump, manifolds and pipes used for ballasting can be safely and effectively drained of oil before ballasting.

## 3 Inspection and testing

### 3.1 Initial survey

**3.1.1** The initial survey required in Ch 7, Sec 4, [6.3.2] is to include a complete inspection of the crude oil washing equipment and arrangements and, except for the cases specified in [3.3.3], an examination of the tanks after they have been crude oil washed and the additional checks specified in [3.3.1] and [3.3.2] to ensure that the washing system efficiency is in accordance with this Appendix.

### 3.2 Piping

**3.2.1** The piping system is to be tested to one and a half times the working pressure after it has been installed on the ship.

### 3.3 Tank washing machines

**3.3.1** To confirm the cleanliness of the tank and to verify the design in respect of the number and location of the tank washing machines, a visual inspection is to be made by entry to the tanks after a crude oil wash but prior to any water rinse which may be specified in the Operations and Equipment Manual. The bottom of the tank to be inspected may, however, be flushed with water and stripped in order to remove any wedge of liquid crude oil remaining on the tank bottom before gas freeing for entry. This inspection is to ensure that the tank is essentially free of oil clingage and deposits. If the flushing procedure is adopted, a similar but unflushed tank is to be used for the test specified in [3.3.2].

**3.3.2** To verify the effectiveness of the stripping and drainage arrangements, a measurement is to be made of the amount of oil floating on top of the departure ballast. The ratio of the volume of oil on top of the departure ballast water to the volume of tanks that contain this water is not to exceed 0,00085. This test is to be carried out after crude oil washing and stripping in a tank similar in all relevant respects to the tank examined in accordance with [3.3.1] above, which has not been subjected to a water rinse or to the intervening water flushing permissible in [3.3.1] above.

**3.3.3** When the Society is satisfied that ships are similar in all relevant respects, the provisions of [3.3.1] and [3.3.2] need only be applied to one such ship. Furthermore, where a ship has a series of tanks that are similar in all relevant respects then, for that series of tanks, the requirements of [3.3.1] need only be applied to one tank of that series.

### 3.4 Stripping system

**3.4.1** Care is to be taken that both longitudinal and transverse drainage are satisfactory. Drainage is to be verified during the inspection required by [3.3].

# Appendix 3 Lists of Oils

## 1 Application

### 1.1 Scope of the lists of oils

**1.1.1** The lists set out in this Appendix include the oils the carriage in bulk of which is covered by the service notations **oil tanker** or **oil tanker, flash point > 60°C** or **oil tanker, asphalt carrier**, under the provisions of Ch 7, Sec 1, [1.1.3].

## 2 Lists of products

### 2.1 List of oils

**2.1.1** The list given in Tab 1 is reproduced from Appendix 1 of the MARPOL 73/78 Convention, except that naphtha solvent is, in the opinion of the Society, to be considered as a chemical to which Part D, Chapter 8 applies. This list is not necessarily comprehensive.

**Table 1 : List of oils**

# Appendix 4 List of Products for which Part D, Chapter 8 and IBC Code do not Apply

## 1 Application

### 1.1 Scope of the list

**1.1.1** The list set out in this Appendix includes all products to which Part D, Chapter 8 and IBC Code do not apply. Such products are allowed to be carried by ships having the service notation **FLS tanker** or, where their flash point is above 60°C, also by ships having the service notation **FLS tanker flash point > 60 °C**.

Where indicated in the list, some products are also allowed to be carried by ships having the service notation **tanker**.

### 1.2 Safety and pollution hazards

#### 1.2.1

- The following are products which have been reviewed for their safety and pollution hazards and determined not to present hazards to such an extent as to warrant application of the IBC Code and Part D, Chapter 8.
- Although the products listed in this Appendix fall outside the scope of the IBC Code and Part D, Chapter 8, some safety precautions are needed for their safe transportation. Relevant requirements are summarized in Tab 1.
- Some liquid substances are identified as falling into pollution category Z and, therefore, subject to certain requirements of MARPOL Annex II.
- Liquid mixtures which are assessed or provisionally assessed under Regulation 6.3 of MARPOL Annex II as falling into pollution category Z or OS, and which do not present safety hazards, may be carried under the appropriate entry in this Appendix for "Noxious or Non-Noxious liquid substances, not otherwise specified (n.o.s.)".
- The liquid substances identified as falling into pollution category OS are not subject to any requirements of MARPOL Annex II in particular in respect of:
  - the discharge of bilge or ballast water or other residues or mixtures containing only such substances
  - the discharge into the sea of clean ballast or segregated ballast.

## 2 List of products for which Part D, Chapter 8 and IBC Code do not apply

### 2.1

**2.1.1** The list of products for which Part D, Chapter 8 and IBC Code do not apply is given in Tab 1. The relevant symbols and notations used in Tab 1 are given in Tab 2.

**Table 1 : List of easy chemicals**

Product name	Pollution category	Electrical equipment temperature class	Electrical equipment apparatus group	Flash-point (°C)	Fire protection	Service notation

**Table 2 : Symbols and notations used in the list of easy chemicals**

Items	Column	Comments
Product name	(a)	Gives the alphabetical name of the products
Pollution category	(b)	The letter Z refers to the pollution category Z as defined in MARPOL Annex II. The symbol OS means that the product was evaluated and found to fall outside the pollution categories X, Y and Z defined in MARPOL Annex II
Electrical equipment temperature class	(c)	The symbols T1 to T6 refer to the electrical equipment temperature classes defined in IEC Publication 60079-20-1:2010
Electrical equipment apparatus group	(d)	The symbols IIA, IIB and IIC refer to the electrical equipment apparatus groups defined in IEC Publication 60079-20-1:2010
Flash point	(e)	NF: non-flammable product
Fire protection	(f)	The letters A, B, C and D refer to the following fire-extinguishing media determined to be effective for certain products: A : Alcohol-resistant foam (or multi-purpose foam) B : Regular foam, encompasses all foams that are not of an alcohol-resistant type, including fluoro-protein and aqueous-film-forming foam (AFFF) C : Water spray D : Dry chemical (powder)
Service notation	(g)	The symbols FLS, FLS>60 and T are defined as follows: FLS : Means that the product is allowed to be carried by a ship having the service notation <b>FLS tanker</b> FLS>60 : Means that the product is allowed to be carried by a ship having the service notation <b>FLS tanker, flash point &gt; 60°C</b> T : Means that the product is allowed to be carried by a ship having the service notation <b>tanker</b>

# Appendix 5 Accidental Oil Outflow Performance

## Symbols

- $d_s$  : Load line draught, equal to the vertical distance, in m, from the moulded baseline at mid-length to the waterline corresponding to the summer freeboard to be assigned to the ship. Calculations pertaining to this regulation are to be based on draught  $d_s$ , notwithstanding assigned draughts that may exceed  $d_s$ , such as the tropical loadline
- $d_B$  : Vertical distance, in metres, from the moulded baseline at mid-length to the waterline corresponding to 30% of the depth  $D_s$
- $B_s$  : Greatest moulded breadth of the ship, in metres, at or below the deepest load line  $d_s$
- $B_B$  : Greatest moulded breadth of the ship, in metres, at or below the waterline  $d_B$
- $D_s$  : Moulded depth, in metres, measured at mid-length to the upper deck at side
- $\rho_s$  : Density of sea water, to be taken as 1025 kg/m<sup>3</sup>
- $\rho_n$  : Nominal density of cargo oil, in kg/m<sup>3</sup>, to be taken equal to:  
 $\rho_n = 1000 (DWT)/C$
- $C$  : Total volume of cargo oil, in m<sup>3</sup>, at 98% tank filling.

## 1 General

### 1.1 Purpose

1.1.1 The purpose of the present Appendix is to provide a method for the calculation of the accidental oil outflow performance referred to in Ch 7, Sec 2, [3.4.1].

### 1.2 Application

1.2.1 The requirements of the present Appendix apply only to ships having one of the following notations:

- oil tanker
- oil tanker, flash point > 60°C
- oil tanker, asphalt carrier.

## 2 Accidental oil outflow performance

### 2.1 Mean oil outflow parameter

2.1.1 To provide adequate protection against oil pollution in the event of collision or stranding the following is to be complied with:

a) For oil tankers of 5000 tonnes deadweight (DWT) and above, the mean oil outflow parameter  $O_M$  is to be as follows:

- for  $C = 200000$  m<sup>3</sup>:  
 $O_M = 0,015$
- for  $200000 \text{ m}^3 < C < 400000 \text{ m}^3$ :  
 $O_M = 0,012 + (0,003/200000) (400000 - C)$
- for  $C = 400000$  m<sup>3</sup>:  
 $O_M = 0,012$

For combination carriers between 5000 tonnes deadweight (DWT) and 200000 m<sup>3</sup> capacity, the mean oil outflow parameter  $O_M$  may be applied, provided calculations are submitted to the satisfaction of the Society, demonstrating that after accounting for its increased structural strength, the combination carrier has at least equivalent oil outflow performance to a standard double hull tanker of the same size having a  $O_M = 0,015$ .

- for  $C = 100000$  m<sup>3</sup>:  
 $O_M = 0,021$
- for  $100000 \text{ m}^3 < C < 200000 \text{ m}^3$ :  
 $O_M = 0,015 + (0,006/100000) (200000 - C)$

b) For oil tankers of less than 5000 tonnes deadweight (DWT):

The length of each cargo tank is not to exceed 10 m or one of the following values, whichever is the greater:

- where no longitudinal bulkhead is provided inside the cargo tanks:  
(0,5  $b_i/B + 0,1$ ) L without exceeding 0,2 L
- where centreline longitudinal bulkhead is provided inside the cargo tanks:  
(0,25  $b_i/B + 0,15$ ) L
- where two or more longitudinal bulkheads are provided inside the cargo tanks:  
as defined in Tab 1.

**Table 1 : Length of each cargo tank for oil tankers of less than 5000 tonnes deadweight (DWT)**

Wing cargo tanks	Centre cargo tanks		
	$b_i/B \geq 0,2 L$	$b_i/B < 0,2 L$	
0,2 L	0,2 L	no centreline longitudinal bulkhead is provided	a centreline longitudinal bulkhead is provided
		(0,5 $b_i/B + 0,1$ ) L	(0,25 $b_i/B + 0,15$ ) L

$b_i$  : Minimum distance from the ship's side to the outer longitudinal bulkhead of the tank in question measured inboard at right angles to the centreline at the level corresponding to the assigned summer freeboard.

**2.2 Calculation**

**2.2.1 Assumptions**

The cargo block length extends between the forward and aft extremities of all tanks arranged for the carriage of cargo oil, including slop tanks.

Where this regulation refers to cargo tanks, it is to be understood to include all cargo tanks, slop tanks and fuel tanks located within the cargo block length.

The ship is to be assumed loaded to the load line draught  $d_s$  without trim or heel.

All cargo oil tanks is to be assumed loaded to 98% of their volumetric capacity.

For the purposes of these outflow calculations, the permeability of each space within the cargo block, including cargo tanks, ballast tanks and other non-oil spaces is to be taken as 0,99, unless proven otherwise.

Suction wells may be neglected in the determination of tank location provided that such wells are as small as practicable and the distance between the well bottom and bottom shell plating is not less than 0,5h, where h is equal to B/15 or 2,0 m, whichever is the lesser, without being taken less than 1,0 m.

**2.2.2 Combination of oil outflow parameters**

The mean oil outflow is to be calculated independently for side damage and for bottom damage and then combined into the non-dimensional oil outflow parameter  $O_M$ , as follows:

$$O_M = (0,4 O_{MS} + 0,6 O_{MB})/C$$

where:

$O_{MS}$  : Outflow for side damage, in  $m^3$

$O_{MB}$  : Outflow for bottom damage, in  $m^3$ .

For bottom damage, independent calculations for mean outflow is to be done for 0 m and minus 2,5 m tide conditions, and then combined as follows:

$$O_{MB} = 0,7 O_{MB(0)} + 0,3 O_{MB(2,5)}$$

where:

$O_{MB(0)}$  : Outflow for 0 m tide condition

$O_{MB(2,5)}$  : Outflow for minus 2,5 m tide condition, in  $m^3$ .

**2.2.3 Mean outflow**

a) The mean outflow, in  $m^3$ , for side damage  $O_{MS}$  is to be calculated as follows:

$$O_{MS} = C_3 \sum (P_{S(i)} O_{S(i)})$$

where:

i : Represents each cargo tank under consideration

n : Total number of cargo tanks

$P_{S(i)}$  : Probability of penetrating cargo tank i from side damage, calculated in accordance with [2.2.4]

$O_{S(i)}$  : Outflow, in  $m^3$ , from side damage to cargo tank i, which is assumed equal to the total volume in cargo tank i at 98% filling

- $C_3$  :
- for ships having two longitudinal bulkheads inside the cargo tanks, provided these bulkheads are continuous over the cargo block and  $P_{S(i)}$  is developed in accordance with this regulation:  
 $C_3 = 0,77$
  - for all other ships:  
 $C_3 = 1,00$

b) The mean outflow for bottom damage is to be calculated for each tidal condition as follows:

$$O_{MB(0)} = \Sigma(P_{B(i)} O_{B(i)} C_{DB(i)})$$

where:

$i$  : Represents each cargo tank under consideration

$n$  : Total number of cargo tanks

$P_{B(i)}$  : Probability of penetrating cargo tank  $i$  from bottom damage calculated in accordance with [2.2.5]

$O_{B(i)}$  : Outflow from cargo tank  $i$ , in  $m^3$  as defined in item c)

$C_{DB(i)}$  : Factor to account for oil capture as defined in item d)

$$O_{MB(2,5)} = \Sigma(P_{B(i)} O_{B(i)} C_{DB(i)})$$

where:

$O_{B(i)}$  : Outflow from cargo tank  $i$ , in  $m^3$ , after tidal change.

c) The oil outflow  $O_{B(i)}$  for each cargo oil tank is to be calculated based on pressure-balance principles, in accordance with the following assumptions:

- the ship is to be assumed stranded with zero trim and heel, with the stranded draught prior to tidal change equal to the load line draught  $d_s$

- the cargo level after damage is to be calculated as follows:

$$h_c = ((d_s + t_c - Z_l) \rho_s - (1000 p) / g) / \rho_n$$

where:

$h_c$  : Height of the cargo oil above  $Z_l$ , in m

$t_c$  : Tidal change, in m. Reductions in tide shall be expressed as negative values

$Z_l$  : Height of the lowest point in the cargo tank above baseline, in m

$p$  : If an inert gas system is fitted, the normal overpressure, in kPa, to be taken as not less than 5 kPa.

If an inert gas system is not fitted, the overpressure may be taken as 0

- for cargo tanks bounded by the bottom shell, unless proven otherwise, oil outflow  $O_{B(i)}$  is to be taken not less than 1% of the total volume of cargo oil loaded in cargo tank  $i$ , to account for initial exchange losses and dynamic effects due to current and waves.

d) In the case of bottom damage, a portion from the outflow from a cargo tank may be captured by non-oil compartments. This effect is approximated by application of the factor  $C_{DB(i)}$  for each tank, which is to be taken as follows:

- for cargo tanks bounded from below by non-oil compartments:

$$C_{DB(i)} = 0,6$$

- for cargo tanks bounded by the bottom shell:

$$C_{DB(i)} = 1,0$$

### 2.2.4 Probability of breaching a compartment from side damage

The probability  $P_S$  of breaching a compartment from side damage is to be calculated as follows:

$$P_S = P_{SL} P_{SV} P_{ST}$$

where:

$P_{SL}$  : Probability the damage extends into the longitudinal zone bounded by  $X_a$  and  $X_f$

$$P_{SL} = 1 - P_{Sf} - P_{Sa}$$

$P_{SV}$  : Probability the damage extends into the vertical zone bounded by  $Z_l$  and  $Z_u$

$$P_{SV} = 1 - P_{Su} - P_{S1}$$

$P_{ST}$  : Probability the damage extends transversely beyond the boundary defined by  $y$

$$P_{ST} = 1 - P_{Sy}$$

$P_{Sar}$ ,  $P_{Sfr}$ ,  $P_{S1}$  and  $P_{Su}$  are to be determined by linear interpolation from Tab 2 of probabilities for side damage provided in Tab 2 where:

$P_{Sa}$  : Probability the damage lies entirely aft of location  $X_a / L$

$P_{Sf}$  : Probability the damage lies entirely forward of location  $X_f / L$

$P_{S1}$  : Probability the damage lies entirely below the tank

$P_{Su}$  : Probability the damage lies entirely above the tank.

$P_{Sy}$ , the probability the damage lies entirely outboard of the tank, is to be determined as follows:

- for  $y / B_s = 0,05$ :  
 $P_{Sy} = (24,96 - 199,6 y / B_s) (y / B_s)$
- for  $0,05 < y / B_s < 0,10$ :  
 $P_{Sy} = 0,749 + (5 - 44,4 (y / B_s - 0,05)) (y / B_s - 0,05)$
- for  $y / B_s = 0,10$ :  
 $P_{Sy} = 0,888 + 0,56 (y / B_s - 0,1)$

$P_{Sy}$  is not to be taken greater than 1.

Compartment boundaries  $X_a$ ,  $X_f$ ,  $Z_l$ ,  $Z_u$  and  $y$  are to be developed as follows:

- $X_a$  : Longitudinal distance from the aft terminal of L to the aftmost point on the compartment being considered, in m
- $X_f$  : Longitudinal distance from the aft terminal of L to the foremost point on the compartment being considered, in m
- $Z_l$  : Vertical distance from the moulded baseline to the lowest point on the compartment being considered, in m
- $Z_u$  : Vertical distance from the moulded baseline to the highest point on the compartment being considered, in m  
 $Z_u$  is not to be taken greater than  $D_s$
- $y$  : Minimum horizontal distance measured at right angles to the centreline between the compartment under consideration and the side shell, in m.

Note 1: For symmetrical tank arrangements, damages are considered for one side of the ship only, in which case all "y" dimensions are to be measured from that same side.

For asymmetrical arrangements refer to the Explanatory Notes on matters related to the accidental oil outflow performance, adopted by the IMO by resolution MEPC.122(52).

**Table 2 : Probabilities for side damage**

$X_a/L$	$P_{Sa}$	$X_f/L$	$P_{Sf}$	$Z_l/D_s$	$P_{Sl}$	$Z_u/D_s$	$P_{Su}$

**2.2.5 Probability of breaching a compartment from bottom damage**

The probability  $P_B$  of breaching a compartment from bottom damage is to be calculated as follows:

$$P_B = P_{BL} P_{BT} P_{BV}$$

where:

$P_{BL}$  : Probability the damage extends into the longitudinal zone bounded by  $X_a$  and  $X_f$

$$P_{BL} = 1 - P_{Bf} - P_{Ba}$$

$P_{BT}$  : Probability the damage extends into the transverse zone bounded by  $Y_p$  and  $Y_s$

$$P_{BT} = 1 - P_{Bp} - P_{Bs}$$

$P_{BV}$  : Probability the damage extends vertically above the boundary defined by  $z$

$$P_{BV} = 1 - P_{Bz}$$

$P_{Bar}$ ,  $P_{Bf}$ ,  $P_{Bp}$  and  $P_{Bs}$  are to be determined by linear interpolation from Tab 3 of probabilities for bottom damage, where:

$P_{Ba}$  : Probability the damage lies entirely aft of location  $X_a / L$

$P_{Bf}$  : Probability the damage lies entirely forward of location  $X_i/L$

$P_{Bp}$  : Probability the damage lies entirely to port of the tank

$P_{Bs}$  : Probability the damage lies entirely to starboard of the tank.

$P_{Bz}$ , the probability the damage lies entirely below the tank, is to be determined as follows:

- for  $z/D_s \leq 0,1$ :  

$$P_{Bz} = (14,5 - 67 z / D_s) (z / D_s)$$
- for  $z/D_s > 0,1$ :  

$$P_{Bz} = 0,78 + 1,1 (z / D_s - 0,1)$$

$P_{Bz}$  is not to be taken greater than 1.

Compartment boundaries  $X_a$ ,  $X_i$ ,  $Y_p$ ,  $Y_s$ , and  $z$  are to be developed as follows:

$X_a$  and  $X_i$ : As defined in [2.2.4]

$Y_p$  : Transverse distance from the port-most point on the compartment located at or below the waterline  $d_B$ , to a vertical plane located  $B_B/2$  to starboard of the ship's centreline, in m

$Y_s$  : Transverse distance from the starboard-most point on the compartment located at or below the waterline  $d_B$ , to a vertical plane located  $B_B/2$  to starboard of the ship's centreline, in m

$z$  : Minimum value of  $z$  over the length of the compartment, where, at any given longitudinal location,  $z$  is the vertical distance from the lower point of the bottom shell at that longitudinal location to the lower point of the compartment at that longitudinal location, in m.

**Table 3 : Probabilities for bottom damage**

$X_a/L$	$P_{Ba}$	$X_i/L$	$P_{Bf}$	$Y_p/B_B$	$P_{Bp}$	$Y_s/B_B$	$P_{Bs}$

1,00	0,761	1,00	0,000	1,00	0,000	1,00	0,844

### 3 Piping arrangements

#### 3.1 Provision regarding piping arrangements

**3.1.1** Lines of piping that run through cargo tanks in a position less than  $0,30 B_s$  from the ship's side or less than  $0,30 D_s$  from the ship's bottom is to be fitted with valves or similar closing devices at the point at which they open into any cargo tank. These valves is to be kept closed at sea at any time when the tanks contain cargo oil, except that they may be opened only for cargo transfer needed for essential cargo operations.

Credit for reducing oil outflow through the use of an emergency rapid cargo transfer system or other system arranged to mitigate oil outflow in the event of an accident may be taken into account only after the effectiveness and safety aspects of the system are approved by the Society.

Section 21	Criteria for Assigning Carriage Requirements for Products Subject to the IBC Code

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **chemical tanker**, in accordance with Pt A, Ch 1, Sec 2, [4.4.4].

**1.1.2** Ships which are intended for the carriage of dangerous chemicals in bulk are to comply with the requirements of the latest version of the International Code for the Construction and Equipment of Ships Carrying Dangerous Chemicals in Bulk (IBC Code), as amended.

**1.1.3** These Rules and the IBC Code refer to ships carrying products which are listed in the table in Chapter 17 of the IBC Code or in the current MEPC.2/Circular, and in Ch 8, Sec 17.

**1.1.4** In general, this Chapter applies to cargo containment and handling systems and to the interfaces between these systems and the remainder of the ship, which are to comply with the additional applicable requirements indicated in Tab 1.

**Table 1 : Additional applicable requirements**

Item		Reference
Ship arrangement	L ≥ 65 m	• Part B

<b>Note 1:</b> NR600: Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m.		

### 1.2 IBC Code requirements and the Society's rules

#### 1.2.1 General

- a) For ships having the service notation **chemical tanker**, the IBC Code requirements are to be considered as rule requirements, unless otherwise specified, and with the exception indicated in [1.2.2].
- b) The rule requirements of this Chapter include:
  - additional requirements to the IBC Code
  - Society's interpretations of the IBC Code.
- c) The requirements of this Chapter are cross referenced to the applicable Chapters, Sections or paragraphs of the IBC Code, as appropriate, under the wording "IBC CODE REFERENCE".

#### 1.2.2 IBC Code requirements not within the scope of classification

The following requirements of the IBC Code are not within the scope of classification:

- Chapter 1, Section 1.4 - Equivalents
- Chapter 1, Section 1.5 - Surveys and certification
- Chapter 2, as far as survival requirements after flooding are concerned, when the additional class notation **SDS** is not assigned
- Chapter 16 - Operational requirements.

These requirements are applied by the Society when acting on behalf of the flag Administration, within the scope of delegation (see [1.2.4]).

**1.2.3 Equivalences**

As far as the requirements for class are concerned, the following wording in the IBC Code is to be given the meanings indicated in Tab 2.

**Table 2 : Equivalences**

IBC Code wording	Meaning for classification only
Administration	Society
IBC Code or Chemical Code	Part D, Chapter 8 of the Rules
Recognised Standard	Rules
should be	is to be or are to be (as appropriate)

**1.2.4 Certificate of Fitness**

- a) The responsibility for interpretation of the IBC Code requirements for the purpose of issuing an International Certificate of Fitness for the Carriage of Dangerous Chemicals in Bulk lies with the Administration of the state whose flag the ship is entitled to fly.
- b) Whenever the Society is authorised by an Administration to issue on its behalf the “Certificate of Fitness for the Carriage of Dangerous Chemicals in Bulk”, or where the Society is authorised to carry out investigations and surveys on behalf of an Administration on the basis of which the “Certificate of Fitness for the Carriage of Dangerous Chemicals in Bulk” will be issued by the Administration, or where the Society is requested to certify compliance with the IBC Code, the full compliance with the requirements of the IBC Code, including the operational requirements mentioned in [1.2.2], is to be granted by the Society.

**2 Additional requirements**

**2.1 Emergency towing arrangement**

**2.1.1** Emergency towing arrangements are to be fitted on chemical tankers of 20.000 dwt and above in accordance with Pt B, Ch 12, Sec 4, [3].

**2.2 Steering gear**

**2.2.1** Additional requirements for steering gear of chemical tankers of 10000 dwt and above are given in Ch 7, Sec 4, [7].

**3 Documentation to be submitted**

**3.1**

**3.1.1** Tab 3 lists the plans, information, analysis, etc. which are to be submitted in addition to the information required in the other Parts of the Rules for the parts of the ship not affected by the cargo, as applicable.

**Table 3 : Documentation to be submitted**

No	A/I	Document
1	I	List of products to be carried, including maximum vapour pressure, maximum liquid cargo temperature, cargo mass density and other important design conditions
2	I	General arrangement plan, showing location of cargo tanks and fuel oil, ballast and other tanks
3	A	Gas-dangerous zones plan
4	A	Location of void spaces and accesses to dangerous zones
5	A	Ventilation duct arrangement in gas-dangerous spaces and adjacent zones
6	A	Details of hull structure in way of cargo tanks, including support arrangement for tanks, saddles, anti-floating and anti-lifting devices, deck sealing arrangements, independent cargo tanks, etc.
7	A	Hull stress analysis
8	A	Hull ship-motion analysis, where a direct analysis is preferred to the methods indicated in Section 4
9	A	Intact and damage stability calculations
10	A	Scantlings, material and arrangement of the cargo containment system
11	A	Details of steel cladding or lining
<b>Note 1:</b> A = to be submitted for approval I = to be submitted for information.		

No	A/I	Document
12	A	Plans, arrangement and calculations of pressure/vacuum valves
13	A	Details of cargo handling, including arrangements and details of piping and fittings and details of heating system, if any
14	A	Details of cargo pumps
15	A	Details of process pressure vessels and relative valving arrangement
16	A	Bilge and ballast system in cargo area
17	A	Gas freeing system in cargo tanks including inert gas system
18	A	Ventilation system in cargo area
19	A	Details of electrical equipment installed in cargo area, including the list of certified safe equipment and apparatus and electrical bonding of cargo tanks and piping
20	A	Schematic electrical wiring diagram
21	A	Gas detection system
22	A	Cargo tank instrumentation
23	A	Details of fire-extinguishing appliances and systems in cargo area
24	I	Loading and unloading operation description, including cargo tank filling limits, where applicable
25	I	Procedure and arrangement manual
<b>Note 1:</b> A = to be submitted for approval I = to be submitted for information.		

# Section 2 Ship Survival Capability and Location of Cargo Tanks

## 1 Freeboard and intact stability

### 1.1 Intact stability

#### 1.1.1 General

IBC CODE REFERENCE: Ch 2, 2.2.2

The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.7] is to be in compliance with the requirements in Pt B, Ch 3, Sec 2.

#### 1.1.2 Free surface effect of liquids

IBC CODE REFERENCE: Ch 2, 2.2.3

The free surface effect is to be calculated in accordance with Pt B, Ch 3, Sec 2, [4].

#### 1.1.3 Information to be supplied

IBC CODE REFERENCE: Ch 2, 2.2.5

The Master of the ship is to be supplied with a Loading Manual as specified in Pt B, Ch 1, Sec 5, [2] and a Trim and Stability booklet as specified in Pt B, Ch 3, App 2.

## 2 Conditions of loading

### 2.1 Additional loading conditions for ships where additional class notation SDS is requested

#### 2.1.1

IBC CODE REFERENCE: Ch 2, 2.9.2.3

Loading conditions other than those in the Loading Manual and the Trim and Stability booklet are to be previously submitted to the Society. Alternatively, such cases may be examined by the Master or a delegated officer when a loading instrument approved in accordance with the requirements in Pt B, Ch 1, Sec 5, [3] is installed on board.

## 3 Location of cargo tanks

### 3.1 Minimum distance of cargo tanks from shell

#### 3.1.1 Exceptions

IBC CODE REFERENCE: Ch 2, 2.6.1

Any cargo tank, irrespective of its location, may be used for collecting contaminated cargo pump room bilge water or tank washings, as an exception to the requirements in IBC Code 2.6.1.1.

### 3.2 Suction wells

#### 3.2.1

IBC CODE REFERENCE: Ch 2, 2.6.2

In general, the area of suction wells is not to be greater than that required to accommodate cargo pumps, suction pipes, valves, heating coils etc., and to ensure efficient flow and the necessary access for cleaning and maintenance.

## 4 Flooding assumptions for ships where additional class notation SDS is requested

### 4.1 Tunnels, ducts and pipes in the damaged zone

#### 4.1.1 Strength of internal structures

IBC CODE REFERENCE: Ch 2, 2.7.7

Tunnels, ducts, pipes, doors, bulkheads and decks which might form watertight boundaries of intact spaces in the case of assumed conventional damage are to have minimum strength adequate to withstand the pressure height corresponding to the deepest equilibrium waterline in damaged conditions.

**4.1.2 Progressive flooding**

IBC CODE REFERENCE: Ch 2, 2.7.7

Progressive flooding is to be considered in accordance with Pt B, Ch 3, Sec 3, [3.3].

**5 Standard of damage for ships where additional class notation SDS is requested**

**5.1 Damage to stepped machinery space forward bulkhead**

**5.1.1**

IBC CODE REFERENCE: Ch 2, 2.8

The concept of a stepped machinery space forward bulkhead is already implicit in the requirements in IBC Code 3.2.1 and Regulation II-2/56 of SOLAS 74(83). For damage stability considerations, when the recess for a pump room or for a cargo pump room extends into the adjacent machinery space or cargo tank by more than 3 metres, damage is to be treated as defined in Fig 1.

**Figure 1 : Damage to stepped machinery space forward bulkhead**

**5.2 Longitudinal extension of damage to superstructure**

**5.2.1**

IBC CODE REFERENCE: Ch 2, 2.8

The longitudinal extent of damage to the superstructure in the case of side damage to a machinery space aft, with the standards of damage as per IBC Code 2.8.1, is generally to be the same as the longitudinal extent of the side damage to the machinery space (see Fig 2).

**6 Survival requirements for ships where additional class notation SDS is requested**

**6.1 General**

**6.1.1**

IBC CODE REFERENCE: Ch 2, 2.9

Ships are to be capable of surviving the assumed damage specified in IBC Code 2.5.1 and 2.5.2 to the standard provided in IBC Code 2.8.1 and for the loading conditions in Pt B, Ch 3, App 2, [1.2.7] in a condition of stable equilibrium and such as to satisfy the criteria in IBC Code 2.9.

## 6.2 Intermediate stages of flooding

### 6.2.1

IBC CODE REFERENCE: Ch 2, 2.9.2.3

The criteria applied to the residual stability during intermediate stages of flooding are to be those relevant to the final stage of flooding as specified in IBC Code 2.9.3. However, small deviation from these criteria may be accepted by the Society on a case by case basis.

## 6.3 Definition of range of positive stability

### 6.3.1

IBC CODE REFERENCE: Ch 2, 2.9

The 20° range may be measured from any angle commencing between the position of equilibrium and the angle of 25° (or 30° if no deck immersion occurs) (see Fig 3).

## 6.4 Survival criterion

### 6.4.1 Unprotected openings

IBC CODE REFERENCE: Ch 2, 2.9.3.1

Other openings capable of being closed weathertight do not include ventilators (complying with ILLC 19(4)) that for operational reasons have to remain open to supply air to the engine room or emergency generator room (if the same is considered buoyant in the stability calculation or protecting openings leading below) for the effective operation of the ship.

## 6.5 Type 3 ships less than 125 m in length

### 6.5.1

IBC CODE REFERENCE: Ch 2, 2.8.1.6

The flooding of the machinery space, if located aft on a type 3 ship less than 125 m in length, is to comply as far as practicable with the criteria in IBC Code 2.9. Relaxation of parts of these requirements may be accepted on a case-by-case basis.

Figure 2 : Longitudinal extent of damage to superstructure

Figure 3 : Range of positive stability

## Section 3 Ship Arrangement

### 1 Cargo segregation

#### 1.1 Segregation of cargoes mutually reacting

##### 1.1.1 Common edges

IBC CODE REFERENCE: Ch 3, 3.1.2

The common edge in a cruciform joint, either vertically or horizontally, may be considered a “double barrier” for the purpose of segregation:

- between mutually reactive products (see Fig 1)
- between water reactive products and water (see Fig 1).

**Figure 1 : Segregation of mutually hazardously reactive cargoes**

##### 1.1.2 Chain lockers

IBC CODE REFERENCE: Ch 3, 3.1.2

The chain locker is to be arranged outside the hazardous areas defined in Ch 8, Sec 10 and at least 10 m measured horizontally from any vent outlet of a controlled tank venting system.

##### 1.1.3 Location of fuel tanks in cargo area

On ships having the service notation **chemical tanker** and carrying liquid cargoes having a flashpoint not exceeding 60°C and/or toxic liquid cargoes, fuel tanks located with a common boundary to cargo or slop tanks are not to be situated within, nor extend partly into, the cargo tank block as defined in Ch 7, Sec 1, [1.2.4]. Such tanks may, however, be situated aft and/or forward of the cargo tank block. They may be accepted when located as independent tanks on open deck in the cargo area subject to spill and fire safety considerations.

The arrangement of independent fuel tanks and associated fuel piping systems, including the pumps, may be as for fuel tanks and associated fuel piping systems located in the machinery spaces. For electrical equipment, requirements applicable to hazardous area classification must however be met.

Note 1: For the purpose of this requirement, toxic liquid cargoes include those for which toxic vapour detection is specified in column “k” of the table of chapter 17 of the IBC Code.

### 1.2 Cargo piping arrangement

#### 1.2.1 Bow or stern loading arrangement

IBC CODE REFERENCE: Ch 3, 3.1.3

The requirement in IBC Code 3.1.3 is considered to be satisfied if the requirements in IBC Code 3.7, relevant to bow or stern loading and unloading arrangements, are complied with.

## 2 Accommodation, service and machinery spaces and control stations

### 2.1 Location of paint lockers

#### 2.1.1

IBC CODE REFERENCE: Ch 3, 3.2.1

Paint lockers, regardless of their use, cannot be located above the cargo area.

### 2.2 Air intakes and other openings to accommodation spaces

#### 2.2.1

IBC CODE REFERENCE: Ch 3, 3.2.2

The requirements relevant to air intakes in IBC Code 3.2.2 are also intended to be applicable to air outlets. This interpretation also applies to the requirements in IBC Code 3.2.3, 3.7.4, 8.2.3, 15.12.1.3 and 19.3.8.

### 2.3 Windows, sidescuttles and doors to accommodation spaces

#### 2.3.1 General requirements

IBC CODE REFERENCE: Ch 3, 3.2.3

- Access facing the cargo area or other prohibited zones is to be restricted to stores for cargo-related and safety equipment, cargo control stations and emergency shower spaces.
- Access to forecastle spaces containing sources of ignition may be permitted through doors facing cargo area provided the doors are located outside hazardous areas as defined in Pt C, Ch 2, Sec 1, [3.25.3] and Ch 8, Sec 10, Tab 1 or Ch 8, Sec 10, Tab 2.  
However, for small ships alternative arrangements may be specially considered by the Society.
- The bolt spacing for bolted plates mentioned in the paragraph in the reference is to be such as to guarantee a suitable gas-tightness.

#### 2.3.2 Ships fitted with deckhouses originating from main deck

IBC CODE REFERENCE: Ch 3, 3.2.3

On all chemical tankers, regardless of the type of products to be carried, where a deckhouse is substituted for a superstructure and liquid products could flow along the sides of the house, the house front is to be continued to the sides of the ship in the form of a sill, or a permanent spillage barrier is to be arranged as described in Regulation II-2/56.6 of SOLAS 74(83).

### 2.4 Access to the bow

**2.4.1** Ships having the service notation **chemical carrier** are to be provided with the means to enable the crew to gain safe access to the bow even in severe weather conditions. Such means of access are to be approved by the Society.

Note 1: The Society accepts means of access complying with the Guidelines for safe access to tanker bows adopted by the Marine Safety Committee of IMO by Resolution MSC.62 (67).

## 3 Cargo pump rooms

### 3.1 General requirement

#### 3.1.1 Means of escape

IBC CODE REFERENCE: Ch 3, 3.3.1

In general, a cargo pump room is to be provided with one set of access/escape ladders. Where it is envisaged that personnel are normally employed in a pump room or the pump room is unusually large, an additional means of escape may be required.

#### 3.1.2 Segregation

IBC CODE REFERENCE: Ch 3, 3.3.1

Cargo pump rooms and pump rooms may not give direct access to other ship spaces and are to be separated from adjacent spaces by means of gas-tight bulkheads and/or decks.

### 3.2 Machinery driven by shafting passing through pump room bulkheads

#### 3.2.1

IBC CODE REFERENCE: Ch 3, 3.3.7

- Bulkhead or deck penetrations of cargo pump rooms, or of pump rooms intended for runs of shafts driving pumps and/or fans, are to be provided with gas-tight sealing devices to the satisfaction of the Society.
- Lubrication or other means of ensuring permanence of gas-tightness of the above-mentioned sealing devices is to be arranged in such a way that it can be checked from outside the cargo pump room.

## 4 Access to spaces in the cargo area

### 4.1 General

#### 4.1.1 Independent cargo tanks

Where independent tanks are installed in hold spaces, requirements in [4.2] and [4.3] are to be applied, as far as practicable, to ballast and void spaces adjacent to hold spaces.

When such requirements are found to be incompatible with the size and arrangement of the ship, smaller dimensions may be accepted by the Society, providing convenient access to any part of those spaces is maintained.

#### 4.1.2 Access to fuel oil tanks

IBC CODE REFERENCE: Ch 3, 3.4.1

The requirements in IBC Code 3.4.1 apply to fuel oil tanks adjacent to cargo tanks even if such fuel oil tanks are not included in the cargo area.

#### 4.1.3 Accesses and escapes from double bottom tanks and similar spaces

IBC CODE REFERENCE: Ch 3, 3.4.1

To cater for restrictions in the movement of personnel and to limit the time needed for a possible emergency escape, two separate means of access are generally to be fitted in double bottom tanks and similar spaces where obstructions impede movement. The two accesses are to be as widely separated as practicable. Only one access may be approved in special circumstances if, it being understood that the escapes have the required dimensions, the ability to readily traverse the space and to remove an injured person can be proved to the satisfaction of the Society.

### 4.2 Horizontal openings

#### 4.2.1

IBC CODE REFERENCE: Ch 3, 3.4.2

The shape of the minimum acceptable clear opening of 600 mm by 600 mm is indicated in Fig 2.

Figure 2 : Shape of minimum acceptable clear opening of 600 mm by 600 mm

### 4.3 Vertical openings

#### 4.3.1

IBC CODE REFERENCE: Ch 3, 3.4.3

For pressure cargo tanks only, access openings may be circular openings having a diameter not less than 600 mm.

The minimum size of vertical oval openings is defined in Fig 3.

Figure 3 : Minimum size of vertical oval openings

## 5 Bilge and ballast arrangements

### 5.1 Ballast segregation

#### 5.1.1 Filling arrangement

IBC CODE REFERENCE: Ch 3, 3.5.1

Where filling arrangements for ballast tanks located in the cargo area are provided in the machinery spaces, a non-return valve and removable spool piece are to be fitted in the supply line outside the machinery spaces.

#### 5.1.2 Eductors

IBC CODE REFERENCE: Ch 3, 3.5.1

An eductor situated in the cargo area using water power from pumps in the machinery spaces may be accepted as a means to discharge permanent ballast from tanks and/or double bottoms adjacent to cargo tanks, provided the supply line is above deck level and a non-return valve and removable spool piece are fitted in the supply line outside the machinery space (see Fig 4).

Figure 4 : Discharge arrangement

#### 5.1.3 Fore peak ballast system

IBC CODE REFERENCE: Ch 3, 3.5.1

The fore peak tank can be ballasted with the system serving other ballast tanks within the cargo area, provided:

- the fore peak tank is considered as a hazardous area, and the hazardous area classification is defined in accordance with Ch 8, Sec 10
- the vent pipe openings are located on open deck at an appropriate distance from sources of ignition. In this respect, the hazardous zones distances are to be defined in accordance with Ch 8, Sec 10
- means are provided, on the open deck, to allow measurement of flammable gas concentrations within the tank by a suitable portable instrument
- the access to the fore peak tank is direct from open deck. Alternatively, indirect access from the open deck to the fore peak tank through an enclosed space may be accepted provided that:
  - In case the enclosed space is separated from the cargo tanks by cofferdams, the access is through a gas tight bolted manhole located in the enclosed space and a warning sign is provided at the manhole stating that the fore peak tank may only be opened after:
    - it has been proven to be gas free; or
    - any electrical equipment which is not certified safe in the enclosed space is isolated.
  - In case the enclosed space has a common boundary with the cargo tanks and is therefore a hazardous area, the enclosed space can be well ventilated.

### 5.2 Ballast filling arrangement

#### 5.2.1 Clarification

IBC CODE REFERENCE: Ch 3, 3.5.2

The filling of cargo tanks with ballast may be performed at deck level by means of pumps serving permanent ballast tanks, as specified in IBC Code 3.5.2, provided that a removable spool piece or flexible hose plus a shut-off valve are fitted on the inlet to the cargo tank. The shut-off valve is in addition to the required non-return valve. Consideration is to be given to the arrangement of the in-tank piping and the possible creation of static electricity (see Fig 4).

### 5.3 Bilge

#### 5.3.1 Arrangement

IBC CODE REFERENCE: Ch 3, 3.5.3

The relaxation relevant to the bilge system for spaces which are separated from cargo tanks by a double bulkhead is to be understood as limited to spaces not enclosing piping which may contain cargo.

**5.3.2 Use of cargo pumps as bilge pumps**

IBC CODE REFERENCE: Ch 3, 3.5.3

- a) Cargo pumps may also be used as bilge pumps provided they are connected to the bilge piping through a shut-off valve and a non-return valve arranged in series.
- b) In the case of carriage of corrosive liquids, one of the cargo pumps may be used for bilge service provided it is connected to the bilge piping through two shut-off valves plus a non-return valve arranged in series.
- c) In cargo pump rooms of ships carrying toxic or corrosive products, suitable means for conveying spills from cargo pumps and valves to collecting trays are to be fitted. Trays may also consist of part of the pump room bottom, suitably bounded and protected against the corrosive action of products. Spills may be disposed of by means of suitable pumps or eductors. In the case of carriage of mutually incompatible products, the above-mentioned means for collecting and disposing of spills are to be different and separated from each other.

**6 Integrated cargo and ballast systems**

**6.1**

**6.1.1** Integrated cargo and ballast pumps are to comply with the provisions of Ch 7, Sec 4, [3.6].

**7 Bow or stern loading and unloading arrangements**

**7.1 Coamings**

**7.1.1**

IBC CODE REFERENCE: Ch 3, 3.7.7

In general, the height of the coaming is to be not less than 150 mm. In any case, it is to be not less than 50 mm above the upper edge of the sheerstrake.

# Section 4 Cargo Containment

## Symbols

$k$  : Material factor for steel, defined in Pt B, Ch 4, Sec 1, [2.2].

## 1 General

### 1.1 Application

1.1.1 The requirements of this sections are to be applied in addition to the Chapter 4 of the IBC Code.

## 2 Structure design principles

### 2.1 Materials

#### 2.1.1 Steels for hull structure

In addition to the requirements of Pt B, Ch 4, Sec 1, [2], materials of cargo tanks are to be considered by the Society on a case-by-case basis for all the products intended to be carried.

#### 2.1.2 Rolled plates

IBC CODE REFERENCE: CHAPTER 4

Rolled plates of non-alloyed steel or stainless steel may be used for the construction of tanks. Mechanical characteristics, approval procedure and testing of these plates are to comply with the applicable requirements in NR216 Materials.

#### 2.1.3 Young's modulus for stainless steels

IBC CODE REFERENCE: CHAPTER 4

For stainless steels, Young's modulus is to be taken equal to 193000 N/mm<sup>2</sup>.

#### 2.1.4 Rubber and synthetic material liner

IBC CODE REFERENCE: CHAPTER 4

The suitability of rubber or synthetic material lining is to be considered by the Society on a case-by-case basis.

### 2.2 Hull structure

#### 2.2.1 Framing arrangement

IBC CODE REFERENCE: CHAPTER 4

In general, within the cargo tank region of chemical tankers of more than 90 m in length, the bottom, the inner bottom and the deck are to be longitudinally framed.

Different framing arrangements are considered by the Society on a case-by-case basis, provided that they are supported by direct calculations.

### 2.3 Bulkhead structure

#### 2.3.1 Corrugated bulkhead connections

For ships with  $L < 120$  m, vertically corrugated transverse or longitudinal bulkheads may be connected to the double bottom and deck plating (see Fig 1).

Figure 1 : Corrugated bulkhead connections without stool

For ships with  $L \geq 120$  m, a lower and an upper stool are generally to be fitted (see Fig 2). Different arrangements may be considered by the Society on a case-by-case basis, provided that they are supported by direct calculations carried out according to Pt B, Ch 8, App 1. These calculations are to investigate, in particular, the zones of connection of the bulkhead with bottom and deck plating and are to be submitted to the Society for review.

**Figure 2 : Corrugated bulkhead connections with lower and upper stools**

### 3 Hull girder loads

#### 3.1 Still water loads

##### 3.1.1 Loading conditions

In addition to the requirements in Pt B, Ch 5, Sec 4, [2.1], still water loads are to be calculated for the following loading conditions:

- homogeneous loading conditions (excluding tanks intended exclusively for segregated ballast tanks) at maximum draught
- partial loading conditions (see [3.1.2])
- high density cargo, heated cargo and segregated cargo loading conditions
- any specified non-homogeneous loading condition
- light and heavy ballast conditions
- mid-voyage conditions related to tank cleaning or other operations where these differ significantly from the ballast conditions.

##### 3.1.2 Partial filling

Loading conditions with partial filling of the tanks by cargoes with a mass density above the cargo mass density used for the design may be allowed.

#### 3.2 Load combinations for direct strength analysis

3.2.1 The loading conditions to be considered for the direct strength analysis are defined in Ch 7, Sec 3, [5.1].

### 4 Hull scantlings

#### 4.1 Plating

##### 4.1.1 Calculation of equivalent thickness for clad plates made of non-alloyed steel - stainless steel

The clad plate thickness is to be not less than that obtained from the following formula:

$$t_p = t + t_s \left( 1 - \frac{E_1}{206000} \right)$$

where:

$t$  : Thickness, in mm, of the clad plate, to be obtained from the applicable formulae in Pt B, Ch 7, Sec 4, as if it were made of homogeneous material with the following properties:

- elastic modulus, in  $N/mm^2$ , to be taken equal to:  
 $E = 206000$
- material factor, to be obtained from the following formula:

$$k_0 = k \frac{E_1}{206000}$$

$k$  : Material factor of the rolled stainless steel plate, defined in Pt B, Ch 4, Sec 1, [2.2]

$E_1$  : Elastic modulus, in  $N/mm^2$ , of the rolled stainless steel plate

$t_s$  : Thickness, in mm, of the stainless steel cladding, to be taken not less than 2,0 mm

Stainless steel cladding thicknesses other than those above are to be considered by the Society on a case-by-case basis.

## 5 Scantlings of independent tank structures

### 5.1 General

5.1.1 Ships designed with independent cargo tanks are to comply with the applicable provisions of Part D, Chapter 7.

## 6 Supports of independent tanks

### 6.1 General

6.1.1 Ships designed with independent cargo tanks are to comply with the applicable provisions of Part D, Chapter 7.

## 7 Other structures

### 7.1 Machinery space

#### 7.1.1 Extension of the hull structures within the machinery space

IBC CODE REFERENCE: CHAPTER 4

Longitudinal bulkheads carried through cofferdams are to continue within the machinery space and be used preferably as longitudinal bulkheads for liquid cargo tanks. This extension is to be compatible with the shape of the structures of the double bottom, of the deck and of platforms in the machinery space.

## 8 Protection of hull metallic structures

### 8.1 Aluminium coatings

#### 8.1.1

IBC CODE REFERENCE: CHAPTER 4

The use of aluminium coatings containing greater than 10% aluminium by weight in the dry film is prohibited in the cargo tanks, cargo tank deck area, pump rooms, cofferdams or any other area where cargo vapour may accumulate.

### 8.2 Passivation treatment

#### 8.2.1

IBC CODE REFERENCE: CHAPTER 4

For a stainless steel structure, a passivation treatment is to be made carefully on the whole area of the tanks for a new ship, and on the whole repaired area in the case of repairs. This applies in particular to the passivation treatment of the welds.

## 9 Construction and testing

### 9.1 Welding and weld connections

#### 9.1.1 General

The requirements in [9.1.2] to [9.1.5] are to be considered in addition to the applicable requirements in Pt B, Ch 13, Sec 2 and Pt B, Ch 13, Sec 3.

#### 9.1.2 Welding of bulkheads of cargo integral tanks of type 1 chemical carriers

IBC CODE REFERENCE: CHAPTER 4

The boundaries of bulkheads of cargo integral tanks of type 1 chemical carriers are to be connected, for their whole length, to the hull structures by means of full penetration welding. As an alternative to full penetration weldings, the weld preparation is to be indicated on the drawings and non-destructive examinations are to be carried out on 100% of the welds.

#### 9.1.3 Welding of bulkheads of cargo integral tanks of type 2 chemical carriers

IBC CODE REFERENCE: CHAPTER 4

The lower part (over 10% in height, as a minimum) of the boundaries of bulkheads of cargo integral tanks, i.e. the connection with the bottom (or double bottom, if any) and the connection with the lower part of the sloping plates, of type 2 chemical carriers are to be connected, for their whole length, to the hull structures by means of full penetration welding. As an alternative to full penetration weldings, the weld preparation is to be indicated on the drawings and non-destructive examinations are to be carried out on 100% of the welds.

The other part of the tank boundaries may be connected by means of fillet welding.

#### 9.1.4 Welding of stiffeners made of non-alloyed steel to stainless steel plates

IBC CODE REFERENCE: CHAPTER 4

In general, stiffeners made of non-alloyed steel may not be directly welded to thin stainless steel plates.

However, where the welding of stiffeners and hull components made of normal strength steel to stainless steel plates is deemed acceptable by the Society, such welding is to be performed using austenitic-ferritic electrodes with high-grade nickel and chromium, such as the electrode type with 24% Cr, 14% Ni and 3% Mo.

### 9.1.5 Welding on clad plates

IBC CODE REFERENCE: CHAPTER 4

Welds carried out on clad plates are to be considered by the Society on a case-by-case basis.

In particular, when fillet welding is carried out directly on the rolled plate, the ultrasonic inspection of the plating bond is to be performed on a strip bond 100 mm wide, centred on the plate perpendicular to the plating. This ultrasonic inspection is to be carried out in accordance with NR216 Materials and Welding, Ch 3, Sec 11, [1.9].

## 9.2 Structural details

**9.2.1** The specific requirements in Pt B, Ch 13, Sec 5, [2.3] for ships with the service notation **chemical tanker** are to be complied with.

# Section 5 Cargo Transfer

## 1 Piping scantlings

### 1.1 General

#### 1.1.1 Other requirements

IBC CODE REFERENCE: Ch 5, 5.1

Cargo pipes and accessories are to satisfy requirements of Pt C, Ch 1, Sec 10.

### 1.2 Pipe classes

#### 1.2.1

IBC CODE REFERENCE: Ch 5, 5.1

According to Pt C, Ch 1, Sec 10, [1.5.2], cargo pipes and associated accessories are considered as:

- class I when the design pressure is above 1,5 MPa, or the pipe is intended for toxic substances requesting full compliance with Ch 17, 15.12 of the IBC Code
- class II when the design pressure is equal to or less than 1,5 MPa
- class III when they are open ended or placed inside cargo tanks.

### 1.3 Pipe wall thickness calculation

#### 1.3.1 Piping subjected to green seas

IBC CODE REFERENCE: Ch 5, 5.1.1

For piping subjected to green seas, the design pressure  $P$ , in MPa, in the formula in 5.1.1 of the IBC Code is to be replaced by an equivalent pressure  $P'$  given by the following formula:

$$P' = \frac{1}{2} \left( P + \sqrt{P^2 + 0,006 R' K \frac{D_C}{D}} \right)$$

where:

- $D_C$  : External diameter of the pipe taking into account the insulation (in mm), whose thickness is to be taken at least equal to:
- 40 mm if  $D \leq 50$  mm
  - 80 mm if  $D \geq 150$  mm
- Intermediate values are to be determined by interpolation
- $R'$  : Drag corresponding to the effect of green seas, in daN/mm<sup>2</sup>, such as given in Tab 1 as a function of the location of the pipes and of their height  $H$  (in m) above the deepest loadline; intermediate values are to be determined by interpolation.

#### 1.3.2 Corrosion allowance

IBC CODE REFERENCE: Ch 5, 5.1.1

The coefficient  $C$  (added corrosion thickness) for the formula in 5.1.1 of the IBC Code is normally to be equal to at least 3 mm. The Society may accept a lesser value for pipes made of austenitic or austenitic-ferritic stainless steel, pipes with internal lining or, if applicable, pipes with acceptable external protective lining or painting.

**Table 1 :**

External diameter of pipe (1)	Aft of the quarter of the ship's length			Forward of the quarter of the ship's length		
	$H \leq 8$	$H = 13$	$H \geq 18$	$H \leq 8$	$H = 13$	$H \geq 18$
$\leq 25$	1500	250	150	2200	350	150
50	1400	250	150	2000	350	150
75	1100	250	150	1600	350	150
100	700	250	150	700	350	150
$\geq 150$	500	250	150	700	350	150

(1)  $D_C$  if the pipe is insulated,  $D$  otherwise.

## **2 Piping fabrication and joining details**

### **2.1 Pipes not required to be joined by welding**

#### **2.1.1**

IBC CODE REFERENCE: Ch 5, 5.2.2

Cargo piping is to be welded except for necessary flanged connections to valves, expansion joints (as permitted in 5.2.2.1 of the IBC Code), spool pieces and similar fittings or where required for coating, lining, fabrication, inspection or maintenance.

### **2.2 Expansion joints**

#### **2.2.1**

IBC CODE REFERENCE: Ch 5, 5.2.4

The use of bellows is not permitted for corrosive and polymerising products, except if provision is made to prevent stagnation of liquids.

### **2.3 Non-destructive testing of welded joints**

#### **2.3.1**

IBC CODE REFERENCE: Ch 5, 5.2.5

- a) Butt welded joints of pipes and accessories are to be submitted to radiographic examination. A minimum of 10% of the welded joints are to be selected at random in agreement with the Surveyor. The selected joints are to be tested over their full length. The Surveyor may require to extend the number of joints to be tested depending on the results of the inspection.
- b) All butt welded joints of pipes and accessories are to be submitted to liquid penetrant examination or equivalent method over their full length
- c) Relaxation of the above requirements may be considered by the Society on a case-by-case basis for pipes welded at workshops. However, this only applies to ships exclusively intended to carry cargoes with minor fire risk.

## **3 Piping arrangements**

### **3.1 Arrangement of cargo piping**

#### **3.1.1 Arrangement of cargo piping under deck**

IBC CODE REFERENCE: Ch 5, 5.5.2

The intent of the provisions in 5.5.2 of the IBC Code is to preclude the hazard of cargo leaking past a shut-off valve gland into the space where the valve is located.

#### **3.1.2 Arrangement of cargo piping on deck**

IBC CODE REFERENCE: Ch 5, 5.5.2

Cargo piping on cargo tanks is to be extended down to the bottom of each tank.

#### **3.1.3 Arrangement of cargo piping inside cargo tanks**

IBC CODE REFERENCE: Ch 5, 5.5.2

The ends of cargo tank filling pipes are to be located as near as possible to the tank bottom in order to reduce the risk of generating static electricity.

#### **3.1.4 Pipe connections**

IBC CODE REFERENCE: Ch 5, 5.3.2

Flanges are to be provided on connections to prevent the projection of liquids in case of leakage if pipes are intended to carry cargoes involving serious risks of skin toxicity.

#### **3.1.5 Aluminised pipes**

IBC CODE REFERENCE: Ch 5, 5.5

Aluminised pipes may be permitted in ballast tanks, in inerted cargo tanks and, provided the pipes are protected from accidental impact, in hazardous areas on open deck.

### **3.2 Removable piping systems**

#### **3.2.1**

IBC CODE REFERENCE: Ch 5, 5.5

Pumps, piping and associated fittings are to constitute a permanently fitted system; in general, removable parts are not allowed, except for specific cases for which it can be proved, to the satisfaction of the Society, that no effective alternative solutions are

available. In such circumstances, the safety measures deemed necessary will be considered by the Society on a case-by-case basis.

## **4 Cargo transfer control systems**

### **4.1 General**

#### **4.1.1**

IBC CODE REFERENCE: Ch 5, 5.6.1

- a) One blank flange is to be provided in addition to the stop valve required in 5.6.1.2 of the IBC Code at each cargo hose connection.
- b) The requirements of 5.6.1 of the IBC Code are not intended to be additional to those for piping below deck in 5.5.2 and 5.5.3 of the IBC Code.

### **4.2 Control, monitoring and alarm devices and cargo control room**

#### **4.2.1**

IBC CODE REFERENCE: Ch 5, 5.6

- a) The cargo pump control is to be fitted in a position which is readily accessible, even in the event that the cargo piping or hoses break. This position is to be clearly indicated.
- b) Where a cargo control room is fitted, the following controls, monitoring and alarms are to be connected to this room:
  - cargo pump control
  - control of loading/unloading valves
  - level gauges
  - temperature indicators
  - high level alarms
  - very high level alarms
  - high/low temperature alarms
  - high/low pressure alarms
  - fixed gas detecting system alarms.
- c) In general, high/low temperature alarms are also to be transduced to the navigating bridge.
- d) The cargo control room is to be located above the weather deck and may be considered as a dangerous space or a safe space, depending on its location and on the possible presence of a product or of its vapours. If it is considered a dangerous space, it is to be provided with a ventilation system capable of supplying at least 20 air changes per hour, it is not to be located in the accommodation area and only safe type electrical equipment is allowed.
- e) A cargo control room without cargo pump and valve control is defined as a “cargo control station”.

## **5 Ship’s cargo hoses**

### **5.1 Compatibility**

#### **5.1.1**

IBC CODE REFERENCE: Ch 5, 5.7.1

The requirement of 5.7.1 of the IBC Code applies to cargo hoses carried on board the vessel and “compatibility with the cargo” means that:

- a) the cargo hose does not lose its mechanical strength or deteriorate unduly when in contact with the cargo, and
- b) the cargo hose material does not affect the cargo in a hazardous way.

Consideration is to be given to internal and external surfaces with respect to the above where hoses may be used as an integral part of, or connected to, emergency cargo pumps and submerged in the cargo tank.

## **6 Bonding**

### **6.1 Static electricity**

#### **6.1.1 Acceptable resistance**

IBC CODE REFERENCE: Ch 10, 10.3

To avoid the hazard of an incendive discharge due to the build-up of static electricity resulting from the flow of the liquid/gases/vapours, the resistance between any point on the surface of the cargo and slop tanks, piping systems and equipment, and the hull of the ship is not to be greater than  $10^6 \Omega$ .

### **6.1.2 Bonding straps**

IBC CODE REFERENCE: Ch 10, 10.3

Bonding straps are required for cargo and slop tanks, piping systems and equipment which are not permanently connected to the hull of the ship, for example:

- a) independent cargo tanks
- b) cargo tank piping systems which are electrically separated from the hull of the ship
- c) pipe connections arranged for the removal of the spool pieces.
- d) wafer-style valves with non-conductive (e.g PTFE) gaskets or seals.

Where bonding straps are required, they are to be:

- a) clearly visible so that any shortcoming can be clearly detected
- b) designed and sited so that they are protected against mechanical damage and are not affected by high resistivity contamination, e.g. corrosive products or paint
- c) easy to install and replace.

## **7 Certification, inspection and testing**

### **7.1 Application**

**7.1.1** The provisions of this Article are related to cargo piping and other equipment fitted in the cargo area. They supplement those given in Pt C, Ch 1, Sec 10, [20] for piping systems.

### **7.2 Inspection and testing**

#### **7.2.1 Testing of materials**

Where required in Tab 2, materials used for pipes, valves and fittings are to be subjected to the tests specified in Pt C, Ch 1, Sec 10, [20.4.2].

#### **7.2.2 Inspection of welded joints**

Where required in Tab 2 Pt C, Ch 1, Sec 10, [3.6] the requirements of Pt C, Ch 1, Sec 10, [3.6.3] are not applicable for chemical carrier cargo piping and are to be replaced by those of [2.3.1].

#### **7.2.3 Hydrostatic testing**

IBC CODE REFERENCE: Ch 5, 5.4.2

- a) Where required in Tab 2, cargo pipes, valves, fittings and pump casings are to be submitted to hydrostatic tests in accordance with the relevant provisions of Pt C, Ch 1, Sec 10, [20.5].
- b) Expansion joints and cargo hoses are to be submitted to hydrostatic tests in accordance with the relevant provisions of Pt C, Ch 1, Sec 10, [20.5].
- c) Where fitted, bellow pieces of gas-tight penetration glands are to be pressure tested.

#### **7.2.4 Tightness tests**

Tightness of the gas-tight penetration glands is to be checked.

Note 1: These tests may be carried out in the workshops or on board.

#### **7.2.5 Certification**

Inspection, tests and certification requirements for cargo piping and other equipment fitted in the cargo area are given in Tab 2.

### **7.3 Shipboard tests**

#### **7.3.1 Pressure test**

IBC CODE REFERENCE: Ch 5, 5.4.3

After installation on board, the cargo piping system is to be checked for leakage under operational conditions.

**Table 2 : Inspection and testing at works**

No	Item	Tests for materials		Inspections and tests for the products			References to the Rules
		Y/N (1)	Type of material certificate (2)	during manufacturing (1)	after completion (1) (3)	Type of product certificate (2)	
1	seamless or stainless steel cargo pipes	Y	<ul style="list-style-type: none"> <li>C where ND&gt;25mm</li> <li>W where ND≤25mm</li> </ul>	Y (4)	Y	C	[7.2.1] [7.2.1] [7.2.2] [7.2.3]
2	pipes of class II, cargo valves and fittings	Y	<ul style="list-style-type: none"> <li>C where ND&gt;100mm</li> <li>W where ND≤100mm</li> </ul>	Y (4)	Y	C	[7.2.1] [7.2.1] [7.2.2] [7.2.3]
3	expansion joints and cargo hoses	Y (5)	W	N	Y	C	[7.2.1] [7.2.3]
4	cargo pumps	Y	<ul style="list-style-type: none"> <li>C for cast body</li> <li>W for welded construction</li> </ul>	Y (6)	Y	C	see note (6) [7.2.3]
5	gas-tight penetration glands	N		N	Y	C	[7.2.3], [7.2.4]
6	cargo tank P/V valves	Y	W	Y	Y	C	[7.2.1] [7.2.2] [7.2.3] Ch 8, Sec 8, [2.1.1]
7	flame arresters	N		N	Y	C	see note (3)

(1) Y = required, N = not required.  
 (2) C = class certificate, W = works' certificate.  
 (3) includes the checking of the rule characteristics according to the approved drawings.  
 (4) only in the case of welded construction.  
 (5) if metallic.  
 (6) inspection during manufacturing is to be carried out according to a program approved by the Society.

# Section 6 Materials for Construction

## 1 General

### 1.1 Material and coating characteristics

#### 1.1.1

IBC CODE REFERENCE: Ch 6

- a) Materials and coating systems of structures and equipment which may come into contact with liquid cargo or vapour are to be selected in accordance with the list of cargoes intended to be carried.
- b) The resistance of materials and coatings and their compatibility with intended cargoes are the responsibility of the Builder or Owner. All supporting documents are, however, to be given to the Society to permit the drafting of the list of cargoes annexed to the classification certificate.

Copy of the charts of coating and/or material resistance issued by the manufacturers is to be kept on board. These documents are to indicate the possible restrictions relative to their use.

- c) As a general requirement, the provisions under NR216 Materials and Welding apply. Materials for tanks are, in any case, to have properties which are not lower than those of hull steels used according to NR216 Materials and Welding.
- d) The above-mentioned materials are, in themselves, to be resistant to the action of the products to be carried. However, materials which are not, in themselves, resistant to such action may be used, provided they are protected by resistant materials after the positive outcome of prior checks and tests performed to the satisfaction of the Society. In this case, the Society may also require surveys to be carried out at shorter intervals than those between normal surveys.
- e) In the construction of cargo tanks intended to carry cargo and sea water ballast alternately, the utmost care is to be given to the selection of structural material (in general austenitic stainless steel) with particular attention to its resistance to different types of isolated corrosion:
  - pitting
  - stress corrosion
  - interstice corrosion.

In addition, these structures are to be constructed with the same type of material to avoid galvanic corrosion, which would arise if dissimilar materials were present. In addition to the structures, the above is also intended to apply to the materials of systems, devices and apparatuses fitted in the tanks.

- f) Sea water ballast tank structures may be partly of stainless steel and partly of hull steel, provided suitable measures are taken against hull steel corrosion. The use of appropriate protective coatings is subject to the positive outcome of the previous checks and tests, to the satisfaction of the Society, which may also require surveys to be performed at shorter intervals than for normal surveys. In estimating the suitability of the protective system, the Society may also require that the cathodic area is drastically reduced (for example, by also suitably protecting stainless steel structures) for the purpose of avoiding extremely isolated corrosion in hull steel structures which could possibly turn out, for various reasons, not to be protected by coating.
- g) The use of aluminium coatings is prohibited in the cargo tanks, cargo tank deck area, pump rooms, cofferdams or any other area where cargo gas may accumulate.

## 2 Special requirements for materials

### 2.1 Miscellaneous requirements

#### 2.1.1 Non-metallic materials

IBC CODE REFERENCE: Ch. 6

Non-metallic materials used in cargo tanks and connected equipment are to be suitable for the liquids and vapours to which they are exposed.

#### 2.1.2 Primers

IBC CODE REFERENCE: Ch. 6

Primers containing zinc may not be used for stainless steel. Where such type of primer is used for other items which are welded to stainless steel, provisions are to be made to avoid the contamination of the stainless steel by zinc.

# Section 7 Cargo Temperature Control

## 1 General

### 1.1 Heated cargoes

#### 1.1.1 Approval

The capacity of a ship to maintain specific cargoes under heated conditions is the responsibility of the Builder or the Owner. However, all relevant supporting documents are to be given to the Society in order to establish the list of cargoes possibly attached to the classification certificate as per Pt A, Ch 1, Sec 2, [4.4.4].

#### 1.1.2 Application

Except for ships intended for restricted voyages, any cargo with a melting point equal to 20°C, or above, is to be capable of being maintained under heated conditions.

Attention is drawn to the fact that, for safety reasons, certain cargoes are not to be heated above a specific temperature.

#### 1.1.3 Temperature indication

When a ship is fitted with a heating system capable of maintaining the liquid temperature above 90°C, the ship's structure and materials are to be checked for this temperature and the maximum permissible temperature is to be stated on the classification certificate or on a memorandum.

### 1.2 Cargo heating and cooling systems

#### 1.2.1 Cargo temperature control systems

IBC CODE REFERENCE: Ch 7, 7.1.1

Wherever a particular temperature (higher or lower than the ambient temperature) is required to be maintained for the preservation of the cargo, one of the following systems is to be adopted:

- thermal insulated tanks capable of maintaining the temperature of the cargo within acceptable limits for the time of the voyage.
- a heating or cooling plant or refrigerating plant.
- a combination of a) and b) above.

#### 1.2.2 Additional requirements for heating and cooling plants

IBC CODE REFERENCE: Ch 7, 7.1.1

- Manifolds for the delivery and backflow of heating media are to be fitted on the weather deck; connections to cargo tanks for inlet and outlet are to be in way of the cargo tank top.
- Where the heat exchanger room is located in the accommodation area and considered as gas-safe, it is to be treated as a machinery space (not a category A machinery space) and provided with independent mechanical extraction ventilation as well as with scuppers discharging directly into the machinery space.

#### 1.2.3 Reference temperature

IBC CODE REFERENCE: Ch 7, 7.1.1

Wherever the cargo temperature is maintained by a heating or refrigerating plant, unless otherwise indicated in the contract specification, the system is to be designed taking into account the reference temperatures indicated in Tab 1.

**Table 1 :**

Reference temperature (°C)		
	Heating system	Cooling system
Sea	0	32
Air	5	45

**1.2.4 Redundancy**

IBC CODE REFERENCE: Ch 7, 7.1.1

Wherever the heating or cooling system is essential for the preservation of the cargo, the following components are to be duplicated:

- a) coils and ducts in cargo tanks
- b) heating or cooling sources
- c) circulating pumps for cargo and heating cooling media; if suitable for the use, cargo pumps may be employed for the circulation of the heating or cooling media
- d) refrigeration plant.

**1.2.5 Maximum surface temperature**

Depending on the class temperature of the cargoes being carried, the maximum surface temperature of the heating system, within enclosed spaces inside the cargo area should not exceed the values of Tab 2.

**Table 2 :**

Class temperature	Maximum surface temperature of the heating system
T1	450°C
T2	300°C
T3	200°C
T4	135°C
T5	100°C
T6	85°C

**1.3 Valves and other fittings**

**1.3.1 Means for purging**

IBC CODE REFERENCE: Ch 7, 7.1.3

Cargo heating or cooling systems are to be fitted with the necessary connections to purge, by inert gas or compressed air, the heating or cooling circuit of each cargo tank and to perform the pressure testing of the system.

**1.4 Cargo temperature measuring system**

**1.4.1 Alarm**

IBC CODE REFERENCE: Ch 7, 7.1.5

- a) An alarm system is required for those products which are carried in a heated condition (see 15.13.6 of the IBC Code) and for which, in column "o" of the tables in Chapter 17 of the IBC Code, reference is made to the requirements of 15.13 of the IBC Code.
- b) An alarm system is required for those products for which a carrying temperature not greater than certain limits is required by Chapter 15 of the IBC Code, such as elementary phosphorus and molten sulphur.
- c) An alarm connection to the navigating bridge and to the cargo control station, if fitted, is to be provided.

**1.5 Requirements for special products**

**1.5.1 Products which may damage the cargo heating or cooling system**

IBC CODE REFERENCE: Ch 7, 7.1.6

- a) The provisions of 7.1.6 of the IBC Code also apply to products which may damage the cargo heating or cooling system.
- b) If the sampling equipment mentioned in 7.1.6.3 of the IBC Code consists of an observation tank for drains, this tank is generally to comply with the following requirements:
  - it is to be located in the cargo area and provided with an air pipe with the end fitted with a flame screen, as per the Rules, and arranged at not less than 3 m from openings of accommodation spaces and from sources of ignition
  - it is to be fitted with a connection for discharge into the slop tanks with associated shut-off valves and sight glass and equipped with a sampling cock for backflowing medium analysis.

# Section 8 Cargo Tank Venting and Gas-Freeing Arrangements

## 1 Cargo tank venting

### 1.1 Venting system drainage

#### 1.1.1 Large amounts of drainage

IBC CODE REFERENCE: Ch 8, 8.2.3

When large amounts of drainage from vent lines of the cargo tanks are envisaged, a hose connection to the drain line of the slop tank is to be provided.

## 2 Types of tank venting system

### 2.1 Controlled tank venting system

#### 2.1.1 Tests of pressure/vacuum valves

IBC CODE REFERENCE: Ch. 8, 8.3.2

The tightness and the setting pressure of the cargo tanks pressure/vacuum or pressure- and vacuum-relief valves are to be checked. Inspections and tests for these valves are given in Ch 8, Sec 5, Tab 2.

#### 2.1.2 By-passing of P/V valves

IBC CODE REFERENCE: Ch 8, 8.3.2

By-passing of P/V valves is allowed during cargo operations for cargoes which do not require a vapor return system, provided that the vent-line outlet is fitted with flame arresters and is located at the required height above the deck level. However, by-passing of high-velocity valves is not permitted.

#### 2.1.3 Flame arresters

IBC CODE REFERENCE: Ch. 8, 8.3.5

Inspections and tests for flame arresters are given in Ch 8, Sec 5, Tab 2.

### 2.2 Position of vent outlets

#### 2.2.1 Outlets from tanks intended for flammable and toxic products

IBC CODE REFERENCE: Ch. 8, 8.3.3

Vent outlets of cargo tanks intended for the carriage of flammable or toxic products are to be arranged at a distance of not less than 3 m from exhaust ducts and as far as possible from inlet ducts to pump rooms and cargo pump rooms.

## 3 Cargo tank gas-freeing

### 3.1 Fans

#### 3.1.1

IBC CODE REFERENCE: Ch 8, 8.6

The impellers and housing of either fixed or portable fans fitted in dangerous spaces are to be of non-sparking materials according to 12.1.8 of the IBC Code.

# Section 9 Environmental Control

## 1 General

### 1.1 Control by padding

#### 1.1.1 Padding medium

IBC CODE REFERENCE: Ch 9, 9.1.3

The padding medium is to be compatible from the point of view of safety with the products to be carried, it is not to react with them and with air and it is to have chemical and physical properties deemed suitable by the Society. The system is to comply with the requirements for inert gas systems, as applicable.

### 1.2 Control by drying

#### 1.2.1 Simultaneous carriage of incompatible products

IBC CODE REFERENCE: Ch 9, 9.1.4

In the case of simultaneous carriage of mutually incompatible products, dry gas supply piping systems to each cargo space are to be separate from each other.

### 1.3 Control by inerting

#### 1.3.1 Application

IBC CODE REFERENCE: Ch 9, 9.1

- a) Ships having the service notations **chemical tanker** and of 8 000 tonnes deadweight and upwards, carrying crude oil or petroleum products having a flashpoint not exceeding 60°C (closed cup test), as determined by an approved flashpoint apparatus, and a Reid vapour pressure which is below the atmospheric pressure, or other liquid products having a similar fire hazard, are to be equipped with an inert gas system complying with the requirements of Article [2], or with equivalent systems or arrangements in accordance with items b) and c).
- b) For ships having the service notations **chemical tanker** and of 8 000 tonnes deadweight and upwards and of less than 20,000 tonnes deadweight, the Society may accept other equivalent arrangements in accordance with item a) and item c)
- c) Equivalent systems or arrangements shall:
  - be capable of preventing dangerous accumulation of explosive mixtures in intact cargo tanks during normal service throughout the ballast voyage and necessary in-tank operations, and
  - be so designed as to minimize the risk of ignition from the generation of static electricity by the system itself.

#### 1.3.2 Simultaneous carriage of incompatible products

IBC CODE REFERENCE: Ch 9, 9.1

The inert gas is to comply with the requirements of 9.1.3 of the IBC Code, adapted, to the satisfaction of the Society, to the individual characteristics of the products to be carried. In the case of simultaneous carriage of mutually incompatible products, inert gas supply piping systems to each cargo space are to be separate from each other.

#### 1.3.3 Ships with no fixed inert gas system

IBC CODE REFERENCE: Ch 9, 9.1

Where no fixed installation for inert gas and/or dry gas production is provided for on board, the minimum quantity to be kept on board is established by the Master, based on the duration of the voyage, the anticipated daily temperature variations, gas leakage through cargo tank seals and experience of previous similar cases.

#### 1.3.4 Additional requirements

IBC CODE REFERENCE: Ch 9, 9.1

- a) In addition to the provisions in 9.1.3 of the IBC Code, the inert gas system is to comply with the requirements of Article [2].
- b) These requirements apply where an inert gas system based on Nitrogen or oil fired inert gas generators is fitted on board chemical tankers. Any proposal to use other sources of inert gas will be specially considered.

### 1.4 Control by ventilation

#### 1.4.1

IBC CODE REFERENCE: Ch 9, 9.1

When a cargo space ventilation system other than the venting system mentioned under 8.2 of the IBC Code is required following these provisions, such system is to be specially examined by the Society.

## 2 Inert gas systems

### 2.1 General requirements

**2.1.1** The inert gas system is to comply with the applicable requirements of Pt C, Ch 4, Sec 15, [13].

**2.1.2** Plans in diagrammatic form are to be submitted for appraisal and are to include the following:

- details and arrangement of inert gas generating plant including all control monitoring devices
- arrangement of piping system for distribution of the inert gas

**2.1.3** An automatic control capable of producing suitable inert gas under all service conditions is to be fitted

### 2.2 Additional requirements for nitrogen generator systems

**2.2.1** The following requirements apply where a nitrogen generator system is fitted on board as required by [1.3.1]. For the purpose, the inert gas is to be produced by separating air into its component gases by passing compressed air through a bundle of hollow fibres, semi-permeable membranes or adsorber materials.

**2.2.2** In addition to the applicable requirements of Pt C, Ch 4, Sec 15, [13], the nitrogen generator system is to comply with Ch 7, Sec 4, [4.3.2], and Ch 7, Sec 4, [4.2.10].

**2.2.3** A nitrogen generator is to consist of a feed air treatment system and any number of membrane or adsorber modules in parallel necessary to meet the requirements of Pt C, Ch 4, Sec 15, [13.2.1], item b) 4).

**2.2.4** The nitrogen generator is to be capable of delivering high purity nitrogen in accordance with Pt C, Ch 4, Sec 15, [13.2.1], item b) 5). In addition to Pt C, Ch 4, Sec 15, [13.2.2], item d), the system is to be fitted with automatic means to discharge "off-spec" gas to the atmosphere during start-up and abnormal operation.

**2.2.5** The system is to be provided with one or more compressors to generate enough positive pressure to be capable of delivering the total volume of gas required by Pt C, Ch 4, Sec 15, [13.2.1], item b). Where two compressors are provided, the total required capacity of the system is preferably to be divided equally between the two compressors, and in no case is one compressor to have a capacity less than 1/3 of the total capacity required.

**2.2.6** The feed air treatment system fitted to remove free water, particles and traces of oil from the compressed air as required by Pt C, Ch 4, Sec 15, [13.4.2], item b), is also to preserve the specification temperature.

**2.2.7** The oxygen-enriched air from the nitrogen generator and the nitrogen-product enriched gas from the protective devices of the nitrogen receiver are to be discharged to a safe location on the open deck.

Note 1: "safe location" needs to address the two types of discharges separately:

- oxygen-enriched air from the nitrogen generator - safe locations on the open deck are:
  - outside of hazardous area;
  - not within 3m of areas traversed by personnel; and
  - not within 6m of air intakes for machinery (engines and boilers) and all ventilation inlets
- nitrogen-product enriched gas from the protective devices of the nitrogen receiver - safe locations on the open deck are:
  - not within 3m of areas traversed by personnel; and
  - not within 6m of air intakes for machinery (engines and boilers) and all ventilation inlets/outlets.

**2.2.8** In order to permit maintenance, means of isolation are to be fitted between the generator and the receiver.

### 2.3 Nitrogen /Inert gas systems fitted for purposes other than inerting required by [1.3.1]

**2.3.1** Nitrogen/inert gas systems fitted on chemical tankers of less than 8 000 tonnes deadweight and for which an inert gas system is not required by [1.3.1] are to comply with the following requirements.

**2.3.2** Requirements of:

- Pt C, Ch 4, Sec 15, [13.2.2], item b)
- Pt C, Ch 4, Sec 15, [13.2.2], item d)
- Pt C, Ch 4, Sec 15, [13.2.4], item b)
- Pt C, Ch 4, Sec 15, [13.2.4], item c)
- Pt C, Ch 4, Sec 15, [13.2.4], item e) 1) regarding oxygen content and power supply to the indicating devices
- Pt C, Ch 4, Sec 15, [13.2.4], item e) 4)
- Pt C, Ch 4, Sec 15, [13.4.2] and
- Pt C, Ch 4, Sec 15, [13.4.3],

apply to the systems.

**2.3.3** The requirements of [2.2] apply except requirements [2.2.1] to [2.2.3] and [2.2.5].

**2.3.4** The two non-return devices as required by Pt C, Ch 4, Sec 15, [13.2.3], item a) 1) are to be fitted in the inert gas main. The non-return devices are to comply with Pt C, Ch 4, Sec 15, [13.2.3], item a) 2) and Pt C, Ch 4, Sec 15, [13.2.3], item a) 3); however, where the connections to the cargo tanks, to the hold spaces or to cargo piping are not permanent, the non-return devices required by Pt C, Ch 4, Sec 15, [13.2.3], item a) 1) may be substituted by two non-return valves.

# Section 10 Electrical Installations

## 1 General

### 1.1 Application

**1.1.1** The requirements in this Section apply, in addition to those contained in Part C, Chapter 2, to chemical tankers.

**1.1.2** The design is to be in accordance with IEC publication 60092-502.

However, where the prescriptive requirements in the present Rules and IEC 60092-502 are not aligned, the prescriptive requirements in the present Rules take precedence and are to be applied.

### 1.2 Documentation to be submitted

**1.2.1** In addition to the documentation requested in Pt C, Ch 2, Sec 1, Tab 1, the following documents are to be submitted for approval:

- a) plan of hazardous areas
- b) document giving details of types of cables and safety characteristics of the equipment installed in hazardous areas
- c) diagrams of tank level indicator systems, high level alarm systems and overflow control systems where requested.

### 1.3 System of supply

#### 1.3.1 Acceptable systems of supply

The following systems of generation and distribution of electrical energy are acceptable:

- a) direct current:
  - two-wire insulated
- b) alternating current:
  - single-phase, two-wire insulated
  - three-phase, three-wire insulated.

In insulated distribution systems, no current carrying part is to be earthed, other than:

- a) through an insulation level monitoring device
- b) through components used for the suppression of interference in radio circuits.

#### 1.3.2 Earthed system with hull return

Earthed systems with hull return are not permitted, with the following exceptions to the satisfaction of the Society:

- a) impressed current cathodic protective systems
- b) limited and locally earthed systems, such as starting and ignition systems of internal combustion engines, provided that any possible resulting current does not flow directly through any hazardous area
- c) insulation level monitoring devices, provided that the circulation current of the device does not exceed 30 mA under the most unfavourable conditions.

#### 1.3.3 Earthed systems without hull return

Earthed systems without hull return are not permitted, with the following exceptions:

- a) earthed intrinsically safe circuits and the following other systems to the satisfaction of the Society
- b) power supplies, control circuits and instrumentation circuits in non-hazardous areas where technical or safety reasons preclude the use of a system with no connection to earth, provided the current in the hull is limited to not more than 5 A in both normal and fault conditions, or
- c) limited and locally earthed systems, such as power distribution systems in galleys and laundries to be fed through isolating transformers with the secondary windings earthed, provided that any possible resulting hull current does not flow directly through any hazardous area, or
- d) alternating current power networks of 1,000 V root mean square (line to line) and over, provided that any possible resulting current does not flow directly through any hazardous area; to this end, if the distribution system is extended to areas remote from the machinery space, isolating transformers or other adequate means are to be provided.

## **1.4 Earth detection**

### **1.4.1 Monitoring of circuits in hazardous areas**

The devices intended to continuously monitor the insulation level of all distribution systems are also to monitor all circuits, other than intrinsically safe circuits, connected to apparatus in hazardous areas or passing through such areas. An audible and visual alarm is to be given, at a manned position, in the event of an abnormally low level of insulation.

## **1.5 Mechanical ventilation of hazardous spaces**

**1.5.1** Electric motors driving fans of the ventilating systems of hazardous spaces are to be located outside the ventilation ducting.

**1.5.2** Motors driving ventilating fans may be located within the ducting provided that they are of a certified safe type.

**1.5.3** The materials used for the fans and their housing are to be in compliance with Pt C, Ch 4, Sec 1, [2.32].

**1.5.4** Cargo pump-rooms and other enclosed spaces which contain cargo-handling equipment and similar spaces in which work is performed on the cargo should be fitted with mechanical ventilation systems, capable of being controlled from outside such spaces.

**1.5.5** Provisions are to be made to ventilate the spaces defined in [1.5.4] prior to entering the compartment and operating the equipment.

## **1.6 Electrical installation precautions**

### **1.6.1 Precautions against corrosion**

Where products are liable to damage the materials normally used in electrical apparatuses, special attention is to be paid to the selection of materials for conductors, insulation and metal parts to be installed in gas-dangerous spaces. Copper, aluminium and insulation materials are to be protected as far as possible in order to prevent contact with products and/or their corrosive vapours (e.g. by means of encasing). This provision applies to those products for which the symbol Z is listed in column "m" of the tables in Chapter 17 of the IBC Code.

### **1.6.2 Precautions against inlet of gases or vapours**

Suitable arrangements are to be provided, to the satisfaction of the Society, so as to prevent the possibility of gases or vapours passing from a gas-dangerous space to another space through runs of cables or their conduits.

## **2 Hazardous locations and types of equipment**

### **2.1 Electrical equipment permitted in hazardous areas for ships carrying dangerous chemicals in bulk having a flash-point not exceeding 60°C and ships carrying dangerous chemicals in bulk having a flash point exceeding 60°C heated to a temperature within 15°C of their flash point or above their flashpoint**

**2.1.1** In order to facilitate the selection of appropriate electrical apparatus and the design of suitable electrical installations, hazardous areas are divided into zone 0, 1 and 2 according to Pt C, Ch 2, Sec 1, [3.25.3]. The different spaces are to be classified according to Tab 1.

The types of electrical equipment admitted, depending on the zone where they are installed, are specified in Pt C, Ch 2, Sec 3, [10].

**2.1.2** A space separated by a gastight boundaries from a hazardous area may be classified as zone 0, 1, 2 or considered as non hazardous, taking into account the sources of release inside that space and its conditions of ventilation.

**2.1.3** Access door and other openings are not to be provided between an area intended to be considered as non-hazardous and a hazardous area or between a space intended to be considered as zone 2 and a zone 1, except where required for operational reasons.

**2.1.4** In enclosed or semi-enclosed spaces having a direct opening into any hazardous space or area, electrical installations are to comply with the requirements for the space or area to which the opening leads.

**2.1.5** Where a space has an opening into an adjacent, more hazardous space or area, it may be made into a less hazardous space or non-hazardous space, taking into account the type of separation and the ventilation system.

**2.1.6** A differential pressure monitoring device or a flow monitoring device, or both, are to be provided for monitoring the satisfactory functioning of pressurisation of spaces having an opening into a more hazardous zone.

In the event of loss of the protection by the over-pressure or loss of ventilation in spaces classified as zone 1 or zone 2, protective measures are to be taken.

**2.2 Electrical equipment permitted in hazardous areas for ships carrying dangerous chemicals in bulk having a flash-point exceeding 60°C unheated or heated to a temperature below and not within 15°C of their flashpoint**

2.2.1 For systems of supply and earth detection, the requirements under Ch 7, Sec 5, [1.3] and Ch 7, Sec 5, [1.4] apply.

2.2.2 Cargo tanks, slop tanks, any pipe work of pressure-relief or other venting systems for cargo and slop tanks, pipes and equipment containing the cargo are to be classified as zone 2.

**2.3 Electrical equipment permitted in tankers carrying cargoes (for example acids) reacting with other products/materials to evolve flammable gases**

2.3.1 The different spaces are to be classified according to Tab 2.

**Table 1 : Space descriptions and hazardous area zones for ships carrying dangerous chemicals in bulk having a flash point not exceeding 60°C and ships carrying dangerous chemicals in bulk having a flash point exceeding 60°C heated to a temperature within 15°C of their flash point or above their flash point**

No.	Description of spaces	Hazardous area
1	The interior of cargo tanks, slop tanks, any pipework of pressure-relief or other venting systems for cargo and slop tanks, pipes and equipment containing the cargo or developing flammable gases and vapours	Zone 0
2	Void space adjacent to, above or below integral cargo tanks	Zone 1
3	Hold spaces	Zone 1
4	Cofferdams and permanent (for example, segregated) ballast tanks adjacent to cargo tanks	Zone 1
5	Cargo pump rooms	Zone 1
6	Enclosed or semi-enclosed spaces, immediately above cargo tanks (for example, between decks) or having bulkheads above and in line with cargo tank bulkheads, unless protected by a diagonal plate acceptable to the Society	Zone 1
7	Spaces, other than cofferdam, adjacent to and below the top of a cargo tank (for example, trunks, passageways and hold)	Zone 1
8	Areas on open deck, or semi-enclosed spaces on open deck, within 3 m of any cargo tank outlet, gas or vapour outlet, cargo manifold valve, cargo valve, cargo pipe flange, cargo pump-room ventilation outlets and cargo tank openings for pressure release provided to permit the flow of small volumes of gas or vapour mixtures caused by thermal variation.	Zone 1
9	Areas on open deck, or semi-enclosed spaces on open deck above and in the vicinity of any cargo gas outlet intended for the passage of large volumes of gas or vapour mixture during cargo loading and ballasting or during discharging, within a vertical cylinder of unlimited height and 6 m radius centred upon the centre of the outlet, and within a hemisphere of 6 m radius below the outlet	Zone 1
10	Areas on open deck, or semi-enclosed spaces on open deck, within 1,5 m of cargo pump room entrances, cargo pump room ventilation inlet, openings into cofferdams, or other zone 1 spaces	Zone 1
11	Areas on open deck within spillage coamings surrounding cargo manifold valves and 3 m beyond these, up to a height of 2,4 m above the deck	Zone 1
12	Areas on open deck over the cargo area where structures are restricting the natural ventilation and to the full breadth of the ship plus 3 m fore and aft of the forward-most and aft-most cargo tank bulkhead, up to a height of 2,4 m above the deck	Zone 1
13	Compartments for cargo hoses	Zone 1
14	Enclosed or semi-enclosed spaces in which pipes containing cargoes are located	Zone 1
15	Areas of 1,5 m surrounding a space of zone 1	Zone 2
16	Spaces 4 m beyond the cylinder and 4 m beyond the sphere defined in item 9	Zone 2
17	Fore peak ballast tank not adjacent to cargo tanks, when ballasted with the system serving ballast tanks in the cargo area according to Ch 8, Sec 3, [5.1.3]	Zone 2
18	Areas on open deck extending to the coamings fitted to keep any spills on deck and away from the accommodation and service area and 3 m beyond these up to a height of 2,4 m above the deck	Zone 2
19	Areas on open deck over the cargo area where unrestricted natural ventilation is guaranteed and to the full breadth of the ship plus 3 m fore and aft of the forward-most and aft-most cargo tank bulkhead, up to a height of 2,4 m above the deck surrounding open or semi-enclosed spaces of zone 1	Zone 2
20	Spaces forward of the open deck areas to which reference is made in 12 and 18, below the level of the main deck, and having an opening on to the main deck or at a level less than 0,5 m above the main deck, unless: <ul style="list-style-type: none"> <li>the doors and all openings are in non-hazardous area; and</li> <li>the spaces are mechanically ventilated</li> </ul>	Zone 2

**Table 2 : Space descriptions and hazardous area zones in tankers carrying cargoes (for example acids) reacting with other products/materials to evolve flammable gases.**

No.	Description of spaces	Hazardous area
1	The interior of cargo tanks, slop tanks, any pipework of pressure-relief or other venting systems for cargo and slop tanks, pipes and equipment containing the cargo or developing flammable gases and vapours.	Zone 1
2	Cargo pump rooms.	Zone 1
3	Compartments for cargo hoses.	Zone 1
4	Areas of 1,5 m surrounding the openings of zone 1 spaces specified above.	Zone 2
5	Void space adjacent to, above or below integral cargo tanks.	Zone 2
6	Hold spaces.	Zone 2
7	Cofferdams and permanent (for example, segregated) ballast tanks adjacent to cargo tanks, fore peak ballast tank when ballasted with the system serving ballast tanks in the cargo area according to Ch 8, Sec 3, [5.1.3]	Zone 2
8	Enclosed or semi-enclosed spaces, immediately above cargo tanks (for example, between decks) or having bulkheads above and in line with cargo tank bulkheads, unless protected by a diagonal plate acceptable to the society.	Zone 2
9	Spaces, other than cofferdam, adjacent to and below the top of a cargo tank (for example, trunks, passageways and hold).	Zone 2
10	Enclosed or semi-enclosed spaces in which pipes containing cargoes are located.	Zone 2
11	Areas on open deck, or semi-enclosed spaces on open deck, within 1,5 m of any cargo tank outlet, gas or vapour outlet, cargo manifold valve, cargo valve, cargo pipe flange, cargo pump-room ventilation outlets, and cargo tank openings for pressure release provided to permit the flow of small volumes of gas or vapour mixtures caused by thermal variation.	Zone 2
12	Areas on open deck within spillage coamings surrounding cargo manifold valves and 1,5 m beyond these, up to a height of 1,5 m above the deck.	Zone 2
13	Areas on open deck, or semi-enclosed spaces on open deck above and in the vicinity of any cargo gas outlet intended for the passage of large volumes of gas or vapour mixture during cargo loading and ballasting or during discharging, within a vertical cylinder of unlimited height and 3 m radius centred upon the centre of the outlet, and within a hemisphere of 3 m radius below the outlet.	Zone 2

# Section 11 Fire Protection and Fire Extinction

## 1 General

### 1.1 Application

#### 1.1.1 Fire-fighting

IBC CODE REFERENCE: Ch 11, 11.1.1.3 and

IBC CODE REFERENCE: Ch 11.1.1.4

Ships having the service notation **chemical tanker** are to comply with the requirements of:

- Pt C, Ch 4, Sec 6, [1]
- Pt C, Ch 4, Sec 6, [3] and
- Pt C, Ch 4, Sec 6, [4] except Pt C, Ch 4, Sec 6, [4.7]

regardless of the size of the ship.

- Pt C, Ch 4, Sec 6, [4.7] only for ships of 2000 gross tonnage and above.

## 2 Cargo pump rooms

### 2.1 Fixed fire-extinguishing systems

#### 2.1.1 Halogenated hydrocarbon system

IBC CODE REFERENCE: Ch 11, 11.2.1.2

With reference to 11.2.1.2 of the IBC Code, it is to be noted that new installations of halogenated hydrocarbon systems have been prohibited on all (new and existing) ships since 1 October 1994.

## 3 Cargo area

### 3.1 Temperature of steam and heating media within the cargo area

#### 3.1.1

IBC CODE REFERENCE: Ch 11, 11.3

The maximum temperature of the steam and heating media in the cargo area is to be adjusted to comply with maximum surface temperature in Ch 8, Sec 7, [1.2.5].

### 3.2 Monitors and foam applicators

#### 3.2.1 Capacity for ships of less than 4000 tonnes deadweight

IBC CODE REFERENCE: Ch 11, 11.3.7

For ships of less than 4000 tonnes deadweight, the minimum required capacity for a monitor is to be not less than 1000 litres/min and the application rate that each monitor is to be capable of supplying is to be at least 10 litres/min per each square metre of the surface to be protected.

### 3.3 Simultaneous use of foam and water systems

#### 3.3.1 Required number of jets of water

IBC CODE REFERENCE: Ch 11, 11.3.12

The simultaneous use of the minimum required number of jets of water is to be possible, in general, on deck over the full length of the ship, in the accommodation and service spaces, in control spaces and in machinery spaces.

### 3.4 Portable fire-extinguishing equipment

#### 3.4.1 Capacity of portable fire-extinguishing equipment

IBC CODE REFERENCE: Ch 11, 11.3.14

The capacity of each item of portable fire-extinguishing equipment is to comply with the relevant provisions of the 1974 SOLAS Convention, as amended.

### **3.5 Ships carrying flammable products**

#### **3.5.1 Internal combustion engines**

IBC CODE REFERENCE: Ch 11, 11.3.15

Internal combustion engines are not to be installed in cargo pump rooms, in pump rooms and in other spaces adjacent to or located above cargo tanks. However, reciprocating steam engines with a working temperature lower than the temperature stated in [3.1] may be installed in the above-mentioned rooms and spaces.

# Section 12 Mechanical Ventilation in the Cargo Area

## 1 Spaces normally entered during cargo handling operations

### 1.1 Miscellaneous requirements

#### 1.1.1 Ventilation system stopping

IBC CODE REFERENCE: Ch 12, 12.1

All required ventilation systems are to be capable of being stopped from a position located outside the served spaces and above the weather deck.

#### 1.1.2 Warning notices

IBC CODE REFERENCE: Ch 12, 12.1

In the proximity of entrances to all spaces served by the required mechanical ventilation systems, a clearly visible warning is to be posted requiring such spaces to be adequately ventilated prior to entering and relevant ventilation systems to be kept in operation all the time persons are present in the spaces themselves.

#### 1.1.3 Prevention of dangerous operation of electric motors

IBC CODE REFERENCE: Ch 12, 12.1

A suitable automatic device is to be fitted to prevent operation of electric motors driving cargo pumps and operation of other electrical equipment not of a certified safe type prior to ventilating the spaces where such motors or equipment are located, in order to render them gas-safe (to this end it is pointed out that IEC provisions require at least 10 changes of air based on the volume of the served space).

#### 1.1.4 Prevention of dangerous operation of cargo pumps

IBC CODE REFERENCE: Ch 12, 12.1

An automatic device is to be fitted capable of stopping motors driving cargo pumps and de-energising any other electrical equipment not of a certified safe type in the case of stoppage of ventilation in spaces where such motors and equipment are fitted. This provisions does not apply to motors and other electrical equipment fitted in the engine room.

#### 1.1.5 Alternative to extraction type ventilation systems

IBC CODE REFERENCE: Ch 12, 12.1

As an alternative to ventilation systems of the extraction type, required in [1.1.4], a ventilation system of the positive pressure type may be accepted:

- in the case of cargo pump rooms adjacent to cargo tanks or to other gas-dangerous spaces, or
- where, in adjacent gas-safe spaces, inclusive of spaces containing motors of cargo pumps, an adequate overpressure is kept in relation to the cargo pump rooms themselves.

#### 1.1.6 Location of upper end of inlet ducts

IBC CODE REFERENCE: Ch 12, 12.1

With reference to the requirements of [1.1.5], the upper ends of inlet ducts are generally to be located at a distance not less than 3 m from ventilation ducts and air intakes serving the safe spaces mentioned therein.

#### 1.1.7 Minimum distance between inlet and extraction ducts

IBC CODE REFERENCE: Ch 12, 12.1

With reference to [1.1.6], the upper ends of (inlet and extraction) ventilation ducts serving the same space are to be located at a distance from each other, measured horizontally, of not less than 3 m and, in general, at an adequate height above the weather deck, but in any case not less than 2,4 m. Greater heights are required in 15.17 of the IBC Code.

#### 1.1.8 Upper ends of ventilation ducts in ships carrying materials producing flammable vapours

IBC CODE REFERENCE: Ch 12, 12.1

For flammable products, or for products which may react with the ship's materials producing flammable vapours (such as strong acids), the upper ends of ventilation ducts are to be located at a distance of not less than 3 m from any source of ignition, as per the provisions of Ch 8, Sec 8, [2.2].

#### 1.1.9 Dampers

IBC CODE REFERENCE: Ch 12, 12.1

Ventilation ducts are to be provided with metallic dampers, fitted with the indication "open" and "closed". The dampers are to be located above the weather deck, in a readily accessible position.

**1.1.10 Location of electric motors of fans**

IBC CODE REFERENCE: Ch 12, 12.1

Electric motors driving fans are to be placed outside the served spaces and outside the ventilation ducts, in a suitable position with respect to the presence of flammable vapours.

**1.1.11 Penetration of motor shafts through bulkheads**

IBC CODE REFERENCE: Ch 12, 12.1

Runs of shafts of electric motors driving fans through bulkheads or decks of gas-dangerous spaces or through ventilation ducts are to be provided with gas-tight seals, with oil glands or equivalent means, deemed suitable by the Society.

They have to be fitted with temperature sensing devices for bulkhead shaft glands bearings and pump casings. Alarms are to be initiated in the cargo control room or the pump control station.

Means are to be provided to compensate for any misalignment.

Shaft bulkhead lubricating means is to be located outside the cargo pump room. If the shaft bulkhead penetration system includes a bellow, this bellow is to be hydraulically tested at a pressure of at least 3,5 bars before being fitted on board.

**1.2 Additional requirements for non-sparking fans**

**1.2.1 Non-sparking fans**

IBC CODE REFERENCE: Ch 12, 12.1

- a) A fan is considered as non-sparking if in both normal and abnormal conditions it is unlikely to produce sparks.
- b) The air gap between the impeller and the casing is to be not less than 0,1 of the shaft diameter in way of the impeller bearing and not less than 2 mm. It need not be more than 13 mm.

**1.2.2 Materials for non-sparking fans**

IBC CODE REFERENCE: Ch 12, 12.1

- a) The impeller and the housing in way of the impeller are to be made of alloys which are recognised as being spark proof by appropriate tests.
- b) Electrostatic charges in both the rotating body and the casing are to be prevented by the use of antistatic materials. Furthermore, the installation on board of the ventilation units is to be such as to ensure their safe bonding to the hull.
- c) Tests may not be required for fans having the following combinations:
  - impellers and/or housings of non-metallic material, due regard being paid to the elimination of static electricity
  - impellers and housings of non-ferrous materials
  - impellers of aluminium alloys or magnesium alloys and a ferrous (including austenitic stainless steel) housing on which a ring of suitable thickness of non-ferrous materials is fitted in way of the impeller
  - any combination of ferrous (including austenitic stainless steel) impellers and housings with not less than 13 mm design tip clearance.
- d) The following impellers and housings are considered as sparking and are not permitted:
  - impellers of an aluminium alloy or magnesium alloy and a ferrous housing, regardless of tip clearance
  - housing made of an aluminium alloy or a magnesium alloy and a ferrous impeller, regardless of tip clearance
  - any combination of ferrous impeller and housing with less than 13 mm design tip clearance.

**1.2.3 Type test for non-sparking fans**

IBC CODE REFERENCE: Ch 12, 12.1

Type tests on the finished product are to be carried out in accordance with the requirements of the Society.

**2 Pump rooms and other enclosed spaces normally entered**

**2.1 Clarification of general requirement**

**2.1.1**

IBC CODE REFERENCE: Ch 12, 12.2

- a) The provisions of 12.2 of the IBC Code apply to all pump rooms, whether or not the control for pumps and valves which are installed in such rooms is fitted externally.
- b) The distance of the upper ends of extraction and inlet ducts from air intakes and other openings of spaces mentioned in 12.1.5 of the IBC Code is not to be less than 3 m measured horizontally. These systems are to be capable of being controlled from outside the spaces they serve and, in the proximity of the entrances to such spaces, the warning notice mentioned in [1.1.2] is to be posted.

### **3 Spaces not normally entered**

#### **3.1 Portable fans**

##### **3.1.1**

IBC CODE REFERENCE: Ch 12, 12.3

The type of portable fans and their connections to spaces to be ventilated are to be deemed suitable by the Society. Portable fans driven by electric or internal combustion motors are not acceptable.

# Section 13 Instrumentation

## 1 Gauging

### 1.1 Types of gauging devices

#### 1.1.1 Arrangement

IBC CODE REFERENCE: Ch 13, 13.1.1

- a) In almost all cases a cargo code which requires a high level alarm and overflow control also requires a closed gauging device. A cargo tank containing such a product therefore requires three sensors:
  - 1) one level gauging
  - 2) one high level alarm
  - 3) one overflow control.
- b) The sensing elements for 1), 2) and 3) are to be separated, although sensors for 2) and 3) (reed switches, float chambers, electronic devices, etc.) may be contained in the same tube.
- c) Electronic, pneumatic and hydraulic circuits required for sensors 1), 2) and 3) are to be independent of each other such that a fault on any one will not render either of the others inoperative.
- d) Where processing units are used to give digital or visual indication, such as in a bridge space, the independence of circuitry is to be maintained at least beyond this point.
- e) The power is to be supplied from distribution boards.
- f) Where a control room or a bridge space containing a modular unit is envisaged, separate level indication and visual alarms are to be provided for each of the functions 1), 2) and 3). An audible alarm is also to be provided but since this is not directional it need not be separate.
- g) An audible alarm is also to be arranged in the cargo area.
- h) Where there is no control room, an audible and visual alarm is to be arranged at the cargo control station.
- i) Testing of sensors is to be arranged from outside the tanks, although entry into product clean tanks is not precluded.
- j) Simulation testing of electronic circuits or circuits which are self-monitored is acceptable.

#### 1.1.2 Example of restricted gauging device

IBC CODE REFERENCE: Ch 13, 13.1.1

A restricted gauging device may consist of a sounding pipe with an inside diameter not greater than 200 mm, fitted with a gas-tight plug. The pipe is to have holes in order to make its internal pressure equal to that of the tank. Therefore the holes are to be located inside the cargo tank in the proximity of the top.

## 2 Vapour detection

### 2.1 Vapour detection instruments

#### 2.1.1 Spaces to be monitored

IBC CODE REFERENCE: Ch 13, 13.2.1

Vapour detection instruments, either fixed or portable, are to be of a type recognised suitable by the Society for the products to be carried. The spaces to be monitored are:

- cargo pump rooms
- spaces containing motors driving cargo pumps, except for the machinery space
- enclosed spaces containing cargo piping, equipment connected with cargo handling, cofferdams, enclosed spaces and double bottoms adjacent to cargo tanks
- pipe tunnels
- other spaces, in the opinion of the Society, depending on the ship type.

Where a fixed system is installed, it is to serve the spaces among those listed above which are normally entered by the crew.

### 2.2 Provisions for installation of gas analysing units

2.2.1 Gas analysing units are to be in compliance with the requirements in Ch 7, Sec 6, [7.4].

## Section 14 Protection of Personnel

### 1 Protective equipment

#### 1.1 Location of protective equipment

##### 1.1.1

IBC CODE REFERENCE: Ch 14, 14.1.2

- a) Lockers for work clothes or protective equipment which are not new or have not undergone a thorough cleaning process are not to open directly into accommodation spaces.
- b) When a locker for clothes which have not undergone a thorough cleaning process is arranged in the accommodation area, it is to be bounded by "A-0" bulkheads and decks and provided with independent exhaust mechanical ventilation. The access to accommodation spaces, if allowed, is to be arranged through two substantially gas-tight self-closing steel doors without any hold-back device.

### 2 Safety equipment

#### 2.1 Additional equipment for ships carrying toxic products

##### 2.1.1

IBC CODE REFERENCE: Ch 14, 14.2.4

With regard to 14.2.4 of the IBC Code, the equivalent quantity of spare bottled air in lieu of the low pressure air line is to be at least 4800 litres.

#### 2.2 Medical first aid equipment

##### 2.2.1

IBC CODE REFERENCE: Ch 14, 14.2.9

First aid equipment, whose preservation in good condition is the Master's responsibility, is to be kept in a special, clearly indicated locker.

## Section 15 Special Requirements

### 1 Ammonium nitrate solution (93% or less)

#### 1.1 Ammonia injection

##### 1.1.1 Injection procedure

IBC CODE REFERENCE: Ch 15, 15.2.6

Gaseous ammonia may be injected into the cargo while the latter is circulated by the cargo pump.

#### 1.2 Cargo pumps

##### 1.2.1 Seal

IBC CODE REFERENCE: Ch 15, 15.2.7

The seal for the centrifugal pump is to be a stuffing box provided with a lantern ring. Fresh water under pressure is to be injected into the stuffing box at the location of the lantern ring (see Fig 1).

Figure 1 : Seal

### 2 Hydrogen peroxide solutions

#### 2.1 Hydrogen peroxide solutions over 60% but not over 70%

##### 2.1.1 Water spray system

IBC CODE REFERENCE: Ch 15, 15.5.10

It is specified that, for the purpose of evaluating the estimated size of the cargo spill in the case of failure, cargo piping/hose failure is to be assumed to be total.

### 3 Propylene oxide and mixtures of ethylene oxide/propylene oxide with an ethylene oxide content of not more than 30% by weight

#### 3.1 Tank cleaning

##### 3.1.1

IBC CODE REFERENCE: Ch 15, 15.8.3

Until an amendment in this respect is prepared at IMO, it is specified that the initial wording of the text of 15.8.3 of the IBC Code "Before carrying these products, ....." is to be intended as follows: "Before initial loading of these products and before each loading of these products subsequent to loading of other products".

#### 3.2 Joints in cargo lines

##### 3.2.1

IBC CODE REFERENCE: Ch 15, 15.8.12

Screwed connections are only allowed for accessory and instrumental lines with an external diameter of 25 mm or less.

### **3.3 Oxygen content in tank vapour spaces**

#### **3.3.1 Analysing equipment**

IBC CODE REFERENCE: Ch 15, 15.8.28

Analysing equipment to determine oxygen and propylene oxide contents is to be of a type recognised as suitable by the Society. When portable analysers are used, there are to be at least two. When a fixed system is installed, a portable analyser is also to be provided.

### **3.4 Valves at cargo hose connections**

#### **3.4.1 Shut-off valve closing time**

IBC CODE REFERENCE: Ch 15, 15.8.30

The closing time of shut-off valves provided at each cargo hose connection is to take account of the loading/unloading rate and is to be such as to avoid dangerous overpressure in cargo piping and hoses mentioned in the paragraphs

## **4 Acids**

### **4.1 Electrical arrangements**

#### **4.1.1**

IBC CODE REFERENCE: Ch 15, 15.11.5

In enclosed spaces adjacent to cargo tanks, electrical materials and equipment complying with the provisions of 10.1.2.1 of the IBC Code are allowed.

### **4.2 Leak detection system**

#### **4.2.1 Electrical equipment**

IBC CODE REFERENCE: Ch 15, 15.11.5

Hazardous areas are to be defined as per Ch 8, Sec 10, Tab 2. Electrical materials and equipment are to have minimum explosion group IIC or IIB+H2 and temperature class T1.

### **4.3 Lining for tanks and piping**

#### **4.3.1 Lining approved for use with acids**

IBC CODE REFERENCE: Ch 15, 15.11.2

“Lining” is an acid-resistant material that is applied to the tank or piping system in a solid state i.e. not spray on.

The requirement for the elasticity of a lining to be not less than the supporting boundary plating is to prevent debonding at the interface between the lining and the lined surface.

## **5 Toxic products**

### **5.1 Return line to shore installation**

#### **5.1.1 Valving on connection to shore installation**

IBC CODE REFERENCE: Ch 15, 15.12.2

The above-mentioned systems are to be fitted with a shut-off valve and a blank flange in way of the vapour return line to the shore installation.

## **6 Cargoes protected by additives**

### **6.1 Prevention of blockage by polymerisation**

#### **6.1.1 Arrangements**

IBC CODE REFERENCE: Ch 15, 13.6

In addition to being designed so as to avoid internal obstructions due to polymer formation, the above-mentioned systems are to be fitted with pressure/vacuum valves and devices to prevent the passage of flame which are accessible for inspection and maintenance.

## **7 Cargoes with a vapour pressure greater than 0,1013 MPa (1,013 bar) absolute at 37,8°C**

### **7.1 General**

#### **7.1.1 System for maintaining cargo temperature below boiling point**

IBC CODE REFERENCE: Ch 15, 15.14.1

- a) Any system installed for the purpose of keeping the cargo temperature below its boiling point is to be constructed to the satisfaction of the Society.
- b) Whenever cargo tanks are designed specifically for the carriage of products dealt with in 15.7 of the IBC Code, they are to be capable of withstanding the vapour pressure of such products corresponding to 45°C.

### **7.2 Return of expelled gases**

#### **7.2.1 Valving of shore connection**

IBC CODE REFERENCE: Ch 15, 15.14.4

The above-mentioned systems are to be fitted with a shut-off valve and a blank flange in way of the vapour return line to the shore installation.

## **8 Special cargo pump room requirements**

### **8.1 Clarification**

#### **8.1.1**

IBC CODE REFERENCE: Ch 15, 15.18

As far as concerns the possibility of allowing the arrangement of cargo pump rooms below deck in specific cases, it is specified that, in practice, no circumstance can be foreseen where such an arrangement may be permitted.

## **9 Overflow control**

### **9.1 Independence of systems**

#### **9.1.1 Gauging devices**

IBC CODE REFERENCE: Ch 15, 15.19

In almost all cases where, for the carriage of a product, a cargo high level alarm or cargo overflow control is required, a closed gauging device is also required.

#### **9.1.2 Separation of device sensing elements**

IBC CODE REFERENCE: Ch 15, 15.19

A cargo tank intended to carry such a product therefore requires:

- a) level gauging
- b) high level alarm
- c) overflow control.

The sensing elements for the devices under a), b) and c) are to be separated, although sensors for b) and c) (micro-switches, float chambers, electronic devices, etc.) may be contained in the same metal tube sections.

#### **9.1.3 Electronic and hydraulic circuits for sensors**

IBC CODE REFERENCE: Ch 15, 15.19

Electronic, pneumatic and hydraulic circuits required for sensors for a), b) and c) are to be independent of each other such that a fault on any one of them will not render either of the others inoperative. Where processing units are used to give digital or visual indication such as in a bridge space, the independence of circuitry is to be maintained at least up to such units. The power is to be supplied from distribution boards.

#### **9.1.4 Alarms in cargo control room**

IBC CODE REFERENCE: Ch 15, 15.19

Where a cargo control room or a bridge space containing a modular unit is envisaged, separate level indications and visual alarms are to be provided for each of the functions a), b) and c). An audible alarm is also to be provided; there need not be a separate alarm for each function since separate alarms could not be distinguished. An audible alarm is also to be arranged in the cargo area.

**9.1.5 Alarms where cargo control room is not provided**

IBC CODE REFERENCE: Ch 15, 15.19

- a) Where no cargo control room is provided, an audible and visual alarm is to be arranged at the cargo control station, which generally coincides with the navigating bridge.
- b) The audible and visual high level and cargo overflow alarms are to be located so as to be easily heard and noticed by the personnel in charge of loading/unloading operations. Attention is drawn to the fact that such alarms are generally grouped together into two independent signals; therefore it is not possible to single out directly the cargo tank from which the alarm signal is coming. In such cases, the Master is to arrange for a person to be present at the cargo control station, in order to be able to warn the personnel in charge of loading operations on deck.

**9.1.6 Testing of sensors**

IBC CODE REFERENCE: Ch 15, 15.19

Testing of sensors is to be arranged from outside the tanks, although entry into product clean tanks is not prohibited. Simulation testing of electronic circuits or circuits which are self-monitoring is acceptable.

# Section 16                      Operational Requirements

## 1 General

### 1.1

**1.1.1** This Section is void, as the provisions of Chapter 16 of the IBC Code are operating requirements which are not mandatory for the class.

# Section 17      Summary of Minimum Requirements

## 1 General

### 1.1

**1.1.1** The list of products and the minimum requirements referred to elsewhere in this Section is the one of Chapter 17 of the IBC code.

# Section 18      List of Chemicals to which this Chapter Does Not Apply

## 1 General

### 1.1

1.1.1 This Section is void, as there are no additional or alternative requirements to those indicated in Chapter 18 of the IBC Code.

# Section 19      Index of Products Carried In Bulk

## 1 General

### 1.1

1.1.1 This Section is void, as there are no additional or alternative requirements to those indicated in Chapter 19 of the IBC Code.

# Section 20      Transport of Liquid Chemical Wastes

## 1 General

### 1.1

**1.1.1** This Section is void, as there are no additional or alternative requirements to those indicated in Chapter 20 of the IBC Code.

# Section 21                      Criteria for Assigning Carriage Requirements for Products Subject to the IBC Code

## 1 General

### 1.1

1.1.1 This Section is void, as there are no additional or alternative requirements to those indicated in Chapter 21 of the IBC Code.

# Part D

## Service Notations

---

### CHAPTER 9

## LIQUEFIED GAS CARRIERS

Section 20	Hull Scantling
Appendix 1	Guidance for Calculation of Pressures and Accelerations
Appendix 2	Correspondances between Part D, Chapter 9 and the IGC Code

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **liquefied gas carrier**, in accordance with Pt A, Ch 1, Sec 2, [4.4.5].

Note 1: The service notation is to be completed by the additional service feature, as defined in Pt A, Ch 1, Sec 2, [4.4.5], indicating the cargo type, the IMO code ship type, the cargo tank design pressure  $P_{design}$  and minimum temperature  $T_{min}$ .

**1.1.2** Ships which are intended for the carriage of liquefied gases are to comply with the requirements of the latest version of the International Code for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk (IGC Code), as amended.

**1.1.3** This Chapter and the IGC Code refer to ships carrying products which are listed in the table in Chapter 19 of the IGC Code and in Ch 9, Sec 19.

**1.1.4** This Chapter and the IGC Code include requirements for the carriage of cargo in containment systems incorporating integral, membrane or independent tank types as detailed in Chapter 4 of the IGC Code and in Ch 9, Sec 4.

**1.1.5** In general, this Chapter applies to cargo containment and handling systems and to the interfaces between these systems and the remainder of the ship, which is to comply with the additional applicable requirements indicated in Tab 1.

**Table 1 : Additional applicable requirements**

Item	Reference
Ship arrangement	Part B
Hull	Part B
Stability	Part B
Machinery and cargo system	Part C
Electrical installations:	Part C
Automation	Part C
Fire protection, detection and extinction	Part C

### 1.1.6 Additional service features for ships using their cargo or other low-flashpoint gaseous fuels

The additional service features **LNGfuel**, **CNGfuel** or **LPGfuel** or, as relevant, other additional service features defined in Pt A, Ch 1, Sec 2, [4.13], may be assigned to **liquefied gas carriers** designed and equipped to use:

- their cargoes as fuel and complying with the requirements of Ch 9, Sec 16 or
- other low-flashpoint gaseous fuels provided that the fuel storage and distribution systems design and arrangements for such gaseous fuels comply with the requirements of the present chapter for gas as a cargo.

The above additional service feature are completed with **singlefuel** when the propulsion system uses only gas as fuel or **dualfuel** when the propulsion system uses both gas and fuel oil as fuel.

## 1.2 IGC Code requirements and the Society's Rules

### 1.2.1 General

- For ships assigned the service notation **liquefied gas carrier**, the IGC Code requirements are to be considered as Rule requirements, unless otherwise specified, and with the exception indicated in [1.2.2].
- The rule requirements of this Chapter include:
  - requirements of the IGC Code
  - additional requirements to the IGC Code
  - Society's interpretations of the IGC Code.
- Requirements of IGC Code, specified in the text, *printed in Italic type*; in reproducing the above text in this Chapter applicable for the purpose of classification, the word "Administration", wherever mentioned, has been replaced by the word "Society".
- The correspondence between the references of the IGC Code and those of the present Chapter are given in App 2.

### **1.2.2 IGC Code requirements not within the scope of classification**

The following requirements of the IGC Code are not within the scope of classification:

- Chapter 1, Section 1.3 - Equivalents
- Chapter 1, Section 1.4 - Surveys and certification
- Chapter 18 - Operating requirements.

These requirements are applied by the Society when acting on behalf of the flag Administration, within the scope of delegation (see [1.2.5]).

### **1.2.3 Carriage of products not listed in the Code**

The requirements of the IGC Code and the additional requirements of this Chapter are also applicable to new products, which may be considered to come within the scope of this Chapter, but are not at present listed in the table in Chapter 19 of the IGC Code.

### **1.2.4 Particularly hazardous products**

For the carriage in bulk of products which are not listed in the table in Chapter 19 of the IGC Code, presenting more severe hazards than those covered by the IGC Code, the Society reserves the right to establish requirements and/or conditions additional to those contained in this Chapter.

### **1.2.5 Certificate of fitness**

- a) The responsibility for interpretation of the IGC Code requirements for the purpose of issuing an International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk lies with the Administration of the state whose flag the ship is entitled to fly.
- b) Whenever the Society is authorised by an Administration to issue on its behalf the "Certificate of Fitness for the Carriage of Liquefied Gases in Bulk", or where the Society is authorised to carry out investigations and surveys on behalf of an Administration on the basis of which the "Certificate of Fitness for the Carriage of Liquefied Gases in Bulk" will be issued by the Administration, or where the Society is requested to certify compliance with the IGC Code, the full compliance with the requirements of the IGC Code, including the operative requirements mentioned in [1.2.2], is to be granted by the Society.

## **2 Application and implementation**

### **2.1**

**2.1.1** *When cargo tanks contain products for which the Code requires a type 1G ship, neither flammable liquids having a flashpoint of 60°C (closed cup test) or less, nor flammable products listed in Ch 9, Sec 19, shall be carried in tanks located within the protective zones described in Ch 9, Sec 2, [4.1.1], item a).*

**2.1.2** *Similarly, when cargo tanks contain products for which the Code requires a type 2G/2PG ship, the flammable liquids as described in [2.1.1], shall not be carried in tanks located within the protective zones described in Ch 9, Sec 2, [4.1.1], item b).*

**2.1.3** *In each case, for cargo tanks loaded with products for which the Code requires a type 1G or 2G/2PG ship, the restriction applies to the protective zones within the longitudinal extent of the hold spaces for those tanks.*

**2.1.4** *The flammable liquids and products described in [2.1.1] may be carried within these protective zones when the quantity of products retained in the cargo tanks, for which the Code requires a type 1G or 2G/2PG ship is solely used for cooling, circulation or fuelling purposes.*

**2.1.5** *Except as provided in [2.1.6], when it is intended to carry products covered by this Code and products covered by the International Code for the Construction and Equipment of Ships Carrying Dangerous Chemicals in Bulk (IBC Code), adopted by IMO resolution MSC.4(48), as amended, the ship shall comply with the requirements of both Codes appropriate to the products carried.*

**2.1.6** *The requirements of this Code shall take precedence when a ship is designed and constructed for the carriage of the following products:*

- a) *those listed exclusively in Ch 9, Sec 19, and*
- b) *one or more of the products that are listed both in the Code and in the International Bulk Chemical Code. These products are marked with (1) in Ch 9, Sec 19, Tab 1, column "Product name".*

**2.1.7** *When a ship is intended to exclusively carry one or more of the products referred to in [2.1.6], item a) the requirements of the International Bulk Chemical Code, as amended, shall apply.*

**2.1.8** *The ship's compliance with the requirements of the International Gas Carrier Code shall be shown by its International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk. Compliance with the amendments to the Code, as appropriate, shall also be indicated in the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk.*

**2.1.9** *Where reference is made in the Code to a paragraph, all the provisions of the subparagraph of that designation shall apply.*

**2.1.10** When a ship is intended to operate for periods at a fixed location in a re-gasification and gas discharge mode or a gas receiving, processing, liquefaction and storage mode, the Society and port Administrations involved in the operation shall take appropriate steps to ensure implementation of the provisions of the Code as are applicable to the proposed arrangements. Furthermore, additional requirements shall be established based on the principles of the Code as well as recognized standards that address specific risks not envisaged by it. Such risks may include, but not be limited to:

- fire and explosion
- evacuation
- extension of hazardous areas
- pressurized gas discharge to shore
- high-pressure gas venting
- process upset conditions
- storage and handling of flammable refrigerants
- continuous presence of liquid and vapour cargo outside the cargo containment system
- tank over-pressure and under-pressure
- ship-to-ship transfer of liquid cargo, and
- collision risk during berthing manoeuvres.

**2.1.11** Where a risk assessment or study of similar intent is utilized within the Code, the results shall also include, but not be limited to, the following as evidence of effectiveness:

- description of methodology and standards applied
- potential variation in scenario interpretation or sources of error in the study
- validation of the risk assessment process by an independent and suitable third party
- quality system under which the risk assessment was developed
- the source, suitability and validity of data used within the assessment
- the knowledge base of persons involved within the assessment
- system of distribution of results to relevant parties, and
- validation of results by an independent and suitable third party.

**2.1.12** Although the Code is legally treated as a mandatory instrument under the SOLAS Convention, the provisions of Ch 9, App 1, [1] and Appendices 1, 3 and 4 of IGC code are recommendatory or informative.

### **3 Additional requirements**

#### **3.1 Emergency towing arrangement**

**3.1.1** Emergency towing arrangements are to be fitted on liquefied gas tankers of 20.000 dwt and above in accordance with Pt B, Ch 12, Sec 4, [3].

#### **3.2 Steering gear**

**3.2.1** Additional requirements for steering gear of liquefied gas carriers of 10.000 dwt and above are given in Ch 7, Sec 4, [7].

### **4 Definitions**

#### **4.1**

**4.1.1** Except where expressly provided otherwise, the following definitions apply to the Code. Additional definitions are provided throughout the Code.

**4.1.2** Accommodation spaces are those spaces used for public spaces, corridors, lavatories, cabins, offices, hospitals, cinemas, games and hobby rooms, barber shops, pantries without cooking appliances and similar spaces.

**4.1.3** "A" class divisions are divisions as defined in regulation II-2/3.2 of the SOLAS Convention.

**4.1.4** Administration means the Government of the State whose flag the ship is entitled to fly. For Administration (port), see port Administration.

**4.1.5** Anniversary date means the day and the month of each year that will correspond to the date of expiry of the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk.

**4.1.6** Boiling point is the temperature at which a product exhibits a vapour pressure equal to the atmospheric pressure.

**4.1.7** *Breadth (B) means the maximum breadth of the ship, measured amidships to the moulded line of the frame in a ship with a metal shell, and to the outer surface of the hull in a ship with a shell of any other material. The breadth (B) shall be measured in metres.*

**4.1.8** *Cargo area is that part of the ship which contains the cargo containment system and cargo pump and compressor rooms and includes the deck areas over the full length and breadth of the part of the ship over these spaces. Where fitted, the cofferdams, ballast or void spaces at the after end of the aftermost hold space or at the forward end of the foremost hold space are excluded from the cargo area.*

**4.1.9** *Cargo containment system is the arrangement for containment of cargo including, where fitted, a primary and secondary barrier, associated insulation and any intervening spaces, and adjacent structure, if necessary, for the support of these elements. If the secondary barrier is part of the hull structure, it may be a boundary of the hold space.*

**4.1.10** *Cargo control room is a space used in the control of cargo handling operations.*

**4.1.11** *Cargo machinery spaces are the spaces where cargo compressors or pumps, cargo processing units, are located, including those supplying gas fuel to the engine-room.*

**4.1.12** *Cargo pumps are pumps used for the transfer of liquid cargo including main pumps, booster pumps, spray pumps, etc.*

**4.1.13** *Cargoes are products listed in Ch 9, Sec 19, that are carried in bulk by ships subject to the Code.*

**4.1.14** *Cargo service spaces are spaces within the cargo area, used for workshops, lockers and store-rooms that are of more than 2 m<sup>2</sup> in area.*

**4.1.15** *Cargo tank is the liquid-tight shell designed to be the primary container of the cargo and includes all such containment systems whether or not they are associated with the insulation or/and the secondary barriers.*

**4.1.16** *Closed loop sampling is a cargo sampling system that minimizes the escape of cargo vapour to the atmosphere by returning product to the cargo tank during sampling.*

**4.1.17** *Cofferdam is the isolating space between two adjacent steel bulkheads or decks. This space may be a void space or a ballast space.*

**4.1.18** *Control stations are those spaces in which ship's radio, main navigating equipment or the emergency source of power is located or where the fire-recording or fire control equipment is centralized. This does not include special fire control equipment, which can be most practically located in the cargo area.*

**4.1.19** *Flammable products are those identified by an "F" in Ch 9, Sec 19, Tab 1, column "Vapour detection".*

**4.1.20** *Flammability limits are the conditions defining the state of fuel-oxidant mixture at which application of an adequately strong external ignition source is only just capable of producing flammability in a given test apparatus.*

**4.1.21** *Gas carrier is a cargo ship constructed or adapted and used for the carriage in bulk of any liquefied gas or other products listed in Ch 9, Sec 19, Tab 1.*

**4.1.22** *Gas combustion unit (GCU) is a means of disposing excess cargo vapour by thermal oxidation.*

**4.1.23** *Gas consumer is any unit within the ship using cargo vapour as a fuel.*

**4.1.24** *Hazardous area is an area in which an explosive gas atmosphere is, or may be expected to be present, in quantities that require special precautions for the construction, installation and use of electrical equipment. When a gas atmosphere is present, the following hazards may also be present: toxicity, asphyxiation, corrosivity, reactivity and low temperature. These hazards shall also be taken into account and additional precautions for the ventilation of spaces and protection of the crew will need to be considered. Examples of hazardous areas include, but are not limited to, the following:*

- *the interiors of cargo containment systems and any pipework of pressure-relief or other venting systems for cargo tanks, pipes and equipment containing the cargo*
- *interbarrier spaces*
- *hold spaces where the cargo containment system requires a secondary barrier*
- *hold spaces where the cargo containment system does not require a secondary barrier*
- *space separated from a hold space by a single gastight steel boundary where the cargo containment system requires a secondary barrier*
- *cargo machinery spaces*
- *areas on open deck, or semi-enclosed spaces on open deck, within 3 m of possible sources of gas release, such as cargo valve, cargo pipe flange, cargo machinery space ventilation outlet, etc.*
- *areas on open deck, or semi-enclosed spaces on open deck within 1,5 m of cargo machinery space entrances, cargo machinery space ventilation inlets*

- areas on open deck over the cargo area and 3 m forward and aft of the cargo area on the open deck up to a height of 2,4 m above the weather deck
- an area within 2,4 m of the outer surface of a cargo containment system where such surface is exposed to the weather
- enclosed or semi-enclosed spaces in which pipes containing cargoes are located, except those where pipes containing cargo products for boil-off gas fuel burning systems are located
- an enclosed or semi-enclosed space having a direct opening into any hazardous area
- void spaces, cofferdams, trunks, passageways and enclosed or semi-enclosed spaces, adjacent to, or immediately above or below, the cargo containment system
- areas on open deck or semi-enclosed spaces on open deck above and in the vicinity of any vent riser outlet, within a vertical cylinder of unlimited height and 6 m radius centred upon the centre of the outlet and within a hemisphere of 6 m radius below the outlet, and
- areas on open deck within spillage containment surrounding cargo manifold valves and 3 m beyond these up to a height of 2,4 m above deck.

Note 1: Refer to Ch 9, Sec 10 for a separate list of examples and classification of hazardous areas for the purpose of selection and design of electrical installations.

**4.1.25** Non-hazardous area is an area other than a hazardous area.

**4.1.26** Hold space is the space enclosed by the ship's structure in which a cargo containment system is situated.

**4.1.27** IBC Code means the International Code for the Construction and Equipment of Ships carrying Dangerous Chemicals in Bulk, adopted by the Maritime Safety Committee of the Organization by resolution MSC.4(48), as amended.

**4.1.28** Independent means that a piping or venting system, for example, is in no way connected to another system and that there are no provisions available for the potential connection to other systems.

**4.1.29** Insulation space is the space, which may or may not be an interbarrier space, occupied wholly or in part by insulation.

**4.1.30** Interbarrier space is the space between a primary and a secondary barrier, whether or not completely or partially occupied by insulation or other material.

**4.1.31** Length (*L*) is the length as defined in the International Convention on Load Lines in force.

**4.1.32** Machinery spaces of category A are those spaces, and trunks to those spaces, which contain either:

- internal combustion machinery used for main propulsion, or  
internal combustion machinery used for purposes other than main propulsion where such machinery has, in the aggregate, a total power output of not less than 375 kW, or
- any oil-fired boiler or oil fuel unit or any oil-fired equipment other than boilers, such as inert gas generators, incinerators, etc.

**4.1.33** Machinery spaces are machinery spaces of category A and other spaces containing propelling machinery, boilers, oil fuel units, steam and internal-combustion engines, generators and major electrical machinery, oil filling stations, refrigerating, stabilizing, ventilation and air-conditioning machinery, and similar spaces and the trunks to such spaces.

**4.1.34** MARVS is the maximum allowable relief valve setting of a cargo tank (gauge pressure).

**4.1.35** Nominated surveyor is a surveyor nominated/appointed by an Administration to enforce the provisions of the SOLAS Convention regulations with regard to inspections and surveys and the granting of exemptions therefrom.

**4.1.36** Oil fuel unit is the equipment used for the preparation of oil fuel for delivery to an oil-fired boiler, or equipment used for the preparation for delivery of heated oil to an internal combustion engine, and includes any oil pressure pumps, filters and heaters dealing with oil at a pressure of more than 0,18 MPa gauge.

**4.1.37** Organization is the International Maritime Organization (IMO).

**4.1.38** Permeability of a space means the ratio of the volume within that space which is assumed to be occupied by water to the total volume of that space.

**4.1.39** Port Administration means the appropriate authority of the country for the port where the ship is loading or unloading.

**4.1.40** Primary barrier is the inner element designed to contain the cargo when the cargo containment system includes two boundaries.

**4.1.41** Products is the collective term used to cover the list of gases indicated in chapter 19 of this Code.

**4.1.42** Public spaces are those portions of the accommodation that are used for halls, dining rooms, lounges and similar permanently enclosed spaces.

**4.1.43** Relative density is the ratio of the mass of a volume of a product to the mass of an equal volume of fresh water.

**4.1.44** Secondary barrier is the liquid-resisting outer element of a cargo containment system, designed to afford temporary containment of any envisaged leakage of liquid cargo through the primary barrier and to prevent the lowering of the temperature of the ship's structure to an unsafe level. Types of secondary barrier are more fully defined in Ch 9, Sec 4.

**4.1.45** Separate systems are those cargo piping and vent systems that are not permanently connected to each other.

**4.1.46** Service spaces are those used for galleys, pantries containing cooking appliances, lockers, mail and specie rooms, store-rooms, workshops other than those forming part of the machinery spaces, and similar spaces and trunks to such spaces.

**4.1.47** SOLAS Convention means the International Convention for the Safety of Life at Sea, 1974, as amended.

**4.1.48** Tank cover is the protective structure intended to either protect the cargo containment system against damage where it protrudes through the weather deck or to ensure the continuity and integrity of the deck structure.

**4.1.49** Tank dome is the upward extension of a portion of a cargo tank. In the case of below-deck cargo containment systems, the tank dome protrudes through the weather deck or through a tank cover

**4.1.50** Thermal oxidation method means a system where the boil-off vapours are utilized as fuel for shipboard use or as a waste heat system subject to the provisions of chapter 16 or a system not using the gas as fuel complying with this Code.

**4.1.51** Toxic products are those defined by a "T" in Ch 9, Sec 19, Tab 1 column "Vapour detection".

**4.1.52** Turret compartments are those spaces and trunks that contain equipment and machinery for retrieval and release of the disconnectable turret mooring system, high-pressure hydraulic operating systems, fire protection arrangements and cargo transfer valves.

**4.1.53** Vapour pressure is the equilibrium pressure of the saturated vapour above the liquid, expressed in Pascals (Pa) absolute at a specified temperature.

**4.1.54** Void space is an enclosed space in the cargo area external to a cargo containment system, other than a hold space, ballast space, oil fuel tank, cargo pumps or compressor room, or any space in normal use by personnel.

## 5 Documentation to be submitted

### 5.1

**5.1.1** Tab 2 lists the plans, information, analysis, etc. which are to be submitted in addition to the information required in the other Parts of the Rules for the parts of the ship not affected by the cargo, as applicable.

**Table 2 : Documents to be submitted**

No.	A/I	Documents
1	I	List of products to be carried, including maximum vapour pressure, maximum liquid temperature and other important design conditions
2	I	General arrangement plan, showing location of cargo tanks and fuel oil, ballast and other tanks
3	A	Gas-dangerous zones plan
4	A	Location of void spaces and accesses to dangerous zones
5	A	Air locks between safe and dangerous zones
6	A	Ventilation duct arrangement in gas-dangerous spaces and adjacent zones
7	A	Details of hull structure in way of cargo tanks, including support arrangement for tanks, saddles, anti-floating and anti-lifting devices, deck sealing arrangements, etc.
8	A	Calculation of the hull temperature in all the design cargo conditions
9	A	Distribution of quality and steel grades in relation to the contemplated actual temperature obtained by the calculation in item 8
10	A	Hull stress analysis
11	A	Hull ship motion analysis, where a direct analysis is preferred to the methods indicated in Ch 9, Sec 4
12	A	Intact and damage stability calculations
13	A	Scantlings, material and arrangement of the cargo containment system, including the secondary barrier, if any
<p><b>Note 1:</b> A : to be submitted for approval I : to be submitted for information.</p>		

No.	A/I	Documents
14	A	Stress analysis of the cargo tanks, including fatigue analysis and crack propagation analysis for type "B" tanks. This analysis may be integrated with that indicated in item 10
15	I	Calculation of the thermal insulation suitability, including boil-off rate and refrigeration plant capability, if any, cooling down and temperature gradients during loading and unloading operations
16	A	Details of insulation
17	A	Details of ladders, fittings and towers in tanks and relative stress analysis, if any
18	A	Details of tank domes and deck sealings
19	A	Plans, arrangement and calculations of safety relief valves
20	A	Details of cargo handling and vapour system, including arrangements and details of piping and fitting
21	A	Details of cargo pumps and cargo compressors
22	A	Details of process pressure vessels and relative valving arrangement
23	A	Piping stress analysis when $T < -110^{\circ}\text{C}$
24	A	Control cargo tank pressure philosophy (description)
25	A	Bilge and ballast system in cargo area
26	A	Gas freeing system in cargo tanks including inert gas system
27	A	Interbarrier space drainage, inerting and pressurisation systems
28	A	Ventilation system in cargo area
29	A	Hull structure heating system, if any
30	A	Refrigeration and reliquefaction plant system diagram, if any
31	A	Details of electrical equipment installed in cargo area, including the list of certified safe equipment and apparatus and electrical bonding of cargo tanks and piping
32	A	Schematic electrical wiring diagram in cargo area
33	A	Gas detection system
34	A	Cargo tank instrumentation, including cargo and hull temperature monitoring system
35	A	Emergency shutdown system
36	A	Jettison system, if any
37	A	Details of fire-extinguishing appliances and systems in cargo area
38	A	Loading and unloading operation description, including cargo tank filling limits
39	A	Cargo operating manual
40	A	Cargo tank testing and inspection procedures for in-service inspection as defined in Ch 9, Sec 4, [2.1.6]
41	A	Programme of gas trials
42	I	When applicable, P & A manual
43	I I A A A I I A A A	For machinery using gas as fuel: a) General arrangement plan of the machinery plant b) Description of the entire plant c) Gas piping plans for the machinery plant d) Complete list of the safety, gas detection and warning equipment e) Drawings of the boilers f) Detailed drawings of the gas inlet and fuel inlet equipment g) Gas characteristics h) General arrangement plan of the gas treatment plant, including gas compressors, prime movers and gas preheaters i) Drawings of the gas storage tanks j) Drawings of the gas compressors and preheaters
<p><b>Note 1:</b> A : to be submitted for approval I : to be submitted for information.</p>		

## 6 Cargo equipment trials

### 6.1 Scope

#### 6.1.1 Trials in working conditions

All the equipment to which this Chapter is applicable is to be tested in actual working conditions.

#### 6.1.2 Trials to be carried out when the ship is loaded

Those trials which may only be carried out when the ship is loaded are to be held at the first loading of the ship.

For LNG carriers, the extent of the examinations that are to be conducted before and after the first loaded voyage is given in [6.2.4].

### 6.2 Extent of the tests

#### 6.2.1 Cargo equipment testing procedure

The cargo equipment testing procedure is to be submitted to the Society for review.

#### 6.2.2 Ships with mechanical refrigeration units

Ships fitted with a mechanical refrigeration unit are to be subjected to an initial testing procedure in order to check the suitability of the plant in respect of the applicable requirements. The recording of the data of the reliquefaction system, such as working duration and ambient conditions, may be carried out during the first loaded voyage.

#### 6.2.3 Use of cargo as fuel

The arrangements for using cargo as fuel are to be subjected to a special testing procedure.

#### 6.2.4 Verifications before and after the first loaded voyage:

- a) Surveyor attendance is required at the first cargo loading and first cargo unloading.
- b) Surveyor attendance during new building gas trials can be considered to comply with the applicable verifications and examinations survey requirements given in item c) and item d), with the exceptions of the survey requirements marked (\*)
- c) The following examinations are to be conducted at gas trials or first full cargo loading, as applicable to cargo containment system:

Note 1: When attending at first full cargo loading, priority is to be given to latter stages of loading.

- verify the satisfactory functionality of the emergency shutdown system during testing
- satisfactory operation of gas detection system
- satisfactory operation of cargo tank pressure monitoring system
- satisfactory operation of interbarrier space(s) and insulation space(s) pressure monitoring system, as applicable
- satisfactory operation of cargo tank temperature monitoring system
- satisfactory operation of cargo tank level indicating system
- satisfactory operation of interbarrier space(s) and inner hull temperature monitoring system, as applicable
- inert gas generator, if operating
- nitrogen generating plant, if operating
- nitrogen pressure control system for insulation, interbarrier, and annular spaces, as applicable
- reliquefaction plant, if fitted
- equipment fitted for the burning of cargo vapours such as boilers, engines, gas combustion units, etc., if operating
- examination of on-deck cargo piping systems including expansion and supporting arrangements
- verification and examination of all piping systems, including valves, fittings and associated equipment for handling cargo or vapours
- advise Master to carry out cold spot examination of the hull and external insulation during transit voyage to unloading port and record in ship's logbook; and
- advise Master to test high-level alarm(s) with liquid cargo during voyage and record in ship's logbook, when loading condition permits.

- d) The following examinations are to be conducted at gas trials or first full cargo unloading, as applicable to cargo containment system:

Note 2: When attending at first full cargo unloading, priority is to be given to the commencement of unloading.

- examination of on-deck cargo piping systems including expansion and supporting arrangements
  - review logbook entry of emergency shutdown system testing prior to commencement of unloading
  - (\*) review cargo logs and alarm reports for cargo tank pressure, temperature, and level indicating systems
  - satisfactory operation of cargo compressors
  - satisfactory operation of cargo pumps
  - inert gas generator, if operating
  - nitrogen generating plant, if operating
  - nitrogen pressure control system for insulation, interbarrier, and annular spaces, as applicable
  - (\*) review of records for satisfactory operation of the reliquefaction plant, if fitted
  - review of records for equipment fitted for the burning of cargo vapours such as boilers, engines, gas combustion units, etc.
  - (\*) on ships fitted with membrane tanks, review records of the cofferdam and inner hull temperature sensors to verify the readings are not below the allowable temperature for the selected grade of steel
  - (\*) cofferdam heating system, if in operation
  - (\*) review logbook entries for cold spot examination; and
  - (\*) review logbook entry for testing of high-level alarm(s) with liquid cargo. If cargo conditions did not permit testing, the Surveyor is to require testing at the first occasion where cargo conditions allow for testing. Master to be advised to record testing in ship's logbook which is to be verified no later than the first annual survey.
- e) To demonstrate satisfactory functionality of the verifications, ship's Master is to be required to arrange and provide to the Surveyor print outs or screen shots showing:
- trends of cargo tanks pressure and temperature
  - trends of pressure and temperature distribution of interbarrier space(s) and insulation space(s), and temperature distribution of inner hull, as applicable
  - trends record of performance of cofferdam heating system, when fitted
  - trends record of consumption of nitrogen gas, and whether any abnormality has been observed.
  - list of any gas alarms, if occurred:
    - Cargo Tanks Containment System Cold Spot Inspection Statement; and
    - activation of Cargo Tanks High-Level Alarm and Overfill Protection tests.

## **7 Additional service features BOG-reliquefaction and LNG-subcooling**

### **7.1 General**

#### **7.1.1 Application**

The service notation **Liquefied gas carrier** is to be completed by the following additional service features indicating which systems are installed on board the ship to control the cargo tank pressure without losing cargo volume during navigation:

- a) The additional service feature **BOG-reliquefaction** is assigned, in accordance with Pt A, Ch 1, Sec 2, [4.4.5], to liquefied gas carriers equipped with a reliquefaction installation complying with the requirements of Ch 9, Sec 7, [3]
- b) The additional service feature **LNG-subcooling** is assigned, in accordance with Pt A, Ch 1, Sec 2, [4.4.5], to liquefied gas carriers equipped with a cooling installation aiming at reducing the cargo temperature and complying with the requirements of Ch 9, Sec 7, [6].

## **8 Additional service feature STL-SPM**

### **8.1 General**

#### **8.1.1 Application**

- a) The additional service feature **STL-SPM** is assigned, in accordance with Pt A, Ch 1, Sec 2, [4.4.5], to liquefied gas carriers used as regasification terminal, fitted forward with equipment for not permanent mooring, or for connection to single buoy, and complying with the requirements of the present Article.
- b) The buoy and the mooring system may be not included within classification. In case the buoy and the mooring are covered by class, the Rules for the Classification of Offshore Loading and Off loading Buoys (NR494) are applicable to the buoy and the **POSA** additional class notation may be assigned to the mooring system.

### 8.1.2 Scope

The following items are covered by the additional service feature **STL-SPM**:

- ship structure, in way of the mooring or the single buoy
- hatch cover
- cylinders
- swivel
- piping and risers
- stoppers
- winch
- interface between equipment and ship structure
- ventilation
- handling equipment (HPU and control system)
- drainage of compartment
- fire and gas detection system
- fire extinction system
- emergency escape.

### 8.1.3 Applicable rules

- a) The items listed in [8.1.2] are to comply with the applicable requirements of IGC code.
- b) Components of the equipment used for mooring at single point are to comply with the applicable requirements of Pt B, Ch 12, Sec 4 for **ETA** (Emergency Towing Arrangement) and Pt F, Ch 11, Sec 3, for **SPM** (Single Point Mooring).
- c) The swivel is to be classed according to Section 8 of the NR494 Rules for the Classification of Offshore Loading and Off loading Buoys.
- d) The lifting appliances are to meet the applicable requirements of NR526 Rules for Lifting Appliances.
- e) The risers are to be specially considered.

## 8.2 Documentation to be submitted

### 8.2.1 Plans and documents to be submitted for approval

In addition to the documents listed in Pt B, Ch 1, Sec 4, the following plans and documents are to be submitted to the Society for approval:

- ship structure drawings, in way of the mooring or the single buoy
- local reinforcements of ship structure below equipment
- ventilation plan
- emergency escape
- drawings of equipment
- fire and gas detection, wiring and arrangement diagram
- cable list
- STL, auxiliary and bridge system
- lighting installation, wiring and arrangement diagram
- electrical starter circuit diagram
- architecture diagram of control and safety system
- control and wiring diagram of:
  - hydraulic system for buoy locking devices
  - winches
- fire extinction
- drainage system.

### 8.2.2 Plans and documents to be submitted for information

The following documents are to be submitted to the Society for information:

- DLOC (design load operating conditions)
- structural calculation
- fatigue calculation
- model test results
- explosion calculation
- CCTV diagram
- operation procedure of system.

### **8.3 Structural design**

#### **8.3.1 Design loads**

- a) Model tests in mooring conditions are generally to be carried out to determine the loads.
- b) For the ship structure, calculations based on test results or mooring and hydrodynamic calculations are to be submitted and subject to special examination by the Society.

#### **8.3.2 Scantlings**

The deck structure supporting accessories is to be reinforced on basis of loads given by the designer.

### **8.4 Mechanical installation**

**8.4.1** When hydraulic installation is used, it is to be in compliance with the applicable requirements of Pt C, Ch 1, Sec 10, [14].

**8.4.2** The hydraulic cylinders are considered as pressure vessels; the scantlings of the shells and the ends are to be in compliance with the applicable requirements of Pt C, Ch 1, Sec 3.

**8.4.3** Securing devices are to be simple to operate and easily accessible.

**8.4.4** Securing devices are to be equipped with mechanical locking arrangement (self locking or separate arrangement), or to be of the gravity type. Where hydraulic securing devices are applied, they have to remain locked in the event of loss of the hydraulic fluid.

**8.4.5** The opening and closing systems as well as securing and locking devices are to be interlocked in such a way that they can only operate in the proper sequence.

**8.4.6** The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits, when in closed position.

### **8.5 Electrical and automation installation**

**8.5.1** Unless otherwise specified, the requirements in Part C, Chapter 2 and Part C, Chapter 3 are applicable to the system fitted in STL.

**8.5.2** The STL room is to be considered as hazardous area. Electrical equipment are to be avoided in this area. When electrical equipment are fitted, they are to be of a safe type IIA T3 and considered as Zone 1.

**8.5.3** The STL system is to be considered as a primary essential service.

**8.5.4** The electrical equipment located in flooded space are to be IP 68 for the appropriate depth.

**8.5.5** The electrical equipment located in non flooded space are to be IP 67.

**8.5.6** Local control of systems is always to be available.

# Section 2 Ship Survival Capability and Location of Cargo Tanks

## 1 General

### 1.1

**1.1.1** Ships subject to the Code shall survive the hydrostatic effects of flooding following assumed hull damage caused by some external force. In addition, to safeguard the ship and the environment, the cargo tanks shall be protected from penetration in the case of minor damage to the ship resulting, for example, from contact with a jetty or tug, and also given a measure of protection from damage in the case of collision or grounding, by locating them at specified minimum distances inboard from the ship's shell plating. Both the damage to be assumed and the proximity of the tanks to the ship's shell shall be dependent upon the degree of hazard presented by the product to be carried. In addition, the proximity of the cargo tanks to the ship's shell shall be dependent upon the volume of the cargo tank.

**1.1.2** Ships subject to the Code shall be designed to one of the following standards:

- a) A type 1G ship is a gas carrier intended to transport the products indicated in Ch 9, Sec 19 that require maximum preventive measures to preclude their escape
- b) A type 2G ship is a gas carrier intended to transport the products indicated in Ch 9, Sec 19, that require significant preventive measures to preclude their escape
- c) A type 2PG ship is a gas carrier of 150 m in length or less intended to transport the products indicated in Ch 9, Sec 19 that require significant preventive measures to preclude their escape, and where the products are carried in type C independent tanks designed (see Ch 9, Sec 4, [10]) for a MARVS of at least 0,7 MPa gauge and a cargo containment system design temperature of  $-55^{\circ}\text{C}$  or above. A ship of this description that is over 150 m in length is to be considered a type 2G ship
- d) A type 3G ship is a gas carrier intended to carry the products indicated in Ch 9, Sec 19 that require moderate preventive measures to preclude their escape.

Therefore, a type 1G ship is a gas carrier intended for the transportation of products considered to present the greatest overall hazard and types 2G/2PG and type 3G for products of progressively lesser hazards. Accordingly, a type 1G ship shall survive the most severe standard of damage and its cargo tanks shall be located at the maximum prescribed distance inboard from the shell plating.

**1.1.3** The ship type required for individual products is indicated in Ch 9, Sec 19, Tab 1.

**1.1.4** If a ship is intended to carry more than one of the products listed in Ch 9, Sec 19, the standard of damage shall correspond to the product having the most stringent ship type requirements. The requirements for the location of individual cargo tanks, however, are those for ship types related to the respective products intended to be carried.

**1.1.5** For the purpose of this Code, the position of the moulded line for different containment systems is shown in Fig 5 to Fig 9.

## 2 Freeboard and stability

### 2.1 General

**2.1.1** Ships subject to the Code may be assigned the minimum freeboard permitted by the International Convention on Load Lines in force. However, the draught associated with the assignment shall not be greater than the maximum draught otherwise permitted by this Code.

**2.1.2** The stability of the ship, in all seagoing conditions and during loading and unloading cargo, shall comply with the requirements of the International Code on Intact Stability. This includes partial filling and loading and unloading at sea, when applicable. Stability during ballast water operations shall fulfil stability criteria.

Note 1: Refer to the International Code on Intact Stability, 2008 (2008 IS Code), adopted by the Maritime Safety Committee of the Organization by resolution MSC.267(85).

**2.1.3** The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.8] is to be in compliance with the requirements in Pt B, Ch 3, Sec 2.

**2.1.4** When calculating the effect of free surfaces of consumable liquids for loading conditions, it shall be assumed that, for each type of liquid, at least one transverse pair or a single centre tank has a free surface. The tank or combination of tanks to be taken into account shall be those where the effect of free surfaces is the greatest. The free surface effect in undamaged compartments shall be calculated by a method according to the International Code on Intact Stability.

**2.1.5** The free surface effect is to be calculated in accordance with Pt B, Ch 3, Sec 2, [4].

**2.1.6** *Solid ballast shall not normally be used in double bottom spaces in the cargo area. Where, however, because of stability considerations, the fitting of solid ballast in such spaces becomes unavoidable, its disposition shall be governed by the need to enable access for inspection and to ensure that the impact loads resulting from bottom damage are not directly transmitted to the cargo tank structure.*

**2.1.7** *The Master of the ship shall be supplied with a loading and stability information booklet. This booklet shall contain details of typical service conditions, loading, unloading and ballasting operations, provisions for evaluating other conditions of loading and a summary of the ship's survival capabilities. The booklet shall also contain sufficient information to enable the Master to load and operate the ship in a safe and seaworthy manner.*

**2.1.8** The Master of the ship is to be supplied with a Loading Manual as specified in Pt B, Ch 1, Sec 5, [2] and a Trim and Stability booklet as specified in Pt B, Ch 3, App 2.

**2.1.9** *All ships, subject to the Code shall be fitted with a stability instrument, capable of verifying compliance with intact and damage stability requirements, approved by the Society having regard to the performance standards recommended by the Organization.*

*Note 1: Refer to part B, chapter 4, of the International Code on Intact Stability, 2008 (2008 IS Code), as amended; the Guidelines for the Approval of Stability Instruments (MSC.1/Circ.1229), annex, section 4, as amended; and the technical standards defined in part 1 of the Guidelines for verification of damage stability requirements for tankers (MSC.1/Circ.1461).*

- a) *ships constructed before 1 July 2016 shall comply with the requirements of [2.1.9] at the first scheduled renewal survey of the ship after 1 July 2016 but not later than 1 July 2021*
- b) *notwithstanding the requirements of item a), a stability instrument installed on a ship constructed before 1 July 2016 need not be replaced provided it is capable of verifying compliance with intact and damage stability, to the satisfaction of the Society, and*
- c) *for the purposes of control under SOLAS regulation XI-1/4, the Society shall issue a document of approval for the stability instrument.*

**2.1.10** *The Society may waive the requirements of [2.1.9] for the following ships, provided the procedures employed for intact and damage stability verification maintain the same degree of safety, as being loaded in accordance with the approved conditions.*

*Note 1: Refer to operational guidance provided in part 2 of the Guidelines for verification of damage stability requirements for tankers (MSC.1/Circ.1461).*

*Any such waiver shall be duly noted on the International Certificate of Fitness:*

- a) *ships which are on a dedicated service, with a limited number of permutations of loading such that all anticipated conditions have been approved in the stability information provided to the Master in accordance with the requirements of [2.1.7]*
- b) *ships where stability verification is made remotely by a means approved by the Society*
- c) *ships which are loaded within an approved range of loading conditions, or*
- d) *ships constructed before 1 July 2016 provided with approved limiting KG/GM curves covering all applicable intact and damage stability requirements.*

#### **2.1.11 Conditions of loading**

*Damage survival capability shall be investigated on the basis of loading information submitted to the Society for all anticipated conditions of loading and variations in draught and trim. This shall include ballast and, where applicable, cargo heel.*

Loading conditions other than those in the Loading Manual and the Trim and Stability booklet are to be previously submitted to the Society. Alternatively, such cases may be examined by the Master or a delegated officer when a loading instrument approved in accordance with the requirements in Pt B, Ch 1, Sec 5, [3] is installed on board.

### **3 Damage assumptions**

#### **3.1 General**

**3.1.1** *The assumed maximum extent of damage shall be as per Tab 1.*

#### **3.2 Other damage**

**3.2.1** *If any damage of a lesser extent than the maximum damage specified in [3.1.1] would result in a more severe condition, such damage shall be assumed*

**3.2.2** *Local damage anywhere in the cargo area extending inboard distance "d" as defined in [4.1.1], measured normal to the moulded line of the outer shell shall be considered. Bulkheads shall be assumed damaged when the relevant list items of [6.1.2] apply. If a damage of a lesser extent than "d" would result in a more severe condition, such damage shall be assumed.*

**Table 1 : Assumed maximum extent of damage**

Side damage	Longitudinal extent:	1/3 L <sup>2/3</sup> or 14,5 m, whichever is less
	Transverse extent: measured inboard from the moulded line of the outer shell at right angles to the centreline at the level of the summer waterline	B/5 or 11,5 m, whichever is less
	Vertical extent: from the moulded line of the outer shell	Upwards, without limit

		For 0,3 L from the forward perpendicular of the ship	Any other part of the ship
Bottom damage	Longitudinal extent:	1/3L <sup>2/3</sup> or 14,5 m, whichever is less	1/3L <sup>2/3</sup> or 14,5 m, whichever is less
	Transverse extent:	B/6 or 10 m, whichever is less	B/6 or 5 m, whichever is less
	Vertical extent:	B/15 or 2 m, whichever is less measured from the moulded line of the bottom shell plating at centreline (see [4.1.4])	B/15 or 2 m, whichever is less measured from the moulded line of the bottom shell plating at centreline (see [4.1.4])

## 4 Location of cargo tanks

### 4.1 General

**4.1.1** Cargo tanks shall be located at the following distances inboard:

a) Type 1G ships:

from the moulded line of the outer shell, not less than the transverse extent of side damage specified in Tab 1 and, from the moulded line of the bottom shell at centreline, not less than the vertical extent of bottom damage specified in Tab 1, and nowhere less than the distance *d*, in m, defined as follows:

- for  $V_c$  below or equal to 1000 m<sup>3</sup>:  $d = 0,8$
- for  $1000 \text{ m}^3 < V_c < 5000 \text{ m}^3$ :  $d = 0,75 + V_c \cdot 0,2/4000$
- for  $5000 \text{ m}^3 \leq V_c < 30000 \text{ m}^3$ :  $d = 0,8 + V_c / 25000$
- for  $V_c \geq 30000 \text{ m}^3$ :  $d = 2,0$

where

$V_c$  : 100% of the gross design volume of the individual cargo tank at 20°C, including domes and appendages (see Fig 1 and Fig 2). For the purpose of cargo tank protective distances, the cargo tank volume is the aggregate volume of all the parts of tank that have a common bulkhead(s), and

*d* : Distance, in m, measured at any cross-section at a right angle from the moulded line of outer shell.

Tank size limitations may apply to type 1G ship cargoes in accordance with Ch 9, Sec 17.

b) Types 2G/2PG:

from the moulded line of the bottom shell at centreline not less than the vertical extent of bottom damage specified in Tab 1 and nowhere less than the distance *d* as indicated in [4.1.1], item a) (see Fig 1 and Fig 2).

c) Type 3G ships:

from the moulded line of the bottom shell at centreline not less than the vertical extent of bottom damage specified in Tab 1 and nowhere less than the distance *d*, where  $d = 0,8$  m from the moulded line of outer shell (see Fig 1 and Fig 4).

**4.1.2** Deck cargo tanks are to be located not less than 800 mm inboard from the side shell.

**4.1.3** For the purpose of tank location, the vertical extent of bottom damage shall be measured to the inner bottom when membrane or semi-membrane tanks are used, otherwise to the bottom of the cargo tanks. The transverse extent of side damage shall be measured to the longitudinal bulkhead when membrane or semi-membrane tanks are used, otherwise to the side of the cargo tanks. The distances indicated in [3] and [4] shall be applied as in Fig 5 to Fig 9. These distances shall be measured plate to plate, from the moulded line to the moulded line, excluding insulation.

**4.1.4** Except for type 1G ships, suction wells installed in cargo tanks may protrude into the vertical extent of bottom damage specified in Tab 1 provided that such wells are as small as practicable and the protrusion below the inner bottom plating does not exceed 25% of the depth of the double bottom or 350 mm, whichever is less. Where there is no double bottom, the protrusion below the upper limit of bottom damage shall not exceed 350 mm. Suction wells installed in accordance with this paragraph may be ignored when determining the compartments affected by damage.

**4.1.5** Cargo tanks shall not be located forward of the collision bulkhead

Figure 1 : Cargo tank location requirements - Centreline profile - Type 1G, 2G, 2GP and 3G ships

Figure 2 : Cargo tank location requirements - Transverse sections - Type 1G ships

Figure 3 : Cargo tank location requirements - Transverse sections - Type 2G and 2PG ships

Figure 4 : Cargo tank location requirements - Transverse sections - Type 3G ships

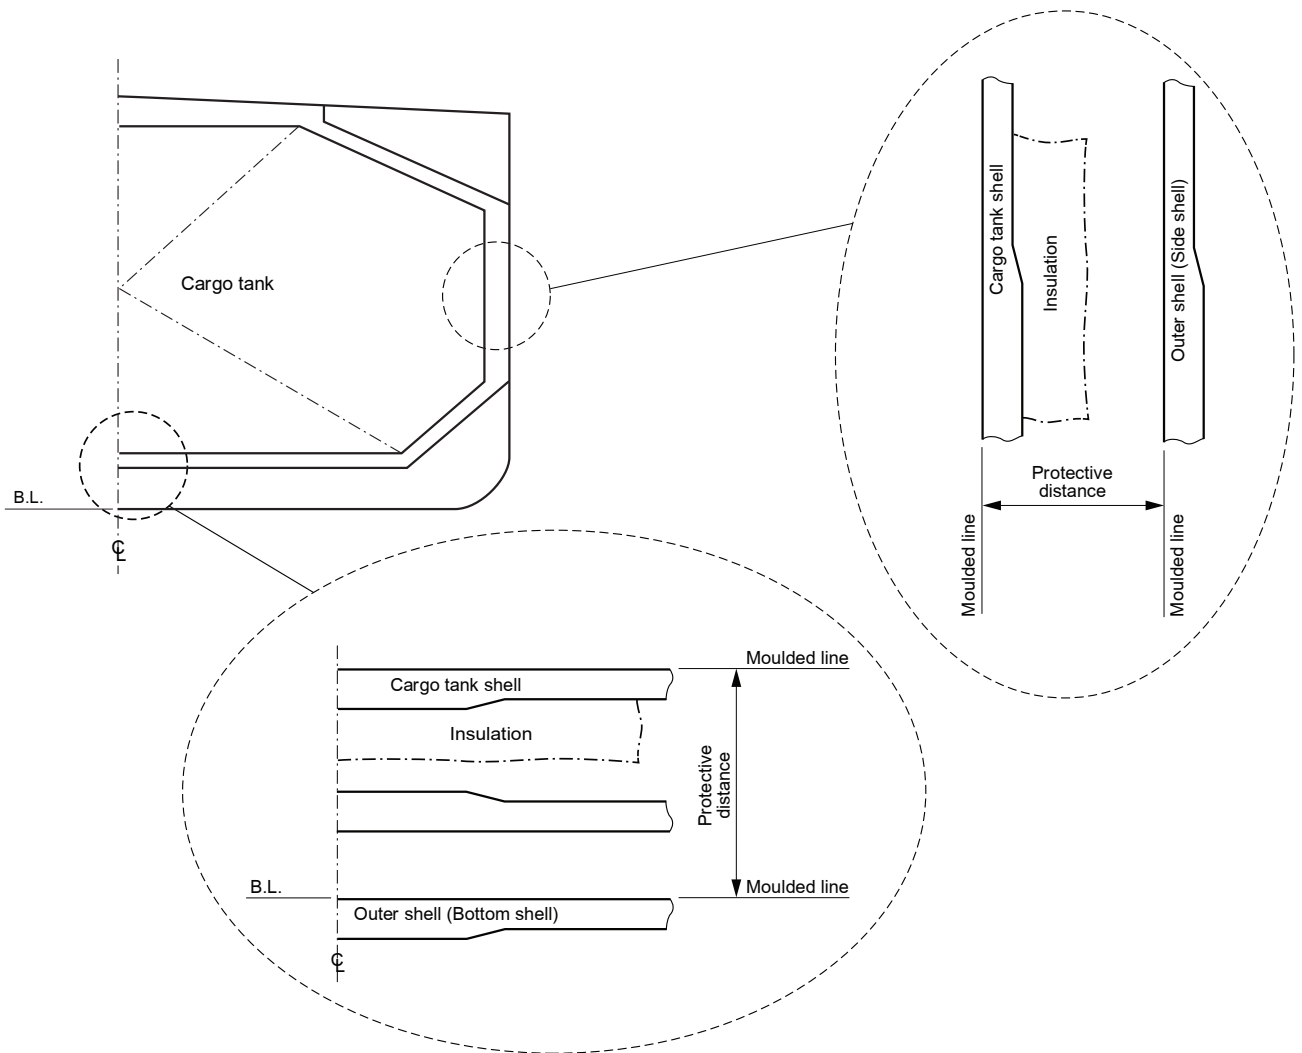

Figure 6 : Protective distance - Semi-membrane tank

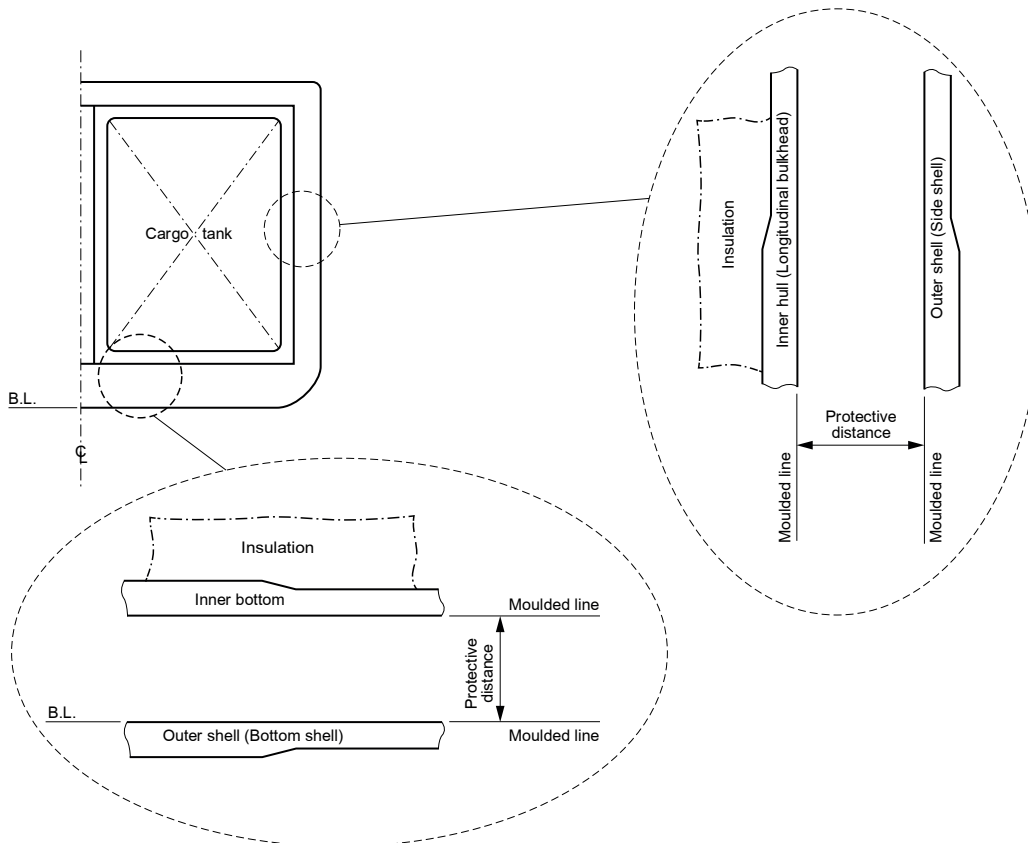

Figure 7 : Protective distance - Membrane tank

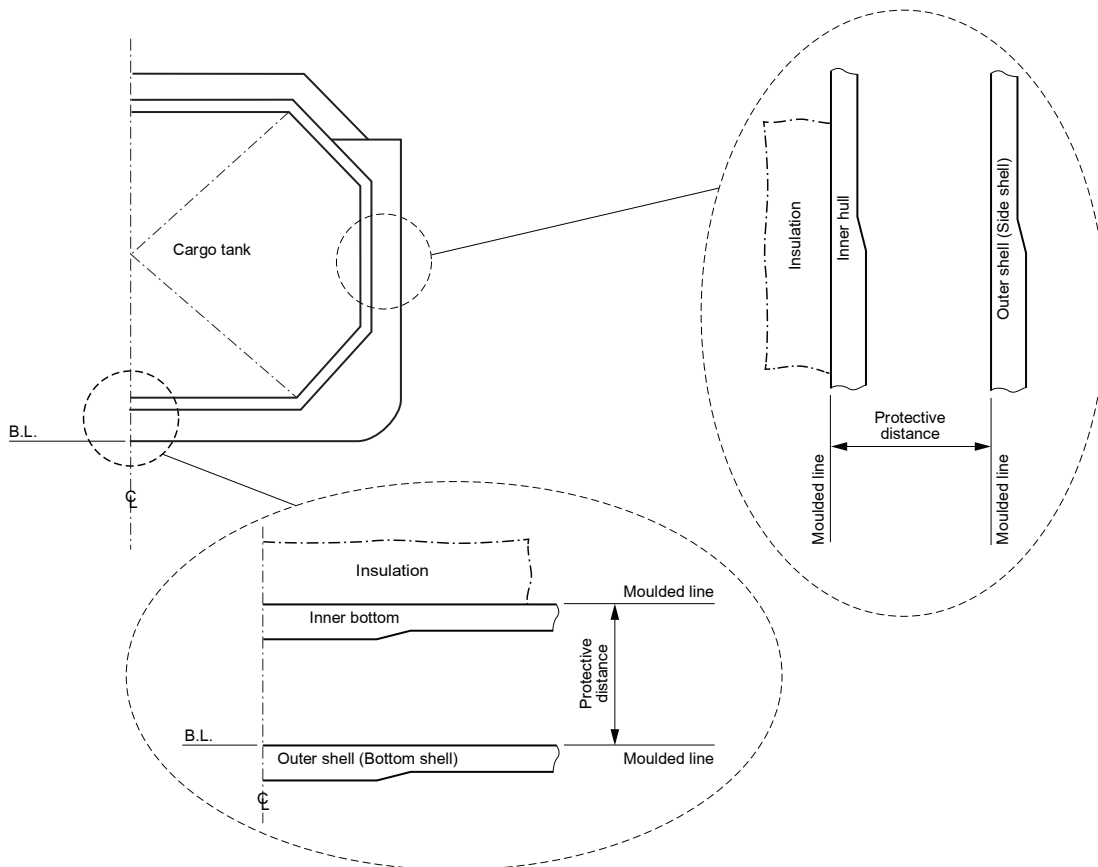

Figure 8 : Protective distance - Spherical tank

Figure 9 : Protective distance - Pressure type tank

## 5 Flood assumptions

### 5.1 General

**5.1.1** The requirements of [7] shall be confirmed by calculations that take into consideration the design characteristics of the ship, the arrangements, configuration and contents of the damaged compartments, the distribution, relative densities and the free surface effects of liquids and the draught and trim for all conditions of loading.

**5.1.2** The permeabilities of spaces assumed to be damaged shall be as per Tab 2.

**5.1.3** Wherever damage penetrates a tank containing liquids, it shall be assumed that the contents are completely lost from that compartment and replaced by salt water up to the level of the final plane of equilibrium.

**5.1.4** Where the damage between transverse watertight bulkheads is envisaged, as specified in [6.1.2], item d), item e) and item f), transverse bulkheads shall be spaced at least at a distance equal to the longitudinal extent of damage specified in Tab 1 (see Side damage / longitudinal extent) in order to be considered effective. Where transverse bulkheads are spaced at a lesser distance, one or more of these bulkheads within such extent of damage shall be assumed as non-existent for the purpose of determining flooded compartments. Further, any portion of a transverse bulkhead bounding side compartments or double bottom compartments shall be assumed damaged if the watertight bulkhead boundaries are within the extent of vertical or horizontal penetration required by [3]. Also, any transverse bulkhead shall be assumed damaged if it contains a step or recess of more than 3 m in length located within the extent of penetration of assumed damage. The step formed by the after peak bulkhead and the after peak tank top shall not be regarded as a step for the purpose of this paragraph.

**5.1.5** The ship shall be designed to keep unsymmetrical flooding to the minimum consistent with efficient arrangements.

**5.1.6** Equalization arrangements requiring mechanical aids such as valves or cross-levelling pipes, if fitted, shall not be considered for the purpose of reducing an angle of heel or attaining the minimum range of residual stability to meet the requirements of [7.1.3], and sufficient residual stability shall be maintained during all stages where equalization is used. Spaces linked by ducts of large cross-sectional area may be considered to be common.

**5.1.7** If pipes, ducts, trunks or tunnels are situated within the assumed extent of damage penetration, as defined in [3], arrangements shall be such that progressive flooding cannot thereby extend to compartments other than those assumed to be flooded for each case of damage.

**5.1.8** Tunnels, ducts, pipes, doors, bulkheads and decks which might form watertight boundaries of intact spaces in the case of assumed conventional damage are to have minimum strength adequate to withstand the pressure height corresponding to the deepest equilibrium waterline in damaged conditions.

**5.1.9** The buoyancy of any superstructure directly above the side damage shall be disregarded. However, the unflooded parts of superstructures beyond the extent of damage may be taken into consideration, provided that:

- they are separated from the damaged space by watertight divisions and the requirements of [7.1.3], item a) in respect of these intact spaces are complied with; and
- openings in such divisions are capable of being closed by remotely operated sliding watertight doors and unprotected openings are not immersed within the minimum range of residual stability required in [7.1.3], item a). However, the immersion of any other openings capable of being closed weathertight may be permitted.

**Table 2 : Permeabilities of spaces assumed to be damaged**

Spaces	Permeabilities
Stores	0,60
Accommodation	0,95
Machinery	0,85
Voids	0,95
Hold spaces	0,951
Consumable liquids	0 to 0,952
Other liquids	0 to 0,952
<b>Note 1:</b> Other values of permeability can be considered based on the detailed calculations. Interpretations of regulation of part B-1 of SOLAS chapter II-1 (MSC/Circ.651) are referred.	
<b>Note 2:</b> The permeability of partially filled compartments shall be consistent with the amount of liquid carried in the compartment.	

## 6 Standard of damage

### 6.1 General

**6.1.1** The longitudinal extent of damage to the superstructure (see also [5.1.9]) in the case of side damage to a machinery space aft, as per [6.1.2], is to be the same as the longitudinal extent of the side damage to the machinery space (see Fig 10).

**Figure 10 : Longitudinal extension of superstructure damage**

**6.1.2** Ships shall be capable of surviving the damage indicated in [3] with the flood assumptions in [5], to the extent determined by the ship's type, according to the following standards:

- a) A type 1G ship shall be assumed to sustain damage anywhere in its length
- b) A type 2G ship of more than 150 m in length shall be assumed to sustain damage anywhere in its length
- c) A type 2G ship of 150 m in length or less shall be assumed to sustain damage anywhere in its length, except involving either of the bulkheads bounding a machinery space located aft
- d) A type 2PG ship shall be assumed to sustain damage anywhere in its length except involving transverse bulkheads spaced further apart than the longitudinal extent of side damage as specified in Tab 1
- e) A type 3G ship of 80 m in length or more shall be assumed to sustain damage anywhere in its length, except involving transverse bulkheads spaced further apart than the longitudinal extent of side damage specified in Tab 1, and
- f) A type 3G ship less than 80 m in length shall be assumed to sustain damage anywhere in its length, except involving transverse bulkheads spaced further apart than the longitudinal extent of side damage specified in Tab 1 and except damage involving the machinery space when located after.

The flooding of the machinery space, if located aft on a type 3G ship less than 80 m in length, is to comply as far as practicable with the criteria in [7]. Relaxation of parts of these requirements may be accepted on a case-by-case basis.

**6.1.3** In the case of small type 2G/2PG and 3G ships that do not comply in all respects with the appropriate requirements of [6.1.2], item c), item e) and item f), special dispensations may only be considered by the Society provided that alternative measures can be taken which maintain the same degree of safety. The nature of the alternative measures shall be approved and clearly stated and be available to the port Administration. Any such dispensation shall be duly noted on the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk.

## 7 Survival requirements

### 7.1 General

**7.1.1** Ships subject to the Code shall be capable of surviving the assumed damage specified in [3], to the standard provided in [6], in a condition of stable equilibrium and shall satisfy the following criteria.

**7.1.2** Ships are to be capable of surviving the assumed damage specified in [3.1.1] and [3.2] to the standard provided in [6.1.2] and for the loading conditions in Pt B, Ch 3, App 2, [1.2.8] in a condition of stable equilibrium and such as to satisfy the criteria in [7].

**7.1.3** In any stage of flooding:

- a) The waterline, taking into account sinkage, heel and trim, shall be below the lower edge of any opening through which progressive flooding or downflooding may take place. Such openings shall include air pipes and openings that are closed by means of weathertight doors or hatch covers and may exclude those openings closed by means of watertight manhole covers and watertight flush scuttles, small watertight cargo tank hatch covers that maintain the high integrity of the deck, remotely operated sliding watertight doors, hinged watertight access doors with open/closed indication locally and at the navigation bridge, of the quick-acting or single-action type that are normally closed at sea, hinged watertight doors that are permanently closed at sea, and sidescuttles of the non-opening type;
- b) The maximum angle of heel due to unsymmetrical flooding shall not exceed 30°, and

c) *The residual stability during intermediate stages of flooding shall not be less than that required by item a).*

The criteria applied to the residual stability during intermediate stages of flooding are to be those relevant to the final stage of flooding as specified in [7.1.4]. However, small deviations from these criteria may be accepted by the Society on a case-by-case basis.

**7.1.4** *At final equilibrium after flooding:*

a) *The righting lever curve shall have a minimum range of 20° beyond the position of equilibrium in association with a maximum residual righting lever of at least 0,1 m within the 20° range; the area under the curve within this range shall not be less than 0,0175 m-radians. The 20° range may be measured from any angle commencing between the position of equilibrium and the angle of 25° (or 30° if no deck immersion occurs). Unprotected openings shall not be immersed within this range unless the space concerned is assumed to be flooded. Within this range, the immersion of any of the openings listed in [7.1.3] and other openings capable of being closed weathertight may be permitted.*

Note 1: "other openings capable of being closed weathertight" do not include ventilators that have to remain open to supply air to the engine room or emergency generator room for the effective operation of the ship.

See also Fig 11.

b) *The emergency source of power shall be capable of operating.*

**Figure 11 : Range of positive stability**

## Section 3 Ship Arrangement

### 1 General

#### 1.1 Segregation of the cargo area

**1.1.1** Hold spaces shall be segregated from machinery and boiler spaces, accommodation spaces, service spaces, control stations, chain lockers, domestic water tanks and from stores. Hold spaces shall be located forward of machinery spaces of category A. Alternative arrangements, including locating machinery spaces of category A forward, may be accepted, based on SOLAS regulation II-2/17, after further consideration of involved risks, including that of cargo release and the means of mitigation.

**1.1.2** Bow thrusters are allowed to be fitted forward of the hold spaces.

**1.1.3** Where cargo is carried in a cargo containment system not requiring a complete or partial secondary barrier, segregation of hold spaces from spaces referred to in [1.1.1] or spaces either below or outboard of the hold spaces may be effected by cofferdams, oil fuel tanks or a single gastight bulkhead of all-welded construction forming an "A-60" class division. A gastight "A-0" class division is acceptable if there is no source of ignition or fire hazard in the adjoining spaces.

**1.1.4** Where cargo is carried in a cargo containment system requiring a complete or partial secondary barrier, segregation of hold spaces from spaces referred to in [1.1.1], or spaces either below or outboard of the hold spaces that contain a source of ignition or fire hazard, shall be effected by cofferdams or oil fuel tanks. A gastight "A-0" class division is acceptable if there is no source of ignition or fire hazard in the adjoining spaces.

**1.1.5** Hold spaces may be separated from each other by single bulkheads. Where cofferdams are used instead of single bulkheads, they may be used as ballast tanks subject to special approval by the Society.

**1.1.6** Turret compartments segregation from spaces referred to in [1.1.1], or spaces either below or outboard of the turret compartment that contain a source of ignition or fire hazard, shall be effected by cofferdams or an A-60 class division. A gastight "A-0" class division is acceptable if there is no source of ignition or fire hazard in the adjoining spaces.

**1.1.7** In addition, the risk of fire propagation from turret compartments to adjacent spaces shall be evaluated by a risk analysis (see Ch 9, Sec 1, [2.1.11]) and further preventive measures, such as the arrangement of a cofferdam around the turret compartment, shall be provided if needed.

**1.1.8** When cargo is carried in a cargo containment system requiring a complete or partial secondary barrier:

- at temperatures below  $-10^{\circ}\text{C}$ , hold spaces shall be segregated from the sea by a double bottom, and
- at temperatures below  $-55^{\circ}\text{C}$ , the ship shall also have a longitudinal bulkhead forming side tanks.

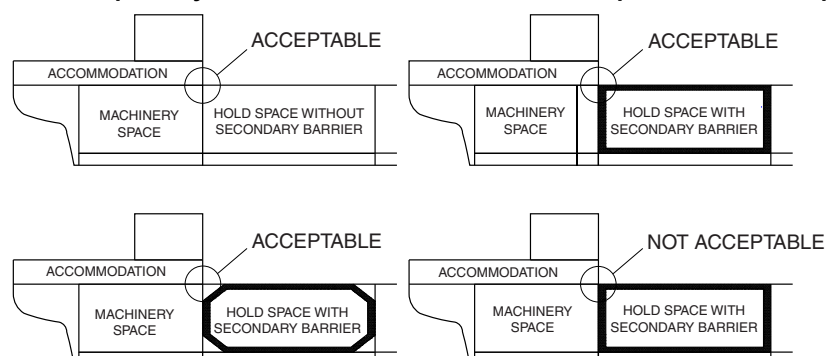

**1.1.9** Arrangements shall be made for sealing the weather decks in way of openings for cargo containment systems.

#### 1.2 Accommodation, service and machinery spaces and control stations

**1.2.1** No accommodation space, service space or control station shall be located within the cargo area. The bulkhead of accommodation spaces, service spaces or control stations that face the cargo area shall be so located as to avoid the entry of gas from the hold space to such spaces through a single failure of a deck or bulkhead on a ship having a containment system requiring a secondary barrier.

**1.2.2** Some acceptable and unacceptable arrangements of accommodation spaces, with respect to cargo tanks, are shown in Fig 1.

**Figure 1 : Acceptability of common corners between hold spaces and other spaces**

**1.2.3** *To guard against the danger of hazardous vapours, due consideration shall be given to the location of air intakes/outlets and openings into accommodation, service and machinery spaces and control stations in relation to cargo piping, cargo vent systems and machinery space exhausts from gas burning arrangements.*

Compliance with the relevant requirements, in particular with [1.2.5], [1.8], Ch 9, Sec 8, [2.1.14] and Ch 9, Sec 12, [1.2.5], as applicable, also ensures compliance with this requirement, relevant to precautions against hazardous vapours.

**1.2.4** *Access through doors, gastight or otherwise, shall not be permitted from a non-hazardous area to a hazardous area except for access to service spaces forward of the cargo area through airlocks, as permitted by [1.6.1], when accommodation spaces are aft.*

**1.2.5** *Entrances, air inlets, air outlets and openings to accommodation spaces, service spaces, machinery spaces and control stations shall not face the cargo area. They shall be located on the end bulkhead not facing the cargo area or on the outboard side of the superstructure or deckhouse or on both at a distance of at least 4% of the length (L) of the ship but not less than 3 m from the end of the superstructure or deckhouse facing the cargo area. This distance, however, need not exceed 5 m.*

**1.2.6** Doors facing the cargo area or located in prohibited zones in the sides are to be restricted to stores for cargo-related and safety equipment, cargo control stations as well as decontamination showers and eye wash.

Where such doors are permitted, the space may not give access to other spaces covered in [1.2.5], [1.2.8] or [1.2.10], and the common boundaries with these spaces are to be insulated with A60 class bulkheads.

The space define above is to be in accordance with Ch 9, Sec 12, [1.2].

**1.2.7** Bolted plates of A60 class for removal of machinery may be accepted on bulkheads facing cargo areas, provided signboards are fitted to warn that these plates may only be opened when the ship is in gas-free condition.

**1.2.8** *Windows and sidescuttles facing the cargo area and on the sides of the superstructures or deckhouses within the distance mentioned in [1.2.5] shall be of the fixed (non-opening) type. Wheelhouse windows may be non-fixed and wheelhouse doors may be located within the limits defined in [1.2.5] so long as they are designed in a manner that a rapid and efficient gas and vapour tightening of the wheelhouse can be ensured.*

**1.2.9** *For ships dedicated to the carriage of cargoes that have neither flammable nor toxic hazards, the Society may approve relaxations from the above requirements.*

**1.2.10** Accesses to forecastle spaces containing sources of ignition may be permitted through a single door facing the cargo area, provided the doors are located outside hazardous areas as defined in Ch 9, Sec 10.

**1.2.11** *Windows and sidescuttles facing the cargo area and on the sides of the superstructures and deckhouses within the limits specified in [1.2.5], except wheelhouse windows, shall be constructed to "A-60" class. Sidescuttles in the shell below the uppermost continuous deck and in the first tier of the superstructure or deckhouse shall be of fixed (non-opening) type.*

**1.2.12** *All air intakes, outlets and other openings into the accommodation spaces, service spaces and control stations shall be fitted with closing devices. When carrying toxic products, they shall be capable of being operated from inside the space. The requirement for fitting air intakes and openings with closing devices operated from inside the space for toxic products need not apply to spaces not normally manned, such as deck stores, forecastle stores, workshops. In addition, the requirement does not apply to cargo control rooms located within the cargo area.*

Note 1: The requirement for fitting air intakes and openings with closing devices operable from inside the space in ships intended to carry toxic products should apply to spaces which are used for the ships' radio and main navigating equipment, cabins, mess rooms, toilets, hospitals, galleys, etc., Engine room casings, cargo machinery spaces, electric motor rooms and steering gear compartments are generally considered as spaces not covered by this paragraph and therefore the requirement for closing devices need not be applied to these spaces.

When internal closing is required, this is to include both ventilation intakes and outlets.

The closing devices are to give a reasonable degree of gas-tightness. Ordinary steel fire-flaps without gaskets/seals are normally not considered satisfactory.

**1.2.13** *Control rooms and machinery spaces of turret systems may be located in the cargo area forward or aft of cargo tanks in ships with such installations. Access to such spaces containing sources of ignition may be permitted through doors facing the cargo area, provided the doors are located outside hazardous areas or access is through airlocks.*

#### **1.2.14 Access to the bow**

Ships having the service notation **liquefied gas carrier** are to be provided with the means to enable the crew to gain safe access to the bow even in severe weather conditions. Such means of access are to be approved by the Society.

Note 1: The Society accepts means of access complying with the Guidelines for safe access to tanker bows adopted by the Marine Safety Committee of IMO by Resolution MSC.62 (67).

Note 2: The text printed in italic type in this requirement refers to the SOLAS Convention.

### **1.3 Cargo machinery spaces and turret compartments**

**1.3.1** Cargo pump rooms and/or cargo compressor rooms of ships carrying flammable gases may not contain electrical equipment, except as provided for in Ch 9, Sec 10, or other ignition sources such as internal combustion engines or steam engines with operating temperature which could cause ignition or explosion of mixtures of such gases, if any, with air.

**1.3.2** *Cargo machinery spaces shall be situated above the weather deck and located within the cargo area. Cargo machinery spaces and turret compartments shall be treated as cargo pump-rooms for the purpose of fire protection according to SOLAS regulation II-2/9.2.4, and for the purpose of prevention of potential explosion according to SOLAS regulation II-2/4.5.10.*

**1.3.3** *When cargo machinery spaces are located at the after end of the aftermost hold space or at the forward end of the foremost hold space, the limits of the cargo area, as defined in Ch 9, Sec 1, [4.1.8], shall be extended to include the cargo machinery spaces for the full breadth and depth of the ship and the deck areas above those spaces.*

**1.3.4** *Where the limits of the cargo area are extended by [1.3.3], the bulkhead that separates the cargo machinery spaces from accommodation and service spaces, control stations and machinery spaces of category A shall be located so as to avoid the entry of gas to these spaces through a single failure of a deck or bulkhead.*

**1.3.5** *Cargo compressors and cargo pumps may be driven by electric motors in an adjacent non-hazardous space separated by a bulkhead or deck, if the seal around the bulkhead penetration ensures effective gastight segregation of the two spaces. Alternatively, such equipment may be driven by certified safe electric motors adjacent to them if the electrical installation complies with the requirements of Ch 9, Sec 10.*

**1.3.6** *Arrangements of cargo machinery spaces and turret compartments shall ensure safe unrestricted access for personnel wearing protective clothing and breathing apparatus, and in the event of injury to allow unconscious personnel to be removed. At least two widely separated escape routes and doors shall be provided in cargo machinery spaces, except that a single escape route may be accepted where the maximum travel distance to the door is 5 m or less.*

An emergency escape hatch with one vertical ladder may be accepted as an escape route if the vertical ladder does not interfere with the opening and closing of hatches and if hatches can be operated by one person, from either side, in both light and dark conditions. Moreover, hatch and vertical ladder are to ensure safe access for personnel wearing protective clothing and breathing apparatus.

**1.3.7** *All valves necessary for cargo handling shall be readily accessible to personnel wearing protective clothing. Suitable arrangements shall be made to deal with drainage of pump and compressor rooms.*

**1.3.8** *Turret compartments shall be designed to retain their structural integrity in case of explosion or uncontrolled high-pressure gas release (overpressure and/or brittle fracture), the characteristics of which shall be substantiated on the basis of a risk analysis with due consideration of the capabilities of the pressure relieving devices.*

### **1.4 Cargo control rooms**

**1.4.1** *Any cargo control room shall be above the weather deck and may be located in the cargo area. The cargo control room may be located within the accommodation spaces, service spaces or control stations, provided the following conditions are complied with:*

- *the cargo control room is a non-hazardous area*
- *if the entrance complies with [1.2.5], the control room may have access to the spaces described above, and*
- *if the entrance does not comply with [1.2.5], the cargo control room shall have no access to the spaces described above and the boundaries for such spaces shall be insulated to "A-60" class.*

**1.4.2** *If the cargo control room is designed to be a non-hazardous area, instrumentation shall, as far as possible, be by indirect reading systems and shall, in any case, be designed to prevent any escape of gas into the atmosphere of that space. Location of the gas detection system within the cargo control room will not cause the room to be classified as a hazardous area, if installed in accordance with Ch 9, Sec 13, [6.1.11].*

**1.4.3** *If the cargo control room for ships carrying flammable cargoes is classified as a hazardous area, sources of ignition shall be excluded and any electrical equipment shall be installed in accordance with Ch 9, Sec 10.*

### **1.5 Access to spaces in the cargo area**

**1.5.1** Designated passageways below and above cargo tanks are to have at least the cross-sections as specified in [1.5.6], item a).

**1.5.2** Where fitted, cofferdams are to have sufficient size for easy access to all their parts. The width of the cofferdams may not be less than 600 mm.

**1.5.3** Pipe tunnels are to have enough space to permit inspection of pipes. The pipes in pipe tunnels are to be installed as high as possible from the ship's bottom.

**1.5.4** Visual inspection of at least one side of the inner hull structure shall be possible without the removal of any fixed structure or fitting. If such a visual inspection, whether combined with those inspections required in [1.5.5], Ch 9, Sec 4, [2.4.3] or Ch 9, Sec 4, [7.4.8] or not, is only possible at the outer face of the inner hull, the inner hull shall not be a fuel-oil tank boundary wall.

**1.5.5** Inspection of one side of any insulation in hold spaces shall be possible. If the integrity of the insulation system can be verified by inspection of the outside of the hold space boundary when tanks are at service temperature, inspection of one side of the insulation in the hold space need not be required.

**1.5.6** Arrangements for hold spaces, void spaces, cargo tanks and other spaces classified as hazardous areas, shall be such as to allow entry and inspection of any such space by personnel wearing protective clothing and breathing apparatus and shall also allow for the evacuation of injured and/or unconscious personnel. Such arrangements shall comply with the following:

a) Access shall be provided as follows:

- 1) Access to all cargo tanks. Access shall be direct from the weather deck
- 2) Access through horizontal openings hatches or manholes. The dimensions shall be sufficient to allow a person wearing a breathing apparatus to ascend or descend any ladder without obstruction, and also to provide a clear opening to facilitate the hoisting of an injured person from the bottom of the space. The minimum clear opening shall be not less than 600 mm x 600 mm.

The term “minimum clear opening of not less than 600 x 600 mm” means that such openings may have corner radii up to a maximum of 100 mm (see Fig 2). In such a case where as a consequence of structural analysis of a given design the stress is to be reduced around the opening, it is considered appropriate to take measures to reduce the stress such as making the opening larger with increased radii, e.g. 600 x 800 with 300 mm radii, in which a clear opening of 600 mm x 600 mm with corner radii up to 100 mm maximum fits.

- 3) Access through vertical openings or manholes providing passage through the length and breadth of the space. The minimum clear opening shall be not less than 600 mm x 800 mm at a height of not more than 600 mm from the bottom plating unless gratings or other footholds are provided.

The term “minimum clear opening of not less than 600 x 800 mm” also includes an opening of the size specified in Fig 3.

Subject to verification of easy evacuation of injured person on a stretcher the vertical opening 850 mm x 620 mm with wider upper half than 600 mm, while the lower half may be less than 600 mm with the overall height not less than 850 mm is considered an acceptable alternative to the traditional opening of 600 mm x 800 mm with corner radii of 300 mm.

If a vertical opening is at a height of more than 600 mm steps and handgrips are to be provided. In such arrangements it is to be demonstrated that an injured person can be easily evacuated.

- 4) Circular access openings to type C tanks shall have a diameter of not less than 600 mm.

**Figure 2 : Minimum horizontal hatch size**

Figure 3 : Minimum size of manholes

- b) The dimensions referred to in [1.5.6], item a) 2) and [1.5.6] may be decreased, if the requirements of [1.5.6] can be met to the satisfaction of the Society.
- c) Where cargo is carried in a containment system requiring a secondary barrier, the requirements of [1.5.6], item a)2) and [1.5.6], item a)3) do not apply to spaces separated from a hold space by a single gastight steel boundary. Such spaces shall be provided only with direct or indirect access from the weather deck, not including any enclosed non-hazardous area.
- d) Access required for inspection shall be a designated access through structures below and above cargo tanks, which shall have at least the cross- sections as required by [1.5.6], item a)3).
- e) For the purpose of [1.5.4] or [1.5.5], the following shall apply:
  - 1) Where it is required to pass between the surface to be inspected, flat or curved, and structures such as deck beams, stiffeners, frames, girders, etc., the distance between that surface and the free edge of the structural elements shall be at least 380 mm. The distance between the surface to be inspected and the surface to which the above structural elements are fitted, e.g. deck, bulkhead or shell, shall be at least 450 mm for a curved tank surface (e.g. for a type C tank), or 600 mm for a flat tank surface (e.g. for a type A tank) (see Fig 4)

Figure 4 :

- 2) Where it is not required to pass between the surface to be inspected and any part of the structure, for visibility reasons the distance between the free edge of that structural element and the surface to be inspected shall be at least 50 mm or half the breadth of the structure's face plate, whichever is the larger (see Fig 5)

Figure 5 :

- 3) If for inspection of a curved surface where it is required to pass between that surface and another surface, flat or curved, to which no structural elements are fitted, the distance between both surfaces shall be at least 380 mm (see Fig 6). Where it is not required to pass between that curved surface and another surface, a smaller distance than 380 mm may be accepted taking into account the shape of the curved surface

Figure 6 :

- 4) If for inspection of an approximately flat surface where it is required to pass between two approximately flat and approximately parallel surfaces, to which no structural elements are fitted, the distance between those surfaces shall be at least 600 mm. Where fixed access ladders are fitted, a clearance of at least 450 mm shall be provided for access (see Fig 7)

Figure 7 :

- 5) The minimum distances between a cargo tank sump and adjacent double bottom structure in way of a suction well shall not be less than those shown in Fig 8 ( Fig 8 shows that the distance between the plane surfaces of the sump and the well is a minimum of 150 mm and that the clearance between the edge between the inner bottom plate, and the vertical side of the well and the knuckle point between the spherical or circular surface and sump of the tank is at least 380 mm). If there is no suction well, the distance between the cargo tank sump and the inner bottom shall not be less than 50 mm

Figure 8 :

6) The distance between a cargo tank dome and deck structures shall not be less than 150 mm (see Fig 9)

**Figure 9 :**

- 7) Fixed or portable staging shall be installed as necessary for inspection of cargo tanks, cargo tank supports and restraints (e.g. anti-pitching, anti-rolling and anti-flotation chocks), cargo tank insulation etc. This staging shall not impair the clearances specified in [1.5.6], item e)1) to [1.5.6], item e) 4), and
- 8) If fixed or portable ventilation ducting shall be fitted in compliance with Ch 9, Sec 12, [1.2.2], such ducting shall not impair the distances required under [1.5.6], item e)1) to [1.5.6], item e) 4).

**1.5.7** Access from the open weather deck to non-hazardous areas shall be located outside the hazardous areas as defined in Ch 9, Sec 10, unless the access is by means of an airlock in accordance with [1.6].

**1.5.8** Turret compartments shall be arranged with two independent means of access/egress.

**1.5.9** Access from a hazardous area below the weather deck to a non-hazardous area is not permitted.

## **1.6 Airlocks**

**1.6.1** Access between hazardous area on the open weather deck and non-hazardous spaces shall be by means of an airlock. This shall consist of two self-closing, substantially gastight, steel doors without any holding back arrangements, capable of maintaining the overpressure, at least 1,5 m but no more than 2,5 m apart. The airlock space shall be artificially ventilated from a non-hazardous area and maintained at an overpressure to the hazardous area on the weather deck.

**1.6.2** Air-locks are to be such as to provide easy passage and are to cover a deck area of not less than 1,5 m<sup>2</sup>. Air-locks are to be kept unobstructed and may not be employed for other uses, such as storage.

**1.6.3** A differential pressure monitoring device shall be provided for monitoring the satisfactory functioning of pressurization of non-hazardous spaces protected by airlocks. Airflow sensors are considered an acceptable alternative in spaces having a ventilation rate not less than 30 air changes per hour.

In spaces where the ventilation rate is less than 30 air changes per hour and where airflow sensors are fitted as an alternative, in addition to the alarms required in [1.6.5], arrangements are to be made to de-energise electrical equipment which is not of the certified safe type if more than one airlock door is moved from the closed position.

**1.6.4** Where spaces are protected by pressurization, the ventilation shall be designed and installed in accordance with recognized standards.

*Note 1: Such as the recommended publication by the International Electrotechnical Commission, in particular IEC 60092-502:1999.*

*However, where the prescriptive requirements in the present Rules and IEC 60092-502 are not aligned, the prescriptive requirements in the present Rules take precedence and are to be applied.*

**1.6.5** An audible and visible alarm system to give a warning on both sides of the airlock shall be provided. The visible alarm shall indicate if one door is open. The audible alarm shall sound if doors on both sides of the airlock are moved from the closed positions.

The alarm systems are to be of the intrinsically safe type. However, signalling lamps may be of a safe type authorised for the dangerous spaces in which they are installed.

**1.6.6** In ships carrying flammable products, electrical equipment that is located in spaces protected by airlocks and not of the certified safe type, shall be de-energized in case of loss of overpressure in the space.

**1.6.7** Lack of overpressure or air flow is not to imply the stopping of motors driving compressors used for the boil-off system mentioned in Ch 9, Sec 16; therefore, such engines are to be of the certified safe type and the relevant control appliance is to be fitted in a non-gas-dangerous space.

The requirement above is not applicable if, during manoeuvring and operations in port, only fuel oil is used or when the automatic transfer from gas to fuel oil, as per Ch 9, Sec 16, [6.2], operates also when such electric motors are stopped without causing the shut-off of the boiler.

After any loss of the overpressure, the spaces protected by airlocks are to be ventilated for the time necessary to give at least 10 air changes prior to energising the non-safe type electrical installations.

**1.6.8** *Electrical equipment for manoeuvring, anchoring and mooring, as well as emergency fire pumps that are located in spaces protected by airlocks, shall be of a certified safe type.*

**1.6.9** *The airlock space shall be monitored for cargo vapours (see Ch 9, Sec 13, [6.1.2]).*

**1.6.10** *Subject to the requirements of the International Convention on Load Lines in force, the door sill shall not be less than 300 mm in height.*

## **1.7 Bilge, ballast and oil fuel arrangements**

**1.7.1** Dry spaces within the cargo area are to be fitted with a bilge or drain arrangement not connected to the machinery space. Spaces not accessible at all times are to be fitted with sounding arrangements.

Spaces without a permanent ventilation system are to be fitted with a pressure/vacuum relief system or with air pipes.

**1.7.2** Bilge arrangements for holds containing cargo tanks and for interbarrier spaces are to be operable from the weather deck.

**1.7.3** The diameter of the bilge main may be smaller than the diameter specified in Pt C, Ch 1, Sec 10, [6.8.1], provided that this diameter is not less than twice the value given in Pt C, Ch 1, Sec 10, [6.8.3]. This reduction of diameter, however, is not applicable to the determination of the capacity of fire pumps according to Pt C, Ch 1, Sec 10, [6.7.4].

**1.7.4** With reference to the means to ascertain leakages in holds and/or in interbarrier spaces, the following requirements apply:

- a) the above-mentioned means is to be suitable to ascertain the presence of water:
  - in holds containing type C independent tanks
  - in holds and interbarrier spaces outside the secondary barrier
- b) the above-mentioned means is to be suitable to ascertain the presence of liquid cargo in the spaces adjacent to cargo tanks which are not type C independent tanks.

Where the aforesaid spaces may be affected by water leakages from the adjacent ship structures, the means is also to be suitable to ascertain the presence of water.

Where the above-mentioned means is constituted by electrical level switches, the relevant circuits are to be of the intrinsically safe type and signals are to be transduced to the wheelhouse and to the cargo control station, if fitted.

**1.7.5** *Where cargo is carried in a cargo containment system not requiring a secondary barrier, suitable drainage arrangements for the hold spaces that are not connected with the machinery space shall be provided. Means of detecting any leakage shall be provided.*

**1.7.6** *Where there is a secondary barrier, suitable drainage arrangements for dealing with any leakage into the hold or insulation spaces through the adjacent ship structure shall be provided. The suction shall not lead to pumps inside the machinery space. Means of detecting such leakage shall be provided.*

**1.7.7** *The hold or interbarrier spaces of type A independent tank ships shall be provided with a drainage system suitable for handling liquid cargo in the event of cargo tank leakage or rupture. Such arrangements shall provide for the return of any cargo leakage to the liquid cargo piping.*

**1.7.8** *Arrangements referred to in [1.7.7] shall be provided with a removable spool piece.*

**1.7.9** *Ballast spaces, including wet duct keels used as ballast piping, oil fuel tanks and non-hazardous spaces, may be connected to pumps in the machinery spaces. Dry duct keels with ballast piping passing through may be connected to pumps in the machinery spaces, provided the connections are led directly to the pumps, and the discharge from the pumps is led directly overboard with no valves or manifolds in either line that could connect the line from the duct keel to lines serving non-hazardous spaces. Pump vents shall not be open to machinery spaces.*

Note 1: For ballast tanks separated by a single gastight boundary from cargo tanks for which no secondary barrier is required - e.g. ballast tanks adjacent to integral tanks -, discharge arrangements are to be outside machinery spaces and accommodation spaces but filling arrangements may be in the machinery spaces provided that such arrangements ensure filling from tank deck level and a non-return valve and removable spool piece are fitted.

Note 2: The requirements of "Pump vents should not be open to machinery spaces" and "Pump vents shall not be open to machinery spaces" apply only to pumps in the machinery spaces serving dry duct keels through which ballast piping passes.

## **1.8 Bow and stern loading and unloading arrangements**

**1.8.1** *Subject to the requirements of this section and Ch 9, Sec 5, cargo piping may be arranged to permit bow or stern loading and unloading.*

**1.8.2** Bow or stern loading and unloading lines that are led past accommodation spaces, service spaces or control stations shall not be used for the transfer of products requiring a type 1G ship. Bow or stern loading and unloading lines shall not be used for the transfer of toxic products as specified in Ch 9, Sec 1, [4.1.51], where the design pressure is above 2,5 MPa.

**1.8.3** Portable arrangements shall not be permitted.

**1.8.4**

- a) Entrances, air inlets, air outlets and openings to accommodation spaces, service spaces, machinery spaces and controls stations, shall not face the cargo shore connection location of bow or stern loading and unloading arrangements. They shall be located on the outboard side of the superstructure or deckhouse at a distance of at least 4% of the length of the ship, but not less than 3 m from the end of the superstructure or deckhouse facing the cargo shore connection location of the bow or stern loading and unloading arrangements.
- b) Windows and sides cuttles facing the shore connection location and on the sides of the superstructure or deckhouse within the distance mentioned above shall be of the fixed (non-opening) type.
- c) In addition, during the use of the bow or stern loading and unloading arrangements, all doors, ports and other openings on the corresponding superstructure or deckhouse side shall be kept closed.
- d) Where, in the case of small ships, compliance with [1.2.5] and [1.8.4] is not possible, the Society may approve relaxations from the above requirements.

**1.8.5** Deck openings and air inlets and outlets to spaces within distances of 10 m from the cargo shore connection location shall be kept closed during the use of bow or stern loading or unloading arrangements.

**1.8.6** Fire fighting arrangements for the bow or stern loading and unloading areas shall be in accordance with Ch 9, Sec 11, [1.3.2], item d) and Ch 9, Sec 11, [1.4.7].

**1.8.7** Devices to stop cargo pumps and cargo compressors and to close cargo valves are to be fitted in a position from which it is possible to keep under control the loading/unloading manifolds.

**1.8.8** Means of communication between the cargo control station and the shore connection location shall be provided and, where applicable, certified for use in hazardous areas.

**1.9 Emergency towing arrangements**

**1.9.1** The requirements of Pt B, Ch 12, Sec 4, [3] are to be complied with on ships of not less than 20000 t deadweight.

# Section 4 Cargo Containment

## Symbols

$R_{eH}$	: Minimum yield stress, in N/mm <sup>2</sup> , of the material, defined in Pt B, Ch 4, Sec 1
$R_m$	: Minimum ultimate tensile strength, in N/mm <sup>2</sup> , of the material
$R_y$	: Minimum yield stress, in N/mm <sup>2</sup> , of the material, to be taken equal to 235/k N/mm <sup>2</sup> , unless otherwise specified
$k$	: Material factor for steel, defined in Pt B, Ch 4, Sec 1, [4.4]
$s$	: Spacing, in mm, of ordinary stiffeners
$d_{shr}$	: Effective shear depth, in mm, as defined in Pt B, Ch 4, Sec 6, [1.4.4]
$l_{bdg}$	: Effective bending span, in m, of ordinary stiffeners defined in Pt B, Ch 4, Sec 6
$l_{shr}$	: Effective shear span, in m, of ordinary stiffeners defined in Pt B, Ch 4, Sec 6
$\alpha_p$	: Correction factor for the panel aspect ratio, to be taken as follows: $\alpha_p = 1,2 - \frac{b}{2,1 a}$ to be taken not greater than 1,0
$b$	: Breadth of plate panel, in mm, as defined in Pt B, Ch 4, Sec 6, [2.1.1]
$T_{SC}$	: Scantling draught, in m, defined in Pt B, Ch 1, Sec 3, [2.1.6].

## 1 General

### 1.1 Scope

**1.1.1** The purpose of this Section is to ensure the safe containment of cargo under all design and operating conditions having regard to the nature of the cargo carried. This will include measures to:

- provide strength to withstand defined loads
- maintain the cargo in a liquid state
- design for or protect the hull structure from low temperature exposure
- prevent the ingress of water or air into the cargo containment system.

### 1.2 Definitions

**1.2.1** A cold spot is a part of the hull or thermal insulation surface where a localized temperature decrease occurs with respect to the allowable minimum temperature of the hull or of its adjacent hull structure, or to design capabilities of cargo pressure/temperature control systems required in Ch 9, Sec 7.

**1.2.2** Design vapour pressure  $P_0$  is the maximum gauge pressure, at the top of the tank, to be used in the design of the tank.

**1.2.3** Design temperature for selection of materials is the minimum temperature at which cargo may be loaded or transported in the cargo tanks.

**1.2.4** Independent tanks are self-supporting tanks. They do not form part of the ship's hull and are not essential to the hull strength. There are three categories of independent tank, which are referred to in [8], [9] and [10].

**1.2.5** Membrane tanks are non-self-supporting tanks that consist of a thin liquid and gastight layer (membrane) supported through insulation by the adjacent hull structure. Membrane tanks are covered in [11].

For membrane tanks, the supports are provided by all elements holding the containment system, such as any local supporting devices connecting to the ship inner hull (for example, small pillars or similar elements in insulation boxes).

**1.2.6** Integral tanks are tanks that form a structural part of the hull and are influenced in the same manner by the loads that stress the adjacent hull structure. Integral tanks are covered in [12].

**1.2.7** Semi-membrane tanks are non-self-supporting tanks in the loaded condition and consist of a layer, parts of which are supported through insulation by the adjacent hull structure. Semi-membrane tanks are covered in [13].

**1.2.8** In addition to the definitions given in Ch 9, Sec 1, the definitions given in this Section shall apply throughout Part D, Chapter 9.

### **1.3 Application**

**1.3.1** Unless otherwise specified in [8] to [13], the requirements of [2] to [6] and Ch 9, Sec 20 shall apply to all types of tanks including those covered in [14].

## **2 Cargo containment**

### **2.1 Functional requirement**

**2.1.1** The design life of the cargo containment system shall not be less than the design life of the ship.

**2.1.2** Cargo containment systems shall be designed for North Atlantic environmental conditions and relevant long-term sea state scatter diagrams for unrestricted navigation. Lesser environmental conditions, consistent with the expected usage, may be accepted by the Society for cargo containment systems used exclusively for restricted navigation. Greater environmental conditions may be required for cargo containment systems operated in conditions more severe than the North Atlantic environment.

**2.1.3** Cargo containment systems shall be designed with suitable safety margins:

- to withstand, in the intact condition, the environmental conditions anticipated for the cargo containment system's design life and the loading conditions appropriate for them, which include full homogeneous and partial load conditions, partial filling within defined limits and ballast voyage loads; and
- being appropriate for uncertainties in loads, structural modeling, fatigue, corrosion, thermal effects, material variability, ageing and construction tolerances.

**2.1.4** The cargo containment system structural strength shall be assessed against failure modes, including but not limited to plastic deformation, buckling and fatigue. The specific design conditions which shall be considered for the design of each cargo containment system are given in [8] to [13]. There are three main categories of design conditions:

- a) Ultimate design conditions – the cargo containment system structure and its structural components shall withstand loads liable to occur during its construction, testing and anticipated use in service, without loss of structural integrity. The design shall take into account proper combinations of the following loads:
  - internal pressure
  - external pressure
  - dynamic loads due to the motion of the ship
  - thermal loads
  - sloshing loads
  - loads corresponding to ship deflections
  - tank and cargo weight with the corresponding reaction in way of supports
  - insulation weight
  - loads in way of towers and other attachments; and
  - test loads.
- b) Fatigue design conditions – the cargo containment system structure and its structural components shall not fail under accumulated cyclic loading.
- c) Accident design condition:

The cargo containment system shall meet the following criteria:

  - Collision: the cargo containment system shall be protectively located in accordance with Ch 9, Sec 2, [4.1.1] and withstand the collision loads specified in [3.5.2] without deformation of the supports, or the tank structure in way of the supports, likely to endanger the tank structure.
  - Fire: the cargo containment systems shall sustain, without rupture, the rise in internal pressure specified in Ch 9, Sec 8, [4.1] under the fire scenarios envisaged therein.
  - Flooded compartment causing buoyancy on tank: the anti-flotation arrangements shall sustain the upward force, specified in [3.5.3], and there shall be no endangering plastic deformation to the hull.
  - Unfavourable static heel scenario: the cargo containment systems shall sustain, without rupture, a static angle within the range 0° to 30°.

**2.1.5** Measures shall be applied to ensure that scantlings required meet the structural strength provisions and be maintained throughout the design life. Measures may include, but are not limited to, material selection, coatings, corrosion additions, cathodic protection and inerting. Corrosion allowance need not be required in addition to the thickness resulting from the structural analysis. However, where there is no environmental control, such as inerting around the cargo tank, or where the cargo is of a corrosive nature, the Society may require a suitable corrosion allowance.

**2.1.6** An inspection/survey plan for the cargo containment system shall be developed and approved by the Society. The inspection/survey plan shall identify areas that need inspection during surveys throughout the cargo containment system's life and, in particular, all necessary in-service survey and maintenance that was assumed when selecting cargo containment system

design parameters. Cargo containment systems shall be designed, constructed and equipped to provide adequate means of access to areas that need inspection as specified in the inspection/survey plan. Cargo containment systems, including all associated internal equipment, shall be designed and built to ensure safety during operations, inspection and maintenance (see Ch 9, Sec 3, [1.5]).

**2.2 Cargo containment safety principles**

**2.2.1** The containment systems shall be provided with a full secondary liquid-tight barrier capable of safely containing all potential leakages through the primary barrier and, in conjunction with the thermal insulation system, of preventing lowering of the temperature of the ship structure to an unsafe level.

**2.2.2** However, the size and configuration or arrangement of the secondary barrier may be reduced where an equivalent level of safety is demonstrated in accordance with the requirements of [2.2.3] to [2.2.5], as applicable.

**2.2.3** Cargo containment systems for which the probability for structural failures to develop into a critical state has been determined to be extremely low, but where the possibility of leakages through the primary barrier cannot be excluded, shall be equipped with a partial secondary barrier and small leak protection system capable of safely handling and disposing of the leakages. The arrangements shall comply with the following requirements:

- failure developments that can be reliably detected before reaching a critical state (e.g. by gas detection or inspection) shall have a sufficiently long development time for remedial actions to be taken; and
- failure developments that cannot be safely detected before reaching a critical state shall have a predicted development time that is much longer than the expected lifetime of the tank.

**2.2.4** No secondary barrier is required for cargo containment systems, e.g. type C independent tanks, where the probability for structural failures and leakages through the primary barrier is extremely low and can be neglected.

**2.2.5** No secondary barrier is required where the cargo temperature at atmospheric pressure is at or above – 10°C.

**2.3 Secondary barriers in relation to tank types**

**2.3.1** Secondary barriers in relation to the tank types defined in [8] to [13] shall be provided in accordance with Tab 1.

**2.4 Design of secondary barriers**

**2.4.1 Secondary barrier extent**

The extent of the secondary barrier is to be not less than that necessary to protect the hull structures assuming that the cargo tank is breached at a static angle of heel of 30°, with an equalisation of the liquid cargo in the tank (see Fig 1).

Note 1: The “liquid level” given in Fig 1 is considered at the maximum allowable filling level in the cargo tank

**2.4.2** Where the cargo temperature at atmospheric pressure is not below – 55°C, the hull structure may act as a secondary barrier based on the following:

- the hull material shall be suitable for the cargo temperature at atmospheric pressure as required by [5.2.4]; and
- the design shall be such that this temperature will not result in unacceptable hull stresses.

**Table 1 : Secondary barriers in relation to tank types**

Cargo temperature at atmospheric pressure		–10°C and above	Below –10°C down to –55°C	Below –55°C
Basic tank type		No secondary barrier required	Hull may act as secondary barrier	Separate secondary barrier where required
Integral			Tank type not normally allowed (1)	
Membrane			Complete secondary barrier	
Semi-membrane			Complete secondary barrier (2)	
Independent	type A		Complete secondary barrier	
	type B		Partial secondary barrier	
	type C	No secondary barrier required		
<p>(1) A complete secondary barrier shall normally be required if cargoes with a temperature at atmospheric pressure below -10°C are permitted in accordance with [12.1].</p> <p>(2) In the case of semi-membrane tanks that comply in all respects with the requirements applicable to type B independent tanks, except for the manner of support, the Society may, after special consideration, accept a partial secondary barrier.</p>				

Figure 1 : Secondary barrier extension

**2.4.3** The design of the secondary barrier shall be such that:

- a) It is capable of containing any envisaged leakage of liquid cargo for a period of 15 days, unless different criteria apply for particular voyages, taking into account the load spectrum referred to in [4.6.6]
- b) Physical, mechanical, or operational events within the cargo tank that could cause failure of the primary barrier shall not impair the due function of the secondary barrier, or vice versa
- c) Failure of a support or an attachment to the hull structure will not lead to loss of liquid tightness of both the primary and secondary barriers
- d) It is capable of being periodically checked for its effectiveness by means acceptable to the Society. This may be by means of a visual inspection or a pressure/vacuum test or other suitable means carried out according to a documented procedure agreed with the Society. Requirements for tightness tests of secondary barriers are detailed in [6.4.4].
- e) The methods required in item d) shall be approved by the Society and shall include, where applicable to the test procedure:
  - details on the size of defect acceptable and the location within the secondary barrier, before its liquid-tight effectiveness is compromised
  - accuracy and range of values of the proposed method for detecting defects in item a)
  - scaling factors to be used in determining the acceptance criteria, if full scale model testing is not undertaken; and
  - effects of thermal and mechanical cyclic loading on the effectiveness of the proposed test; and
- f) The secondary barrier shall fulfil its functional requirements at a static angle of heel of 30°.

## 2.5 Partial secondary barriers and primary barrier small leak protection system

**2.5.1** Partial secondary barriers as permitted in [2.2.3] shall be used with a small leak protection system and meet all the requirements in [2.4.3]. The small leak protection system shall include means to detect a leak in the primary barrier, provision such as a spray shield to deflect any liquid cargo down into the partial secondary barrier, and means to dispose of the liquid, which may be by natural evaporation.

**2.5.2** The capacity of the partial secondary barrier shall be determined, based on the cargo leakage corresponding to the extent of failure resulting from the load spectrum referred to in [4.6.6], after the initial detection of a primary leak. Due account may be taken of liquid evaporation, rate of leakage, pumping capacity and other relevant factors.

**2.5.3** The required liquid leakage detection may be by means of liquid sensors, or by an effective use of pressure, temperature or gas detection systems, or any combination thereof.

## 2.6 Supporting arrangements

**2.6.1** The supporting arrangements are to comply with the requirements defined in [7.1].

## **2.7 Associated structure and equipment**

**2.7.1** Cargo containment systems shall be designed for the loads imposed by associated structure and equipment. This includes pump towers, cargo domes, cargo pumps and piping, stripping pumps and piping, nitrogen piping, access hatches, ladders, piping penetrations, liquid level gauges, independent level alarm gauges, spray nozzles, and instrumentation systems (such as pressure, temperature and strain gauges).

## **2.8 Thermal insulation**

**2.8.1** Thermal insulation shall be provided, as required, to protect the hull from temperatures below those allowable (see [5.2]) and limit the heat flux into the tank to the levels that can be maintained by the pressure and temperature control system applied in Ch 9, Sec 7.

**2.8.2** In determining the insulation performance, due regard shall be given to the amount of the acceptable boil-off in association with the reliquefaction plant on board, main propulsion machinery or other temperature control system.

## **2.9 Use of cargo heater to raise the cargo temperature**

**2.9.1** Where a cargo heater, intended to raise the cargo temperature to a value permissible for cargo tanks, is envisaged, the following requirements are to be complied with:

- The piping and valves involved are to be suitable for the design loading temperature
- A thermometer is to be fitted at the heater outlet. It is to be set at the design temperature of the tanks and, when activated, it is to give a visual and audible alarm. This alarm is to be installed in the cargo control station or, when such a station is not foreseen, in the wheelhouse.
- The following note is to be written on the Certificate of Fitness: "The minimum permissible temperature in the cargo preheater is..... °C".

## **3 Design loads**

### **3.1 General**

**3.1.1** This section defines the design loads to be considered with regard to the requirements in [4]. This includes:

- load categories (permanent, functional, environmental and accidental) and the description of the loads;
- the extent to which these loads shall be considered depending on the type of tank, and is more fully detailed in the following paragraphs; and
- tanks, together with their supporting structure and other fixtures, that shall be designed taking into account relevant combinations of the loads described below.

### **3.2 Permanent loads**

#### **3.2.1 Gravity loads**

The weight of tank, thermal insulation, loads caused by towers and other attachments shall be considered.

#### **3.2.2 Permanent external loads**

Gravity loads of structures and equipment acting externally on the tank shall be considered.

### **3.3 Functional loads**

**3.3.1** Loads arising from the operational use of the tank system shall be classified as functional loads. All functional loads that are essential for ensuring the integrity of the tank system, during all design conditions, shall be considered. As a minimum, the effects from the following criteria, as applicable, shall be considered when establishing functional loads:

- internal pressure
- external pressure
- thermally induced loads
- vibration
- interaction loads
- loads associated with construction and installation
- test loads
- static heel loads; and
- weight of cargo.

### **3.3.2 Internal pressure**

- a) In all cases, including item b),  $P_o$  shall not be less than MARVS.
- b) For cargo tanks, where there is no temperature control and where the pressure of the cargo is dictated only by the ambient temperature,  $P_o$  shall not be less than the gauge vapour pressure of the cargo at a temperature of 45°C except as follows:
- lower values of ambient temperature may be accepted by the Society for ships operating in restricted areas. Conversely, higher values of ambient temperature may be required; and
  - for ships on voyages of restricted duration,  $P_o$  may be calculated based on the actual pressure rise during the voyage, and account may be taken of any thermal insulation of the tank.
- c) Subject to special consideration by the Society and to the limitations given in [8] to [13], for the various tank types, a vapour pressure  $P_h$  higher than  $P_o$  may be accepted for site specific conditions (harbour or other locations), where dynamic loads are reduced. Any relief valve setting resulting from this paragraph shall be recorded in the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk.
- d) Where the vapour pressure in harbour conditions is greater than  $P_o$ , defined in [1.2.2], this value is to be specified in the operating instructions for the ship's Master.
- e) The internal pressure  $P_{eq}$  results from the vapour pressure  $P_o$  or  $P_h$  plus the maximum associated dynamic liquid pressure  $P_{gd}$ , but not including the effects of liquid sloshing loads. Guidance formulae for associated dynamic liquid pressure  $P_{gd}$  are given in Ch 9, App 1, [1.1].
- f) The internal pressure to be considered for integral tanks and membrane tanks is defined in Ch 9, App 1, [2].

### **3.3.3 External pressure**

External design pressure loads shall be based on the difference between the minimum internal pressure and the maximum external pressure to which any portion of the tank may be simultaneously subjected.

### **3.3.4 Thermally induced loads**

Transient thermally induced loads during cooling down periods shall be considered for tanks intended for cargo temperatures below -55°C.

Stationary thermally induced loads shall be considered for cargo containment systems where the design supporting arrangements or attachments and operating temperature may give rise to significant thermal stresses (see Ch 9, Sec 7, [2]).

For normal service, the upper ambient design temperature is to taken as:

- sea: 32°C
- air: 45°C.

For service in particularly hot or cold zones, these ambient design temperatures are to be increased or decreased, to the satisfaction of the Society. The overall capacity of the system is to be such that it can control the pressure within the design conditions without venting to atmosphere.

### **3.3.5 Vibration**

The potentially damaging effects of vibration on the cargo containment system shall be considered.

### **3.3.6 Interaction loads**

The static component of loads resulting from interaction between cargo containment system and the hull structure, as well as loads from associated structure and equipment, shall be considered.

### **3.3.7 Loads associated with construction and installation**

Loads or conditions associated with construction and installation, e.g. lifting, shall be considered.

### **3.3.8 Test loads**

Account shall be taken of the loads corresponding to the testing of the cargo containment system referred to in [8] to [13].

### **3.3.9 Static heel loads**

Loads corresponding to the most unfavourable static heel angle within the range 0° to 30° shall be considered.

Guidance for calculation of static pressure for 30° heel angle is given in Ch 9, App 1, [3].

### **3.3.10 Other loads**

Any other loads not specifically addressed, which could have an effect on the cargo containment system, shall be taken into account.

## **3.4 Environmental loads**

### **3.4.1 Definition**

Environmental loads are defined as those loads on the cargo containment system that are caused by the surrounding environment and that are not otherwise classified as a permanent, functional or accidental load.

### **3.4.2 Loads due to ship motion**

- a) *The determination of dynamic loads shall take into account the long-term distribution of ship motion in irregular seas, which the ship will experience during its operating life. Account may be taken of the reduction in dynamic loads due to necessary speed reduction and variation of heading.*
- b) *The ship's motion shall include surge, sway, heave, roll, pitch and yaw. The accelerations acting on tanks shall be estimated at their centre of gravity and include the following components:*
  - *vertical acceleration: motion accelerations of heave, pitch and, possibly, roll (normal to the ship base);*
  - *transverse acceleration: motion accelerations of sway, yaw and roll and gravity component of roll; and*
  - *longitudinal acceleration: motion accelerations of surge and pitch and gravity component of pitch.*
- c) *Methods to predict accelerations due to ship motion shall be proposed and approved by the Society.*
- d) *Guidance formulae for acceleration components are given in Ch 9, App 1, [1.2].*
- e) *Ships for restricted service may be given special consideration.*

### **3.4.3 Dynamic interaction loads**

*Account shall be taken of the dynamic component of loads resulting from interaction between cargo containment systems and the hull structure, including loads from associated structures and equipment.*

### **3.4.4 Sloshing loads**

*The sloshing loads on a cargo containment system and internal components shall be evaluated based on allowable filling levels. When significant sloshing-induced loads are expected to be present, special tests and calculations shall be required covering the full range of intended filling levels.*

The sloshing loads may be disregarded for type C tanks where wash bulkheads are positioned so as to limit a risk of resonance of the cargo movements (see Pt B, Ch 11, Sec 4, [1.5]).

Guidance for calculation of sloshing pressure for integral tanks and membrane tanks is given in Ch 9, App 1, [2] and, as applicable, in [3.4.5].

### **3.4.5 Methodology to determine dynamic design sloshing loads**

Methodology to determine dynamic design sloshing loads on the boundaries of a membrane cargo tank at its partial filling due to the sloshing effects for all its operational filling levels is to comply with the following minimum functional requirements:

- a) Methodology:

The methodology is to contain the following input data on source specifications describing the operation during the whole ship's design life, including:

- 1) The ship's main particulars including the ship lines.
- 2) The geometry of cargo tanks at the primary barrier level, the arrangement of cargo containments over the full breadth and length.
- 3) The following density and kinematic viscosity values of LNG, at  $-163^{\circ}\text{C}$  to be considered:
  - LNG density is equal to  $470 \text{ kg/m}^3$
  - LNG kinematic viscosity is equal to  $0.2857 \text{ m}^2/\text{s}$
- 4) The operational filling levels:
  - standard filling levels correspond to:
    - 0 to 10% H and
    - 70% H to 98% V
  - partial filling levels correspond to 10% to 70% H

where:

H : Maximum height of the tank, in m, taken at the primary barrier level.

If the cargo containment design does not comply with or is not checked against the partial filling levels, the partial filling levels are not allowed; this restriction of the ship operation is to be traced on ship certificate.

- 5) The ship speed and distribution law of heading.

The characteristics of ship's loading conditions (the centre of gravity and centre of buoyancy position, metacentric height as per the trim and stability booklet) and the corresponding roll radius of gyration for each loading condition.

- 6) Statistics on irregular sea parameters (the provisions of IACS Recommendation No. 34 are to be met) the environmental conditions:

The environmental data for sloshing analysis is to refer to North Atlantic route with significant wave height envelope fitted to 40-year return period. North Atlantic trade route conditions are defined by Standard Wave Data (IACS Rec. No. 34).

- 7) For ice class notations, the design speed for ice condition operations is to be provided.

b) In general, the loads are to be determined for all the cargo tanks where the partial filling is provided. In case of the available tanks identical in terms of geometrical features, it is allowed to determine the loads for those tanks where the maximum sloshing loads are expected. In addition, the methodology is to contain substantiation for the tanks selected for calculation regarding:

- geometrical features and shapes of the tanks
- tank position.

c) Mandatory seakeeping analysis.

A seakeeping analysis taking into account the coupling between the ship motions and the internal liquid motions within the cargo tanks is to be carried out. The calculated ship motions (6 degrees of freedom) are directly used for sloshing model tests. Methodology is to contain the ship's rolling calculations. As a result of the calculation, the characteristics of oscillating movements are to be obtained for all types of rolling at irregular seas applicable to all selected operating conditions (amplitude versus frequency response characteristics or implementation on a time scale). During the rolling calculation, the methods may be applied based on the three-dimensional potential theory and other pitching and rolling calculation methods agreed with the Society.

The input data for this seakeeping analysis are as follows:

- ship lines (see a) above)
- ship's loading conditions and the corresponding roll radius of gyration (see a) above)
- LNG cargo tanks arrangement and geometry (see a) above)
- operational filling levels (see a) above)
- environmental conditions including ice condition operations (See a) above).

The output of the seakeeping analysis are the ship's motions time series (6 degrees of freedom) for the sloshing model tests.

d) Mandatory sloshing model test:

Methodology is to contain the results of model sloshing tests in design cargo tanks. The design sloshing loads acting on the boundaries of the membrane cargo tanks are to be determined by the mandatory sloshing model tests. These design sloshing loads are to be determined for all the cargo tanks and for all operational filling levels.

The sloshing model test program is to comply with the following minimum requirements:

- all assumptions used during model tests are to be specified
- the description of the used test bench and equipment used for measuring and processing the measurement results are to be provided for approval to the Society
- the justification for the value of scaling load factor is to be provided
- the irregular time histories are to be considered for the ship's motions, the ship's oscillating movement at irregular seas is to be modelled (ship's motion characteristics are to be scaled in the model test based on the Froude similarity criterion)
- the duration of each model test and scope of parameters characterizing each test is to be agreed by the Society.

The sloshing model test report is to include description of statistical analysis of model test results. The long-term approach is to be considered for the evaluation of the design sloshing loads. The description of statistical methods for the derivation of short-term as well as long-term sloshing loads distribution that is required to determine the maximum design loads on the boundaries of the cargo tanks is to be provided.

e) Sister ships:

When determining the maximum design loads, the results of model tests performed for sister ships with similar main dimensions and geometrical features of cargo tanks may be used provided the Society's agreement. Feasible use of the results of earlier tests is to be justified considering the review of the compliance degree of, at least, the following characteristics:

- the selected initial technical data
- the selected design cargo tanks
- the rolling and pitching seakeeping analysis results and a comparison of the initial and the target ship global accelerations results
- the main assumptions used during model tests.

### **3.4.6 Snow and ice loads**

*Snow and icing shall be considered, if relevant.*

### **3.4.7 Loads due to navigation in ice**

*Loads due to navigation in ice shall be considered for vessels intended for such service.*

## **3.5 Accidental loads**

### **3.5.1 Definition**

*Accidental loads are defined as loads that are imposed on a cargo containment system and its supporting arrangements under abnormal and unplanned conditions.*

### 3.5.2 Collision loads

The collision load shall be determined based on the cargo containment system under fully loaded condition with an inertial force corresponding to 0,5 g in the forward direction and 0,25 g in the aft direction, where g is gravitational acceleration.

Guidance for calculation of dynamic pressure, to be considered in addition to static pressure, is given in Ch 9, App 1, [4]

### 3.5.3 Loads due to flooding on ship

For independent tanks, loads caused by the buoyancy of an empty tank in a hold space flooded to the summer load draught shall be considered in the design of the anti-flotation chocks and the supporting hull structure.

## 4 Structural integrity

### 4.1 General

**4.1.1** The structural design shall ensure that tanks have an adequate capacity to sustain all relevant loads with an adequate margin of safety. This shall take into account the possibility of plastic deformation, buckling, fatigue and loss of liquid and gas tightness

**4.1.2** The structural integrity of cargo containment systems shall be demonstrated by compliance with [8] to [13], as appropriate, for the cargo containment system type.

**4.1.3** The structural integrity of cargo containment system types that are of novel design and differ significantly from those covered by [8] to [13] shall be demonstrated by compliance with [14] to ensure that the overall level of safety provided in this Section is maintained.

### 4.2 Structural analyses

#### 4.2.1 Analysis

- The design analyses shall be based on accepted principles of statics, dynamics and strength of materials.
- Simplified methods or simplified analyses may be used to calculate the load effects, provided that they are conservative. Model tests may be used in combination with, or instead of, theoretical calculations. In cases where theoretical methods are inadequate, model or full-scale tests may be required.
- When determining responses to dynamic loads, the dynamic effect shall be taken into account where it may affect structural integrity.

#### 4.2.2 Load scenarios

- For each location or part of the cargo containment system to be considered and for each possible mode of failure to be analysed, all relevant combinations of loads that may act simultaneously shall be considered.
- The most unfavourable scenarios for all relevant phases during construction, handling, testing and in service, and conditions shall be considered.

**4.2.3** When the static and dynamic stresses are calculated separately, and unless other methods of calculation are justified, the total stresses shall be calculated according to:

$$\sigma_x = \sigma_{x,st} \pm \sqrt{\sum (\sigma_{x,dyn})^2}$$

$$\sigma_y = \sigma_{y,st} \pm \sqrt{\sum (\sigma_{y,dyn})^2}$$

$$\sigma_z = \sigma_{z,st} \pm \sqrt{\sum (\sigma_{z,dyn})^2}$$

$$\tau_{xy} = \tau_{xy,st} \pm \sqrt{\sum (\tau_{xy,dyn})^2}$$

$$\tau_{xz} = \tau_{xz,st} \pm \sqrt{\sum (\tau_{xz,dyn})^2}$$

$$\tau_{yz} = \tau_{yz,st} \pm \sqrt{\sum (\tau_{yz,dyn})^2}$$

where:

$\sigma_{x,st}$ ,  $\sigma_{y,st}$ ,  $\sigma_{z,st}$ ,  $\tau_{xy,st}$ ,  $\tau_{xz,st}$  and  $\tau_{yz,st}$  are static stresses; and

$\sigma_{x,dyn}$ ,  $\sigma_{y,dyn}$ ,  $\sigma_{z,dyn}$ ,  $\tau_{xy,dyn}$ ,  $\tau_{xz,dyn}$  and  $\tau_{yz,dyn}$  are dynamic stresses,

each shall be determined separately from acceleration components and hull strain components due to deflection and torsion.

### 4.3 Stress categories

4.3.1 For the purpose of stress evaluation, stress categories are defined in this section as follows:

- Normal stress is the component of stress normal to the plane of reference.
- Membrane stress is the component of normal stress that is uniformly distributed and equal to the average value of the stress across the thickness of the section under consideration.
- Bending stress is the variable stress across the thickness of the section under consideration, after the subtraction of the membrane stress.
- Shear stress is the component of the stress acting in the plane of reference.
- Primary stress is a stress produced by the imposed loading, which is necessary to balance the external forces and moments. The basic characteristic of a primary stress is that it is not self-limiting. Primary stresses that considerably exceed the yield strength will result in failure or at least in gross deformations.
- Primary general membrane stress is a primary membrane stress that is so distributed in the structure that no redistribution of load occurs as a result of yielding.
- Primary local membrane stress arises where a membrane stress produced by pressure or other mechanical loading and associated with a primary or a discontinuity effect produces excessive distortion in the transfer of loads for other portions of the structure. Such a stress is classified as a primary local membrane stress, although it has some characteristics of a secondary stress. A stress region may be considered as local, if:

$$S_1 \leq 0,5 \sqrt{Rt}$$

$$S_2 \geq 2,5 \sqrt{Rt}$$

where:

$S_1$  : Distance in the meridional direction over which the equivalent stress exceeds  $1,1 f$

$S_2$  : Distance in the meridional direction to another region where the limits for primary general membrane stress are exceeded

$R$  : Mean radius of the vessel

$t$  : Wall thickness of the vessel at the location where the primary general membrane stress limit is exceeded; and

$f$  : Allowable primary general membrane stress.

- Secondary stress is a normal stress or shear stress developed by constraints of adjacent parts or by self-constraint of a structure. The basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions that cause the stress to occur.

### 4.4 Design conditions

4.4.1 All relevant failure modes shall be considered in the design for all relevant load scenarios and design conditions. The design conditions are given in [4.5] to [4.7], and the load scenarios are covered by [4.2.2].

### 4.5 Ultimate design condition

4.5.1 Structural capacity may be determined by testing, or by analysis, taking into account both the elastic and plastic material properties, by simplified linear elastic analysis or by the Code provisions.

a) Plastic deformation and buckling shall be considered.

b) Analysis shall be based on characteristic load values as follows:

- permanent loads: expected values
- functional loads: specified values
- environmental loads: for wave loads: most probable largest load encountered during  $10^8$  wave encounters.

c) For the purpose of ultimate strength assessment, the following material parameters apply:

- $R_e$  = specified minimum yield stress at room temperature ( $N/mm^2$ ). If the stress-strain curve does not show a defined yield stress, the 0.2% proof stress applies.
- $R_m$  = specified minimum tensile strength at room temperature ( $N/mm^2$ ).

For welded connections where under-matched welds, i.e. where the weld metal has lower tensile strength than the parent metal, are unavoidable, such as in some aluminium alloys, the respective  $R_e$  and  $R_m$  of the welds, after any applied heat treatment, shall be used. In such cases, the transverse weld tensile strength shall not be less than the actual yield strength of the parent metal. If this cannot be achieved, welded structures made from such materials shall not be incorporated in cargo containment systems.

The above properties shall correspond to the minimum specified mechanical properties of the material, including the weld metal in the as-fabricated condition. Subject to special consideration by the Society, account may be taken of the enhanced yield stress and tensile strength at low temperature. The temperature on which the material properties are based shall be shown on the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk.

d) The equivalent stress  $\sigma_C$  (von Mises, Huber) shall be determined by:

$$\sigma_C = \sqrt{\sigma_x^2 + \sigma_y^2 + \sigma_z^2 - \sigma_x\sigma_y - \sigma_x\sigma_z - \sigma_y\sigma_z + 3(\tau_{xz}^2 + \tau_{xy}^2 + \tau_{yz}^2)}$$

where:

- $\sigma_x$  : Total normal stress in x-direction
- $\sigma_y$  : Total normal stress in y-direction
- $\sigma_z$  : Total normal stress in z-direction
- $\tau_{xy}$  : Total shear stress in x-y plane
- $\tau_{xz}$  : Total shear stress in x-z plane; and
- $\tau_{yz}$  : Total shear stress in y-z plane.

The above values shall be calculated as described in [4.2.3].

- e) Allowable stresses for materials other than those covered by Ch 9, Sec 6 shall be subject to approval by the Society in each case.
- f) Stresses may be further limited by fatigue analysis, crack propagation analysis and buckling criteria.

## 4.6 Fatigue design condition

4.6.1 The fatigue design condition is the design condition with respect to accumulated cyclic loading.

4.6.2 Where a fatigue analysis is required, the cumulative effect of the fatigue load shall comply with:

$$\sum \frac{n_i}{N_i} + \frac{n_{\text{Loading}}}{N_{\text{Loading}}} \leq C_w$$

where:

- $n_i$  : Number of stress cycles at each stress level during the life of the tank
- $N_i$  : Number of cycles to fracture for the respective stress level according to the Wohler (S-N) curve
- $n_{\text{Loading}}$  : Number of loading and unloading cycles during the life of the tank, not to be less than 1000. Loading and unloading cycles include a complete pressure and thermal cycle

Note 1: 1000 cycles normally corresponds to 20 years of operation.

- $N_{\text{Loading}}$  : Number of cycles to fracture for the fatigue loads due to loading and unloading; and
- $C_w$  : Maximum allowable cumulative fatigue damage ratio.

The fatigue damage shall be based on the design life of the tank but not less than  $10^8$  wave encounters.

4.6.3 Where required, the cargo containment system shall be subject to fatigue analysis, considering all fatigue loads and their appropriate combinations for the expected life of the cargo containment system. Consideration shall be given to various filling conditions.

### 4.6.4

- a) Design S-N curves used in the analysis shall be applicable to the materials and weldments, construction details, fabrication procedures and applicable state of the stress envisioned.
- b) The S-N curves shall be based on a 97,6% probability of survival corresponding to the mean-minus-two-standard-deviation curves of relevant experimental data up to final failure. Use of S-N curves derived in a different way requires adjustments to the acceptable  $C_w$  values specified in [4.6.7] to [4.6.9].

4.6.5 Analysis shall be based on characteristic load values as follows:

- permanent loads: expected values
- functional loads: specified values or specified history
- environmental loads: expected load history, but not less than  $10^8$  cycles.

If simplified dynamic loading spectra are used for the estimation of the fatigue life, they shall be specially considered by the Society.

4.6.6

- a) Where the size of the secondary barrier is reduced, as is provided for in [2.2.3], fracture mechanics analyses of fatigue crack growth shall be carried out to determine:
- crack propagation paths in the structure
  - crack growth rate
  - the time required for a crack to propagate to cause a leakage from the tank
  - the size and shape of through thickness cracks; and
  - the time required for detectable cracks to reach a critical state.
- The fracture mechanics are, in general, based on crack growth data taken as a mean value plus two standard deviations of the test data.
- b) In analysing crack propagation, the largest initial crack not detectable by the inspection method applied shall be assumed, taking into account the allowable non-destructive testing and visual inspection criterion, as applicable.
- c) Crack propagation analysis under the condition specified in [4.6.7]: the simplified load distribution and sequence over a period of 15 days may be used. Such distributions may be obtained as indicated in Fig 2. Load distribution and sequence for longer periods, such as in [4.6.8] and [4.6.9] shall be approved by the Society.
- d) The arrangements shall comply with [4.6.7] to [4.6.9], as applicable.

Figure 2 : Simplified load distribution

$\sigma_0$  is the most probable maximum stress over the life of the ship

Response cycle scale is logarithmic; the value of  $2 \cdot 10^5$  is given as an example of estimate

**4.6.7** For failures that can be reliably detected by means of leakage detection,  $C_w$  shall be less than or equal to 0,5. Predicted remaining failure development time, from the point of detection of leakage till reaching a critical state, shall not be less than 15 days, unless different requirements apply for ships engaged in particular voyages.

**4.6.8** For failures that cannot be detected by leakage but that can be reliably detected at the time of in-service inspections,  $C_w$  shall be less than or equal to 0,5. Predicted remaining failure development time, from the largest crack not detectable by in-service inspection methods until reaching a critical state, shall not be less than three times the inspection interval.

**4.6.9** In particular locations of the tank, where effective defect or crack development detection cannot be assured, the following, more stringent, fatigue acceptance criteria shall be applied as a minimum:  $C_w$  shall be less than or equal to 0,1. Predicted failure development time, from the assumed initial defect until reaching a critical state, shall not be less than three times the lifetime of the tank.

**4.7 Accident design condition**

**4.7.1** The accident design condition is a design condition for accidental loads with extremely low probability of occurrence.

**4.7.2** Analysis shall be based on the characteristic values as follows:

- permanent loads: expected values
- functional loads: specified values
- environmental loads: specified values
- accidental loads: specified values or expected values.

**4.7.3** Loads mentioned in [3.3.9] and [3.5] need not be combined with each other or with wave-induced loads.

## 5 Materials

### 5.1 General

**5.1.1** *The purpose of this article is to ensure that the cargo containment system, the thermal insulation, adjacent ship structure and other materials in the cargo containment system are constructed from materials of suitable properties for the conditions they will experience, both in normal service and in the event of failure of the primary barrier, where applicable.*

### 5.2 Materials forming ship structure

**5.2.1** *To determine the grade of plate and sections used in the hull structure, a temperature calculation shall be performed for all tank types when the cargo temperature is below  $-10^{\circ}\text{C}$ . The following assumptions shall be made in this calculation:*

- a) *The primary barrier of all tanks shall be assumed to be at the cargo temperature.*
- b) *In addition to item a), where a complete or partial secondary barrier is required, it shall be assumed to be at the cargo temperature at atmospheric pressure for any one tank only.*
- c) *For worldwide service, ambient temperatures shall be taken as  $5^{\circ}\text{C}$  for air and  $0^{\circ}\text{C}$  for seawater. Higher values may be accepted for ships operating in restricted areas and, conversely, lower values may be fixed by the Society for ships trading to areas where lower temperatures are expected during the winter months.*  
*For the temperature calculation performed in view of the selection of steel grade for hull structures adjacent to the cargo containment system but not directly subject to the outside air, temperature is to be taken in accordance with the technical documentation submitted in the scope of the ship project review.*

*Note 1: When the additional class notation **COLD (H t<sub>DH</sub>, E t<sub>DE</sub>)** is assigned to the ship, two sets of temperature calculations are required, as defined in Pt F, Ch 8, Sec 4, [5.1.7]. The most stringent result is to be selected to determine the grade steel used in the hull structure.*

- d) *Still air and seawater conditions shall be assumed, i.e. no adjustment for forced convection.*
- e) *Degradation of the thermal insulation properties over the life of the ship due to factors such as thermal and mechanical ageing, compaction, ship motions and tank vibrations, as defined in [5.4.6] and [5.4.7], shall be assumed.*
- f) *The cooling effect of the rising boil-off vapour from the leaked cargo shall be taken into account, where applicable.*
- g) *Credit for hull heating may be taken in accordance with [5.2.5], provided the heating arrangements are in compliance with [5.2.6].*
- h) *No credit shall be given for any means of heating, except as described in [5.2.5]; and*
- i) *For members connecting inner and outer hulls, the mean temperature may be taken for determining the steel grade.*

*The ambient temperatures used in the design, described in this paragraph, shall be shown on the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk.*

**5.2.2** *The shell and deck plating of the ship and all stiffeners attached thereto shall be in accordance with recognized standards. If the calculated temperature of the material in the design condition is below  $-5^{\circ}\text{C}$  due to the influence of the cargo temperature, the material shall be in accordance with Ch 9, Sec 6, Tab 6*

**5.2.3** *The materials of all other hull structures for which the calculated temperature in the design condition is below  $0^{\circ}\text{C}$ , due to the influence of cargo temperature and that do not form the secondary barrier, shall also be in accordance with Ch 9, Sec 6, Tab 6. This includes hull structure supporting the cargo tanks, inner bottom plating, longitudinal bulkhead plating, transverse bulkhead plating, floors, webs, stringers and all attached stiffening members.*

**5.2.4** *The hull material forming the secondary barrier shall be in accordance with Ch 9, Sec 6, Tab 3. Where the secondary barrier is formed by the deck or side shell plating, the material grade required by Ch 9, Sec 6, Tab 3 shall be carried into the adjacent deck or side shell plating, where applicable, to a suitable extent.*

**5.2.5** *Means of heating structural materials may be used to ensure that the material temperature does not fall below the minimum allowed for the grade of material specified in Ch 9, Sec 6, Tab 6. In the calculations required in [5.2.1], credit for such heating may be taken in accordance with the following:*

- a) *For any transverse hull structure*
- b) *For longitudinal hull structure referred to in [5.2.2] and [5.2.3] where colder ambient temperatures are specified, provided the material remains suitable for the ambient temperature conditions of  $+5^{\circ}\text{C}$  for air and  $0^{\circ}\text{C}$  for seawater with no credit taken in the calculations for heating; and*
- c) *As an alternative to item b), for longitudinal bulkhead between cargo tanks, credit may be taken for heating, provided the material remain suitable for a minimum design temperature of  $-30^{\circ}\text{C}$ , or a temperature  $30^{\circ}\text{C}$  lower than that determined by [5.2.1] with the heating considered, whichever is less. In this case, the ship's longitudinal strength shall comply with requirements of Part B, Chapter 6 for both when those bulkhead(s) are considered effective and not.*

**5.2.6** *The means of heating referred to in [5.2.5] shall comply with the following requirements:*

- a) *The heating system shall be arranged so that, in the event of failure in any part of the system, standby heating can be maintained equal to not less than 100% of the theoretical heat requirement*
- b) *The heating system shall be considered as an essential auxiliary. All electrical components of at least one of the systems provided in accordance with [5.2.5] a) shall be supplied from the emergency source of electrical power; and*
- c) *The design and construction of the heating system shall be included in the approval of the containment system by the Society.*

With reference to application of a) to c), the following requirements is to be considered:

- Where the above requirements are met by duplication of the system components, i.e., heaters, glycol circulation pumps, electrical control panel, auxiliary boilers etc., all electrical components of at least one of the systems are to be supplied from the emergency source of electrical power.
- Where duplication of the primary source of heat, e.g., oil-fired boiler is not feasible, alternative proposals may be accepted such as an electric heater capable of providing 100% of the theoretical heat requirement provided and supplied by an individual circuit arranged separately on the emergency switchboard. Other solutions may be considered towards satisfying the requirements of [5.2.5] provided a risk assessment is conducted to the satisfaction of the Society. The requirement of the previous bullet point continues to apply to all other electrical components in the system.

### **5.2.7 Segregation of heating plant**

Where a hull heating system complying with [5.2.5] is installed, this system is to be contained solely within the cargo area or the drain returns from the hull heating coils in the wing tanks, cofferdams and double bottom are to be led to a degassing tank. The degassing tank is to be located in the cargo area and the vent outlets are to be located in a safe position and fitted with a flame screen.

Note 1: In the case of an indirect heating system applied to the heating of cofferdams, degassing tank is not mandatory.

### **5.2.8 First loaded voyage**

Attention is drawn to the requirements of Ch 9, Sec 1, [6.2.4] regarding the satisfactory operation of the heating plant, that is to be ascertained during the first full loading and the subsequent first unloading of ships carrying liquefied natural gases (LNG) in bulk.

## **5.3 Materials of primary and secondary barrier**

**5.3.1** *Metallic materials used in the construction of primary and secondary barriers not forming the hull, shall be suitable for the design loads that they may be subjected to, and be in accordance with Ch 9, Sec 6, Tab 2, Ch 9, Sec 6, Tab 3 and Ch 9, Sec 6, Tab 4.*

**5.3.2** *Materials, either non-metallic or metallic but not covered by Ch 9, Sec 6, Tab 2, Ch 9, Sec 6, Tab 3 and Ch 9, Sec 6, Tab 4 used in the primary and secondary barriers may be approved by the Society, considering the design loads that they may be subjected to, their properties and their intended use.*

**5.3.3** *Where non-metallic materials, including composites, are used for, or incorporated in the primary or secondary barriers, they shall be tested for the following properties, as applicable, to ensure that they are adequate for the intended service:*

- *compatibility with the cargoes*
- *ageing*
- *mechanical properties*
- *thermal expansion and contraction*
- *abrasion*
- *cohesion*
- *resistance to vibrations*
- *resistance to fire and flame spread; and*
- *resistance to fatigue failure and crack propagation.*

**5.3.4** *The above properties, where applicable, shall be tested for the range between the expected maximum temperature in service and +5°C below the minimum design temperature, but not lower than -196°C.*

**5.3.5** *Where non-metallic materials, including composites, are used for the primary and secondary barriers, the joining processes shall also be tested as described above.*

**5.3.6** *Guidance on the use of non-metallic materials in the construction of primary and secondary barriers is provided in Appendix 4 of the IGC Code.*

**5.3.7** *Consideration may be given to the use of materials in the primary and secondary barrier, which are not resistant to fire and flame spread, provided they are protected by a suitable system such as a permanent inert gas environment, or are provided with a fire-retardant barrier.*

## **5.4 Thermal insulation and other materials used in cargo containment systems**

**5.4.1** *Load-bearing thermal insulation and other materials used in cargo containment systems shall be suitable for the design loads.*

**5.4.2** *Thermal insulation and other materials used in cargo containment systems shall have the following properties, as applicable, to ensure that they are adequate for the intended service:*

- *compatibility with the cargoes*
- *solubility in the cargo*
- *absorption of the cargo*
- *shrinkage*
- *ageing*
- *closed cell content*
- *density*
- *mechanical properties, to the extent that they are subjected to cargo and other loading effects, thermal expansion and contraction*
- *abrasion*
- *cohesion*
- *thermal conductivity*
- *resistance to vibrations*
- *resistance to fire and flame spread; and*
- *resistance to fatigue failure and crack propagation.*

**5.4.3** *The above properties, where applicable, shall be tested for the range between the expected maximum temperature in service and 5°C below the minimum design temperature, but not lower than –196°C.*

**5.4.4** *Due to location or environmental conditions, thermal insulation materials shall have suitable properties of resistance to fire and flame spread and shall be adequately protected against penetration of water vapour and mechanical damage. Where the thermal insulation is located on or above the exposed deck, and in way of tank cover penetrations, it shall have suitable fire resistance properties in accordance with recognized standards or be covered with a material having low flame-spread characteristics and forming an efficient approved vapour seal.*

**5.4.5** *Thermal insulation that does not meet recognized standards for fire resistance may be used in hold spaces that are not kept permanently inerted, provided its surfaces are covered with material with low flame-spread characteristics and that forms an efficient approved vapour seal.*

**5.4.6** *Testing for thermal conductivity of thermal insulation shall be carried out on suitably aged samples.*

**5.4.7** *Where powder or granulated thermal insulation is used, measures shall be taken to reduce compaction in service and to maintain the required thermal conductivity and also prevent any undue increase of pressure on the cargo containment system.*

**5.4.8** The materials for insulation are to be approved by the Society.

The approval of bonding materials, sealing materials, lining constituting a vapour barrier or mechanical protection is to be considered by the Society on a case-by-case basis. In any event, these materials are to be chemically compatible with the insulation material.

A particular attention is to be paid to the continuity of the insulation in way of tank supports.

**5.4.9** Before applying the insulation, the surfaces of the tank structures or of the hull are to be carefully cleaned.

**5.4.10** Where applicable, the insulation system is to be suitable to be visually examined at least on one side.

**5.4.11** When the insulation is sprayed or foamed, the minimum steel temperature at the time of application is to be not less than the temperature given in the specification of the insulation.

## **6 Construction processes**

### **6.1 General**

**6.1.1** *The purpose of this article is to define suitable construction processes and test procedures in order to ensure, as far as reasonably practical, that the cargo containment system will perform satisfactorily in service in accordance with the assumptions made at the stage design.*

## **6.2 Weld joint design**

**6.2.1** *All welded joints of the shells of independent tanks shall be of the in-plane butt weld full penetration type. For dome-to-shell connections only, tee welds of the full penetration type may be used depending on the results of the tests carried out at the approval of the welding procedure. Except for small penetrations on domes, nozzle welds shall also be designed with full penetration.*

The applicability of the expression “For dome-to-shell connections only” is clarified as follows:

- Welded corners (i.e. corners made of weld metal) are not to be used in the main tank shell construction, i.e. corners between shell side (sloped plane surfaces parallel to hopper or top side inclusive if any) and bottom or top of the tank, and between tank end transverse bulkheads and bottom, top or shell sides (sloped plane surfaces inclusive if any) of the tank. Instead, tank corners which are constructed using bent plating aligned with the tank surfaces and connected with in-plane welds are to be used.
- Tee welds can be accepted for other localised constructions of the shell such as suction well, sump, dome, etc. where tee welds of full penetration type are also to be used.

Note 1: This requirement is applicable to independent tanks of type A or type B, primarily constructed of plane surfaces. This includes the tank corners which are constructed using bent plating which is aligned with the tank surfaces and connected with in-plane welds.

**6.2.2** *Welding joint details for type C independent tanks, and for the liquid-tight primary barriers Design for gluing of type B independent tanks primarily constructed of curved surfaces, shall be as follows:*

- *all longitudinal and circumferential joints shall be of butt welded, full penetration, double vee or single vee type. Full penetration butt welds shall be obtained by double welding or by the use of backing rings. If used, backing rings shall be removed except from very small process pressure vessels. Other edge preparations may be permitted, depending on the results of the tests carried out at the approval of the welding procedure; and*
- *the bevel preparation of the joints between the tank body and domes and between domes and relevant fittings shall be designed according to a standard acceptable to the Society. All welds connecting nozzles, domes or other penetrations of the vessel and all welds connecting flanges to the vessel or nozzles shall be full penetration welds.*

This requirement is applicable to type C independent tanks including bi-lobe tanks, primarily constructed of curved surfaces fitted with a centreline bulkhead. The applicability of the expression “Other edge preparations” is clarified as follows:

- Cruciform full penetration welded joints in a bi-lobe tank with centreline bulkhead can be accepted for the tank structure construction at tank centreline welds with bevel preparation subject to the approval of the Society, based on the results of the tests carried out at the approval of the welding procedure.

**6.2.3** *Where applicable, all the construction processes and testing, except that specified in [6.4], shall be done in accordance with the applicable provisions of Ch 9, Sec 6.*

**6.2.4** The following provisions apply to independent tanks:

- tracing, cutting and shaping are to be carried out so as to prevent, at the surface of the pieces, the production of defects detrimental to their use. In particular, marking the plates by punching and starting welding arcs outside the welding zone are to be avoided.
- before welding, the edges to be welded are to be carefully examined, with possible use of non-destructive examination, in particular when chamfers are carried out.
- in all cases, the working units are to be efficiently protected against bad weather.
- the execution of provisional welds, where any, is to be subjected to the same requirements as the constructional welds. After elimination of the fillets, the area is to be carefully ground and inspected (the inspection is to include, if necessary, a penetrant fluid test).
- all welding consumables are subject to agreement. Welders are also to be agreed.

## **6.3 Design for gluing and other joining processes**

**6.3.1** *The design of the joint to be glued (or joined by some other process except welding) shall take account of the strength characteristics of the joining process.*

## **6.4 Testing**

**6.4.1** *All cargo tanks and process pressure vessels shall be subjected to hydrostatic or hydropneumatic pressure testing in accordance with [8] to [13], as applicable for the tank type.*

**6.4.2** *All tanks shall be subject to a tightness test which may be performed in combination with the pressure test referred to in [6.4.1].*

**6.4.3** *Requirements with respect to inspection of secondary barriers shall be decided by the Society in each case, taking into account the accessibility of the barrier (see [2.4.3]).*

**6.4.4** For containment systems with glued secondary barriers:

- at the time of construction, a tightness test should be carried out in accordance with approved system designers' procedures and acceptance criteria before and after initial cool down. Low differential pressures tests are not considered an acceptable test.
- if the designer's threshold values are exceeded, an investigation is to be carried out and additional testing such as thermographic or acoustic emissions testing should be carried out.
- the values recorded should be used as reference for future assessment of secondary barrier tightness.

For containment systems with welded metallic secondary barriers, a tightness test after initial cool down is not required.

**6.4.5** The Society may require that for ships fitted with novel type B independent tanks, or tanks designed according to [14.1] at least one prototype tank and its supporting structures shall be instrumented with strain gauges or other suitable equipment to confirm stress levels. Similar instrumentation may be required for type C independent tanks, depending on their configuration and on the arrangement of their supports and attachments.

**6.4.6** The overall performance of the cargo containment system shall be verified for compliance with the design parameters during the first full loading and discharging of the cargo, in accordance with the survey procedure and requirements in IGC Code, 1.6, and the requirements of the Society. Records of the performance of the components and equipment essential to verify the design parameters, shall be maintained and be available to the Society.

**6.4.7** Heating arrangements, if fitted in accordance with [5.2.5] and [5.2.6], shall be tested for required heat output and heat distribution.

**6.4.8** The cargo containment system shall be inspected for cold spots during, or immediately following, the first loaded voyage. Inspection of the integrity of thermal insulation surfaces that cannot be visually checked shall be carried out in accordance with recognized standards.

**6.4.9** If the tests are performed while the cargo tanks are filled or partially filled, they are to be performed at the minimum service temperature, as far as practicable.

**6.4.10** The reliquefaction and inert gas production systems, if any, and the installation, if any, for use of gas as fuel for boilers and internal combustion engines are also to be tested to the satisfaction of the Surveyor.

**6.4.11**

- All operating data and temperatures read during the first voyage of the loaded ship are to be sent to the Society
- Attention is drawn to the requirements of Ch 9, Sec 1, [6.2.4] regarding the cold spots examination that is to be carried out during the first loaded voyage.

**6.4.12** All data and temperatures read during subsequent voyages are to be kept at the disposal of the Society for a suitable period of time.

## **7 Supports**

### **7.1 Supporting arrangement**

**7.1.1** The cargo tanks shall be supported by the hull in a manner that prevents bodily movement of the tank under the static and dynamic loads defined in [3.2] to [3.5], where applicable, while allowing contraction and expansion of the tank under temperature variations and hull deflections without undue stressing of the tank and the hull.

**7.1.2** Supports and supporting arrangements shall withstand the loads defined in [3.3.9] and [3.5], but these loads need not be combined with each other or with wave-induced loads

**7.1.3** The reaction forces in way of tank supports are to be transmitted as directly as possible to the hull primary supporting members, minimising stress concentrations.

Where the reaction forces are not in the plane of primary members, web plates and brackets are to be provided in order to transmit these loads by means of shear stresses.

**7.1.4** Special attention is to be paid to continuity of structure between circular tank supports and the primary supporting members of the ship.

**7.1.5** Openings in tank supports and hull structures in way of tank supports are to be minimized and local strengthening may be necessary.

**7.1.6** Insulating materials for tank supports are to be type approved by the Society.

Note 1: In addition to the justification of mechanical properties, the water absorption of the material should not be more than 6% when determined in accordance with DIN 53 495.

## 7.2 Calculation of reaction forces in way of tank supports

**7.2.1** The reaction forces in way of tank supports are to be obtained from the structural analysis of the tank or stiffening rings in way of tank supports, considering the loads specified in [3.2] to [3.5].

The final distribution of the reaction forces at the supports is not to show any tensile forces.

## 7.3 Checking criteria

**7.3.1** The requirements specified in [7.4] and [7.5] are to be checked regarding the following criteria:

- a) For supports analysed through beam model, it is to be checked that the combined stress  $\sigma_C$ , in N/mm<sup>2</sup>, is in compliance with the following formula:  $\sigma_C \leq \sigma_{ALL}$

where:

$\sigma_{ALL}$  : Allowable stress, in N/mm<sup>2</sup>, defined in Tab 2 for each acceptance criteria.

- b) For supports analysed through finite element model, the yield criteria, defined in Pt B, Ch 8, App 1, [5.2.3] for standard mesh size or in Pt B, Ch 8, App 2, [4.1.3] for fine mesh models, is to be checked.

The maximum permissible stresses are based on the mesh size of 50 x 50 mm. Where a smaller mesh size is used, an area weighted Von Mises stress calculated over an area equal to the specified mesh size may be used to compare with the permissible stresses.

**Table 2 : Beam model: Allowable stresses  $\sigma_{ALL}$  in N/mm<sup>2</sup> in all types of supports**

Acceptance criteria	AC-1	AC-2	AC-3 (1)
$\sigma_{ALL}$ , in N/mm <sup>2</sup>	The lower of: <ul style="list-style-type: none"> <li>• 0,9 R<sub>m</sub> / 2,66</li> <li>• 0,9 R<sub>eH</sub> / 1,33</li> </ul>	The lower of: <ul style="list-style-type: none"> <li>• R<sub>m</sub> / 2,66</li> <li>• R<sub>eH</sub> / 1,33</li> </ul>	0,85 Ry
(1) Flooding, static heel 30° and collision conditions are to be checked considering AC-3 criteria			

## 7.4 Supports of type A and type B independent tanks

**7.4.1** For parts, such as supporting structures, not otherwise covered by the requirements of the Code, stresses shall be determined by direct calculations, taking into account the loads referred to in [3.2] to [3.5] as far as applicable, and the ship deflection in way of supporting structures.

**7.4.2** The tanks with supports shall be designed for the accidental loads specified in [3.5]. These loads need not be combined with each other or with environmental loads.

**7.4.3** Moreover the tanks with supports are also to be designed for a static angle of heel of 30°.

### 7.4.4 Vertical supports

The structure of the tank and of the ship is to be reinforced in way of the vertical supports so as to withstand the reactions and the corresponding moments.

### 7.4.5 Antirolling supports

Antirolling supports are to be checked under transverse and vertical accelerations, as defined in [7.2.1] for the inclined ship conditions, and applied on the maximum weight of the full tank.

Antirolling supports are also to be checked for a static angle of heel of 30°.

### 7.4.6 Antipitching supports

Antipitching supports are to be checked under longitudinal accelerations and vertical accelerations, as defined in [7.2.1] for the upright conditions, and applied on the maximum weight of the full tank.

Antipitching supports are also to be checked for a static angle of heel of 30°.

### 7.4.7 Anticollision supports

Anticollision supports are to be provided to withstand a collision force acting on the tank corresponding to one half the weight of the tank and cargo in the forward direction and one quarter the weight of the tank and cargo in the aft direction.

Antipitching supports may be combined with anticollision supports.

### 7.4.8 Antiflotation supports

- a) Anti-flotation arrangements shall be provided for independent tanks and capable of withstanding the loads defined in [3.5.3] without plastic deformation likely to endanger the hull structure.

- b) Adequate clearance between the tanks and the hull structures is to be provided in all operating conditions.

**7.4.9** Antiflotation supports are to be provided and are to be suitable to withstand an upward force caused by an empty tank in a hold space flooded to the scantling draught T<sub>sc</sub>.

## 7.5 Supports of type C independent tanks

**7.5.1** The tanks with supports shall be designed for the accidental loads specified in [3.5]. These loads need not be combined with each other or with environmental loads.

**7.5.2** Moreover the tanks with supports are also to be designed for a static angle of heel of 30°.

**7.5.3** The net scantlings of plating, ordinary stiffeners and primary supporting members of tank supports and hull structures in way of the supports are to be not less than those obtained by applying the criteria in Part B, Chapter 7.

The hull girder loads and the lateral pressure to be considered in the formulae above are to be obtained from the formulae in Part B, Chapter 5.

**7.5.4** In addition to [7.5.3], the anticollision supports and antil flotation supports are to be checked according to [7.4.7] to [7.4.8].

## 8 Type A independent tanks

### 8.1 Design basis

**8.1.1** Type A independent tanks are tanks primarily designed using classical ship-structural analysis procedures in accordance with recognized standards. Where such tanks are primarily constructed of plane surfaces, the design vapour pressure  $P_o$  shall be less than 0.07 MPa.

**8.1.2** If the cargo temperature at atmospheric pressure is below  $-10^{\circ}\text{C}$ , a complete secondary barrier shall be provided as required in [2.3]. The secondary barrier shall be designed in accordance with [2.4].

### 8.2 Structural analyses

**8.2.1** A structural analysis shall be performed taking into account the internal pressure as indicated in [3.3.2], and the interaction loads with the supporting and keying system as well as a reasonable part of the ship's hull.

### 8.3 Ultimate design condition

**8.3.1** For tanks primarily constructed of plane surfaces, the nominal membrane stresses for primary and secondary members (stiffeners, web frames, stringers, girders), when calculated by classical analysis procedures, shall not exceed the lower of  $R_m / 2,66$  or  $R_{eH} / 1,33$  for nickel steels, carbon-manganese steels, austenitic steels and aluminium alloys, where  $R_m$  and  $R_{eH}$  are defined in [4.5], item c). However, if detailed calculations are carried out for the primary members, the equivalent stress  $\sigma_e$ , as defined in [4.5], item d), may be increased over that indicated above to a stress acceptable to the Society. Calculations shall take into account the effects of bending, shear, axial and torsional deformation as well as the hull/cargo tank interaction forces due to the deflection of the double bottom and cargo tank bottoms.

**8.3.2** Tank boundary scantlings shall meet at least the requirements of the Society for deep tanks taking into account the internal pressure as indicated in [3.3.2] and any corrosion allowance required by [2.1.5].

#### 8.3.3 Plating

a) The net thickness of plating of type A independent tanks, in mm, is to comply with the slenderness requirements of NR615 Buckling Assessment of plated structures.

b) The net thickness of plating subject to lateral pressure, in mm, is to be checked according to Pt B, Ch 7, Sec 4, [1.1.1], considering:

$$P = p_{IGC}$$

where:

$p_{IGC}$  : Internal lateral pressure, in  $\text{kN/m}^2$ , in the tank, as defined in [3.3.2] item e)

c) The net thickness of plating subject to testing pressure, in mm, is to be checked according to Pt B, Ch 7, Sec 4, [1.1.1], considering:

$$P = p_{ST}$$

where:

$p_{ST}$  : Testing pressure, in  $\text{kN/m}^2$ , obtained according to [8.5].

d) The net thickness of plating subject to sloshing pressure is to be checked using the formula given in Pt B, Ch 7, Sec 4, [4].

#### 8.3.4 Ordinary stiffeners

a) The net thickness of web and face plate of ordinary stiffeners, in mm, is to comply with the slenderness requirements of NR615 Buckling Assessment of plated structures.

b) The net section modulus  $Z$ , in  $\text{cm}^3$ , and the net web thickness  $t_w$ , in mm, of ordinary stiffeners subjected to lateral pressure are to be checked according to Pt B, Ch 7, Sec 5, [1.1] considering:

$$P = p_{IGC}$$

$$C_s = C_t = \min \left[ 0,75 ; 0,37 \left( \frac{R_m}{R_{eH}} \right) \right]$$

where:

$p_{IGC}$  : Internal lateral pressure, in kN/m<sup>2</sup>, as defined in [3.3.2] item e)

- c) The net section modulus  $Z$ , in cm<sup>3</sup>, and the net web thickness  $t_{wv}$ , in mm, of ordinary stiffeners subjected to testing pressure are to be checked according to Pt B, Ch 7, Sec 5, [1.1] considering:

$$P = p_{ST}$$

where:

$p_{ST}$  : Testing pressure, in kN/m<sup>2</sup>, obtained according to [8.5].

- d) The net section modulus of ordinary stiffeners subject to sloshing pressure, including longitudinals, are to be checked using the formulae given in Pt B, Ch 7, Sec 5, [1.3].

### 8.3.5 Primary supporting members

- a) The net thickness of web plating and flange of primary supporting members, in mm, is to comply with the slenderness requirements detailed in Section 2 of NR615 Buckling Assessment of plated structures.
- b) The scantlings of primary supporting members are to be not less than those obtained considering the lateral pressure  $P_{IGC}$  defined in [3.3.2], item e) and checking criteria specified in d).

The tank is here considered independently from the global structure of the ship, simply supported on his supports. Therefore only internal pressures are taken into account and hull girder loads are neglected.

- c) The scantlings of primary supporting members are to be not less than those obtained considering the hull girder loads and lateral pressures calculated according to Part B, Chapter 5 and checking criteria specified in d).

When calculating the internal pressure, the tank dome part to be considered in the accepted total tank volume is to be calculated according to Ch 9, App 1, [1.1.2].

- d) Checking criteria:

- for primary supporting members analysed through beam model, it is to be checked that the combined stress, in N/mm<sup>2</sup>, is in compliance with the following formula:

$$\sigma_C \leq \sigma_{ALL}$$

where:

$\sigma_{ALL}$  : Allowable stress, in N/mm<sup>2</sup>, defined in Tab 3.

- for primary supporting members analysed through finite element model, the yield criteria defined in Pt B, Ch 8, App 1, [5.2.3] and Pt B, Ch 8, App 2, [4.1.3] as relevant, is to be checked considering the permissible yield utilisation factor  $\lambda_{yperm}$  defined in Tab 3.

**Table 3 : Type A primary supporting members - Permissible coefficients**

Acceptance criteria	Beam model $\sigma_{ALL}$ in N/mm <sup>2</sup>	$\lambda_{yperm}$ for finite element analysis
AC-2	The lower of: • $R_m / 2,66$ • $R_{eH} / 1,33$	Standard mesh • $\lambda_{yperm} = 0,9$
		Fine mesh (1) • $\lambda_{yperm} = 1,53 f_i$ for elements not adjacent to welding • $\lambda_{yperm} = 1,35 f_i$ for elements adjacent to welding
(1) The fatigue factor $f_i$ is to be taken as: • $f_i = 1,0$ in general, including the free edge of base material • $f_i = 1,2$ for details assessed by very fine mesh analysis complying with the fatigue assessment criteria given in Ch 10, Sec 1		

### 8.3.6 Buckling

The scantlings of cargo tank structure of type A independent tank are to be not less than those obtained in compliance with Pt B, Ch 9, Sec 1 considering an allowable buckling utilisation factor  $\eta_{ALL}$  equal to 0,8 for AC- 1 and 0,9 for AC-2 criteria.

## 8.4 Accident design conditions

**8.4.1** The tanks and the tank supports shall be designed for the accidental loads and design conditions specified in [2.1.4], item c) and [3.5], as relevant.

**8.4.2** When subjected to the accidental loads specified in [3.5] and [3.3.9], the stress shall comply with the acceptance criteria specified in [8.3], modified as appropriate, taking into account their lower probability of occurrence.

**8.4.3 Collision condition**

For collision loads, the lateral pressure to be considered is to be calculated according to [3.5.2].

The verification is to be carried out for structural members of transverse bulkhead up to the first adjacent web frame, as shown in Fig 3.

Plating, ordinary stiffeners and primary structural members are to be checked using the formula given in Part B, Chapter 7 and Pt B, Ch 8, App 1, [5.2.3] and Pt B, Ch 8, App 2, [4.1.3] as relevant, taking into account permissible coefficients specified in Tab 4.

Buckling check is not required for collision condition.

**Figure 3 : Extent of structural assessment for collision condition**

**8.4.4 Heel Condition**

Plating, ordinary stiffeners and primary structural members are to be checked using the formula given in Part B, Chapter 7 and Pt B, Ch 8, App 1, [5.2.3] and Pt B, Ch 8, App 2, [4.1.3] as relevant, taking into account permissible coefficients specified in Tab 4.

Buckling check is not required for heel condition.

**Table 4 : Permissible coefficients for collision and 30° heel conditions**

Plating	Ordinary stiffeners	Primary supporting members	
		Beam model	$\lambda_{yperm}$ for finite element analysis
$C_a$	$C_{sr}, C_{tr}, C_{comb}$	$C_{sr}, C_{tr}, C_{comb}$	Standard mesh • $\lambda_{yperm} = 0,9$
1	1	0,85	Fine mesh (1) • $\lambda_{yperm} = 1,53 f_i$ for elements not adjacent to welding • $\lambda_{yperm} = 1,35 f_i$ for elements adjacent to welding
(1) The fatigue factor $f_i$ is to be taken as: <ul style="list-style-type: none"> <li><math>f_i = 1,0</math> in general, including the free edge of base material</li> <li><math>f_i = 1,2</math> for details assessed by very fine mesh analysis complying with the fatigue assessment criteria given in Ch 10, Sec 1</li> </ul>			

**8.5 Testing**

**8.5.1 Testing**

All type A independent tanks shall be subjected to a hydrostatic or hydropneumatic test. This test shall be performed such that the stresses approximate, as far as practicable, the design stresses, and that the pressure at the top of the tank corresponds at least to the MARVS. When a hydropneumatic test is performed, the conditions shall simulate, as far as practicable, the design loading of the tank and of its support structure, including dynamic components, while avoiding stress levels that could cause permanent deformation.

**8.5.2** The conditions in which testing is performed are to simulate as far as possible the actual loading on the tank and its supports.

**8.5.3** When testing takes place after installation of the cargo tank, provision is to be made prior to the launching of the ship in order to avoid excessive stresses in the ship structures.

**9 Type B independent tanks**

**9.1 Design basis**

**9.1.1** Type B independent tanks are tanks designed using model tests, refined analytical tools and analysis methods to determine stress levels, fatigue life and crack propagation characteristics. Where such tanks are primarily constructed of plane surfaces (prismatic tanks), the design vapour pressure  $P_o$  shall be less than 0,07 MPa.

**9.1.2** If the cargo temperature at atmospheric pressure is below  $-10^{\circ}C$ , a partial secondary barrier with a small leak protection system shall be provided as required in [2.3]. The small leak protection system shall be designed according to [2.5].

## 9.2 Structural analyses

**9.2.1** The effects of all dynamic and static loads shall be used to determine the suitability of the structure with respect to:

- plastic deformation
- buckling
- fatigue failure; and
- crack propagation.

Finite element analysis or similar methods and fracture mechanics analysis, or an equivalent approach, shall be carried out.

**9.2.2** A three-dimensional analysis shall be carried out to evaluate the stress levels, including interaction with the ship's hull. The model for this analysis shall include the cargo tank with its supporting and keying system, as well as a reasonable part of the hull.

### 9.2.3 Analysis criteria

The analysis of the primary supporting members of the tank subjected to lateral pressure based on a three dimensional model is to be carried out according to the following requirements:

- the structural modeling is to comply with the requirements in Pt B, Ch 8, App 1, [2.4]
- the stress calculation is to comply with the requirements in Pt B, Ch 8, App 1, [5.2.1]
- the model extension is to comply with [9.2.4]
- the wave hull girder loads and the wave pressures to be applied on the model are to comply with [9.2.5]
- the inertial loads to be applied on the model are to comply with [3.3.2].

### 9.2.4 Model extension

The longitudinal extension of the structural model is to comply with Pt B, Ch 8, App 1, [2.2.1]. In any case, the structural model is to include the hull and the tank with its supporting and keying system.

### 9.2.5 Wave hull girder loads and wave pressures

A complete analysis of the particular ship accelerations and motions in irregular waves, and of the response of the ship and its cargo tanks to these forces and motions shall be performed, unless the data is available from similar ships.

Wave hull girder loads and wave pressures are to be obtained as the most probable the ship may experience during its operating life, for a probability level of  $10^{-8}$ .

Calculation are to be submitted to the Society for approval, unless these data are available from similar ships.

## 9.3 Ultimate design condition

### 9.3.1 Plating and ordinary stiffeners

The thickness of the skin plate and the size of the stiffener shall not be less than those required for type A independent tanks.

Scantlings of plating and ordinary stiffeners are to be calculated according to [8.3].

### 9.3.2 Primary supporting members

a) Type B independent tanks primarily constructed of bodies of revolution

- 1) The equivalent stresses of primary supporting members of type B independent tanks primarily constructed of bodies of revolution are to comply with the following formula:

$$\sigma_E \leq \sigma_{ALL}$$

where:

$\sigma_E$  : Equivalent stress, in N/mm<sup>2</sup>, to be obtained from the formula in [4.5.1] item d) for each of the following stress categories, defined in:

- primary general membrane stress
- primary local membrane stress
- primary bending stress
- secondary stress

$\sigma_{ALL}$  : Allowable stress, defined in 2) for each of the stress categories above.

- 2) For type B independent tanks, primarily constructed of bodies of revolution, the allowable stresses shall not exceed:

$$\sigma_m \leq f$$

$$\sigma_L \leq 1,5 f$$

$$\sigma_b \leq 1,5 F$$

$$\sigma_L + \sigma_b \leq 1,5 F$$

$$\sigma_m + \sigma_b \leq 1,5 F$$

$$\sigma_m + \sigma_b + \sigma_g \leq 3,0 F$$

$$\sigma_L + \sigma_b + \sigma_g \leq 3,0 F$$

where:

- $\sigma_m$  : Equivalent primary general membrane stress
- $\sigma_L$  : Equivalent primary local membrane stress
- $\sigma_b$  : Equivalent primary bending stress
- $\sigma_g$  : Equivalent secondary stress
- $f$  : The lesser of  $(R_m / A)$  or  $(R_e / B)$ ; and
- $F$  : The lesser of  $(R_m / C)$  or  $(R_e / D)$

with  $R_m$  and  $R_e$  as defined in [4.5.1], item c). With regard to the stresses  $\sigma_m$ ,  $\sigma_L$ ,  $\sigma_b$  and  $\sigma_g$ , the definition of stress categories in [4.3] are referred. The values A and B (and C and D) shall be shown on the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk and shall have at least minimum values as per Tab 5.

The above figures may be altered, taking into account the design condition considered in acceptance with the Society.

b) Type B independent tanks, primarily constructed of plane surfaces

1) The equivalent stresses of primary supporting members of type B independent tanks primarily constructed of plane surfaces are to comply with the following formula:

$$\sigma_E \leq \sigma_{ALL}$$

where:

$\sigma_E$  : Equivalent stress, in N/mm<sup>2</sup>, to be obtained from the formulae in Pt B, Ch 8, App 1, [5.2.1], as a result of direct calculations to be carried out in accordance with [9.2.3]

$\sigma_{ALL}$  : Allowable stress, in N/mm<sup>2</sup>, defined in item 2).

2) For type B independent tanks, primarily constructed of plane surfaces, the allowable membrane equivalent stresses applied for finite element analysis shall not exceed:

- for nickel steels and carbon-manganese steels, the lesser of  $R_m / 2$  or  $R_e / 1,2$ ;
- for austenitic steels, the lesser of  $R_m / 2,5$  or  $R_e / 1,2$ ; and
- for aluminium alloys, the lesser of  $R_m / 2.5$  or  $R_e / 1.2$ .

The above figures may be amended, taking into account the locality of the stress, stress analysis methods and design condition considered in acceptance with the Society.

**Table 5 : Minimum values of material coefficients**

	Nickel steels and carbon manganese steels	Austenitic steels	Aluminium alloys
A	3	3,5	4
B	2	1,6	1,5
C	3	3	3
D	1,5	1,5	1,5

**9.3.3 Buckling**

a) Buckling strength analyses of cargo tanks subject to external pressure and other loads causing compressive stresses shall be carried out in accordance with recognized standards. The method shall adequately account for the difference in theoretical and actual buckling stress as a result of plate edge misalignment, lack of straightness or flatness, ovality and deviation from true circular form over a specified arc or chord length, as applicable.

b) The scantlings of plating and ordinary stiffeners of type B independent tanks are to be not less than those obtained from the applicable formulae in Pt B, Ch 9, Sec 1.

c) A local buckling check is to be carried out according to Pt B, Ch 9, Sec 1 for plate panels which constitute primary supporting members.

In performing this check, the stresses in the plate panels are to be obtained from direct calculations to be carried out in accordance with [9.2.3].

**9.4 Fatigue design condition**

**9.4.1** Fatigue and crack propagation assessment shall be performed in accordance with [4.6]. The acceptance criteria shall comply with [4.6.7], [4.6.8], [4.6.9] depending on the detectability of the defect.

**9.4.2** Fatigue analysis shall consider construction tolerances.

**9.4.3** Where deemed necessary by the Society, model tests may be required to determine stress concentration factors and fatigue life of structural elements.

**9.4.4 Fatigue analysis**

a) General

The fatigue analysis is to be performed for areas where high wave induced stresses or large stress concentrations are expected, for welded joints and parent material. Such areas are to be defined by the Designer and agreed by the Society on a case-by-case basis.

b) Material properties

The material properties affecting fatigue of the items checked are to be documented. Where this documentation is not available, the Society may request to obtain these properties from experiments performed in accordance with recognised standards.

c) Wave loads

In upright ship and in inclined ship conditions the wave loads to be considered for the fatigue analysis of the tank include:

- maximum and minimum wave hull girder loads and wave pressures, to be obtained from a complete analysis of the ship motion and accelerations in irregular waves, to be submitted to the Society for approval, unless these data are available from similar ships. These loads are to be obtained as the most probable the ship may experience during its operating life, for a probability level of  $10^{-8}$ .
- maximum and minimum inertial pressures, to be obtained from the formulae in [3.3.2] as a function of the arbitrary direction  $\beta$ .

d) Simplified stress distribution for fatigue analysis

The simplified long-term distribution of wave loads indicated in [4.6.6], item c) may be represented by means of 8 stress ranges, each characterised by an alternating stress  $\pm \sigma_i$  and a number of cycles  $n_i$  (see Fig 4). The corresponding values of  $\sigma_i$  and  $n_i$  are to be obtained from the following formulae:

$$\sigma_i = \sigma_0 \left( 1,0625 - \frac{i}{8} \right)$$

$$n_i = 0,9 \cdot 10^i$$

where:

$\sigma_i$  : Stress ( $i = 1, 2, \dots, 8$ ), in  $N/mm^2$  (see Fig 4)

$\sigma_0$  : Most probable maximum stress over the life of the ship, in  $N/mm^2$ , for a probability level of  $10^{-8}$

$n_i$  : Number of cycles for each stress  $\sigma_i$  considered ( $i = 1, 2, \dots, 8$ ).

e) Conventional cumulative damage

For each structural detail for which the fatigue analysis is to be carried out, the conventional cumulative damage is to be calculated according to the following procedure:

- the long-term value of hot spot stress range  $\Delta\sigma_{s,0}$  is to be obtained from the following formula:

$$\Delta\sigma_{s,0} = |\sigma_{s,max} - \sigma_{s,min}|$$

where:

$\sigma_{s,max}, \sigma_{s,min}$ : Maximum and minimum hot spot stress to be obtained from a structural analysis carried out in accordance with Part B, Chapter 10 and NI611, where the wave loads are those defined in [9.4.4] item c).

- the long-term value of the notch stress range  $\Delta\sigma_{N,0}$  is obtained from the formulae in Pt B, Ch 10, Sec 1 as a function of the hot spot stress range  $\Delta\sigma_{s,0}$ .
- the long-term distribution of notch stress ranges  $\Delta\sigma_{N,i}$  is to be calculated. Each stress range  $\Delta\sigma_{N,i}$  of the distribution, corresponding to  $n_i$  stress cycles, is obtained from the formulae in item d), where  $\sigma_0$  is taken equal to  $\Delta\sigma_{N,0}$ .
- for each notch stress range  $\Delta\sigma_{N,i}$  the number of stress cycles  $N_i$  which cause the fatigue failure is to be obtained by means of S-N curves corresponding to the as-rolled condition (see Fig 5). The criteria adopted for obtaining the S-N curves are to be documented. Where this documentation is not available, the Society may require the curves to be obtained from experiments performed in accordance with recognised standards.
- the conventional cumulative damage for the  $i$  notch stress ranges  $\Delta\sigma_{N,i}$  is to be obtained from the formula in [4.6.2].

f) Check criteria

The conventional cumulative damage, to be calculated according to item e) is to be not greater than  $C_w$ , defined in [4.6.2].

Figure 4 : Simplified stress distribution for fatigue analysis

Figure 5 : Fatigue check based on conventional cumulative damage method

9.4.5 Crack propagation analysis

a) General

The crack propagation analysis is to be carried out for highly stressed areas. The latter are to be defined by the Designer and agreed by the Society on a case-by-case basis. Propagation rates in the parent material, weld metal and heat-affected zone are to be considered.

The following checks are to be carried out:

- crack propagation from an initial defect, in order to check that the defect will not grow and cause a brittle fracture before the defect is detected; this check is to be carried out according to item d)
- crack propagation from an initial through thickness defect, in order to check that the defect, resulting in a leakage, will not grow and cause a brittle fracture less than 15 days after its detection; this check is to be carried out according to item e).

b) Material properties

The material fracture mechanical properties used for the crack propagation analysis, i.e. the properties relating the crack propagation rate to the stress intensity range at the crack tip, are to be documented for the various thicknesses of parent material and weld metal alike. Where this documentation is not available, the Society may request to obtain these properties from experiments performed in accordance with recognised standards.

c) Simplified stress distribution for crack propagation analysis

The simplified wave load distribution indicated in [4.6.6] item c) may be represented over a period of 15 days by means of 5 stress ranges, each characterised by an alternating stress  $\pm \sigma_i$  and number of cycles,  $n_i$  (see Fig 6). The corresponding values of  $\sigma_i$  and  $n_i$  are to be obtained from the following formulae:

$$\sigma_i = \sigma_0 \left( 1,1 - \frac{i}{5,3} \right)$$

$$n_i = 0,913 \cdot 10^i$$

where:

$\sigma_i$  : Stress ( $i = 1,06; 2,12; 3,18; 4,24; 5,30$ ), in N/mm<sup>2</sup> (see Fig 6)

$\sigma_0$  : Defined in [9.4.4], item d)

$n_i$  : Number of cycles for each stress  $\sigma_i$  considered ( $i = 1,06; 2,12; 3,18; 4,24; 5,30$ ).

d) Crack propagation analysis from an initial defect

It is to be checked that an initial crack will not grow, under wave loading based on the stress distribution in [9.4.4] d), beyond the allowable crack size.

The initial size and shape of the crack is to be considered by the Society on a case-by-case basis, taking into account the structural detail and the inspection method.

The allowable crack size is to be considered by the Society on a case-by-case basis; in any event, it is to be taken less than that which may lead to a loss of effectiveness of the structural element considered.

e) Crack propagation analysis from an initial through thickness defect

It is to be checked that an initial through thickness crack will not grow, under dynamic loading based on the stress distribution in item c), beyond the allowable crack size.

The initial size of the through thickness crack is to be taken not less than that through which the minimum flow size that can be detected by the monitoring system (e.g. gas detectors) may pass.

The allowable crack size is to be considered by the Society on a case-by-case basis; in any event, it is to be taken far less than the critical crack length, defined in item f).

f) Critical crack length

The critical crack length is the crack length from which a brittle fracture may initiate and it is to be considered by the Society on a case-by-case basis. In any event, it is to be evaluated for the most probable maximum stress experienced by the structural element in the ship life, which is equal to the stress in the considered detail obtained from the structural analysis to be performed in accordance with [9.2.3].

Figure 6 : Simplified stress distribution for crack propagation analysis

9.5 Accident design condition

9.5.1 The tanks and the tank supports shall be designed for the accidental loads and design conditions specified in [2.1.4], item c) and [3.5], as applicable.

9.5.2 When subjected to the accidental loads specified in [3.5] and [3.3.9], the stress shall comply with the acceptance criteria specified in [9.3], modified as appropriate, taking into account their lower probability of occurrence.

9.5.3 Collision condition

The structure of the tank is to be checked for collision loads using pressure and criteria defined in [8.4.3].

9.5.4 Heel condition

The structure of the tank is to be checked for heel loads using pressure and criteria defined in [8.4.4].

9.6 Testing

9.6.1 Type B independent tanks shall be subjected to a hydrostatic or hydropneumatic test as follows:

- the test shall be performed as required in [8.5] for type A independent tanks; and
- in addition, the maximum primary membrane stress or maximum bending stress in primary members under test conditions shall not exceed 90% of the yield strength of the material (as fabricated) at the test temperature. To ensure that this condition is satisfied, when calculations indicate that this stress exceeds 75% of the yield strength, the prototype test shall be monitored by the use of strain gauges or other suitable equipment.

9.6.2 The conditions in which testing is performed are to simulate as far as possible the actual loading on the tank and its supports.

9.6.3 When testing takes place after installation of the cargo tank, provision is to be made prior to the launching of the ship in order to avoid excessive stresses in the ship structures.

9.7 Marking

9.7.1 Any marking of the pressure vessel shall be achieved by a method that does not cause unacceptable local stress raisers.

## 10 Type C independent tanks

### 10.1 Design basis

**10.1.1** The design basis for type C independent tanks is based on pressure vessel criteria modified to include fracture mechanics and crack propagation criteria. The minimum design pressure defined in item [10.1.2] is intended to ensure that the dynamic stress is sufficiently low, so that an initial surface flaw will not propagate more than half the thickness of the shell during the lifetime of the tank.

**10.1.2** The design vapour pressure, in MPa, shall not be less than:

$$P_o = 0.2 + AC(\rho_r)^{1,5}$$

where:

$$A = 0,00185 \left( \frac{\sigma_m}{\Delta\sigma_A} \right)^2$$

with:

$\sigma_m$  : Design primary membrane stress

$\Delta\sigma_A$  : Allowable dynamic membrane stress (double amplitude at probability level  $Q = 10^{-8}$ ) and equal to:

- 55 N/mm<sup>2</sup> for ferritic-perlitic, martensitic and austenitic steel
- 25 N/mm<sup>2</sup> for aluminium alloy (5083-O)

$C$  : A characteristic tank dimension to be taken as the greatest of the following:

- $h$
- $0,75 b$
- $0,45 \ell$

with

$h$  : Height of tank (dimension in ship's vertical direction), in m

$b$  : Width of tank (dimension in ship's transverse direction), in m

$\ell$  : Length of tank (dimension in ship's longitudinal direction), in m

$\rho_r$  : The relative density of the cargo ( $\rho_r = 1$  for fresh water) at the design temperature.

When a specified design life of the tank is longer than  $10^8$  wave encounters,  $\Delta\sigma_A$  shall be modified to give equivalent crack propagation corresponding to the design life.

**10.1.3** The Society may allocate a tank complying with the criteria of type C tank minimum design pressure as in [10.1.2], to a type A or type B, dependent on the configuration of the tank and the arrangement of its supports and attachments.

### 10.2 Shell thickness

**10.2.1** The shell thickness shall be as follows:

- a) For pressure vessels, the thickness calculated according to [10.2.4] shall be considered as a minimum thickness after forming, without any negative tolerance.
- b) For pressure vessels, the minimum thickness of shell and heads including corrosion allowance, after forming, shall not be less than 5 mm for carbon-manganese steels and nickel steels, 3 mm for austenitic steels or 7 mm for aluminium alloys.
- c) The welded joint efficiency factor to be used in the calculation according to [10.2.4] shall be 0,95 when the inspection and the non-destructive testing referred to in Ch 9, Sec 6, [5.6.7] are carried out. This figure may be increased up to 1 when account is taken of other considerations, such as the material used, type of joints, welding procedure and type of loading. For process pressure vessels, the Society may accept partial non-destructive examinations, but not less than those of Ch 9, Sec 6, [5.6.6], depending on such factors as the material used, the design temperature, the nil-ductility transition temperature of the material, as fabricated, and the type of joint and welding procedure, but in this case an efficiency factor of not more than 0,85 shall be adopted. For special materials, the above-mentioned factors shall be reduced, depending on the specified mechanical properties of the welded joint.

**10.2.2** The design liquid pressure defined in [3.3.2] shall be taken into account in the internal pressure calculations.

**10.2.3** The design external pressure  $P_e$ , in MPa, used for verifying the buckling of the pressure vessels, shall not be less than that given by:

$$P_e = P_1 + P_2 + P_3 + P_4$$

where:

$P_1$  : Setting value of vacuum relief valves. For vessels not fitted with vacuum relief valves,  $P_1$  shall be specially considered, but shall not, in general, be taken as less than 0,025 MPa

$P_2$  : The set pressure of the pressure relief valves (PRVs) for completely closed spaces containing pressure vessels or parts of pressure vessels; elsewhere  $P_2=0$

- $P_3$  : Compressive actions in or on the shell due to the weight and contraction of thermal insulation, weight of shell including corrosion allowance and other miscellaneous external pressure loads to which the pressure vessel may be subjected. These include, but are not limited to, weight of domes, weight of towers and piping, effect of product in the partially filled condition, accelerations and hull deflection. In addition, the local effect of external or internal pressures or both shall be taken into account; and
- $P_4$  : External pressure due to head of water for pressure vessels or part of pressure vessels on exposed decks; elsewhere  $P_4 = 0$ .

**10.2.4** Scantlings based on internal pressure shall be calculated as follows: the thickness and form of pressure-containing parts of pressure vessels, under internal pressure, as defined in [3.3.2], including flanges, shall be determined. These calculations shall in all cases be based on accepted pressure vessel design theory. Openings in pressure-containing parts of pressure vessels shall be reinforced in accordance with recognized standards.

**10.2.5** Stress analysis in respect of static and dynamic loads shall be performed as follows:

- pressure vessel scantlings shall be determined in accordance with [10.2.1] to [10.2.4] and [10.3].
- calculations of the loads and stresses in way of the supports and the shell attachment of the support shall be made. Loads referred to in [3.2] to [3.5] shall be used, as applicable. Stresses in way of the supporting structures shall be to a recognized standard acceptable to the Society. In special cases, a fatigue analysis may be required by the Society.
- if required by the Society, secondary stresses and thermal stresses shall be specially considered.

### 10.3 Ultimate design condition

**10.3.1** The type C independent cargo tanks are to comply with the requirements of Pt C, Ch 1, Sec 3 related to class 1 pressure vessels. The allowable stresses are defined in [10.3.2].

#### 10.3.2 Plastic deformation

For type C independent tanks, the allowable stresses shall not exceed:

$$\sigma_m \leq f$$

$$\sigma_l \leq 1,5 f$$

$$\sigma_b \leq 1,5 f$$

$$\sigma_l + \sigma_b \leq 1,5 f$$

$$\sigma_m + \sigma_b \leq 1,5 f$$

$$\sigma_m + \sigma_b + \sigma_g \leq 3,0 f$$

$$\sigma_l + \sigma_b + \sigma_g \leq 3,0 f$$

where:

$\sigma_m$  : Equivalent primary general membrane stress

$\sigma_l$  : Equivalent primary local membrane stress

$\sigma_b$  : Equivalent primary bending stress

$\sigma_g$  : Equivalent secondary stress

$f$  : The lesser of  $(R_m / A)$  or  $(R_e / B)$

with  $R_m$  and  $R_e$  as defined in [4.5], item c). With regard to the stresses  $\sigma_m$ ,  $\sigma_l$ ,  $\sigma_b$  and  $\sigma_g$ , the definition of stress categories in [4.3] are referred. The values A and B shall be shown on the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk and shall have at least the minimum values as per Tab 6.

**Table 6 : Minimum values of material coefficients**

	Nickel steels and carbon manganese steels	Austenitic steels	Aluminium alloys
A	3	3,5	4
B	1,5	1,5	1,5

#### 10.3.3 Buckling

Buckling criteria shall be as follows: the thickness and form of pressure vessels subject to external pressure and other loads causing compressive stresses shall be based on calculations using accepted pressure vessel buckling theory and shall adequately account for the difference in theoretical and actual buckling stress as a result of plate edge misalignment, ovality and deviation from true circular form over a specified arc or chord length.

#### 10.3.4 Stiffening rings in way of tanks supports

a) Structural model:

The stiffening rings in way of supports of horizontal cylindrical tanks are to be modeled as circumferential beams constituted by web, flange, doubler plate, if any, and plating attached to the stiffening rings.

## b) Width of attached plating:

On each side of the web, the width of the attached plating to be considered for the yielding and buckling checks of the stiffening rings, as in item e) and item f), respectively, is to be obtained, in mm, from the following formulae:

- for cylindrical shell:

$$b = 0,78 \sqrt{rt}$$

- for longitudinal bulkheads (in the case of lobe tanks):

$$b = 20 t_b$$

where:

r : Mean radius, in mm, of the cylindrical shell

t : Shell thickness, in mm

t<sub>b</sub> : Bulkhead thickness, in mm.

A doubler plate, if any, may be considered as belonging to the attached plating.

## c) Boundary conditions:

The boundary conditions of the stiffening ring are to be modeled as follows:

- circumferential forces applied on each side of the ring, whose resultant is equal to the shear force in the tank and calculated through the bi-dimensional shear flow theory
- reaction forces in way of tank supports, to be obtained according to [7.2].

## d) Lateral pressure:

The lateral pressure to be considered for the check of the stiffening rings is to be obtained from [3.3.2].

## e) Yielding check:

The equivalent stress in stiffening rings in way of supports is to comply with the following formula:

$$\sigma_E \leq \sigma_{ALL}$$

where:

$\sigma_E$  : Equivalent stress in stiffening rings calculated for the load cases defined in [7.1.2] and to be obtained from the following formula:

$$\sigma_E = \sqrt{(\sigma_N + \sigma_B)^2 + 3\tau^2}$$

$\sigma_N$  : Normal stress, in N/mm<sup>2</sup>, in the circumferential direction of the stiffening ring

$\sigma_B$  : Bending stress, in N/mm<sup>2</sup>, in the circumferential direction of the stiffening ring

$\tau$  : Shear stress, in N/mm<sup>2</sup>, in the stiffening ring

$\sigma_{ALL}$  : Allowable stress, in N/mm<sup>2</sup>, to be taken equal to the lesser of the following values:

- 0,57 R<sub>m</sub>
- 0,85 R<sub>eH</sub>

## f) Buckling check:

The buckling strength of the stiffening rings is to be checked in compliance with the applicable formulae in Pt B, Ch 9, Sec 1.

**10.4 Fatigue design condition**

**10.4.1** For large type C independent tanks, where the cargo at atmospheric pressure is below -55°C, the Society may require additional verification to check their compliance with [10.1.1] regarding static and dynamic stress.

**10.5 Accident design condition**

**10.5.1** The tanks and the tank supporting structures shall be designed for the accidental loads and design conditions specified in [2.1.4], item c) and [3.5], as applicable.

**10.5.2** When subjected to the accidental loads specified in [3.5] and [3.3.9], the stress shall comply with the acceptance criteria specified in [10.3.1], modified as appropriate taking into account their lower probability of occurrence.

**10.5.3 Collision condition**

The structure of the tank is to be checked for collision loads using pressure and criteria defined in [8.4.3].

**10.5.4 Heel condition**

The structure of the tank is to be checked for heel loads using pressure and criteria defined in [8.4.4].

**10.6 Testing**

**10.6.1** Each pressure vessel shall be subjected to a hydrostatic test at a pressure measured at the top of the tanks, of not less than 1,5 P<sub>o</sub>. In no case during the pressure test shall the calculated primary membrane stress at any point exceed 90% of the yield stress of the material. To ensure that this condition is satisfied where calculations indicate that this stress will exceed 0,75 times

the yield strength, the prototype test shall be monitored by the use of strain gauges or other suitable equipment in pressure vessels other than simple cylindrical and spherical pressure vessels.

**10.6.2** The temperature of the water used for the test shall be at least 30°C above the nil-ductility transition temperature of the material, as fabricated.

**10.6.3** The pressure shall be held for 2 h per 25 mm of thickness, but in no case less than 2 h.

**10.6.4** Where necessary for cargo pressure vessels, a hydropneumatic test may be carried out under the conditions prescribed in [10.6.1] to [10.6.3].

**10.6.5** Special consideration may be given to the testing of tanks in which higher allowable stresses are used, depending on service temperature. However, the requirements of [10.6.1] shall be fully complied with.

**10.6.6** After completion and assembly, each pressure vessel and its related fittings shall be subjected to an adequate tightness test which may be performed in combination with the pressure testing referred to in [10.6.1].

**10.6.7** Pneumatic testing of pressure vessels other than cargo tanks shall only be considered on an individual case basis. Such testing shall only be permitted for those vessels designed or supported such that they cannot be safely filled with water, or for those vessels that cannot be dried and are to be used in a service where traces of the testing medium cannot be tolerated.

**10.6.8** The conditions in which testing is performed are to simulate as far as possible the actual loading on the tank and its supports.

**10.6.9** When testing takes place after installation of the cargo tank, provision is to be made prior to the launching of the ship in order to avoid excessive stresses in the ship structures.

## **10.7 Marking**

**10.7.1** The required marking of the pressure vessel shall be achieved by a method that does not cause unacceptable local stress raisers.

## **11 Membrane tanks**

### **11.1 Design Basis**

**11.1.1** The design basis for membrane containment systems is that thermal and other expansion or contraction is compensated for without undue risk of losing the tightness of the membrane.

**11.1.2** If the cargo temperature at atmospheric pressure is below –10°C, a complete secondary barrier shall be provided as required in [2.3]. The secondary barrier shall be designed according to [2.4].

**11.1.3** A systematic approach based on analysis and testing shall be used to demonstrate that the system will provide its intended function in consideration of the events identified in service as specified in [11.2.1].

**11.1.4** The design vapour pressure  $P_o$  shall not normally exceed 0,025 MPa. If the hull scantlings are increased accordingly and consideration is given, where appropriate, to the strength of the supporting thermal insulation,  $P_o$  may be increased to a higher value, but less than 0,07 MPa.

**11.1.5** The definition of membrane tanks does not exclude designs such as those in which non-metallic membranes are used or where membranes are included or incorporated into the thermal insulation.

**11.1.6** The thickness of the membranes shall not normally exceed 10 mm.

**11.1.7** The circulation of inert gas throughout the primary insulation space and the secondary insulation space, in accordance with Ch 9, Sec 9, [1.2.1], shall be sufficient to allow for effective means of gas detection.

### **11.2 Design consideration**

**11.2.1** Potential incidents that could lead to loss of fluid tightness over the life of the membranes shall be evaluated. These include, but are not limited to:

a) Ultimate design events:

- tensile failure of membranes
- compressive collapse of thermal insulation
- thermal ageing
- loss of attachment between thermal insulation and hull structure
- loss of attachment of membranes to thermal insulation system

- structural integrity of internal structures and their supporting structures; and
- failure of the supporting hull structure.

b) *Fatigue design events:*

- fatigue of membranes including joints and attachments to hull structure
- fatigue cracking of thermal insulation
- fatigue of internal structures and their supporting structures; and
- fatigue cracking of inner hull leading to ballast water ingress.

c) *Accident design events:*

- accidental mechanical damage (such as dropped objects inside the tank while in service)
- accidental overpressurization of thermal insulation spaces
- accidental vacuum in the tank; and
- water ingress through the inner hull structure.

Designs where a single internal event could cause simultaneous or cascading failure of both membranes are unacceptable.

**11.2.2** *The necessary physical properties (mechanical, thermal, chemical, etc.) of the materials used in the construction of the cargo containment system shall be established during the design development in accordance with [11.1.3].*

### **11.3 Loads and loads combinations**

**11.3.1** *Particular consideration shall be given to the possible loss of tank integrity due to either an overpressure in the interbarrier space, a possible vacuum in the cargo tank, the sloshing effects, hull vibration effects, or any combination of these events.*

### **11.4 Structural analysis**

**11.4.1** *Structural analyses and/or testing for the purpose of determining the ultimate strength and fatigue assessments of the cargo containment and associated structures, e.g. structures as defined in [2.7], shall be performed. The structural analysis shall provide the data required to assess each failure mode that has been identified as critical for the cargo containment system.*

**11.4.2** *Structural analyses of the hull shall take into account the internal pressure as indicated in [3.3.2]. Special attention shall be paid to deflections of the hull and their compatibility with the membrane and associated thermal insulation.*

**11.4.3** *The analyses referred to in [11.4.1] and [11.4.2] shall be based on the particular motions, accelerations and response of ships and cargo containment systems.*

### **11.5 Structural details**

#### **11.5.1 Cut-outs and connections in membrane tanks**

For ordinary stiffeners located below the upper deck level and subject to sloshing loads, cut-outs made in inner hull and cofferdam bulkhead for their passage through the vertical webs are to be closed by collar plates welded to the inner hull or transverse bulkhead plating.

Where deemed necessary, adequate reinforcements are to be fitted in the double hull and transverse cofferdams at connection of the cargo containment system to the hull structure. Details of the connection are to be submitted to the Society for approval.

### **11.6 Ultimate design condition**

**11.6.1** *The structural resistance of every critical component, subsystem or assembly shall be established, in accordance with [11.1.3], for in-service conditions.*

**11.6.2** *The choice of strength acceptance criteria for the failure modes of the cargo containment system, its attachments to the hull structure and internal tank structures, shall reflect the consequences associated with the considered mode of failure.*

**11.6.3** *The inner hull scantlings shall meet the requirements for deep tanks, taking into account the internal pressure as indicated in [3.3.2] and the specified appropriate requirements for sloshing load as defined in [3.4.4].*

### **11.7 Fatigue design condition**

**11.7.1** *Fatigue analysis shall be carried out for structures inside the tank, i.e. pump towers, and for parts of membrane and pump tower attachments, where failure development cannot be reliably detected by continuous monitoring.*

**11.7.2** *The fatigue calculations shall be carried out in accordance with [4.6], with relevant requirements depending on:*

- the significance of the structural components with respect to structural integrity; and
- availability for inspection.

**11.7.3** *For structural elements for which it can be demonstrated by tests and/or analyses that a crack will not develop to cause simultaneous or cascading failure of both membranes,  $C_w$  shall be less than or equal to 0,5.*

**11.7.4** *Structural elements subject to periodic inspection, and where an unattended fatigue crack can develop to cause simultaneous or cascading failure of both membranes, shall satisfy the fatigue and fracture mechanics requirements stated in [4.6.8].*

**11.7.5** *Structural element not accessible for in-service inspection, and where a fatigue crack can develop without warning to cause simultaneous or cascading failure of both membranes, shall satisfy the fatigue and fracture mechanics requirements stated in [4.6.9].*

**11.7.6** At design stage, the fatigue assessment aims to ensure that critical details are adequately designed to reach at least the fatigue life required in [4.6.2]. The associated fatigue assessment methodology is based on S-N curve/cumulative damage approach as mentioned in [4.6.1].

Fatigue assessment may be performed either by means of S-N curve/cumulative damage approach at design stage or for life extension for example as stated in [4.6.1] or by means of fracture mechanics analysis for repair decision when cracks are detected as mentioned in [4.6.6] to [4.6.9].

**11.7.7** The following structural details are to be checked for fatigue:

- a) Singular point of metallic membrane:
  - knots, i.e. intersections between corrugations
  - corrugations or raised edges
  - end of corrugations or raised edges
- b) Attachment of primary and secondary barrier on:
  - the corners (dihedron and trihedron)
  - the cargo domes
  - the pump towers support
- c) Connection of the cargo dome with hull
- d) Cargo dome pipe penetrations
- e) Connection of the pump tower support with double bottom
- f) Structures of the pump tower

In case of specific arrangement, the Society may ask additional fatigue assessments for specific structural details not listed above.

**11.7.8** The S-N curves and the fracture mechanics material characteristics are to be validated by the Society for minimal temperature that the cargo containment system elements under consideration may reach for the corresponding materials.

**11.7.9** For the considered materials, the effects of corrosive environment on fatigue life are to be taken into account by means of:

- increase of stress in the considered detail due to thickness decrease induced by corrosion phenomenon
- decrease of fatigue strength

In general, for stainless steels and for aluminium alloys, no corrosion effect has to be considered for the fatigue strength.

**11.7.10** The fatigue phenomenon is normally divided in two different domains:

- high stress, low-cycle fatigue occurring for a low number of cycles, less than  $10^4$ , in the range of plastic deformations
- low stress, high-cycle fatigue occurring for a large number of cycles more than  $10^4$ , in the range of elastic deformations

As required in [4.6.3], the low and high cycles are to be considered for the fatigue life verification.

**11.7.11** The fatigue assessment of structural details at design stage is to be performed according to S-N curves approach.

Fatigue assessment is to be performed for structural details in order to prevent all the fatigue failure modes possibly occurring.

The stress assessment methods for each of these fatigue failure modes is to be agreed by the Society.

**11.7.12** The post-weld treatment of joints treated by grinding, TIG dressing or other local means are disregarded for reducing the fatigue damage.

**11.7.13** When designing the cold stamping of membrane parts, it is necessary to take into account the permanent plastic deformations arising in the material.

## **11.8 Accident design condition**

**11.8.1** *The containment system and the supporting hull structure shall be designed for the accidental loads specified in [3.5]. These loads need not be combined with each other or with environmental loads.*

**11.8.2** *Additional relevant accident scenarios shall be determined based on a risk analysis. Particular attention shall be paid to securing devices inside tanks.*

## 11.9 Design development testing

**11.9.1** The design development testing required in [11.1.3], shall include a series of analytical and physical models of both the primary and secondary barriers, including corners and joints, tested to verify that they will withstand the expected combined strains due to static, dynamic and thermal loads. This will culminate in the construction of a prototype-scaled model of the complete cargo containment system. Testing conditions considered in the analytical and physical models shall represent the most extreme service conditions the cargo containment system will be likely to encounter over its life. Proposed acceptance criteria for periodic testing of secondary barriers required in [2.4.3] may be based on the results of testing carried out on the prototype-scaled model.

**11.9.2** The fatigue performance of the membrane materials and representative welded or bonded joints in the membranes shall be determined by tests. The ultimate strength and fatigue performance of arrangements for securing the thermal insulation system to the hull structure shall be determined by analyses or tests.

## 11.10 Testing

**11.10.1** All tanks and other spaces that may normally contain liquid and are adjacent to the hull structure supporting the membrane, shall be hydrostatically tested.

**11.10.2** All hold structures supporting the membrane shall be tested for tightness before installation of the cargo containment system.

**11.10.3** Pipe tunnels and other compartments that do not normally contain liquid need not be hydrostatically tested.

**11.10.4** The testing of membrane tanks is to comply with the requirements in Pt B, Ch 13, Sec 6.

## 11.11 Certification of materials and products

**11.11.1** Material and products used in membrane cargo containment system are to be certified and tested according to the requirements of Tab 7.

**Table 7 : Certification of materials and products**

No.	Materials and Products	Product Certification			
		TA / DA	Raw material certificate	Examination and testing	Product Certificate
MEMBRANE CARGO CONTAINMENT SYSTEM WITH FOAM INSULATION IN GENERAL USE

## 12 Integral tanks

### 12.1 Design basis

**12.1.1** Integral tanks that form a structural part of the hull and are affected by the loads that stress the adjacent hull structure shall comply with the following:

- the design vapour pressure  $P_o$  as defined in [1.2.2] shall not normally exceed 0,025 MPa. If the hull scantlings are increased accordingly,  $P_o$  may be increased to a higher value, but less than 0,07 MPa
- integral tanks may be used for products, provided the boiling point of the cargo is not below  $-10^{\circ}\text{C}$ . A lower temperature may be accepted by the Society subject to special consideration, but in such cases a complete secondary barrier shall be provided; and
- products required by Ch 9, Sec 19 to be carried in type 1G ships shall not be carried in integral tanks.

### 12.2 Structural analysis

**12.2.1** The structural analysis of integral tanks shall be in accordance with recognized standards.

**12.2.2** The net scantlings of plating, ordinary stiffeners and primary supporting members of integral tanks are to be not less than those obtained from Part B, Chapter 7, where the hull girder loads and the internal pressure are to be calculated according to Part B, Chapter 5.

### 12.3 Ultimate design condition

**12.3.1** The tank boundary scantlings shall meet the requirements for deep tanks, taking into account the internal pressure as indicated in [3.3.2].

**12.3.2** For integral tanks, allowable stresses shall normally be those given for hull structure in the requirements of the Society.

### 12.4 Accident design condition

**12.4.1** The tanks and the tank supports shall be designed for the accidental loads specified in [2.1.4], item c) and [3.5], as relevant.

**12.4.2** When subjected to the accidental loads specified in [3.5] and [3.3.9], the stress shall comply with the acceptance criteria specified in [12.3], modified as appropriate, taking into account their lower probability of occurrence.

### 12.5 Testing

**12.5.1** All integral tanks shall be hydrostatically or hydropneumatically tested. The test shall be performed so that the stresses approximate, as far as practicable, to the design stresses and that the pressure at the top of the tank corresponds at least to the MARVS.

**12.5.2** The testing of integral tanks is to comply with the requirements in Pt B, Ch 13, Sec 6.

## 13 Semi-membrane tanks

### 13.1 Design basis

**13.1.1** Semi-membrane tanks are non-self-supporting tanks when in the loaded condition and consist of a layer, parts of which are supported through thermal insulation by the adjacent hull structure, whereas the rounded parts of this layer connecting the above-mentioned supported parts are designed also to accommodate the thermal and other expansion or contraction.

**13.1.2** The design vapour pressure  $P_o$  shall not normally exceed 0,025 MPa. If the hull scantlings are increased accordingly, and consideration is given, where appropriate, to the strength of the supporting thermal insulation,  $P_o$  may be increased to a higher value, but less than 0,07 MPa.

**13.1.3** For semi-membrane tanks the relevant requirements in this section for independent tanks or for membrane tanks shall be applied as appropriate.

**13.1.4** In the case of semi-membrane tanks that comply in all respects with the requirements applicable to type B independent tanks, except for the manner of support, the Society may, after special consideration, accept a partial secondary barrier.

## 14 Cargo containment systems of novel configuration

### 14.1 Limit state design for novel concepts

**14.1.1** Cargo containment systems that are of a novel configuration that cannot be designed using [8] to [13] shall be designed using this sub-article and Articles [2] and [3], and also Articles [4], [5] and [6] as applicable. Cargo containment system design according to this section shall be based on the principles of limit state design which is an approach to structural design that can be applied to established design solutions as well as novel designs. This more generic approach maintains a level of safety similar to that achieved for known containment systems as designed using [8] to [13].

**14.1.2** The limit state design is a systematic approach where each structural element is evaluated with respect to possible failure modes related to the design conditions identified in [2.1.4]. A limit state can be defined as a condition beyond which the structure, or part of a structure, no longer satisfies the requirements.

**14.1.3** For each failure mode, one or more limit states may be relevant. By consideration of all relevant limit states, the limit load for the structural element is found as the minimum limit load resulting from all the relevant limit states. The limit states are divided into the three following categories:

- Ultimate limit states (ULS), which correspond to the maximum load-carrying capacity or, in some cases, to the maximum applicable strain or deformation; under intact (undamaged) conditions.
- Fatigue limit states (FLS), which correspond to degradation due to the effect of time varying (cyclic) loading.
- Accident limit states (ALS), which concern the ability of the structure to resist accidental situations.

**14.1.4** The procedure and relevant design parameters of the limit state design shall comply with the Standards for the Use of limit state methodologies in the design of cargo containment systems of novel configuration (LSD Standard), as set out in Appendix 5 of the IGC Code.

**14.1.5** The testing of semi-membrane tanks is to comply with the requirements in Pt B, Ch 13, Sec 6.

# Section 5 Process Pressure Vessels and Liquid, Vapour and Pressure Piping Systems

## 1 General

### 1.1

**1.1.1** *The requirements of this Section shall apply to products and process piping, including vapour piping, gas fuel piping and vent lines of safety valves or similar piping. Auxiliary piping systems not containing cargo are exempt from the general requirements of this Section.*

**1.1.2** Cargo and process pipings have to comply with the applicable requirements of Pt C, Ch 1, Sec 10 for class I pressure piping, unless otherwise specified in IGC Code or in the present Article.

**1.1.3** *The requirements for type C independent tanks provided in Ch 9, Sec 4 may also apply to process pressure vessels. If so required, the term "pressure vessels" as used in Ch 9, Sec 4, covers both type C independent tanks and process pressure vessels.*

**1.1.4** *Process pressure vessels include surge tanks, heat exchangers and accumulators that store or treat liquid or vapour cargo.*

**1.1.5** Process pressure vessels handling cargo are to be considered as class 1 pressure vessels, in accordance with Pt C, Ch 1, Sec 3, [1.4.1].

## 2 System requirements

### 2.1

**2.1.1** The connections, if any, to the cargo tanks of relief valve discharges fitted on the liquid phase cargo piping are not to be fitted with shut-off valves, but are to be provided with non-return valves in the proximity of the tanks.

**2.1.2** Overpressure relief valves on cargo pumps may be omitted in the case of centrifugal pumps having a maximum delivery head, the delivery valve being completely closed, not greater than that permitted for the piping.

**2.1.3** *The cargo handling and cargo control systems shall be designed taking into account the following:*

- *prevention of an abnormal condition escalating to a release of liquid or vapour cargo*
- *the safe collection and disposal of cargo fluids released*
- *prevention of the formation of flammable mixtures*
- *prevention of ignition of flammable liquids or gases and vapours released, and*
- *limiting the exposure of personnel to fire and other hazards.*

### 2.2 Arrangements: General

**2.2.1** *Any piping system that may contain cargo liquid or vapour shall:*

- *be segregated from other piping systems, except where interconnections are required for cargo-related operations such as purging, gas-freeing or inerting. The requirements of Ch 9, Sec 9, [1.4.5] shall be taken into account with regard to preventing back-flow of cargo. In such cases, precautions shall be taken to ensure that cargo or cargo vapour cannot enter other piping systems through the interconnections*
- *except as provided in Ch 9, Sec 16, not pass through any accommodation space, service space or control station or through a machinery space other than a cargo machinery space*
- *be connected to the cargo containment system directly from the weather decks except where pipes installed in a vertical trunkway or equivalent are used to traverse void spaces above a cargo containment system and except where pipes for drainage, venting or purging traverse cofferdams*
- *be located in the cargo area above the weather deck except for bow or stern loading and unloading arrangements in accordance with Ch 9, Sec 3, [1.8], emergency cargo jettisoning piping systems in accordance with [3.1], turret compartment systems in accordance with [3.3] and except in accordance with Ch 9, Sec 16, and*
- *be located inboard of the transverse tank location requirements of Ch 9, Sec 2, [4.1.1], except for athwartship shore connection piping not subject to internal pressure at sea or emergency cargo jettisoning piping systems.*

**2.2.2** *Suitable means shall be provided to relieve the pressure and remove liquid cargo from loading and discharging crossover headers; likewise, any piping between the outermost manifold valves and loading arms or cargo hoses to the cargo tanks, or other suitable location, prior to disconnection.*

**2.2.3** Piping systems carrying fluids for direct heating or cooling of cargo shall not be led outside the cargo area unless a suitable means is provided to prevent or detect the migration of cargo vapour outside the cargo area (see Ch 9, Sec 13, [6.1.2], item f)).

**2.2.4** Relief valves discharging liquid cargo from the piping system shall discharge into the cargo tanks. Alternatively, they may discharge to the cargo vent mast, if means are provided to detect and dispose of any liquid cargo that may flow into the vent system. Where required to prevent overpressure in downstream piping, relief valves on cargo pumps shall discharge to the pump suction.

### **3 Arrangements for cargo piping outside the cargo area**

#### **3.1 Emergency cargo jettisoning**

**3.1.1** If fitted, an emergency cargo jettisoning piping system shall comply with [2.2], as appropriate, and may be led aft, external to accommodation spaces, service spaces or control stations or machinery spaces, but shall not pass through them. If an emergency cargo jettisoning piping system is permanently installed, a suitable means of isolating the piping system from the cargo piping shall be provided within the cargo area.

#### **3.2 Bow and stern loading arrangements**

**3.2.1** Subject to the requirements of Ch 9, Sec 3, [1.8], this sub-article and [10.1], cargo piping may be arranged to permit bow or stern loading and unloading.

**3.2.2** Arrangements shall be made to allow such piping to be purged and gas-freed after use. When not in use, the spool pieces shall be removed and the pipe ends blank-flanged. The vent pipes connected with the purge shall be located in the cargo area.

#### **3.3 Turret compartment transfer systems**

**3.3.1** For the transfer of liquid or vapour cargo through an internal turret arrangement located outside the cargo area, the piping serving this purpose shall comply with [2.2], as applicable, [10.2] and the following:

- a) piping shall be located above the weather deck, except for the connection to the turret
- b) portable arrangements shall not be permitted, and
- c) arrangements shall be made to allow such piping to be purged and gas-freed after use. When not in use, the spool pieces for isolation from the cargo piping shall be removed and the pipe ends blank-flanged. The vent pipes connected with the purge shall be located in the cargo area.

#### **3.4 Gas fuel piping systems**

**3.4.1** Gas fuel piping in machinery spaces shall comply with all applicable requirements of this Section in addition to the requirements of Ch 9, Sec 16.

### **4 Design pressure**

#### **4.1**

**4.1.1** The design pressure  $P_o$ , used to determine minimum scantlings of piping and piping system components, shall be not less than the maximum gauge pressure to which the system may be subjected in service. The minimum design pressure used shall not be less than 1 MPa gauge, except for open-ended lines or pressure relief valve discharge lines, where it shall be not less than the lower of 0,5 MPa gauge, or 10 times the relief valve set pressure.

**4.1.2** The greater of the following design conditions shall be used for piping, piping systems and components, based on the cargoes being carried:

- for vapour piping systems or components that may be separated from their relief valves and which may contain some liquid, the saturated vapour pressure at a design temperature of 45°C. Higher or lower values may be used (see Ch 9, Sec 4, [3.3.2], item b)), or
- for systems or components that may be separated from their relief valves and which contain only vapour at all times, the superheated vapour pressure at 45°C. Higher or lower values may be used (see Ch 9, Sec 4, [3.3.2], item b)), assuming an initial condition of saturated vapour in the system at the system operating pressure and temperature, or
- the MARVS of the cargo tanks and cargo processing systems, or
- the pressure setting of the associated pump or compressor discharge relief valve, or
- the maximum total discharge or loading head of the cargo piping system considering all possible pumping arrangements or the relief valve setting on a pipeline system.

Note 1: For each piping section, the maximum pressure value among those applicable in paragraph above is to be considered.

**4.1.3** Those parts of the liquid piping systems that may be subjected to surge pressures shall be designed to withstand this pressure and relevant justifications are to be submitted.

**4.1.4** The design pressure of the outer pipe or duct of gas fuel systems shall not be less than the maximum working pressure of the inner gas pipe. Alternatively, for gas fuel piping systems with a working pressure greater than 1 MPa, the design pressure of the outer duct shall not be less than the maximum built-up pressure arising in the annular space considering the local instantaneous peak pressure in way of any rupture and the ventilation arrangements.

The design pressure of the outer pipe or duct is either of the following:

- the maximum pressure that can act on the outer pipe or equipment enclosure after the inner pipe rupture as documented by suitable calculations taking into account the venting arrangements; or
- for gas fuel systems with inner pipe working pressure greater than 1 Mpa, the “maximum built-up pressure arising in the annular space”, after the inner pipe rupture, which is to be calculated in accordance with [4.1.5].

The expression “duct” means to include the equipment enclosure required in Ch 9, Sec 16, [4.3] (e.g. GUV enclosure) as well as the structural pipe duct intended to contain any release of gas from inner pipe or equipment. The term “structural pipe duct” means an outer duct forming part of a structure such as a hull structure or superstructure or deck house, where permitted, other than gas valve unit rooms.

**4.1.5** For high-pressure piping the design pressure of the ducting is to be taken as the higher of the following:

- a) the maximum built up pressure:
  - Static pressure in way of the rupture resulting from the gas flowing in the annular space
- b) local instantaneous peak pressure in way of the rupture:
  - This pressure is to be taken as the critical pressure and is given by the following expression:

$$p^* = p_0 \left( \frac{2}{k+1} \right)^{\frac{k}{k-1}}$$

with:

- $p_0$  : Maximum working pressure of the inner pipe
- $k$  : Constant pressure specific heat divided by the constant volume specific heat:  
 $k = C_p / C_v$   
 $k = 1,31$  for  $CH_4$

The tangential membrane stress of a straight pipe is not to exceed the tensile strength divided by 1,5 ( $R_m / 1,5$ ) when subjected to the above pressure. The pressure ratings of all other piping components are to reflect the same level of strength as straight pipes.

As an alternative to using the peak pressure from the above formula, the peak pressure found from representative tests can be used. Test reports must then be submitted.

## 5 Cargo system valve requirements

### 5.1

**5.1.1** Every cargo tank and piping system shall be fitted with manually operated valves for isolation purposes as specified in this Article.

In addition, remotely operated valves shall also be fitted, as appropriate, as part of the emergency shutdown (ESD) system the purpose of which is to stop cargo flow or leakage in the event of an emergency when cargo liquid or vapour transfer is in progress. The ESD system is intended to return the cargo system to a safe static condition so that any remedial action can be taken. Due regard shall be given in the design of the ESD system to avoid the generation of surge pressures within the cargo transfer pipework. The equipment to be shut down on ESD activation includes manifold valves during loading or discharge, any pump or compressor, etc., transferring cargo internally or externally (e.g. to shore or another ship/barge) and cargo tank valves, if the MARVS exceeds 0,07 MPa.

#### 5.1.2 Cargo tank connections

All liquid and vapour connections, except for safety relief valves and liquid level gauging devices, shall have shutoff valves located as close to the tank as practicable. These valves shall provide full closure and shall be capable of local manual operation. They may also be capable of remote operation.

For cargo tanks with a MARVS exceeding 0,07 MPa gauge, the above connections shall also be equipped with remotely controlled ESD valves. These valves shall be located as close to the tank as practicable. A single valve may be substituted for the two separate valves, provided the valve complies with the requirements of Ch 9, Sec 18, [3.2] and provides full closure of the line.

### 5.2 Cargo manifold connections

**5.2.1** One remotely controlled ESD valve shall be provided at each cargo transfer connection in use to stop liquid and vapour transfer to or from the ship. Transfer connections not in use shall be isolated with suitable blank flanges.

**5.2.2** If the cargo tank MARVS exceeds 0,07 MPa, an additional manual valve shall be provided for each transfer connection in use, and may be inboard or outboard of the ESD valve to suit the ship's design.

### **5.3**

**5.3.1** Excess flow valves may be used in lieu of ESD valves, if the diameter of the protected pipe does not exceed 50 mm. Excess flow valves shall close automatically at the rated closing flow of vapour or liquid as specified by the manufacturer. The piping including fittings, valves and appurtenances protected by an excess flow valve shall have a capacity greater than the rated closing flow of the excess flow valve. Excess flow valves may be designed with a bypass not exceeding the area of a 1 mm diameter circular opening to allow equalization of pressure after a shutdown activation.

**5.3.2** Cargo tank connections for gauging or measuring devices need not be equipped with excess flow valves or ESD valves, provided that the devices are constructed so that the outward flow of tank contents cannot exceed that passed by a 1,5 mm diameter circular hole.

In case of tanks with an MARVS not exceeding 0.07 MPa, the outward flow of tank contents can exceed that passed by a 1,5 mm diameter circular hole.

**5.3.3** All pipelines or components which may be isolated in a liquid full condition shall be protected with relief valves for thermal expansion and evaporation.

Note 1: For pipe sections that would be closed by ESD system, a fire scenario is to be considered for sizing, as defined in [5.3.4].

**5.3.4** All pipelines or components which may be isolated automatically due to a fire with a liquid volume of more than 0,05 m<sup>3</sup> entrapped shall be provided with PRVs sized for a fire condition.

**5.3.5** Pressure relief valves are to be set to discharge at a pressure not greater than the design pressure such that the overpressure during discharge does not exceed 110% of the design pressure, as defined in Ch 9, Sec 8.

## **6 Cargo transfer arrangements**

### **6.1 General**

**6.1.1** When two or more pumps located in different cargo tanks are operating at the same time discharging into a common header, the stopping of the pumps is to activate an alarm at the centralised cargo control location.

**6.1.2** Where cargo transfer is by means of cargo pumps that are not accessible for repair with the tanks in service, at least two separate means shall be provided to transfer cargo from each cargo tank, and the design shall be such that failure of one cargo pump or means of transfer will not prevent the cargo transfer by another pump or pumps, or other cargo transfer means.

**6.1.3** The procedure for transfer of cargo by gas pressurization shall preclude lifting of the relief valves during such transfer. Gas pressurization may be accepted as a means of transfer of cargo for those tanks where the design factor of safety is not reduced under the conditions prevailing during the cargo transfer operation. If the cargo tank relief valves or set pressure are changed for this purpose, as it is permitted in accordance with Ch 9, Sec 8, [2.1.9] and Ch 9, Sec 8, [2.1.10], the new set pressure shall not exceed  $P_h$  as is defined in Ch 9, Sec 4, [3.3.2].

### **6.2 Vapour return connections**

**6.2.1** Connections for vapour return to the shore installations shall be provided.

### **6.3 Cargo tank vent piping systems**

**6.3.1** The pressure relief system shall be connected to a vent piping system designed to minimize the possibility of cargo vapour accumulating on the decks, or entering accommodation spaces, service spaces, control stations and machinery spaces, or other spaces where it may create a dangerous condition.

### **6.4 Cargo sampling connections**

**6.4.1** Connections to cargo piping systems for taking cargo liquid samples shall be clearly marked and shall be designed to minimize the release of cargo vapours. For vessels permitted to carry toxic products, the sampling system shall be of a closed loop design to ensure that cargo liquid and vapour are not vented to atmosphere.

Note 1: These requirements are only applicable if such a sampling system is fitted on board. Connections used for control of atmosphere in cargo tanks during inerting or gassing up are not considered as cargo sampling connections.

**6.4.2** Liquid sampling systems shall be provided with two valves on the sample inlet. One of these valves shall be of the multi-turn type to avoid accidental opening, and shall be spaced far enough apart to ensure that they can isolate the line if there is blockage, by ice or hydrates for example.

**6.4.3** On closed loop systems, the valves on the return pipe shall also comply with [6.4.2].

**6.4.4** The connection to the sample container shall comply with recognized standards and be supported so as to be able to support the weight of a sample container. Threaded connections shall be tack-welded, or otherwise locked, to prevent them

being unscrewed during the normal connection and disconnection of sample containers. The sample connection shall be fitted with a closure plug or flange to prevent any leakage when the connection is not in use.

**6.4.5** Sample connections used only for vapour samples may be fitted with a single valve in accordance with Articles [5], [8] and [13], and shall also be fitted with a closure plug or flange.

**6.4.6** Sampling operations shall be undertaken as prescribed in IGC Code, Chapter 18, [18.9].

## **6.5 Cargo filters**

**6.5.1** The cargo liquid and vapour systems shall be capable of being fitted with filters to protect against damage by extraneous objects. Such filters may be permanent or temporary, and the standards of filtration shall be appropriate to the risk of debris, etc., entering the cargo system. Means shall be provided to indicate that filters are becoming blocked, and to isolate, depressurize and clean the filters safely.

Means to indicate that filters are becoming blocked and filter maintenance is required is to be provided for fixed in-line filter arrangement and portable filter installations where dedicated filter housing piping is provided.

Where portable filters for fitting to manifold presentation flanges are used without dedicated filter housing, and these can be visually inspected after each loading and discharging operation, no additional arrangements for indicating blockage or facilitating drainage are required.

## **7 Installation requirements**

### **7.1 Design for expansion and contraction**

**7.1.1** Provision shall be made to protect the piping, piping system and components and cargo tanks from excessive stresses due to thermal movement and from movements of the tank and hull structure. The preferred method outside the cargo tanks is by means of offsets, bends or loops, but multi-layer bellows may be used if offsets, bends or loops are not practicable.

### **7.2 Precautions against low temperature**

**7.2.1** Low temperature piping shall be thermally isolated from the adjacent hull structure, where necessary, to prevent the temperature of the hull from falling below the design temperature of the hull material. Where liquid piping is dismantled regularly, or where liquid leakage may be anticipated, such as at shore connections and at pump seals, protection for the hull beneath shall be provided.

**7.2.2** Where the piping system is intended for liquids having a boiling point lower than 30°C, permanent means to avoid possibility of contact between leaks and hull structures are to be provided in all those locations where leakage might be expected, such as shore connections, pump seals, flanges subject to frequent dismantling, etc.

**7.2.3** The means to detect the presence of liquid cargo may be constituted by electrical level switches whose circuit is intrinsically safe. The alarm signals given by the level switches are to be transmitted to the wheelhouse and to the cargo control station, if provided.

**7.2.4** High temperature pipes are to be thermally isolated from the adjacent structures. In particular, the temperature of pipelines is not to exceed 220°C in gas-dangerous zones.

### **7.3 Water curtain**

**7.3.1** For cargo temperatures below -110°C, a water distribution system shall be fitted in way of the hull under the shore connections to provide a low-pressure water curtain for additional protection of the hull steel and the ship's side structure. This system is in addition to the requirements of Ch 9, Sec 11, [1.3.2], d), and shall be operated when cargo transfer is in progress.

Note 1: The flow is to be the same as required for water spray system defined in Ch 9, Sec 11.

### **7.4 Bonding**

**7.4.1** Where tanks or cargo piping and piping equipment are separated from the ship's structure by thermal isolation, provision shall be made for electrically bonding both the piping and the tanks. All gasketed pipe joints and hose connections shall be electrically bonded. Except where bonding straps are used, it shall be demonstrated that the electrical resistance of each joint or connection is less than 1MΩ.

**7.4.2** Bonding straps are required for cargo and slop tanks, piping systems and equipment which are not permanently connected to the hull of the ship, for example:

- a) independent cargo tanks
- b) cargo tank piping systems which are electrically separated from the hull of the ship
- c) pipe connections arranged for the removal of the spool pieces.

Where bonding straps are required, they are to be:

- a) clearly visible so that any shortcoming can be clearly detected
- b) designed and sited so that they are protected against mechanical damage and are not affected by high resistivity contamination, e.g. corrosive products or paint
- c) easy to install and replace.

## **8 Piping fabrication and joining details**

### **8.1 General**

**8.1.1** *The requirements of this Article apply to piping inside and outside the cargo tanks. Relaxation from these requirements may be accepted, in accordance with recognized standards for piping inside cargo tanks and open-ended piping.*

### **8.2 Direct connections**

**8.2.1** *The following direct connection of pipe lengths, without flanges, may be considered:*

- *butt-welded joints with complete penetration at the root may be used in all applications. For design temperatures colder than  $-10^{\circ}\text{C}$ , butt welds shall be either double welded or equivalent to a double welded butt joint. This may be accomplished by use of a backing ring, consumable insert or inert gas backup on the first pass. For design pressures in excess of 1 MPa and design temperatures of  $-10^{\circ}\text{C}$  or colder, backing rings shall be removed*
- *slip-on welded joints with sleeves and related welding, having dimensions in accordance with recognized standards, shall only be used for instrument lines and open-ended lines with an external diameter of 50 mm or less and design temperatures not colder than  $-55^{\circ}\text{C}$ , and*
- *screwed couplings complying with recognized standards shall only be used for accessory lines and instrumentation lines with external diameters of 25 mm or less.*

### **8.3 Flanged connections**

**8.3.1** *Flanges in flanged connections shall be of the welded neck, slip-on or socket welded type.*

**8.3.2** *Flanges shall comply with recognized standards for their type, manufacture and test. For all piping, except open ended, the following restrictions apply:*

- *for design temperatures colder than  $-55^{\circ}\text{C}$ , only welded-neck flanges shall be used, and*
- *for design temperatures colder than  $-10^{\circ}\text{C}$ , slip-on flanges shall not be used in nominal sizes above 100 mm and socket welded flanges shall not be used in nominal sizes above 50 mm.*

### **8.4 Expansion joints**

**8.4.1** *Where bellows and expansion joints are provided in accordance with [7.1], the following requirements apply:*

- *if necessary, bellows shall be protected against icing, and*
- *slip joints shall not be used except within the cargo tanks.*

### **8.5 Other connections**

**8.5.1** *Piping connections shall be joined in accordance with [8.2] to [8.4], but for other exceptional cases the Society may consider alternative arrangements.*

## **9 Welding, post-weld heat treatment and non-destructive testing**

### **9.1 General**

**9.1.1** *Welding shall be carried out in accordance with Ch 9, Sec 6, [5].*

### **9.2 Post-weld heat treatment**

**9.2.1** *Post-weld heat treatment shall be required for all butt welds of pipes made with carbon, carbon-manganese and low alloy steels. The Society may waive the requirements for thermal stress relieving of pipes with wall thickness less than 10 mm in relation to the design temperature and pressure of the piping system concerned.*

### 9.3 Non-destructive testing

**9.3.1** In addition to normal controls before and during the welding, and to the visual inspection of the finished welds, as necessary for proving that the welding has been carried out correctly and according to the requirements of this Article, the following tests shall be required:

- a) 100% radiographic or ultrasonic inspection of butt-welded joints for piping systems with design temperatures colder than – 10°C, and with inside diameters of more than 75 mm, or wall thicknesses greater than 10 mm
- b) when such butt-welded joints of piping sections are made by automatic welding procedures approved by the Society, then a progressive reduction in the extent of radiographic or ultrasonic inspection can be agreed, but in no case to less than 10% of each joint. If defects are revealed, the extent of examination shall be increased to 100% and shall include inspection of previously accepted welds. This approval can only be granted if well-documented quality assurance procedures and records are available to assess the ability of the manufacturer to produce satisfactory welds consistently, and
- c) for other butt-welded joints of pipes not covered by items a) and b), spot radiographic or ultrasonic inspection or other non-destructive tests shall be carried out depending upon service, position and materials. In general, at least 10% of butt-welded joints of pipes shall be subjected to radiographic or ultrasonic inspection.

## 10 Installation requirements for cargo piping outside the cargo area

### 10.1 Bow and stern loading arrangements

**10.1.1** The following requirements shall apply to cargo piping and related piping equipment located outside the cargo area:

- cargo piping and related piping equipment outside the cargo area shall have only welded connections. The piping outside the cargo area shall run on the weather decks and shall be at least 0,8 m inboard, except for athwartships shore connection piping. Such piping shall be clearly identified and fitted with a shutoff valve at its connection to the cargo piping system within the cargo area. At this location, it shall also be capable of being separated by means of a removable spool piece and blank flanges, when not in use, and
- the piping shall be full penetration butt-welded and subjected to full radiographic or ultrasonic inspection, regardless of pipe diameter and design temperature. Flange connections in the piping shall only be permitted within the cargo area and at the shore connection.

### 10.2 Turret compartment transfer systems

**10.2.1** The following requirements shall apply to liquid and vapour cargo piping where it is run outside the cargo area:

- cargo piping and related piping equipment outside the cargo area shall have only welded connections, and
- the piping shall be full penetration butt-welded, and subjected to full radiographic or ultrasonic inspection, regardless of pipe diameter and design temperature. Flange connections in the piping shall only be permitted within the cargo area and at connections to cargo hoses and the turret connection.

### 10.3 Gas fuel piping

**10.3.1** Gas fuel piping, as far as practicable, shall have welded joints. Those parts of the gas fuel piping that are not enclosed in a ventilated pipe or duct according to Ch 9, Sec 16, [4.3], and are on the weather decks outside the cargo area, shall have full penetration butt-welded joints and shall be subjected to full radiographic or ultrasonic inspection.

## 11 Piping system component requirements

### 11.1 General

**11.1.1** Piping systems shall be designed in accordance with recognized standards.

### 11.2 Piping scantlings

**11.2.1** The following criteria shall be used for determining pipe wall thickness.

**11.2.2** The wall thickness of pipes  $t$ , in mm, shall not be less than:

$$t = \frac{t_0 + b + c}{1 - \frac{a}{100}}$$

where:

$t_0$  : Theoretical thickness, in mm, determined by the following formula:

$$t_0 = \frac{P \cdot D}{2K \cdot e + P}$$

with:

- $P$  : Design pressure, in MPa, referred to in Article [4]
- $D$  : Outside diameter, in mm
- $K$  : Allowable stress, in N/mm<sup>2</sup>, referred to in [11.3]
- $e$  : Efficiency factor equal to 1 for seamless pipes and for longitudinally or spirally welded pipes, delivered by approved manufacturers of welded pipes, that are considered equivalent to seamless pipes when non-destructive testing on welds is carried out in accordance with recognized standards. In other cases, an efficiency factor of less than 1, in accordance with recognized standards, may be required, depending on the manufacturing process
- $b$  : Allowance for bending, in mm. The value of  $b$  shall be chosen so that the calculated stress in the bend, due to internal pressure only, does not exceed the allowable stress. Where such justification is not given,  $b$  shall be:
- $$b = \frac{D \cdot t_o}{2,5r}$$
- with:
- $r$  : Mean radius of the bend, in mm
- $c$  : Corrosion allowance, in mm. If corrosion or erosion is expected, the wall thickness of the piping shall be increased over that required by other design requirements. This allowance shall be consistent with the expected life of the piping
- $a$  : Negative manufacturing tolerance for thickness, in %.

### 11.2.3 Piping subject to green seas

In particular for piping subject to green seas, the design pressure  $P$  in the formula in [4.1] is to be replaced by an equivalent pressure  $P'$  given by the following formula:

$$P' = \frac{1}{2} \left( P + \sqrt{P^2 + 6R'K \frac{D_c}{D}} \right)$$

where:

- $K$  : Allowable stress, in MPa.  
 $K$  is to be the lower of  $(R/2,7)$  and  $(R_e/1,8)$ ,  
 where:  
 $R$  : Specified minimum tensile strength at room temperature, in MPa  
 $R_e$  : Specified lower minimum yield stress or 0,2% yield stress at room temperature, in MPa
- $D$  : External diameter of the pipe, in mm
- $D_c$  : External diameter of the pipe taking into account the insulation (in mm), whose thickness is to be taken at least equal to:  
 40 mm if  $D \leq 50$  mm  
 80 mm if  $D \geq 150$  mm  
 Intermediate values are to be determined by interpolation.
- $R'$  : Drag corresponding to the effect of green seas, in MPa, such as given in Tab 1 as a function of the location of the pipes and of their height  $H$  (in m) above the deepest loadline; intermediate values are to be determined by interpolation.

**11.2.4** The minimum wall thickness shall be in accordance with recognized standards.

**11.2.5** Where necessary for mechanical strength to prevent damage, collapse, excessive sag or buckling of pipes due to superimposed loads, the wall thickness shall be increased over that required by [11.2.2] or, if this is impracticable or would cause excessive local stresses, these loads may be reduced, protected against or eliminated by other design methods. Such superimposed loads may be due to: supporting structures, ship deflections, liquid pressure surge during transfer operations, the weight of suspended valves, reaction to loading arm connections, or otherwise.

## 11.3 Allowable stress

**11.3.1** For pipes, the allowable stress  $K$  referred to in the formula in [11.2] is the lower of the following values:

$$\frac{R_m}{A} \text{ or } \frac{R_e}{B}$$

where:

- $R_m$  : Specified minimum tensile strength at room temperature, in N/mm<sup>2</sup>
- $R_e$  : Specified minimum yield stress at room temperature, in N/mm<sup>2</sup>. If the stress-strain curve does not show a defined yield stress, the 0,2% proof stress applies.

The values of  $A$  and  $B$  shall be shown on the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk, and have values of at least  $A = 2,7$  and  $B = 1,8$ .

### 11.4 High-pressure gas fuel outer pipes or ducting scantlings

11.4.1 In fuel gas piping systems of design pressure greater than the critical pressure, the tangential membrane stress of a straight section of pipe or ducting shall not exceed the tensile strength divided by 1,5 ( $R_m/1,5$ ) when subjected to the design pressure specified in Article [4]. The pressure ratings of all other piping components shall reflect the same level of strength as straight pipes.

### 11.5 Stress analysis

11.5.1 When the design temperature is  $-110^\circ\text{C}$  or lower, a complete stress analysis, taking into account all the stresses due to the weight of pipes, including acceleration loads if significant, internal pressure, thermal contraction and loads induced by hog and sag of the ship for each branch of the piping system shall be submitted to the Society. For temperatures above  $-110^\circ\text{C}$ , a stress analysis may be required by the Society in relation to such matters as the design or stiffness of the piping system and the choice of materials. In any case, consideration shall be given to thermal stresses even though calculations are not submitted. The analysis may be carried out according to a code of practice acceptable to the Society.

11.5.2 When such an analysis is required, it is to be carried out in accordance with the requirements listed below. Subject to this condition, calculations in accordance with recognised standards are admitted by the Society.

11.5.3 The calculations are to be made for every possible case of operation, but only those leading to the most unfavourable results are required to be submitted.

**Table 1 : Drag R' corresponding to the effect of green seas (in MPa)**

External diameter of pipe (1)	Aft of the quarter of the ship's length			Forward of the quarter of the ship's length		
	H ≤ 8	H = 13	H ≥ 18	H ≤ 8	H = 13	H ≥ 18
≤ 25	0,015	0,0025	0,0015	0,022	0,0035	0,0015
50	0,014	0,0025	0,0015	0,020	0,0035	0,0015
75	0,011	0,0025	0,0015	0,016	0,0035	0,0015
100	0,007	0,0025	0,0015	0,007	0,0035	0,0015
≥150	0,005	0,0025	0,0015	0,007	0,0035	0,0015

(1)  $D_c$  if the pipe is insulated, D otherwise.

### 11.5.4 Loads to be taken for calculation

The calculations are to be carried out taking into account the following loads:

- a) piping not subject to green seas:
  - pressure
  - weight of the piping with insulation and of the internal fluid
  - contraction
- b) piping subject to green seas that is liable to be in operation at sea and in port:
  - pressure
  - weight of the piping with insulation and of the internal fluid
  - green seas
  - contraction
  - ship motion accelerations
- c) piping subject to green seas that is in operation only in port; the more severe of the following two combinations of loads:
  - pressure
  - weight of the piping with insulation and of the internal fluid
  - contraction
 and
  - weight of the piping with insulation
  - green seas
  - expansion, assuming that the thermal stresses are fully relaxed.

### 11.5.5 Green sea directions

When green seas are considered, their effects are to be studied, unless otherwise justified, in the following three directions:

- axis of the ship
- vertical
- horizontal, perpendicular to the axis of the ship. The load on the pipes is the load R' defined in [11.2.3].

### 11.5.6 Stress intensity

The stress intensity is to be determined as specified in the formulae in Pt C, Ch 1, Sec 10, [2.3.2] for pipes intended for high temperatures:

- a) for primary stresses resulting from:
  - pressure
  - weight
  - green seas
- b) for primary stresses and secondary stresses resulting from contraction.

### 11.5.7 Stress intensity limits

- a) For the first case, the stress intensity is to be limited to the lower of:  
 $0,8 R_e$  and  $0,4 R_m$
- b) For the second case, the stress intensity is to be limited to the lower of:  
 $1,6 R_e$  and  $0,8 R_m$ .

### 11.5.8 Piping with expansion devices

For piping fitted with expansion devices, their characteristics are to be submitted to the Society. Where these characteristics are such that the forces and moments at the ends of the devices are negligible for the contraction they must absorb, the calculation of the loads due to contraction in the corresponding piping is not required. It is, however, to be checked that the stress intensity corresponding to the primary stresses does not exceed the limits given in [11.5.7].

### 11.5.9 Flexibility coefficient

The flexibility coefficient of elbows is to be determined from the formulae given in Pt C, Ch 1, Sec 10, [2.3.2] for pipes intended for high temperatures.

### 11.5.10 Local stresses

Particular attention is to be paid to the calculation of local stresses in the assemblies subjected to axial forces and bending moments. The Society reserves the right to request additional justifications or local strengthening where considered necessary.

## 11.6 Flanges, valves and fittings

**11.6.1** *Flanges, valves and other fittings shall comply with recognized standards, taking into account the material selected and the design pressure defined in Article [4]. For bellows expansion joints used in vapour service, a lower minimum design pressure may be accepted.*

**11.6.2** *For flanges not complying with a recognized standard, the dimensions of flanges and related bolts shall be to the satisfaction of the Society.*

**11.6.3** For flanges not complying with a standard, the dimensions and type of gaskets are to be to the satisfaction of the Society.

**11.6.4** *All emergency shutdown valves shall be of the "fail-closed" type (see [13.3.1] and Ch 9, Sec 18, [3.2]), i.e. emergency shutdown valves are to close automatically in case of fire (due to loss of actuating power).*

**11.6.5** *The design and installation of expansion bellows shall be in accordance with recognized standards and be fitted with means to prevent damage due to over-extension or compression.*

**11.6.6** Expansion joints are to be protected from extensions and compressions greater than the limits fixed for them and the connected piping is to be suitably supported and anchored. Bellow expansion joints are to be protected from mechanical damage.

## 11.7 Ship's cargo hoses

**11.7.1** Ship's cargo hoses are to be type approved by the Society.

**11.7.2** All hoses are to be tested at the plant of manufacturer in the presence of the Surveyor. An alternative survey scheme, BV Mode I as per NR320, may be agreed with the Society.

**11.7.3** *Liquid and vapour hoses used for cargo transfer shall be compatible with the cargo and suitable for the cargo temperature.*

**11.7.4** *Hoses subject to tank pressure, or the discharge pressure of pumps or vapour compressors, shall be designed for a bursting pressure not less than five times the maximum pressure the hose will be subjected to during cargo transfer.*

**11.7.5** *Each new type of cargo hose, complete with end-fittings, shall be prototype-tested at a normal ambient temperature, with 200 pressure cycles from zero to at least twice the specified maximum working pressure. After this cycle pressure test has been carried out, the prototype test shall demonstrate a bursting pressure of at least 5 times its specified maximum working pressure at the upper and lower extreme service temperature. Hoses used for prototype testing shall not be used for cargo service.*

Thereafter, before being placed in service, each new length of cargo hose produced shall be hydrostatically tested at ambient temperature to a pressure not less than 1,5 times its specified maximum working pressure, but not more than two fifths of its bursting pressure. The hose shall be stencilled, or otherwise marked, with the date of testing, its specified maximum working pressure and, if used in services other than ambient temperature services, its maximum and minimum service temperature, as applicable. The specified maximum working pressure shall not be less than 1 MPa gauge.

## **12 Materials**

### **12.1**

**12.1.1** The choice and testing of materials used in piping systems shall comply with the requirements of Ch 9, Sec 6, taking into account the minimum design temperature. However, some relaxation may be permitted in the quality of material of open-ended vent piping, provided that the temperature of the cargo at the pressure relief valve setting is not lower than  $-55^{\circ}\text{C}$ , and that no liquid discharge to the vent piping can occur. Similar relaxations may be permitted under the same temperature conditions to open-ended piping inside cargo tanks, excluding discharge piping and all piping inside membrane and semi-membrane tanks.

**12.1.2** Materials having a melting point below  $925^{\circ}\text{C}$  shall not be used for piping outside the cargo tanks except for short lengths of pipes attached to the cargo tanks, in which case fire-resisting insulation shall be provided.

**12.1.3** Aluminised pipes may be fitted in ballast tanks, in inerted cargo tanks and, provided the pipes are protected from accidental impact, in hazardous areas on open deck.

Note 1: The paragraph [12.1.2] of the Revised IGC Code does not apply to valves installed on cargo lines or gas supply machinery.

The valve use of Teflon or PTFE will only be allowed if the valve is tested in fire and Teflon (or PTFE) can only be used for internal seals of the valve.

#### **12.1.4 Cargo piping insulation system**

Cargo piping systems shall be provided with a thermal insulation system as required to minimize heat leak into the cargo during transfer operations and to protect personnel from direct contact with cold surfaces.

Where applicable, due to location or environmental conditions, insulation materials shall have suitable properties of resistance to fire and flame spread and shall be adequately protected against penetration of water vapour and mechanical damage.

Note 1: The expression "a thermal insulation system as required to minimize heat leak into the cargo during transfer operations" means that properties of the piping insulation are to be taken into consideration when calculating the heat balance of the containment system and capacity of the pressure/temperature control system.

Note 2: The expression "cargo piping systems shall be provided with a thermal insulation system as required... to protect personnel from direct contact with cold surfaces" means that surfaces of cargo piping systems with which personnel is likely to contact under normal conditions are to be protected by a thermal insulation, with the exception of the following examples:

- surfaces of cargo piping systems which are protected by physical screening measures to prevent such direct contact
- surfaces of manual valves, having extended spindles that protect the operator from the cargo temperature, and
- surfaces of cargo piping systems whose design temperature (to be determined from inner fluid temperature) is above minus  $10^{\circ}\text{C}$ .

**12.1.5** Where the cargo piping system is of a material susceptible to stress corrosion cracking in the presence of a salt-laden atmosphere, adequate measures to avoid this occurring shall be taken by considering material selection, protection of exposure to salty water and/or readiness for inspection.

A protective coating is to be applied on cargo pipes made in 304L and located on the open deck. Cargo pipes made in 316L are not required to be coated.

**12.1.6** A Society certificate is to be provided for the raw material of parts of valves or pumps that will be in direct contact with cargo and with a working temperature below  $-55^{\circ}\text{C}$ .

## **13 Testing requirements**

### **13.1 General**

**13.1.1** The piping components mentioned in the present Article are subject to a type approval by the Society.

### **13.2 Type testing of Cargo pumps**

#### **13.2.1 Type approval**

- a) Each size and type of pump is to be approved through design assessment and prototype testing. Prototype testing is to be witnessed in the presence of the Surveyor.  
In lieu of prototype testing, satisfactory in-service experience, of an existing pump design approved by a Society submitted by the manufacturer may be considered
- b) Prototype testing is to include hydrostatic test of the pump body equal to 1,5 times the design pressure and a capacity test. For submerged electric motor driven pumps, the capacity test is to be carried out with the design medium or with a medium below the minimum working temperature. For shaft driven deep well pumps, the capacity test may be carried out with water.

In addition, for shaft driven deep well pumps, a spin test to demonstrate satisfactory operation of bearing clearances, wear rings and sealing arrangements is to be carried out at the minimum design temperature. The full length of shafting is not required for the spin test, but must be of sufficient length to include at least one bearing and sealing arrangements. After completion of tests, the pump is to be opened out for examination.

### 13.2.2 Unit production testing

- a) All pumps are to be tested at the plant of manufacturer in the presence of the Surveyor. Testing is to include hydrostatic test of the pump body equal to 1,5 times the design pressure and a capacity test. For submerged electric motor driven pumps, the capacity test is to be carried out with the design medium or with a medium below the minimum working temperature. For shaft driven deep well pumps, the capacity test may be carried out with water
- b) As an alternative to the above, if so requested by the relevant Manufacturer, the certification of a pump may be issued, subject to an alternative survey scheme as per Rule Note NR320 as amended, and the following:
  - The pump has been approved as required by [13.2.1], and
  - The manufacturer has a recognised quality system that has been assessed and certified by the Society subject to periodic audits, and
  - The quality control plan contains a provision to subject each pump to a hydrostatic test of the pump body equal to 1,5 times the design pressure and a capacity test. The manufacturer is to maintain records of such tests.

## 13.3 Type testing of Valves

### 13.3.1 General

Each type of valve intended to be used at a working temperature below  $-55^{\circ}\text{C}$  shall be subject to the following type tests:

- each size and type of valve shall be subjected to seat tightness testing over the full range of operating pressures for bi-directional flow and temperatures, at intervals, up to the rated design pressure of the valve. Allowable leakage rates shall be to the requirements of the Society. During the testing, satisfactory operation of the valve shall be verified
- the flow or capacity shall be certified to a recognized standard for each size and type of valve

Note 1: For pressure relief valves (PRVs) that are subject to requirement of Ch 9, Sec 8, [2.1.7], the flow or capacity are to be certified by the Society.

For other types of valves, the manufacturer is to certify the flow properties of the valves based on tests carried out according to recognized standards.

- pressurized components shall be pressure tested to at least 1,5 times the rated pressure, and
- for emergency shutdown valves, with materials having melting temperatures lower than  $925^{\circ}\text{C}$ , the type testing shall include a fire test to a standard acceptable to the Society.

Note 2: Refer to SIGTTO Publication on "The Selection and Testing of Valves for LNG Applications".

Note 3: "Emergency shutdown valves, with materials having melting temperatures lower than  $925^{\circ}\text{C}$ " does not include an emergency shutdown valve in which components made of materials having melting temperatures lower than  $925^{\circ}\text{C}$  do not contribute to the shell or seat tightness of the valve.

### 13.3.2 Type approval

Each size and type of valve intended to be used at a working temperature below  $-55^{\circ}\text{C}$  is to be approved through design assessment and prototype testing. Prototype testing for all valves to the minimum design temperature or lower and to a pressure not lower than the maximum design pressure foreseen for the valves is to be witnessed in the presence of the Surveyor. Prototype testing is to include hydrostatic test of the valve body at a pressure equal to 1,5 times the design pressure, and cryogenic testing consisting of valve operation or safety valve set pressure, and leakage verification. In addition, for valves other than safety valves, a seat and stem leakage test at a pressure equal to 1,1 times the design pressure.

For valves intended to be used at a working temperature above  $-55^{\circ}\text{C}$ , prototype testing is not required.

### 13.3.3 Unit production testing

All valves are to be tested at the plant of manufacturer in the presence of the Surveyor. Testing is to include hydrostatic test of the valve body at a pressure equal to 1,5 times the design pressure for all valves, seat and stem leakage test at a pressure equal to 1,1 times the design pressure for valves other than safety valves. In addition, cryogenic testing consisting of valve operation and leakage verification for a minimum of 10% of each type and size of valve for valves other than safety valves intended to be used at a working temperature below  $-55^{\circ}\text{C}$ . The set pressure of safety valves is to be tested at ambient temperature.

For valves used for isolation of instrumentation in piping not greater than 25mm, unit production testing need not be witnessed by the surveyor. Records of testing are to be available for review.

As an alternative to the above, if so requested by the relevant Manufacturer, the certification of a valve may be issued, subject to an alternative survey scheme as per Rule Note NR320 as amended, and the following:

- The valve has been approved as required by [13.3.2] for valves intended to be used at a working temperature below  $-55^{\circ}\text{C}$ , and
- The manufacturer has a recognized quality system that has been assessed and certified by the Society subject to periodic audits, and
- The quality control plan contains a provision to subject each valve to a hydrostatic test of the valve body at a pressure equal to 1,5 times the design pressure for all valves and seat and stem leakage test at a pressure equal to 1,1 times the design

pressure for valves other than safety valves. The set pressure of safety valves is to be tested at ambient temperature. The manufacturer is to maintain records of such tests, and

- Cryogenic testing consisting of valve operation and leakage verification for a minimum of 10% of each type and size of valve for valves other than safety valves intended to be used at a working temperature below  $-55^{\circ}\text{C}$  in the presence of the Surveyor.

### **13.4 Type testing of expansion bellows**

#### **13.4.1 General**

*The following type tests shall be performed on each type of expansion bellows intended for use on cargo piping outside the cargo tank and where required by the Society, on those installed within the cargo tanks:*

- *elements of the bellows, not pre-compressed, shall be pressure tested at not less than five times the design pressure without bursting. The duration of the test shall not be less than 5 min*
- *a pressure test shall be performed on a type expansion joint, complete with all the accessories such as flanges, stays and articulations, at the minimum design temperature and twice the design pressure at the extreme displacement conditions recommended by the manufacturer, without permanent deformation*
- *a cyclic test (thermal movements) shall be performed on a complete expansion joint, which shall withstand at least as many cycles under the conditions of pressure, temperature, axial movement, rotational movement and transverse movement as it will encounter in actual service. Testing at ambient temperature is permitted when this testing is at least as severe as testing at the service temperature, and*
- *a cyclic fatigue test (ship deformation) shall be performed on a complete expansion joint, without internal pressure, by simulating the bellows movement corresponding to a compensated pipe length, for at least 2000000 cycles at a frequency not higher than 5 Hz. This test is only required when, due to the piping arrangement, ship deformation loads are actually experienced.*

#### **13.4.2 Unit production testing**

All bellows are to be tested at the plant of manufacturer in the presence of the Surveyor. Testing is to include hydro- static test of the bellow at a pressure equal to 1,5 times the design pressure. An alternative survey scheme, BV Mode I as per NR320, may be agreed with the Society.

### **13.5 System testing requirements**

**13.5.1** *The requirements of this sub-article shall apply to piping inside and outside the cargo tanks.*

**13.5.2** *After assembly, all cargo and process piping shall be subjected to a strength test with a suitable fluid. The test pressure shall be at least 1,5 times the design pressure (1,25 times the design pressure where the test fluid is compressible) for liquid lines and 1,5 times the maximum system working pressure (1,25 times the maximum system working pressure where the test fluid is compressible) for vapour lines. When piping systems or parts of systems are completely manufactured and equipped with all fittings, the test may be conducted prior to installation on board the ship, as defined in Pt C, Ch 1, Sec 10, [20.5.1]. Joints welded on board shall be tested to at least 1,5 times the design pressure.*

Note 1: IMO wanted to distinguish between the pneumatic test with air or other gas (compressible fluid) and the hydraulic test with water (incompressible fluid).

**13.5.3** *After assembly on board, each cargo and process piping system shall be subjected to a leak test using air, or other suitable medium, to a pressure depending on the leak detection method applied.*

**13.5.4** *In double wall gas-fuel piping systems, the outer pipe or duct shall also be pressure tested to show that it can withstand the expected maximum pressure at gas pipe rupture.*

The expression "duct" means to include the equipment enclosure required in Ch 9, Sec 16, [4.3] (e.g. GUV enclosure) as well as the structural pipe duct intended to contain any release of gas from inner pipe or equipment. The term "structural pipe duct" means an outer duct forming part of a structure such as a hull structure or superstructure or deck house, where permitted, other than gas valve unit rooms.

The expression "maximum pressure at gas pipe rupture" is the maximum pressure to which the outer pipe or duct is subjected after the inner pipe rupture and for testing purposes it is the same as the design pressure used in [4.1.4].

**13.5.5** *All piping systems, including valves, fittings and associated equipment for handling cargo or vapours, shall be tested under normal operating conditions not later than at the first loading operation, in accordance with recognized standards.*

**13.5.6** Attention is drawn to the requirements of Ch 9, Sec 1, [6.2.4] regarding the examination of the on-deck cargo piping system, that are to be conducted on ships carrying liquefied natural gases (LNG) in bulk during the first full loading and the subsequent first unloading of the ship.

### **13.6 Emergency shutdown valves**

**13.6.1** *The closing characteristics of emergency shutdown valves used in liquid cargo piping systems shall be tested to demonstrate compliance with Ch 9, Sec 18, [3.2.1], item c). This testing may be carried out on board after installation.*

# Section 6 Materials of Construction and Quality Control

## 1 Definitions

### 1.1

**1.1.1** Where reference is made in this Section to A, B, D, E, AH, DH, EH and FH hull structural steels, these steel grades are hull structural steels according to recognized standards.

#### 1.1.2 Piece

A piece is the rolled product from a single slab or billet or from a single ingot, if this is rolled directly into plates, strips, sections or bars.

#### 1.1.3 Batch

A batch is the number of items or pieces to be accepted or rejected together, on the basis of the tests to be carried out on a sampling basis. The size of a batch is given in the recognized standards.

#### 1.1.4 Controlled rolling (CR)

Controlled rolling (CR) is a rolling procedure in which the final deformation is carried out in the normalizing temperature range, resulting in a material condition generally equivalent to that obtained by normalizing.

#### 1.1.5 Thermo-mechanical controlled processing (TMCP)

Thermo-mechanical controlled processing (TMCP) is a procedure that involves strict control of both the steel temperature and the rolling reduction. Unlike CR, the properties conferred by TMCP cannot be reproduced by subsequent normalizing or other heat treatment. The use of accelerated cooling on completion of TMCP may also be accepted, subject to approval by the Society. The same applies for the use of tempering after completion of TMCP.

#### 1.1.6 Accelerated cooling (AcC)

Accelerated cooling (AcC) is a process that aims to improve mechanical properties by controlled cooling with rates higher than air cooling, immediately after the final TMCP operation. Direct quenching is excluded from accelerated cooling. The material properties conferred by TMCP and AcC cannot be reproduced by subsequent normalizing or other heat treatment.

## 2 Scope and general requirements

### 2.1

**2.1.1** This Section gives the requirements for metallic and non-metallic materials used in the construction of the cargo system. This includes requirements for joining processes, production process, personnel qualification, NDT and inspection and testing including production testing. The requirements for rolled materials, forgings and castings are given in Article [4] and in Tab 2 to Tab 6. The requirements for weldments are given in Article [5], and the guidance for non-metallic materials is given in Appendix 4 of the IGC Code. A quality assurance/ quality control programme shall be implemented to ensure that the requirements of this Article [2] are complied with.

**2.1.2** The manufacture, testing, inspection and documentation shall be in accordance with recognized standards and the specific requirements given in the Code.

**2.1.3** Where post-weld heat treatment is specified or required, the properties of the base material shall be determined in the heat-treated condition, in accordance with the applicable table of this Section, and the weld properties shall be determined in the heat treated condition in accordance with Article [5]. In cases where a post-weld heat treatment is applied, the test requirements may be modified at the discretion of the Society.

## 3 General test requirements and specifications

### 3.1 Tensile test

**3.1.1** Tensile testing shall be carried out in accordance with recognized standards.

**3.1.2** Tensile strength, yield stress and elongation shall be to the satisfaction of the Society. For carbon-manganese steel and other materials with definitive yield points, consideration shall be given to the limitation of the yield to tensile ratio.

Note 1: The test specimens and mechanical testing procedures for materials are defined in NR216 Materials and Welding, and reference should be made to international standard as ISO, etc...

**3.2 Toughness test**

**3.2.1** Acceptance tests for metallic materials shall include Charpy V-notch toughness tests, unless otherwise specified by the Society. The specified Charpy V-notch requirements are minimum average energy values for three full size (10 mm x 10 mm) specimens and minimum single energy values for individual specimens. Dimensions and tolerances of Charpy V-notch specimens shall be in accordance with recognized standards. The testing and requirements for specimens smaller than 5 mm in size shall be in accordance with recognized standards. Minimum average values for subsized specimens shall be as defined in Tab 1. Only one individual value may be below the specified average value, provided it is not less than 70% of that value.

**Table 1 : Minimum average energy values for subsized specimens**

Charpy V-notch specimen size (mm)	Minimum average energy of three specimens
10 x 10	KV
10 x 7,5	5/6 KV
10 x 5,0	2/3 KV

**Note 1:** KV : Energy values, in J, specified in Tab 2 to Tab 5.

**3.2.2** For base metal, the largest size Charpy V-notch specimens possible for the material thickness shall be machined with the specimens located as near as practicable to a point midway between the surface and the centre of the thickness and the length of the notch perpendicular to the surface as shown in Fig 1.

Note 1: In the case where the material thickness is 40mm or below, the Charpy V-notch impact test specimens are to be cut with their edge within 2mm from the “as rolled” surface with their longitudinal axes either parallel or transverse to the final direction of rolling of the material.

**3.2.3** For a weld test specimen, the largest size Charpy V-notch specimens possible for the material thickness shall be machined, with the specimens located as near as practicable to a point midway between the surface and the centre of the thickness. In all cases, the distance from the surface of the material to the edge of the specimen shall be approximately 1 mm or greater. In addition, for double-V butt welds, specimens shall be machined closer to the surface of the second welded section. The specimens shall be taken generally at each of the five following locations, as shown in Fig 2: on the centreline of the welds, the fusion line and 1 mm, 3 mm and 5 mm from the fusion line.

**Figure 1 : Orientation of base metal test specimen**

**Figure 2 : Orientation of weld test specimen**

Single-V butt weld

Double-V butt weld

**3.2.4** *If the average value of the three initial Charpy V-notch specimens fails to meet the stated requirements, or the value for more than one specimen is below the required average value, or when the value for one specimen is below the minimum value permitted for a single specimen, three additional specimens from the same material may be tested and the results be combined with those previously obtained to form a new average. If this new average complies with the requirements and if no more than two individual results are lower than the required average and no more than one result is lower than the required value for a single specimen, the piece or batch may be accepted.*

### **3.3 Bend test**

**3.3.1** *The bend test may be omitted as a material acceptance test, but is required for weld tests. Where a bend test is performed, this shall be done in accordance with recognized standards.*

**3.3.2** *The bend tests shall be transverse bend tests, which may be face, root or side bends at the discretion of the Society. However, longitudinal bend tests may be required in lieu of transverse bend tests in cases where the base material and weld metal have different strength levels.*

### **3.4 Section observation and other testing**

**3.4.1** *Macrosection, microsection observations and hardness tests may also be required by the Society, and they shall be carried out in accordance with recognized standards, where required.*

## **4 Requirements for metallic materials**

### **4.1 General requirements for metallic materials**

**4.1.1** The use of high manganese austenitic steel for cryogenic service may be permitted in accordance with IACS Recommendation No.169.

Refer also to IMO Circular MSC.1/Circ.1599: Interim guidelines on the application of high manganese austenitic steel for cryogenic service.

**4.1.2** The use of aluminium coatings is prohibited in the cargo tanks, cargo tank deck area, pump rooms, cofferdams or any other area where cargo gas may accumulate.

**4.1.3** *The requirements for materials of construction are shown in the tables as follows:*

- *Tab 2: Plates, pipes (seamless and welded), sections and forgings for cargo tanks and process pressure vessels for design temperatures not lower than 0°C*
- *Tab 3: Plates, sections and forgings for cargo tanks, secondary barriers and process pressure vessels for design temperatures below 0°C and down to -55°C*
- *Tab 4: Plates, sections and forgings for cargo tanks, secondary barriers and process pressure vessels for design temperatures below -55°C and down to -165°C*
- *Tab 5: Pipes (seamless and welded), forgings and castings for cargo and process piping for design temperatures below 0°C and down to -165°C*
- *Tab 6: Plates and sections for hull structures required by Ch 9, Sec 4, [6.2.2] and Ch 9, Sec 4, [6.2.3].*

**4.1.4** Impact tests are required for:

- castings in steel grades 304, 304L, 321 and 347 when the service temperature is below -60°C
- castings in steel grades 316 and 316L (which contain molybdenum) at any temperature. A reduction of the tests may be granted for design temperatures above -60°C after examination of each case by the Society.

**Table 2 : Plates, pipes (seamless and welded) -see Note 1 and Note 2-, sections and forgings for cargo tanks and process pressure vessels for design temperatures not lower than 0°C**

CHEMICAL COMPOSITION AND HEAT TREATMENT	
• Carbon-manganese steel	
• Fully killed fine grain steel	
• Small additions of alloying elements by agreement with the Society	
• Composition limits to be approved by the Society	
• Normalized, or quenched and tempered <b>(1)</b>	

TENSILE AND TOUGHNESS (IMPACT) TEST REQUIREMENTS				
Sampling frequency	• Plates	Each "piece" to be tested		
	• Sections and forgings	Each "batch" to be tested		
Mechanical properties	• Tensile properties	Specified minimum yield stress not to exceed 410 N/mm <sup>2</sup> <b>(2)</b>		
Toughness (Charpy V-notch test)	• Plates	Transverse test pieces. Minimum average energy value (KV) 27 J		
	• Sections and forgings	Longitudinal test pieces. Minimum average energy value (KV) 41 J		
	• Test temperature <b>(3)</b>	Thickness t (mm)	Test temperature	
		t ≤ 20	0°C	
		20 < t ≤ 40	-20°C	
		40 < t ≤ 50 <b>(4)</b>	-20°C <b>(5)</b>	
40 < t ≤ 50 <b>(4)</b>	-30°C <b>(6)</b>			

- (1)** A controlled rolling procedure or TMCP may be used as an alternative.
- (2)** Materials with specified minimum yield stress exceeding 410 N/mm<sup>2</sup> may be approved by the Society. For these materials, particular attention shall be given to the hardness of the welded and heat affected zones.
- (3)** This Table is generally applicable for material thicknesses t up to 40 mm. Proposals for greater thicknesses shall be approved by the Society.
- (4)** A further set of impact test at mid thickness for products with t>40mm is required except rolled steels specified in IACS UR W11 or IACS UR W16.
- (5)** Applies to type C independent tanks and process pressure vessels. In addition, post-weld stress relief heat treatment shall be performed. Exemption to post-weld stress relief heat treatment based on alternative approach (e.g. Engineering Critical Assessment) shall be approved by the Classification Society or shall be to recognized standards.
- (6)** Applies to cargo tank other than type C.
- Note 1:** For seamless pipes and fittings normal practice applies. The use of longitudinally and spirally welded pipes shall be specially approved by the Society.
- Note 2:** Charpy V-notch impact tests are not required for pipes.

**Table 3 : Plates, sections and forgings -see Note 1- for cargo tanks, secondary barriers and process pressure vessels for design temperatures below 0°C and down to -55°C**

CHEMICAL COMPOSITION AND HEAT TREATMENT	
<ul style="list-style-type: none"> <li>Carbon-manganese steel</li> </ul>	
<ul style="list-style-type: none"> <li>Fully killed, aluminium treated fine grain steel</li> </ul>	
<ul style="list-style-type: none"> <li>Chemical composition (ladle analysis): C: 0,16% max <b>(1)</b> ; Mn: 0,70-1,60% ; Si: 0,10-0,50% ; S: 0,025% max ; P: 0,025% max</li> </ul>	
<ul style="list-style-type: none"> <li>Optional additions: Alloys and grain refining elements may be generally in accordance with the following: Ni: 0,80% max ; Cr: 0,25% max ; Mo: 0,08% max ; Cu:0,35% max ; Nb: 0,05% max ; V: 0,10% max Al content total: 0,020% min (acid soluble: 0,015% min)</li> </ul>	
<ul style="list-style-type: none"> <li>Normalized, or quenched and tempered <b>(2)</b></li> </ul>	

TENSILE AND TOUGHNESS (IMPACT) TEST REQUIREMENTS		
Sampling frequency	• Plates	Each "piece" to be tested
	• Sections and forgings	Each "batch" to be tested
Mechanical properties	• Tensile properties	Specified minimum yield stress not to exceed 410 N/mm <sup>2</sup> <b>(3)</b>
Toughness (Charpy V-notch test)	• Plates	Transverse test pieces. Minimum average energy value (KV) 27 J
	• Sections and forgings	Longitudinal test pieces. Minimum average energy value (KV) 41 J
	• Test temperature, t ≤ 25 mm <b>(4)</b>	5°C below the design temperature or -20°C, whichever is lower

- (1)** By special agreement with the Society, the carbon content may be increased to 0,18% maximum, provided the design temperature is not lower than -40°C.
- (2)** A controlled rolling procedure or TMCP may be used as an alternative.
- (3)** Materials with specified minimum yield stress exceeding 410 N/mm<sup>2</sup> may be approved by the Society. For these materials, particular attention shall be given to the hardness of the welded and heat affected zones.
- (4)** This Table is applicable for material thicknesses t up to 25 mm. For material thicknesses of more than 25 mm, Charpy V-notch tests shall be conducted at the following temperatures:

Thickness t (mm)	Test temperature
25 mm < t ≤ 30 mm	10°C below the design temperature or -20°C, whichever is lower
30 mm < t ≤ 35 mm	15°C below the design temperature or -20°C, whichever is lower
35 mm < t ≤ 40 mm	20°C below the design temperature
40 mm < t ≤ 50 mm <b>(a)</b>	5°C below the design temperature or -20°C, whichever is lower <b>(b)</b>
40 mm < t ≤ 45 mm <b>(a)</b>	25°C below the design temperature <b>(c)</b>
45 mm < t ≤ 50 mm <b>(a)</b>	30°C below the design temperature <b>(c)</b>

The impact energy value shall be in accordance with the Table for the applicable type of test specimen.

Materials for tanks and parts of tanks which are completely thermally stress relieved after welding may be tested at a temperature 5°C below design temperature or -20°C, whichever is lower.

For thermally stress relieved reinforcements and other fittings, the test temperature shall be the same as that required for the adjacent tank-shell thickness.

- (a)** A further set of impact test at mid thickness for products with t > 40 mm is required except rolled steels specified in IACS UR W11 or IACS UR W16.
- (b)**
- For design temperatures below 0°C and strictly down to -10°C:  
Applies to type C independent tanks and process pressure vessels. In addition, post-weld stress relief heat treatment shall be performed. Exemption to post-weld stress relief heat treatment based on alternative approach (e.g. Engineering Critical Assessment) shall be approved by the Classification Society or shall be to recognized standards.
  - For design temperatures below -10°C and down to -55°C:  
[6.2.2] applies with regards to post-weld stress relief heat treatment. Exemption to post-weld stress relief heat treatment based on alternative approach (e.g. Engineering Critical Assessment) shall be approved by the Classification Society or shall be to recognized standards.
- (c)** Applies to cargo tank other than type C.

**Note 1:** The Charpy V-notch and chemistry requirements for forgings may be specially considered by the Society.

**Note 2:** For materials exceeding 25 mm in thickness for which the test temperature is -60°C or lower, the application of specially treated steels or steels in accordance with Table 4 may be necessary.

**Table 4 : Plates, sections and forgings -see Note 1- for cargo tanks, secondary barriers and process pressure vessels for design temperatures below –55°C and down to –165°C**

Minimum design temperature (1)	CHEMICAL COMPOSITION (2) AND HEAT TREATMENT	Impact test temperature	
–60°C	1,5% nickel steel – normalized or normalized and tempered or quenched and tempered or TMCP (5)	t ≤ 25 mm (3)	–65°C
–65°C	2,25% nickel steel – normalized or normalized and tempered or quenched and tempered or TMCP (5) (6)		–70°C
–90°C	3,5% nickel steel – normalized or normalized and tempered or quenched and tempered or TMCP (5) (6)		–95°C
–105°C	5,0% nickel steel – normalized or normalized and tempered or quenched and tempered (5) (6) (7)		–110°C
–165°C	9,0% nickel steel – double normalized and tempered or quenched and tempered (5)	(4)	–196°C
–165°C	Austenitic steels, such as types 304, 304L, 316, 316L, 321 and 347. Solution treated (8)		–196°C
–165°C	Aluminium alloys, such as type 5083 annealed		Not required
–165°C	Austenitic Fe-Ni alloy (36% nickel). Heat treatment as agreed		Not required

TENSILE AND TOUGHNESS (IMPACT) TEST REQUIREMENTS

Sampling frequency	• Plates	Each "piece" to be tested
	• Sections and forgings	Each "batch" to be tested
Toughness (Charpy V-notch test)	• Plates	Transverse test pieces. Minimum average energy value (KV) 27 J
	• Sections and forgings	Longitudinal test pieces. Minimum average energy value (KV) 41 J

- (1) The requirements for design temperatures below –165°C shall be specially agreed with the Society.
- (2) The chemical composition limits shall be in accordance with recognized standards.
- (3) This Table is applicable for material thicknesses t up to 25 mm. For materials 1,5% Ni, 2,25% Ni, 3,5% Ni and 5,0% Ni, with thicknesses greater than 25 mm, the impact tests shall be conducted at the following temperatures:

Thickness t (mm)	Test temperature
25 mm < t ≤ 30 mm	10°C below the design temperature
30 mm < t ≤ 35 mm	15°C below the design temperature
35 mm < t ≤ 40 mm	20°C below the design temperature
40 mm < t ≤ 45 mm (a)	25°C below the design temperature
45 mm < t ≤ 50 mm (a)	30°C below the design temperature

The energy value shall be in accordance with the Table for the applicable type of test specimen.

- (a) A further set of impact test at mid thickness for products with t>40mm is required except rolled steels specified in IACS UR W11 or IACS UR W16.
- (4) For 9,0% Ni steels, austenitic stainless steels and aluminium alloys, thickness greater than 25 mm may be used.
- (5) TMCP nickel steels will be subject to acceptance by the Society.
- (6) A lower minimum design temperature for quenched and tempered steels may be specially agreed with the Society.
- (7) A specially heat treated 5,0% nickel steel, for example triple heat treated 5,0% nickel steel, may be used down to –165°C, provided that the impact tests are carried out at –196°C.
- (8) The impact test of austenitic stainless steel is required only for service temperature less than –105°C.

**Note 1:** The impact test required for forgings used in critical applications shall be subject to special consideration by the Society.

**Table 5 : Pipes (seamless and welded) -see Note 1-, forgings and castings -see Note 2- for cargo and process piping for design temperatures below 0°C and down to -165°C**

Minimum design temperature (1)	CHEMICAL COMPOSITION (2) AND HEAT TREATMENT	Impact test, t ≤ 25 mm	
		Test temperature	Minimum average energy (KV)
-55°C	Carbon-manganese steel. Fully killed fine grain. Normalized or as agreed (4)	(3)	27 J
-65°C	2,25% nickel steel. Normalized, normalized and tempered or quenched and tempered (4)	-70°C	34 J
-90°C	3,5% nickel steel. Normalized, normalized and tempered or quenched and tempered (4)	-95°C	34 J
-165°C	9,0% nickel steel (5). Double normalized and tempered or quenched and tempered	-196°C	41 J
	Austenitic steels, such as types 304, 304L, 316, 316L, 321 and 347. Solution treated (6)	-196°C	41 J
	Aluminium alloys, such as type 5083 annealed	Not required

## 5 Welding of metallic materials and non-destructive testing

### 5.1 General

**5.1.1** This Article shall apply to primary and secondary barriers only, including the inner hull where this forms the secondary barrier. Acceptance testing is specified for carbon, carbon-manganese, nickel alloy and stainless steels, but these tests may be adapted for other materials. At the discretion of the Society, impact testing of stainless steel and aluminium alloy weldments may be omitted and other tests may be specially required for any material.

Note 1: This requirement is also applicable for austenitic steels and aluminium alloy.

### 5.2 Welding consumables

**5.2.1** Consumables intended for welding of cargo tanks shall be in accordance with recognized standards. Deposited weld metal tests and butt weld tests shall be required for all consumables. The results obtained from tensile and Charpy V-notch impact tests shall be in accordance with recognized standards. The chemical composition of the deposited weld metal shall be recorded for information.

The content of this requirement is also to cover process pressure vessels and secondary barriers.

### 5.3 Welding procedure tests for cargo tanks and process pressure vessels

**5.3.1** Welding procedure tests for cargo tanks and process pressure vessels are required for all butt welds.

**5.3.2** The test assemblies shall be representative of:

- each base material
- each type of consumable and welding process, and
- each welding position.

**5.3.3** For butt welds in plates, the test assemblies shall be so prepared that the rolling direction is parallel to the direction of welding. The range of thickness qualified by each welding procedure test shall be in accordance with recognized standards. Radiographic or ultrasonic testing may be performed at the option of the fabricator.

**5.3.4** The following welding procedure tests for cargo tanks and process pressure vessels shall be carried out in accordance with Article [3], with specimens made from each test assembly:

- cross-weld tensile tests
- longitudinal all-weld testing, where required by the recognized standards
- transverse bend tests, which may be face, root or side bends. However, longitudinal bend tests may be required in lieu of transverse bend tests in cases where the base material and weld metal have different strength levels
- one set of three Charpy V-notch impacts, generally at each of the following locations, as shown in Fig 2:
  - centreline of the weld
  - fusion line
  - 1 mm from the fusion line
  - 3 mm from the fusion line, and
  - 5 mm from the fusion line, and
- macrosection, microsection and hardness survey may also be required.

**5.3.5** Each test shall satisfy the following requirements:

- tensile tests: cross-weld tensile strength shall not be less than the specified minimum tensile strength for the appropriate parent materials. For materials such as aluminium alloys, reference shall be made to Ch 9, Sec 4, [4.5.1], item c) with regard to the requirements for weld metal strength of under-matched welds (where the weld metal has a lower tensile strength than the parent metal). In every case, the position of fracture shall be recorded for information.
- bend tests: no fracture is acceptable after a 180° bend over a former of a diameter four times the thickness of the test pieces, and

As an alternative to the bend test indicated, a test over a mandrel having a diameter equal to 3 times the thickness with a bend angle up to 120° may be required.

- Charpy V-notch impact tests: Charpy V-notch tests shall be conducted at the temperature prescribed for the base material being joined. The results of weld metal impact tests, minimum average energy (KV), shall be no less than 27 J. The weld metal requirements for subsize specimens and single energy values shall be in accordance with [3.2]. The results of fusion line and heat-affected zone impact tests shall show a minimum average energy (KV) in accordance with the transverse or longitudinal requirements of the base material, whichever is applicable, and for subsize specimens, the minimum average energy (KV) shall be in accordance with [3.2]. If the material thickness does not permit machining either full-size or standard subsize specimens, the testing procedure and acceptance standards shall be in accordance with recognized standards.

**5.3.6** Procedure tests for fillet welding shall be in accordance with recognized standards. In such cases, consumables shall be so selected that exhibit satisfactory impact properties.

## **5.4 Welding procedure tests for piping**

**5.4.1** Welding procedure tests for piping shall be carried out and shall be similar to those detailed for cargo tanks in [5.3].

## **5.5 Production weld tests**

**5.5.1** For all cargo tanks and process pressure vessels, except integral and membrane tanks, production weld tests shall generally be performed for approximately each 50 m of butt-weld joints and shall be representative of each welding position. For secondary barriers, the same type production tests as required for primary tanks shall be performed, except that the number of tests may be reduced subject to agreement with the Society. Tests, other than those specified in [5.5.2] to [5.5.5] may be required for cargo tanks or secondary barriers.

**5.5.2** The production tests for type A and type B independent tanks and semi-membrane tanks shall include bend tests and, where required for procedure tests, one set of three Charpy V-notch tests. The tests shall be made for each 50 m of weld. The Charpy V-notch tests shall be made with specimens having the notch alternately located in the centre of the weld and in the heat-affected zone (most critical location based on procedure qualification results). For austenitic stainless steel, all notches shall be in the centre of the weld.

**5.5.3** For type C independent tanks and process pressure vessels, transverse weld tensile tests are required in addition to the tests listed in [5.5.2]. Tensile tests shall meet the requirements of [5.3.5].

**5.5.4** The quality assurance/quality control programme shall ensure the continued conformity of the production welds as defined in the material manufacturers quality manual.

**5.5.5** The test requirements for integral and membrane tanks are the same as the applicable test requirements listed in [5.3].

## **5.6 Non-destructive testing**

**5.6.1** The following provisions apply to independent tanks:

- a) Tracing, cutting and shaping are to be carried out so as to prevent, at the surface of the pieces, the production of defects detrimental to their use. In particular, marking the plates by punching and starting welding arcs outside the welding zone are to be avoided.
- b) Before welding, the edges to be welded are to be carefully examined, with possible use of non-destructive examination, in particular when chamfers are carried out.
- c) In all cases, the working units are to be efficiently protected against bad weather.
- d) The execution of provisional welds, where any, is to be subjected to the same requirements as the constructional welds. After elimination of the fillets, the area is to be carefully ground and inspected (the inspection is to include, if necessary, a penetrant fluid test).
- e) All welding consumables are subject to agreement. Welders are also to be agreed.

**5.6.2** All test procedures and acceptance standards shall be in accordance with recognized standards, unless the designer specifies a higher standard in order to meet design assumptions. Radiographic testing shall be used, in principle, to detect internal defects. However, an approved ultrasonic test procedure in lieu of radiographic testing may be conducted, but, in addition, supplementary radiographic testing at selected locations shall be carried out to verify the results. Radiographic and ultrasonic testing records shall be retained.

**5.6.3** For type A independent tanks and semi-membrane tanks, where the design temperature is below  $-20^{\circ}\text{C}$ , and for type B independent tanks, regardless of temperature, all full penetration butt welds of the shell plating of cargo tanks shall be subjected to non-destructive testing suitable to detect internal defects over their full length. Ultrasonic testing in lieu of radiographic testing may be carried out under the same conditions as described in [5.6.2].

**5.6.4** Where the design temperature is higher than  $-20^{\circ}\text{C}$ , all full penetration butt welds in way of intersections and at least 10% of the remaining full penetration welds of tank structures shall be subjected to radiographic testing or ultrasonic testing under the same conditions as described in [5.6.2].

**5.6.5** In each case, the remaining tank structure, including the welding of stiffeners and other fittings and attachments, shall be examined by magnetic particle or dye penetrant methods, as considered necessary.

**5.6.6** For type C independent tanks, the extent of non-destructive testing shall be total or partial according to recognized standards, but the controls to be carried out shall not be less than the following:

- a) Total non-destructive testing referred to in Ch 9, Sec 4, [10.2]:
  - Radiographic testing:
    - all butt welds over their full length

- *Non-destructive testing for surface crack detection:*
  - *all welds over 10% of their length*
  - *reinforcement rings around holes, nozzles, etc., over their full length.*

*As an alternative, ultrasonic testing as described in [5.6.2] may be accepted as a partial substitute for the radiographic testing. In addition, the Society may require total ultrasonic testing on welding of reinforcement rings around holes, nozzles, etc.*

b) *Partial non-destructive testing referred to in Ch 9, Sec 4, [10.2]:*

- *Radiographic testing:*
  - *all butt-welded crossing joints and at least 10% of the full length of butt welds at selected positions uniformly distributed*
- *Non-destructive testing for surface crack detection:*
  - *reinforcement rings around holes, nozzles, etc., over their full length*
- *Ultrasonic testing:*
  - *as may be required by the Society in each instance.*

**5.6.7** *The quality assurance/quality control programme shall ensure the continued conformity of the non-destructive testing of welds, as defined in the material manufacturer's quality manual.*

**5.6.8** *Inspection of piping shall be carried out in accordance with the requirements of Ch 9, Sec 5.*

**5.6.9** *The secondary barrier shall be non-destructive tested for internal defects as considered necessary. Where the outer shell of the hull is part of the secondary barrier, all sheer strake butts and the intersections of all butts and seams in the side shell shall be tested by radiographic testing.*

## **6 Other requirements for construction in metallic materials**

### **6.1 General**

**6.1.1** *Inspection and non-destructive testing of welds shall be in accordance with the requirements of [5.5] and [5.6]. Where higher standards or tolerances are assumed in the design, they shall also be satisfied.*

### **6.2 Independent tank**

**6.2.1** *For type C tanks and type B tanks primarily constructed of bodies of revolution, the tolerances relating to manufacture, such as out-of-roundness, local deviations from the true form, welded joints alignment and tapering of plates having different thicknesses, shall comply with recognized standards. The tolerances shall also be related to the buckling analysis referred to in Ch 9, Sec 4, [9.3], item b) and Ch 9, Sec 4, [10.3], item b).*

**6.2.2** *For type C tanks of carbon and carbon-manganese steel, post-weld heat treatment shall be performed after welding, if the design temperature is below  $-10^{\circ}\text{C}$ . Post-weld heat treatment in all other cases and for materials other than those mentioned above shall be to recognized standards. The soaking temperature and holding time shall be to the recognized standards.*

**6.2.3** *In the case of type C tanks and large cargo pressure vessels of carbon or carbon-manganese steel, for which it is difficult to perform the heat treatment, mechanical stress relieving by pressurizing may be carried out as an alternative to the heat treatment and subject to the following conditions:*

- *complicated welded pressure vessel parts such as sumps or domes with nozzles, with adjacent shell plates shall be heat treated before they are welded to larger parts of the pressure vessel*
- *the mechanical stress relieving process shall preferably be carried out during the hydrostatic pressure test required by Ch 9, Sec 4, [10.6], by applying a higher pressure than the test pressure required by Ch 9, Sec 4, [10.6], item a). The pressurizing medium shall be water*
- *for the water temperature, Ch 9, Sec 4, [10.6], item b) applies*
- *stress relieving shall be performed while the tank is supported by its regular saddles or supporting structure or, when stress relieving cannot be carried out on board, in a manner which will give the same stresses and stress distribution as when supported by its regular saddles or supporting structure*
- *the maximum stress relieving pressure shall be held for 2 h per 25 mm of thickness, but in no case less than 2 h*

- the upper limits placed on the calculated stress levels during stress relieving shall be the following:
  - equivalent general primary membrane stress:  $0,9 R_e$
  - equivalent stress composed of primary bending stress plus membrane stress:  $1,35 R_e$ , where  $R_e$  is the specific lower minimum yield stress or 0,2% proof stress at test temperature of the steel used for the tank
- strain measurements will normally be required to prove these limits for at least the first tank of a series of identical tanks built consecutively. The location of strain gauges shall be included in the mechanical stress relieving procedure to be submitted in accordance with [6.2.3]
- the test procedure shall demonstrate that a linear relationship between pressure and strain is achieved at the end of the stress relieving process when the pressure is raised again up to the design pressure
- high-stress areas in way of geometrical discontinuities such as nozzles and other openings shall be checked for cracks by dye penetrant or magnetic particle inspection after mechanical stress relieving. Particular attention in this respect shall be paid to plates exceeding 30 mm in thickness
- steels which have a ratio of yield stress to ultimate tensile strength greater than 0,8 shall generally not be mechanically stress relieved. If, however, the yield stress is raised by a method giving high ductility of the steel, slightly higher rates may be accepted upon consideration in each case
- mechanical stress relieving cannot be substituted for heat treatment of cold formed parts of tanks, if the degree of cold forming exceeds the limit above which heat treatment is required
- the thickness of the shell and heads of the tank shall not exceed 40 mm. Higher thicknesses may be accepted for parts which are thermally stress relieved
- local buckling shall be guarded against, particularly when tori-spherical heads are used for tanks and domes, and
- the procedure for mechanical stress relieving shall be to a recognized standard.

### **6.3 Secondary barriers**

**6.3.1** During construction, the requirements for testing and inspection of secondary barriers shall be approved or accepted by the Society (see Ch 9, Sec 4, [2.4.3], item e) and Ch 9, Sec 4, [2.4.3], item f)).

### **6.4 Semi-membrane tanks**

**6.4.1** For semi-membrane tanks, the relevant requirements in Article [6] for independent tanks or for membrane tanks shall be applied as appropriate.

### **6.5 Membrane tanks**

**6.5.1** The quality assurance/quality control programme shall ensure the continued conformity of the weld procedure qualification, design details, materials, construction, inspection and production testing of components. These standards and procedures shall be developed during the prototype testing programme.

## **7 Non-metallic materials**

### **7.1 General**

**7.1.1** The information in Appendix 4 of the IGC Code is given for guidance in the selection and use of these materials, based on the experience to date.

# Section 7 Cargo Pressure / Temperature Control

## 1 Methods of control

### 1.1 General

**1.1.1** With the exception of tanks designed to withstand full gauge vapour pressure of the cargo under conditions of the upper ambient design temperatures, cargo tanks' pressure and temperature shall be maintained at all times within their design range by either one, or a combination of, the following methods:

- reliquefaction of cargo vapours
- thermal oxidation of vapours
- pressure accumulation, and
- liquid cargo cooling.

**1.1.2** For certain cargoes, where required by Ch 9, Sec 17, the cargo containment system shall be capable of withstanding the full vapour pressure of the cargo under conditions of the upper ambient design temperatures, irrespective of any system provided for dealing with boil-off gas.

**1.1.3** Venting of the cargo to maintain cargo tank pressure and temperature shall not be acceptable except in emergency situations. The Society may permit certain cargoes to be controlled by venting cargo vapours to the atmosphere at sea. This may also be permitted in port with the authorization of the port Administration.

## 2 Design of systems

### 2.1 General

**2.1.1** For normal service, the upper ambient design temperature shall be:

- sea: 32°C
- air: 45°C.

For service in particularly hot or cold zones, these design temperatures shall be increased or decreased, to the satisfaction of the Society. The overall capacity of the system shall be such that it can control the pressure within the design conditions without venting to atmosphere.

**2.1.2** Any subcooling units and reliquefaction units installed on board are to be considered as essential service as per Pt C, Ch 2, Sec 1, [3.4.1].

**2.1.3** Subject to special consideration by the Society and to Shipowner agreement, the requirement stated in [2.1.2] may be waived if justifications are provided to demonstrate that these systems are not essential for the boil-off gas management.

## 3 Reliquefaction of cargo vapours

### 3.1

**3.1.1** In general, in addition to the requirements of this Article, the specific requirements stated in Part C and Part D, Chapter 9 of the Rules for various machinery and equipment are also applicable to refrigerating installation components.

**3.1.2** Attention is drawn to the requirements of Ch 9, Sec 1, [6.2.4] regarding the satisfactory operation of the reliquefaction plant, if installed, and of any other equipment fitted for the burning of cargo vapours, that is to be ascertained during the first full loading and the subsequent first unloading of ships carrying liquefied natural gasses (LNG) in bulk.

### 3.1.3 General

The reliquefaction system may be arranged in one of the following ways:

- a) a direct system, where evaporated cargo is compressed, condensed and returned to the cargo tanks
- b) an indirect system, where cargo or evaporated cargo is cooled or condensed by refrigerant without being compressed
- c) a combined system, where evaporated cargo is compressed and condensed in a cargo/refrigerant heat exchanger and returned to the cargo tanks, and
- d) if the reliquefaction system produces a waste stream containing methane during pressure control operations within the design conditions, these waste gases, as far as reasonably practicable, are disposed of without venting to atmosphere.

Note 1: The requirements of Ch 9, Sec 17 and Ch 9, Sec 19 may preclude the use of one or more of these systems or may specify the use of a particular system.

### **3.1.4 Compatibility**

*Refrigerants used for reliquefaction shall be compatible with the cargo they may come into contact with. In addition, when several refrigerants are used and may come into contact, they shall be compatible with each other.*

## **3.2 Refrigerating installation components**

### **3.2.1 Pressure vessels and heat exchangers**

- a) Pressure vessels of refrigerating plants are to comply with the relevant requirements of Pt C, Ch 1, Sec 3 and Ch 9, Sec 5.
- b) Notch toughness of steels used in low temperature plants is to be suitable for the thickness and the lowest design temperature. A check of the notch toughness properties may be required where the working temperature is below minus 40°C.

### **3.2.2 Piping systems**

- a) Refrigerant pipes are generally to be regarded as pressure pipes.
- b) Refrigerant pipes are to be considered as belonging to the following classes:
  - class I: where they are intended for ammonia or toxic and flammable substances
  - class II: for other refrigerants
- c) In general, the pipes conveying the cooling medium are not to come into direct contact with the ship's structure; they are to be carefully insulated on their run outside the refrigerated spaces, and more particularly when passing through bulkheads and decks.
- d) The materials used for the pipes are to be appropriate to the fluids that they convey. Copper, brass, bronze and other copper alloys are not to be used for pipes likely to convey ammonia. Methods proposed for joining such pipes are to be submitted to the Society for consideration.
- e) Notch toughness of the steels used is to be suitable for the application concerned.
- f) Where necessary, cooling medium pipes within refrigerated spaces or embedded in insulation are to be externally protected against corrosion; for steel pipes, this protection is to be ensured by galvanisation or equivalent. All useful precautions are to be taken to protect the joints of such pipes against corrosion.

## **3.3 Refrigerants**

### **3.3.1 Prohibited refrigerants**

The use of the following refrigerants is not allowed for shipboard installations:

- Methyl chloride
- R11 - Trichloromonofluoromethane (C Cl<sub>3</sub> F)

### **3.3.2 Statutory requirements**

Particular attention is to be paid to any limitation on the use of refrigerants imposed by the Administration of the State whose flag the ship is flying.

## **4 Thermal oxidation of vapours**

### **4.1 General**

**4.1.1** Article [8] states that unless an alternative means of controlling the cargo pressure/temperature is provided to the satisfaction of the Society, a standby unit (or units) affording spare capacity at least equal to the largest required single unit is (are) to be fitted.

For the purpose of complying with the above, a suitable alternative means of pressure/temperature control would be:

- a) auxiliary boiler(s) capable of burning the boil-off vapours and disposing of the generated steam or an alternative waste heat system acceptable to the Society. Consideration will be given to systems burning only part of the boil-off vapour if it can be shown that MARVS will not be reached within a period of 21 days.
- b) controlled venting of cargo vapours as specified in [1.1.3] if permitted by the Administration concerned.

**4.1.2** *Maintaining the cargo tank pressure and temperature by means of thermal oxidation of cargo vapours, as defined in Ch 9, Sec 1, [4.1.50] and Ch 9, Sec 16, [2] shall be permitted only for LNG cargoes. In general:*

- *thermal oxidation systems shall exhibit no externally visible flame and shall maintain the uptake exhaust temperature below 535°C*
- *arrangement of spaces where oxidation systems are located shall comply with Ch 9, Sec 16, [3] and supply systems shall comply with Ch 9, Sec 16, [4], and*
- *if waste gases coming from any other system are to be burnt, the oxidation system shall be designed to accommodate all anticipated feed gas compositions.*

## **4.2 Thermal oxidation systems**

**4.2.1** Thermal oxidation systems shall comply with the following:

- each thermal oxidation system shall have a separate uptake
- each thermal oxidation system shall have a dedicated forced draught system, and
- combustion chambers and uptakes of thermal oxidation systems shall be designed to prevent any accumulation of gas.

**4.2.2** Gas combustion units are to comply with the provisions of Pt C, Ch 1, Sec 3, [7].

## **4.3 Burners**

**4.3.1** Burners shall be designed to maintain stable combustion under all design firing conditions.

## **4.4 Safety**

**4.4.1** Suitable devices shall be installed and arranged to ensure that gas flow to the burner is cut off unless satisfactory ignition has been established and maintained.

**4.4.2** Each oxidation system shall have provision to manually isolate its gas fuel supply from a safely accessible position.

**4.4.3** Provision shall be made for automatic purging the gas supply piping to the burners by means of an inert gas, after the extinguishing of these burners.

**4.4.4** In case of flame failure of all operating burners for gas or oil or for a combination thereof, the combustion chambers of the oxidation system shall be automatically purged before relighting.

**4.4.5** Arrangements shall be made to enable the combustion chamber to be manually purged.

## **5 Pressure accumulation systems**

### **5.1 General**

**5.1.1** The containment system insulation, design pressure or both shall be adequate to provide for a suitable margin for the operating time and temperatures involved. No additional pressure and temperature control system is required. Conditions for acceptance shall be recorded in the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk.

Note 1: The operating time corresponds to a period not less than 21 days.

## **6 Liquid cargo cooling**

### **6.1 General**

**6.1.1** The bulk cargo liquid may be refrigerated by coolant circulated through coils fitted either inside the cargo tank or onto the external surface of the cargo tank.

## **7 Segregation**

### **7.1 General**

**7.1.1** Where two or more cargoes that may react chemically in a dangerous manner are carried simultaneously, separate systems as defined in Ch 9, Sec 1, [4.1.45], each complying with availability criteria as specified in [8], shall be provided for each cargo. For simultaneous carriage of two or more cargoes that are not reactive to each other but where, due to properties of their vapour, separate systems are necessary, separation may be by means of isolation valves.

## **8 Availability**

### **8.1 General**

**8.1.1** The availability of the system and its supporting auxiliary services shall be such that:

- a) in case of a single failure of a mechanical non-static component or a component of the control systems, the cargo tanks' pressure and temperature can be maintained within their design range without affecting other essential services

Note 1: "mechanical non-static component" refers to pumps, fan or compressors.

Note 2: "component of the control systems" refers to electronical cards.

- b) redundant piping systems are not required

- c) *heat exchangers that are solely necessary for maintaining the pressure and temperature of the cargo tanks within their design ranges shall have a standby heat exchanger, unless they have a capacity in excess of 25% of the largest required capacity for pressure control and they can be repaired on board without external resources. Where an additional and separate method of cargo tank pressure and temperature control is fitted that is not reliant on the sole heat exchanger, then a standby heat exchanger is not required.*

A single heat exchanger without margin (i.e. designed for 100% capacity) may also be not duplicated if another means of pressure/temperature control is provided with a capacity that is at least equivalent to the missing 25% capacity for the heat exchanger, and

- d) *for any cargo heating or cooling medium, provisions shall be made to detect the leakage of toxic or flammable vapours into an otherwise safe location or overboard in accordance with Ch 9, Sec 13, [6]. Any vent outlet from this leak detection arrangement shall be to a safe location and be fitted with a flame screen.*

Any non-static component (e.g. pump, compressor, fan) is to be duplicated in such a way that a single failure of one of these components will not impair the performance of the pressure/temperature control system. Static components such as piping or heat exchanger are not necessarily to be duplicated: no redundancy is required for piping and heat exchangers having an operational margin (+25% capacity).

# Section 8 Vent Systems for Cargo Containment

## 1 General

### 1.1

**1.1.1** All cargo tanks shall be provided with a pressure relief system appropriate to the design of the cargo containment system and the cargo being carried. Hold spaces and interbarrier spaces, which may be subject to pressures beyond their design capabilities, shall also be provided with a suitable pressure relief system. Pressure control systems specified in Ch 9, Sec 7 shall be independent of the pressure relief systems.

## 2 Pressure relief systems

### 2.1 General

**2.1.1** Cargo tanks, including deck tanks, shall be fitted with a minimum of two pressure relief valves (PRVs), each being of equal size within manufacturer's tolerances and suitably designed and constructed for the prescribed service.

**2.1.2** Interbarrier spaces shall be provided with pressure relief devices.

For membrane systems, the designer shall demonstrate adequate sizing of interbarrier space PRVs.

#### 2.1.3 Protection of interbarrier spaces

- The relieving capacity of pressure relief devices of interbarrier spaces surrounding independent type B cargo tanks may be determined on the basis of the method given in Article [2]; however, the leakage rate is to be determined in accordance with Ch 9, Sec 4, [2.5.2].
- The relieving capacity of pressure relief devices for interbarrier spaces of membrane and semi-membrane tanks is to be evaluated on the basis of specific membrane/semi-membrane tank design.
- The relieving capacity of pressure relief devices for interbarrier spaces adjacent to integral type cargo tanks may, if applicable, be determined as for type A independent cargo tanks.

#### 2.1.4 Size of pressure relief devices

The combined relieving capacity, in m<sup>3</sup>/s, of the pressure relief devices for interbarrier spaces surrounding type A independent cargo tanks where the insulation is fitted to the cargo tanks may be determined by the following formula:

$$Q_{sa} = 3,4 \cdot A_C \cdot \frac{\rho}{\rho_v} \cdot \sqrt{h}$$

where:

$Q_{sa}$  : Minimum required discharge rate of air in standard conditions of 273 K and 1,013 bar

$A_C$  : Design crack opening area, in m<sup>2</sup>, equal to:

$$A_C = \frac{\pi}{4} \cdot \delta \cdot l$$

where:

$\delta$  : Maximum crack opening width, in m, equal to:

$$\delta = 0,2 t$$

$t$  being the thickness of tank bottom plating, in m

$l$  : Design crack length, in m, equal to the diagonal of the largest plate panel of the tank bottom (see Fig 1)

$h$  : Maximum liquid height above tank bottom plus 10 × MARVS, in m

$\rho$  : Density of product liquid phase, in kN/m<sup>3</sup>, at the set pressure of the interbarrier space relief device

$\rho_v$  : Density of product vapour phase, in kN/m<sup>3</sup>, at the set pressure of the interbarrier space relief device and a temperature of 273 K.

**2.1.5** The setting of the PRVs shall not be higher than the vapour pressure that has been used in the design of the tank. Where two or more PRVs are fitted, valves comprising not more than 50% of the total relieving capacity may be set at a pressure up to 5% above MARVS to allow sequential lifting, minimizing unnecessary release of vapour.

Figure 1 : Determination of I

**2.1.6** The following temperature requirements apply to PRVs fitted to pressure relief systems:

- PRVs on cargo tanks with a design temperature below 0°C shall be designed and arranged to prevent their becoming inoperative due to ice formation
- the effects of ice formation due to ambient temperatures shall be considered in the construction and arrangement of PRVs
- PRVs shall be constructed of materials with a melting point above 925°C. Lower melting point materials for internal parts and seals may be accepted, provided that fail-safe operation of the PRV is not compromised, and
- sensing and exhaust lines on pilot operated relief valves shall be of suitably robust construction to prevent damage.

### 2.1.7 Valve testing

a) PRVs shall be type-tested. Type tests shall include:

- verification of relieving capacity
- cryogenic testing when operating at design temperatures colder than -55°C
- seat tightness testing, and
- pressure containing parts are pressure tested to at least 1,5 times the design pressure.

PRVs shall be tested in accordance with recognized standards.

Note 1: ISO 21013-1:2008 - Cryogenic vessels - Pressure-relief accessories for cryogenic service - part 1: Recloseable pressure-relief valves; and ISO 4126-1; 2004 Safety devices for protection against excessive pressure - part 1 and part 4: Safety valves.

b) Each PRV shall be tested to ensure that:

- it opens at the prescribed pressure setting, with an allowance not exceeding  $\pm 10\%$  for 0 to 0,15 MPa,  $\pm 6\%$  for 0,15 to 0,30 MPa,  $\pm 3\%$  for 0,30 MPa and above
- seat tightness is acceptable, and
- pressure containing parts will withstand at least 1,5 times the design pressure.

**2.1.8** PRVs shall be set and sealed by the Society, and a record of this action, including the valves' set pressure, shall be retained on board the ship.

**2.1.9** Cargo tanks may be permitted to have more than one relief valve set pressure in the following cases:

- installing two or more properly set and sealed PRVs and providing means, as necessary, for isolating the valves not in use from the cargo tank, or
- installing relief valves whose settings may be changed by the use of a previously approved device not requiring pressure testing to verify the new set pressure. All other valve adjustments shall be sealed.

**2.1.10** Changing the set pressure under the provisions of [2.1.9] and the corresponding resetting of the alarms referred to in Ch 9, Sec 13, [4.1.2] shall be carried out under the supervision of the Master in accordance with approved procedures and as specified in the ship's operating manual. Changes in set pressure shall be recorded in the ship's log and a sign shall be posted in the cargo control room, if provided, and at each relief valve, stating the set pressure.

**2.1.11** In the event of a failure of a cargo tank-installed PRV, a safe means of emergency isolation shall be available:

- a) Procedures shall be provided and included in the cargo operations manual (see IGC Code 18.2).
- b) The procedures shall allow only one of the cargo tank installed PRVs to be isolated.

Note 1: The basic principle is to ensure a safe isolation before removing the PRV for maintenance. The use of balloons can be a solution and accepted in principle, but their efficiency (tightness) shall be demonstrated. A procedure to reinstall or change the balloon after use shall also be prepared. For systems where the outlets of several PRVs are connected to a common vent header, safe isolation means, where balloons are used, one balloon at the inlet of the PRV and one at the outlet.

- c) Isolation of the PRV shall be carried out under the supervision of the Master. This action shall be recorded in the ship's log and a sign posted in the cargo control room, if provided, and at the PRV.
- d) The tank shall not be loaded until the full relieving capacity is restored.

**2.1.12** Each PRV installed on a cargo tank shall be connected to a venting system, which shall be:

- so constructed that the discharge will be unimpeded and directed vertically upwards at the exit
- arranged to minimize the possibility of water or snow entering the vent system
- arranged such that the height of vent exits shall not be less than  $B/3$  or 6 m, whichever is the greater, above the weather deck, and
- 6 m above working areas and walkways.

**2.1.13** The height of vent exits as indicated in [2.1.12] is also to be measured above storage tanks and cargo liquid lines, where applicable.

**2.1.14** Cargo PRV vent exits shall be arranged at a distance at least equal to  $B$  or 25 m, whichever is less, from the nearest air intake, outlet or opening to accommodation spaces, service spaces and control stations, or other non-hazardous areas.

For ships less than 90 m in length, smaller distances may be permitted.

All other vent outlets connected to the cargo containment system shall be arranged at a distance of at least 10 m, measured horizontally, from the nearest air intake, outlet or opening to accommodation spaces, service spaces and control stations, or other non-hazardous areas.

In the case of carriage of flammable and/or toxic products, the vent exits are to be arranged at a distance of at least 5 m, measured horizontally, from exhaust ducts and at least 10 m, measured horizontally, from intake ducts serving cargo pump rooms and/or cargo compressor rooms.

**2.1.15** All other cargo vent outlets not dealt with in other chapters shall be arranged in accordance with [2.1.12] and [2.1.12], items a) and b). Means shall be provided to prevent liquid overflow from vent mast outlets, due to hydrostatic pressure from spaces to which they are connected.

Note 1: The meaning of this recommendation is to avoid the presence of liquid in the vent mast and in the pipes so that there was no overflow from vent mast outlets, the designer has to demonstrated that liquid will never reach the outlet of the vent mast in case of any single failure. For example install a knockout drum is acceptable.

**2.1.16** If cargoes that react in a dangerous manner with each other are carried simultaneously, a separate pressure relief system shall be fitted for each one.

**2.1.17** In the vent piping system, means for draining liquid from places where it may accumulate shall be provided. The PRVs and piping shall be arranged so that liquid can, under no circumstances, accumulate in or near the PRVs.

Note 1: The words 'draining liquid' means, in this paragraph water, and/or snow.

**2.1.18** Suitable protection screens of not more than 13 mm square mesh shall be fitted on vent outlets to prevent the ingress of extraneous objects without adversely affecting the flow. Other requirements for protection screens apply when carrying specific cargoes (see Ch 9, Sec 17, [9] and Ch 9, Sec 17, [21]).

**2.1.19** All vent piping shall be designed and arranged not to be damaged by the temperature variations to which it may be exposed, forces due to flow or the ship's motions.

**2.1.20** PRVs shall be connected to the highest part of the cargo tank above deck level. PRVs shall be positioned on the cargo tank so that they will remain in the vapour phase at the filling limit (FL) as defined in Ch 9, Sec 15, under conditions of 15° list and 0,015 L trim, where L is defined in Ch 9, Sec 1, [4.1.31].

**2.1.21** The adequacy of the vent system fitted on tanks loaded in accordance with Ch 9, Sec 15, [1.5.2] shall be demonstrated, taking into account IMO resolution A.829(19)). A relevant certificate shall be permanently kept on board the ship. For the purposes of this paragraph, vent system means:

- the tank outlet and the piping to the PRV
- the PRV, and
- the piping from the PRVs to the location of discharge to the atmosphere, including any interconnections and piping that joins other tanks.

### 3 Vacuum protection systems

#### 3.1 General

**3.1.1** Cargo tanks not designed to withstand a maximum external pressure differential 0,025 MPa, or tanks that cannot withstand the maximum external pressure differential that can be attained at maximum discharge rates with no vapour return into the cargo tanks, or by operation of a cargo refrigeration system, or by thermal oxidation, shall be fitted with:

- a) two independent pressure switches to sequentially alarm and subsequently stop all suction of cargo liquid or vapour from the cargo tank and refrigeration equipment, if fitted, by suitable means at a pressure sufficiently below the maximum external designed pressure differential of the cargo tank, or
- b) vacuum relief valves with a gas flow capacity at least equal to the maximum cargo discharge rate per cargo tank, set to open at a pressure sufficiently below the external design differential pressure of the cargo tank.

**3.1.2** Subject to the requirements of Ch 9, Sec 17, the vacuum relief valves shall admit an inert gas, cargo vapour or air to the cargo tank and shall be arranged to minimize the possibility of the entrance of water or snow. If cargo vapour is admitted, it shall be from a source other than the cargo vapour lines.

**3.1.3** The vacuum protection system shall be capable of being tested to ensure that it operates at the prescribed pressure.

### 4 Sizing of pressure relieving system

#### 4.1 Sizing of pressure relief valves

**4.1.1** PRVs shall have a combined relieving capacity for each cargo tank to discharge the greater of the following, with not more than a 20% rise in cargo tank pressure above the MARVS:

- a) The maximum capacity of the cargo tank inerting system, if the maximum attainable working pressure of the cargo tank inerting system exceeds the MARVS of the cargo tanks, or
- b) Vapours generated under fire exposure computed using the following formula:

$$Q = FGA^{0,82}$$

where:

Q : Minimum required rate of discharge, in m<sup>3</sup>/s, of air at standard conditions of 273,15 Kelvin (K) and 0,1013 MPa

F : Fire exposure factor for different cargo types as follows:

- 1,0 for tanks without insulation located on deck
- 0,5 for tanks above the deck, when insulation is approved by the Society. Approval will be based on the use of a fireproofing material, the thermal conductance of insulation and its stability under fire exposure
- 0,5 for uninsulated independent tanks installed in holds
- 0,2 for insulated independent tanks in holds (or uninsulated independent tanks in insulated holds)
- 0,1 for insulated independent tanks in inerted holds (or uninsulated independent tanks in inerted, insulated holds)
- 0,1 for membrane and semi-membrane tanks. For independent tanks partly protruding through the weather decks, the fire exposure factor shall be determined on the basis of the surface areas above and below deck

A : External surface area of the tank, in m<sup>2</sup>, as defined in Ch 9, Sec 1, [4.1.15], for different tank types, as shown in Fig 2

Note 1: L<sub>min</sub>, for non-tapered tanks, is the smaller of the horizontal dimensions of the flat bottom of the tank. For tapered tanks, as would be used for the forward tank, L<sub>min</sub> is the smaller of the length and the average width.

- For prismatic tanks whose distance between the flat bottom of the tank and bottom of the hold space is equal to or less than L<sub>min</sub>/10, A is to be taken equal to the external surface area minus flat bottom surface area
- For prismatic tanks whose distance between the flat bottom of the tank and bottom of the hold space is greater than L<sub>min</sub>/10, A is to be taken equal to the external surface area.

*G* : Gas factor according to formula:

$$G = \frac{12,4}{LD} \sqrt{\frac{ZT}{M}}$$

with:

*T* : Temperature in degrees Kelvin at relieving conditions, i.e. 120% of the pressure at which the pressure relief valve is set

*L* : Latent heat of the material being vaporized at relieving conditions, in kJ/kg

*D* : A constant based on relation of specific heats and is calculated as follows:

$$D = \sqrt{k \left( \frac{2}{k+1} \right)^{\frac{k+1}{k-1}}}$$

*k* : Ratio of specific heats at relieving conditions, and the value of which is between 1,0 and 2,2. If *k* is not known, *D* = 0,606 shall be used

*Z* : Compressibility factor of the gas at relieving conditions. If not known, *Z* = 1 shall be used

*M* : Molecular mass of the product.

The gas factor of each cargo to be carried shall be determined and the highest value shall be used for PRV sizing.

The required mass flow of air at relieving conditions is given by the formula:

$$M_{air} = Q \rho_{air}$$

where:

$\rho_{air}$  : Density of air, taken equal to 1,296 kg/m<sup>3</sup> (air at 273,15 K and 0,1013 MPa).

## 4.2 Sizing of vent pipe system

4.2.1 Pressure losses upstream and downstream of the PRVs shall be taken into account when determining their size to ensure the flow capacity required by [4.1].

## 4.3 Upstream pressure losses

4.3.1 The pressure drop in the vent line from the tank to the PRV inlet shall not exceed 3% of the valve set pressure at the calculated flow rate, in accordance with [4.1].

4.3.2 Pilot-operated PRVs shall be unaffected by inlet pipe pressure losses when the pilot senses directly from the tank dome.

4.3.3 Pressure losses in remotely sensed pilot lines shall be considered for flowing type pilots.

## 4.4 Downstream pressure losses

4.4.1 Where common vent headers and vent masts are fitted, calculations shall include flow from all attached PRVs.

4.4.2 The built-up back pressure in the vent piping from the PRV outlet to the location of discharge to the atmosphere, and including any vent pipe interconnections that join other tanks, shall not exceed the following values:

- for unbalanced PRVs: 10% of MARVS
- for balanced PRVs: 30% of MARVS, and
- for pilot operated PRVs: 50% of MARVS.

Alternative values provided by the PRV manufacturer may be accepted.

## 4.5 Blow-down

4.5.1 To ensure stable PRV operation, the blow-down shall not be less than the sum of the inlet pressure loss and 0,02 MARVS at the rated capacity.

Figure 2 : External surface area of the tank

# Section 9 Cargo Containment System Atmosphere Control

## 1 General

### 1.1 Atmosphere control within the cargo containment system

**1.1.1** A piping system shall be arranged to enable each cargo tank to be safely gas-freed, and to be safely filled with cargo vapour from a gas-free condition. The system shall be arranged to minimize the possibility of pockets of gas or air remaining after changing the atmosphere.

**1.1.2** For flammable cargoes, the system shall be designed to eliminate the possibility of a flammable mixture existing in the cargo tank during any part of the atmosphere change operation by utilizing an inerting medium as an intermediate step.

**1.1.3** Piping systems that may contain flammable cargoes shall comply with [1.1.1] and [1.1.2].

**1.1.4** A sufficient number of gas sampling points shall be provided for each cargo tank and cargo piping system to adequately monitor the progress of atmosphere change. Gas sampling connections shall be fitted with a single valve above the main deck, sealed with a suitable cap or blank (see Ch 9, Sec 5, [6.4.5]).

**1.1.5** Inert gas utilized in these procedures may be provided from the shore or from the ship.

### 1.2 Atmosphere control within the hold spaces (cargo containment systems other than type C independent tanks)

**1.2.1** Interbarrier and hold spaces associated with cargo containment systems for flammable gases requiring full or partial secondary barriers shall be inerted with a suitable dry inert gas and kept inerted with make-up gas provided by a shipboard inert gas generation system, or by shipboard storage, which shall be sufficient for normal consumption for at least 30 days.

**1.2.2** Alternatively, subject to the restrictions specified in Ch 9, Sec 17, the spaces referred to in [1.2.1] requiring only a partial secondary barrier may be filled with dry air provided that the ship maintains a stored charge of inert gas or is fitted with an inert gas generation system sufficient to inert the largest of these spaces, and provided that the configuration of the spaces and the relevant vapour detection systems, together with the capability of the inerting arrangements, ensures that any leakage from the cargo tanks will be rapidly detected and inerting effected before a dangerous condition can develop. Equipment for the provision of sufficient dry air of suitable quality to satisfy the expected demand shall be provided.

**1.2.3** For non-flammable gases, the spaces referred to in [1.2.1] and [1.2.2] may be maintained with a suitable dry air or inert atmosphere.

### 1.3 Environmental control of spaces surrounding type C independent tanks

**1.3.1** Spaces surrounding cargo tanks that do not have secondary barriers shall be filled with suitable dry inert gas or dry air and be maintained in this condition with make-up inert gas provided by a shipboard inert gas generation system, shipboard storage of inert gas, or with dry air provided by suitable air drying equipment. If the cargo is carried at ambient temperature, the requirement for dry air or inert gas is not applicable.

**1.3.2** As far as the requirements relevant to the dew point are concerned, the following additional provisions apply:

- a) Where cargo tank insulation is not protected from water vapour penetration by means of an effective vapour barrier, accepted by the Society, the maximum value of the dew point is to be less than the design temperature
- b) Where cargo tank insulation is protected by an effective vapour barrier, accepted by the Society, the maximum value of the dew point is to be less than the minimum temperature which may be found on any surface within the spaces filled with dry inert gas or dry air
- c) The temperature of the hull structures adjacent to cargo tanks is not to become lower than the minimum permissible working temperature, specified in Ch 9, Sec 6 for the steel grade employed for such hull structures
- d) The capacity of dry air or inert gas equipment to produce dry air is to be verified in workshop
- e) Means are to be provided on board to measure the dryness of the hold space atmosphere. The equipment may be portable provided permanent connections and/or sampling pipes are fitted.

## **1.4 Inerting**

**1.4.1** *Inerting refers to the process of providing a non-combustible environment. Inert gases shall be compatible chemically and operationally at all temperatures likely to occur within the spaces and the cargo. The dew points of the gases shall be taken into consideration.*

**1.4.2** Precautions are to be taken to minimise the risk that static electricity generated by the inert gas system may become a source of ignition.

**1.4.3** *Where inert gas is also stored for fire-fighting purposes, it shall be carried in separate containers and shall not be used for cargo services.*

**1.4.4** *Where inert gas is stored at temperatures below 0°C, either as a liquid or as a vapour, the storage and supply system shall be designed so that the temperature of the ship's structure is not reduced below the limiting values imposed on it.*

**1.4.5** *Arrangements to prevent the backflow of cargo vapour into the inert gas system that are suitable for the cargo carried, shall be provided. If such plants are located in machinery spaces or other spaces outside the cargo area, two non-return valves or equivalent devices and, in addition, a removable spool piece shall be fitted in the inert gas main in the cargo area. When not in use, the inert gas system shall be made separate from the cargo system in the cargo area except for connections to the hold spaces or interbarrier spaces.*

**1.4.6** *The arrangements shall be such that each space being inerted can be isolated and the necessary controls and relief valves, etc., shall be provided for controlling pressure in these spaces.*

**1.4.7** *Where insulation spaces are continually supplied with an inert gas as part of a leak detection system, means shall be provided to monitor the quantity of gas being supplied to individual spaces.*

## **1.5 Inert gas production on board**

**1.5.1** Attention is drawn to the requirements of Ch 9, Sec 1, [6.2.4] regarding the satisfactory operation of the inert gas generating plant and of the associated control system that is to be ascertained during the first full loading and the subsequent first unloading of ships carrying liquefied natural gasses (LNG) in bulk.

### **1.5.2**

- a) Spaces associated with cargo containment adjacent to cargo tanks containing flammable products having a flashpoint equal to or less than 60°C are to be kept in an inert gas environment.
- b) Inert gas generating systems are to be considered as essential services and are to comply with the applicable Sections of the Rules, as far as applicable.
- c) Where, in addition to inert gas produced on board, it is possible to introduce dry air into the above mentioned spaces, where this is acceptable depending on the type of cargo tank adopted, or to introduce inert gas from a supply existing on board, it is not necessary that standby or spare components for the inert gas system are kept on board.

**1.5.3** *The equipment shall be capable of producing inert gas with an oxygen content at no time greater than 5% by volume, subject to the special requirements of Ch 9, Sec 17. A continuous-reading oxygen content meter shall be fitted to the inert gas supply from the equipment and shall be fitted with an alarm set at a maximum of 5% oxygen content by volume, subject to the requirements of Ch 9, Sec 17.*

**1.5.4** *An inert gas system shall have pressure controls and monitoring arrangements appropriate to the cargo containment system.*

**1.5.5** *Spaces containing inert gas generation plants shall have no direct access to accommodation spaces, service spaces or control stations, but may be located in machinery spaces. Inert gas piping shall not pass through accommodation spaces, service spaces or control stations.*

**1.5.6** *Combustion equipment for generating inert gas shall not be located within the cargo area. Special consideration may be given to the location of inert gas generating equipment using a catalytic combustion process.*

## **1.6 Engineering specifications for nitrogen / inert gas systems**

### **1.6.1 Requirements of:**

- Pt C, Ch 4, Sec 15, [13.2.2], item b)
- Pt C, Ch 4, Sec 15, [13.2.2], item d)
- Pt C, Ch 4, Sec 15, [13.2.4], item b)
- Pt C, Ch 4, Sec 15, [13.2.4], item c)
- Pt C, Ch 4, Sec 15, [13.2.4], item e) 1) regarding oxygen content and power supply to the indicating devices
- Pt C, Ch 4, Sec 15, [13.2.4], item e) 4)
- Pt C, Ch 4, Sec 15, [13.4.2] and
- Pt C, Ch 4, Sec 15, [13.4.3],

apply to the systems.

**1.6.2** The nitrogen generator is to be capable of delivering high purity nitrogen in accordance with Pt C, Ch 4, Sec 15, [13.2.1], item b) 5). In addition to Pt C, Ch 4, Sec 15, [13.2.2], item d), the system is to be fitted with automatic means to discharge “off-spec” gas to the atmosphere during start-up and abnormal operation.

**1.6.3** The feed air treatment system fitted to remove free water, particles and traces of oil from the compressed air as required by Pt C, Ch 4, Sec 15, [13.4.2], item b), is also to preserve the specification temperature.

**1.6.4** The oxygen-enriched air from the nitrogen generator and the nitrogen-product enriched gas from the protective devices of the nitrogen receiver are to be discharged to a safe location on the open deck.

Note 1: “safe location” needs to address the two types of discharges separately:

- oxygen-enriched air from the nitrogen generator - safe locations on the open deck are:
  - outside of hazardous area;
  - not within 3m of areas traversed by personnel; and
  - not within 6m of air intakes for machinery (engines and boilers) and all ventilation inlets
- nitrogen-product enriched gas from the protective devices of the nitrogen receiver - safe locations on the open deck are:
  - not within 3m of areas traversed by personnel; and
  - not within 6m of air intakes for machinery (engines and boilers) and all ventilation inlets/outlets.

**1.6.5** In order to permit maintenance, means of isolation are to be fitted between the generator and the receiver.

**1.6.6** The two non-return devices as required by Pt C, Ch 4, Sec 15, [13.2.3], item a) 1) are to be fitted in the inert gas main. The non-return devices are to comply with Pt C, Ch 4, Sec 15, [13.2.3], item a) 2) and Pt C, Ch 4, Sec 15, [13.2.3], item a) 3); however, where the connections to the cargo tanks, to the hold spaces or to cargo piping are not permanent, the non-return devices required by Pt C, Ch 4, Sec 15, [13.2.3], item a) 1) may be substituted by two non-return valves.

# Section 10 Electrical Installations

## 1 General

### 1.1 Application

1.1.1 The requirements in this Section apply, in addition to those contained in Part C, Chapter 2 to gas carriers.

### 1.2 Documentation to be submitted

1.2.1 In addition to the documentation requested in Pt C, Ch 2, Sec 1, Tab 1 the following are to be submitted for approval:

- plan of hazardous areas
- document giving details of types of cables and safety characteristics of the equipment installed in hazardous areas
- diagrams of tank level indicator systems, high level alarm systems and overflow control systems where requested.

### 1.3 Definitions

1.3.1 For the purpose of this Section, unless expressly provided otherwise, the definitions below shall apply.

#### 1.3.2 Hazardous area

*Hazardous area is an area in which an explosive gas atmosphere is or may be expected to be present, in quantities such as to require special precautions for the construction, installation and use of electrical apparatus.*

*Note 1: Examples of hazardous area zoning may be found in Tab 1.*

#### 1.3.3 Zone 0 hazardous

*Zone 0 hazardous area is an area in which an explosive gas atmosphere is present continuously or is present for long periods.*

#### 1.3.4 Zone 1 hazardous

*Zone 1 hazardous area is an area in which an explosive gas atmosphere is likely to occur in normal operation.*

#### 1.3.5 Zone 2 hazardous

*Zone 2 hazardous area is an area in which an explosive gas atmosphere is not likely to occur in normal operation and, if it does occur, is likely to do so infrequently and for a short period only.*

#### 1.3.6 Non-hazardous

*Non-hazardous area is an area in which an explosive gas atmosphere is not expected to be present in quantities such as to require special precautions for the construction, installation and use of electrical apparatus.*

### 1.4 General requirements

1.4.1 *Electrical installations shall be such as to minimize the risk of fire and explosion from flammable products.*

1.4.2 *Suitable arrangements are to be provided, to the satisfaction of the Society, so as to prevent the possibility of gases or vapours passing from a hazardous area to another area through runs of cables or their conduits.*

1.4.3 *Electrical installations shall be in accordance with recognized standards.*

*Note 1: Refer to the recommendation published by the International Electrotechnical Commission in particular to publication IEC 60092-502:1999.*

*However, where the prescriptive requirements in the present Rules and IEC 60092-502 are not aligned, the prescriptive requirements in the present Rules take precedence and are to be applied.*

1.4.4 *Electrical equipment or wiring shall not be installed in hazardous areas, unless essential for operational purposes or safety enhancement.*

1.4.5 *Where electrical equipment is installed in hazardous areas as provided in [1.4.4], it shall be selected, installed and maintained in accordance with standards not inferior to those acceptable to the Society. The types of electrical equipment admitted, depending on the zone where they are installed, are specified in Pt C, Ch 2, Sec 3, [10]. Equipment for hazardous areas shall be type approved by the Society. Automatic isolation of non-certified equipment on detection of a flammable gas shall not be accepted as an alternative to the use of certified equipment.*

1.4.6 *To facilitate the selection of appropriate electrical apparatus and the design of suitable electrical installations, hazardous areas are divided into zone 0, 1 and 2 according to [1.3]. The different spaces are to be classified according to Tab 1.*

Table 1 : Space descriptions and hazardous area zones

No.	Description of spaces	Hazardous area
1	The interior of cargo tanks, any pipework of pressure-relief or other venting systems for cargo, pipes and equipment containing the cargo or developing flammable gases and vapours	Zone 0
2	Interbarrier spaces, hold spaces where cargo is carried in a cargo containment system requiring a secondary barrier	Zone 0
3	Void space adjacent to, above or below integral cargo tanks	Zone 1
4	Hold spaces where cargo is carried in a cargo containment system not requiring a secondary barrier	Zone 1
5	Cofferdams and permanent (for example, segregated) ballast tanks adjacent to cargo tanks	Zone 1
6	Cargo pump rooms and cargo compressor rooms	Zone 1
7	Enclosed or semi-enclosed spaces, immediately above cargo tanks (for example, between decks) or having bulkheads above and in line with cargo tank bulkheads, unless protected by a diagonal plate acceptable to the society	Zone 1
8	Spaces, other than cofferdam, adjacent to and below the top of a cargo tank (for example, trunks, passageways and hold)	Zone 1
9	Areas on open deck, or semi-enclosed spaces on open deck, within 3 m of any cargo tank outlet, gas or vapour outlet, cargo manifold valve, cargo valve, cargo pipe flange, cargo pump-room ventilation outlets, cargo compressor room ventilation outlets and cargo tank openings for pressure release provided to permit the flow of small volumes of gas or vapour mixtures caused by thermal variation	Zone 1
10	Areas on open deck, or semi-enclosed spaces on open deck above and in the vicinity of any cargo gas outlet intended for the passage of large volumes of gas or vapour mixture during cargo loading and ballasting or during discharging, within a vertical cylinder of unlimited height and 6 m radius centred upon the centre of the outlet, and within a hemisphere of 6 m radius below the outlet	Zone 1
11	Areas on open deck, or semi-enclosed spaces on open deck, within 1,5 m of cargo pump room entrances, cargo pump room ventilation inlet, openings into cofferdams, cargo compressor room entrances, cargo compressor room ventilation inlets or other zone 1 spaces	Zone 1
12	Areas on open deck within spillage coamings surrounding cargo manifold valves and 3 m beyond these, up to a height of 2,4 m above the deck	Zone 1
13	Areas on open deck over the cargo area where structures are restricting the natural ventilation and to the full breadth of the ship plus 3 m fore and aft of the forward-most and aft-most cargo tank bulkhead, up to a height of 2,4 m above the deck	Zone 1
14	Compartments for cargo hoses	Zone 1
15	Enclosed or semi-enclosed spaces in which pipes containing cargoes are located	Zone 1
16	A space separated from a hold space, where cargo is carried in a cargo tank requiring a secondary barrier, by a single gastight boundary	Zone 1
17	Enclosed or semi-enclosed spaces in which pipes containing cargo products for boil-off gas fuel burning systems are located, unless special precautions approved by the society are provided to prevent product gas escaping into such spaces	Zone 1
18	Areas of 1,5 m surrounding a space of zone 1	Zone 2
19	Spaces 4 m beyond the cylinder and 4 m beyond the sphere defined in item 10	Zone 2
20	The spaces forming an airlock as defined in Ch 9, Sec 3, [1.6]	Zone 2
21	Areas on open deck extending to the coamings fitted to keep any spills on deck and away from the accommodation and service area and 3 m beyond these up to a height of 2,4 m above the deck.	Zone 2
22	Areas on open deck over the cargo area where unrestricted natural ventilation is guaranteed and to the full breadth of the ship plus 3 m fore and aft of the forward-most and aft-most cargo tank bulkhead, up to a height of 2,4 m above the deck surrounding open or semi-enclosed spaces of zone 1.	Zone 2
23	Spaces forward of the open deck areas to which reference is made in 13 and 22, below the level of the main deck, and having an opening on to the main deck or at a level less than 0,5 m above the main deck, unless: <ul style="list-style-type: none"> <li>• the doors and all openings are in non-hazardous area; and</li> <li>• the spaces are mechanically ventilated</li> </ul>	Zone 2
24	An area within 2,4 m of the outer surface of a cargo tank where such surface is exposed to the weather.	Zone 2

**1.4.7** *Electrical generation and distribution systems, and associated control systems shall be designed such that a single fault will not result in the loss of ability to maintain cargo tank pressures, as required by Ch 9, Sec 7, [8.1.1], item a) and hull structure temperature, as required by Ch 9, Sec 4, [5.2.1], item f), within normal operating limits. Failure modes and effects shall be analysed and documented to a standard not inferior to those acceptable to the Administration.*

*Note 1: IEC 60812, Edition 2.0 2006-01 "Analysis techniques for system reliability - Procedure for failure mode and effects analysis (FMEA)".*

**1.4.8** *The lighting system in hazardous areas shall be divided between at least two branch circuits. All switches and protective devices shall interrupt all poles or phases and shall be located in a non-hazardous area.*

**1.4.9** *Electrical depth sounding or log devices and impressed current cathodic protection system anodes or electrodes shall be housed in gastight enclosures.*

**1.4.10** *Submerged cargo pump motors and their supply cables may be fitted in cargo containment systems. Arrangements shall be made to automatically shut down the motors in the event of low-liquid level. This may be accomplished by sensing low pump discharge pressure, low motor current or low liquid level. This shutdown shall be alarmed at the cargo control station. Cargo pump motors shall be capable of being isolated from their electrical supply during gas-freeing operations.*

## **1.5 System of supply**

### **1.5.1 Acceptable systems of supply**

The following systems of generation and distribution of electrical energy are acceptable:

- a) direct current:
  - two-wire insulated
- b) alternating current:
  - single-phase, two-wire insulated
  - three-phase, three-wire insulated.

In insulated distribution systems, no current carrying part is to be earthed, other than:

- a) through an insulation level monitoring device
- b) through components used for the suppression of interference in radio circuits.

### **1.5.2 Earthed system with hull return**

Earthed systems with hull return are not permitted, with the following exceptions to the satisfaction of the Society:

- a) impressed current cathodic protective systems
- b) limited and locally earthed systems, such as starting and ignition systems of internal combustion engines, provided that any possible resulting current does not flow directly through any hazardous area
- c) insulation level monitoring devices, provided that the circulation current of the device does not exceed 30 mA under the most unfavourable conditions.

### **1.5.3 Earthed systems without hull return**

Earthed systems without hull return are not permitted, with the following exceptions:

- a) earthed intrinsically safe circuits and the following other systems to the satisfaction of the Society
- b) power supplies, control circuits and instrumentation circuits in non-hazardous areas where technical or safety reasons preclude the use of a system with no connection to earth, provided the current in the hull is limited to not more than 5 A in both normal and fault conditions, or
- c) limited and locally earthed systems, such as power distribution systems in galleys and laundries to be fed through isolating transformers with the secondary windings earthed, provided that any possible resulting hull current does not flow directly through any hazardous area, or
- d) alternating current power networks of 1,000 V root mean square (line to line) and over, provided that any possible resulting current does not flow directly through any hazardous area; to this end, if the distribution system is extended to areas remote from the machinery space, isolating transformers or other adequate means are to be provided.

## **1.6 Earth detection**

### **1.6.1 Monitoring of circuits in hazardous areas**

The devices intended to continuously monitor the insulation level of all distribution systems are also to monitor all circuits, other than intrinsically safe circuits, connected to apparatus in hazardous areas or passing through such areas. An audible and visual alarm is to be given, at a manned position, in the event of an abnormally low level of insulation.

## **1.7 Mechanical ventilation of hazardous spaces**

**1.7.1** Electric motors driving fans of the ventilating systems of hazardous spaces are to be located outside the ventilation ducting.

**1.7.2** Motors driving ventilating fans may be located within the ducting provided that they are of a certified safe type.

**1.7.3** The materials used for the fans and their housing are to be in compliance with Pt C, Ch 4, Sec 1, [2.32].

**1.7.4** Cargo compressor rooms and other enclosed spaces which contain cargo-handling equipment and similar spaces in which work is performed on the cargo should be fitted with mechanical ventilation systems, capable of being controlled from outside such spaces.

**1.7.5** Provisions are to be made to ventilate the spaces defined in [1.7.4] prior to entering the compartment and operating the equipment.

## **2 Hazardous locations and types of equipment**

### **2.1 Electrical equipment permitted in gas-dangerous spaces and zones**

**2.1.1** A space separated by a gastight boundaries from a hazardous area may be classified as zone 0, 1, 2 or considered as non hazardous, taking into account the sources of release inside that space and its conditions of ventilation.

**2.1.2** Access door and other openings are not to be provided between an area intended to be considered as non-hazardous and a hazardous area or between a space intended to be considered as zone 2 and a zone 1, except where required for operational reasons.

**2.1.3** In enclosed or semi-enclosed spaces having a direct opening into any hazardous space or area, electrical installations are to comply with the requirements for the space or area to which the opening leads.

**2.1.4** Where a space has an opening into an adjacent, more hazardous space or area, it may be made into a less hazardous space or non-hazardous space, taking into account the type of separation and the ventilation system.

**2.1.5** A differential pressure monitoring device or a flow monitoring device, or both, are to be provided for monitoring the satisfactory functioning of pressurisation of spaces having an opening into a more hazardous zone.

In the event of loss of the protection by the over-pressure or loss of ventilation in spaces classified as zone 1 or zone 2, protective measures are to be taken.

### **2.2 Submerged cargo pumps**

#### **2.2.1 Exceptions**

Submerged cargo pumps are not permitted in connection with the following cargoes:

- diethyl ether
- vinyl ethyl ether
- ethylene oxide
- propylene oxide
- mixtures of ethylene oxide and propylene oxide.

#### **2.2.2 Submerged electric motors**

In addition to the requirements of [1.4.10], where submerged electric motors are employed, means are to be provided, e.g. by the arrangements specified in Ch 9, Sec 17, [6] to avoid the formation of explosive mixtures during loading, cargo transfer and unloading.

## **3 Product classification**

### **3.1 Temperature class and explosion group**

**3.1.1** Tab 2 specifies temperature class and explosion group data for the products indicated in Ch 9, Sec 19. The data shown in brackets have been derived from similar products.

**Table 2 : Temperature class and explosion group of certain products**

Product name	Temperature class	Explosion group
Acetaldehyde	T4	II A
Ammonia anhydrous	T1	II A
Butadiene	T2	II B
Butane	T2	II A
Butane/propane mixture	T2	II A
Butylenes	T3	II A
Carbon dioxide	NF	NF

Product name	Temperature class	Explosion group
Chlorine	NF	NF
Diethyl ether	T4	II B
Dimethylamine	T2	II A
Dimethyl ether	T3	II B
Ethane	T1	II A
Ethyl chloride	T2	II A
Ethylene	T2	II B
Ethylene oxide	T2	II B
Ethylene oxide propylene oxide mixture (max. 30% w/w ethylene oxide)	T2	II B
Isoprene	T3	II B
Isopropylamine	T2	II A
Methane	T1	II A
Methyl acetylene propadiene mixture	T4	II A
Methyl bromide	T3	II A
Methyl chloride	T1	II A
Monoethylamine	T2	II A
Nitrogen	NF	NF
Pentane (all isomers)	(T2)	(II A)
Pentene (all isomers)	(T3)	(II B)
Propane	T1	II A
Propylene	T2	II B
Propylene oxide	T2	II B
Refrigerant gases	NF	NF
Sulphur dioxide	(T3)	(II B)
Vinyl chloride	T2	II A
Vinyl ethyl ether	T3	II B
Vinylidene chloride	T2	II A

# Section 11 Fire Protection and Extinction

## 1 General

### 1.1 Fire safety requirements

**1.1.1** The requirements for tankers in SOLAS chapter II-2 shall apply to ships covered by the Code, irrespective of tonnage including ships of less than 500 gross tonnage, except that:

- a) regulations 4.5.1.6 and 4.5.10 do not apply
- b) requirements of 10.4 and 10.5 shall apply as they would apply to tankers of 2,000 gross tonnage and over
- c) regulation 10.5.6 shall apply to ships of 2,000 gross tonnage and over
- d) the regulations of SOLAS chapter II-2 related to tankers listed in Tab 1 do not apply and are replaced by requirements of this Chapter as detailed in Tab 1
- e) regulations 13.3.4 and 13.4.3 shall apply to ships of 500 gross tonnage and over.

**Table 1 :**

SOLAS Chapter II-2 Regulation	Replaced by the following requirements
10.10	[1.6]
4.5.1.1 and 4.5.1.2	Ch 9, Sec 3
4.5.5	Relevant requirements in this Section
10.8	[1.3] and [1.4]
10.9	[1.5]
10.2	from [1.2.1] to [1.2.4]

**1.1.2** All sources of ignition shall be excluded from spaces where flammable vapour may be present, except as otherwise provided in Ch 9, Sec 10 and Ch 9, Sec 16.

**1.1.3** The maximum temperature of the steam and heating media in the cargo area is to be adjusted to take into account the temperature class of the cargo.

**1.1.4** The provisions of this Section shall apply in conjunction with Ch 9, Sec 3.

**1.1.5** For the purposes of fire fighting, any weather deck areas above cofferdams, ballast or void spaces at the after end of the aftermost hold space or at the forward end of the forwardmost hold space shall be included in the cargo area.

### 1.2 Fire mains and hydrants

**1.2.1** Irrespective of size, ships carrying products that are subject to the Code shall comply with the requirements of regulation II-2/10.2 of the SOLAS Convention, as applicable to cargo ships, except that the required fire pump capacity and fire main and water service pipe diameter shall not be limited by the provisions of regulations II-2/10.2.2.4.1 and II-2/10.2.1.3, when a fire pump is used to supply the water-spray system, as permitted by [1.3.5]. The capacity of this fire pump shall be such that these areas can be protected when simultaneously supplying two jets of water from fire hoses with 19 mm nozzles at a pressure of at least 0.5 MPa gauge.

**1.2.2** The arrangements shall be such that at least two jets of water can reach any part of the deck in the cargo area and those portions of the cargo containment system and tank covers that are above the deck. The necessary number of fire hydrants shall be located to satisfy the above arrangements and to comply with the requirements of regulations II-2/10.2.1.5.1 and II-2/10.2.3.3 of the SOLAS Convention, with hose lengths as specified in regulation II-2/10.2.3.1.1. In addition, the requirements of regulation II-2/10.2.1.6 shall be met at a pressure of at least 0.5 MPa gauge.

**1.2.3** Stop valves shall be fitted in any crossover provided and in the fire main or mains in a protected location, before entering the cargo area and at intervals ensuring isolation of any damaged single section of the fire main, so that [1.2.2] can be complied with using not more than two lengths of hoses from the nearest fire hydrant. The water supply to the fire main serving the cargo area shall be a ring main supplied by the main fire pumps or a single main supplied by fire pumps positioned fore and aft of the cargo area, one of which shall be independently driven.

**1.2.4** Nozzles shall be of an approved dual-purpose type (i.e. spray/jet type) incorporating a shutoff.

**1.2.5** After installation, the pipes, valves, fittings and assembled system shall be subject to a tightness and function test.

**1.2.6** When the ship is fitted with a total flooding high expansion foam system protecting the engine-room (to comply with Pt C, Ch 4, Sec 6, [3.1.1], item b) and Pt C, Ch 4, Sec 6, [4.2.1]) and the emergency fire pump is intended to supply sea water to this system and to the water-spray system in pursuance of [1.3.6], then, the emergency fire pump is to be sized to cover the foam system for dealing with an engine-room fire, when the main fire pumps are disabled. On the basis of the principle of dealing with one single fire incident at a time, the emergency fire pump does not need to be sized to cover all three systems above (i.e. water spray, hydrants and foam) at the same time and only needs to be sized to cover the most demanding area and required systems, as follows:

- the foam system + two hydrants; or
- the water spray system + two hydrants;

whichever is greater.

### **1.3 Water-spray system**

**1.3.1** A stop valve is to be fitted on the water-spray main as close as possible to the poop front so that the accommodation spaces are always protected in the case of a spray-main failure.

**1.3.2** *On ships carrying flammable and/or toxic products, a water-spray system, for cooling, fire prevention and crew protection shall be installed to cover:*

- exposed cargo tank domes, any exposed parts of cargo tanks and any part of cargo tank covers that may be exposed to heat from fires in adjacent equipment containing cargo such as exposed booster pumps/heaters/re-gasification or re-liquefaction plants, hereafter addressed as gas process units, positioned on weather decks*
- exposed on-deck storage vessels for flammable or toxic products*
- gas process units positioned on deck*
- cargo liquid and vapour discharge and loading connections, including the presentation flange and the area where their control valves are situated, which shall be at least equal to the area of the drip trays provided*
- all exposed emergency shut-down (ESD) valves in the cargo liquid and vapour pipes, including the master valve for supply to gas consumers*
- exposed boundaries facing the cargo area, such as bulkheads of superstructures and deckhouses normally manned, cargo machinery spaces, store-rooms containing high fire-risk items and cargo control rooms. Exposed horizontal boundaries of these areas do not require protection unless detachable cargo piping connections are arranged above or below. Boundaries of unmanned forecastle structures not containing high fire-risk items or equipment do not require water-spray protection*
- exposed lifeboats, liferafts and muster stations facing the cargo area, regardless of distance to cargo area, and*

*Note 1:* The survival crafts on board including remote survival crafts required by SOLAS III/31.1.4 facing the cargo area are to be protected by a water-spray system taking into consideration cargo area extension for fire-fighting purposes as stated in [1.1.5].

Remote liferafts located in areas covered by water-spray protection as required in item f) may be considered as adequately protected.

- any semi-enclosed cargo machinery spaces and semi-enclosed cargo motor room.*

*Ships intended for operation as listed in Ch 9, Sec 1, [2.1.10] shall be subject to special consideration (see [1.3.5]).*

The water spray system mentioned in [1.3.2] is also to cover boundaries of spaces containing internal combustion engines and/or fuel treatment units, of store-rooms for flammable liquids having a flashpoint equal to or less than 60°C and of paint lockers.

**1.3.3** *The system shall be capable of covering all areas mentioned in [1.3.2], with a uniformly distributed water application rate of at least 10 litre/m<sup>2</sup>/min for the largest projected horizontal surfaces and 4 litre/m<sup>2</sup>/min for vertical surfaces. For structures having no clearly defined horizontal or vertical surface, the capacity of the water-spray system shall not be less than the projected horizontal surface multiplied by 10 ℓ/m<sup>2</sup>/min.*

**1.3.4** *On vertical surfaces, spacing of nozzles protecting lower areas may take account of anticipated rundown from higher areas. Stop valves shall be fitted in the main supply line(s) in the water-spray system, at intervals not exceeding 40 m, for the purpose of isolating damaged sections. Alternatively, the system may be divided into two or more sections that may be operated independently, provided the necessary controls are located together in a readily accessible position outside the cargo area. A section protecting any area included in [1.3.2], items a) and b), shall cover at least the entire athwartship tank grouping in that area. Any gas process unit(s) included in [1.3.2] may be served by an independent section.*

The number and location of spray nozzles are to be suitable to spread the sprayed water uniformly on areas to be protected.

**1.3.5** *The capacity of the water-spray pumps shall be capable of simultaneous protection of the greater of the following:*

- any two complete athwartship tank groupings, including any gas process units within these areas, or*

Note 1: The expression "two complete athwartship tank groupings" means any two groups of tanks where one group is defined as tanks located in transverse direction from ship side to ship side. Where there is only one cargo tank occupying a hold space from ship side to ship side, it will be considered as a "grouping" for the purpose of this requirement.

"Any two complete athwartship tank groupings" represents an area equal to the combined area of the two largest tank groupings including any gas process units within these areas.

b) for ships intended for operation as listed in Ch 9, Sec 1, [2.1.10], necessary protection subject to special consideration under [1.3.2] of any added fire hazard and the adjacent athwartship tank grouping,

in addition to surfaces specified in [1.3.2] Alternatively, the main fire pumps may be used for this service, provided that their total capacity is increased by the amount needed for the water-spray system. In either case, a connection, through a stop valve, shall be made between the fire main and water-spray system main supply line outside the cargo area.

**1.3.6** The boundaries of superstructures and deckhouses normally manned, and lifeboats, liferafts and muster areas facing the cargo area, shall also be capable of being served by one of the fire pumps or the emergency fire pump, if a fire in one compartment could disable both fire pumps.

If all the fire pumps supplying the water spray system (for covering the superstructures and deckhouses) may be disabled due to a fire in any one compartment; then the emergency fire pump is to be sized to cover:

- the water spray system for the boundaries of the superstructures and deckhouses, and lifeboats, liferafts and muster areas facing the cargo area; and
- two fire hydrants as required by [1.2.2].

Note 1: The term "fire pumps" where not qualified by the word "emergency" refers to the fire pumps required in accordance with Pt C, Ch 4, Sec 6, [1.2.6], item b).

Note 2: The expression "fire in one compartment" means a compartment provided with A-class boundaries in which is located the fire pump(s), or the source of power of the fire pump(s), serving the water-spray system in accordance with [1.3.5].

**1.3.7** Water pumps normally used for other services may be arranged to supply the water-spray system main supply line.

**1.3.8** All pipes, valves, nozzles and other fittings in the water-spray system shall be resistant to corrosion by seawater. Piping, fittings and related components within the cargo area (except gaskets) shall be designed to withstand 925°C. The water-spray system shall be arranged with in-line filters to prevent blockage of pipes and nozzles. In addition, means shall be provided to back-flush the system with fresh water.

Where fuel oil tanks are installed at the after end of the aftermost hold space or at the forward end of the forwardmost hold space instead of cofferdams as allowed for in requirement of Ch 9, Sec 3, [1.1.3] and Ch 9, Sec 3, [1.1.4], the weather deck area above these tanks is to be regarded as a "cargo area" for the purpose of applying this requirement.

**1.3.9** Remote starting of pumps supplying the water-spray system and remote operation of any normally closed valves in the system shall be arranged in suitable locations outside the cargo area, adjacent to the accommodation spaces and readily accessible and operable in the event of fire in the protected areas.

**1.3.10** After installation, the pipes, valves, fittings and assembled system shall be subject to a tightness and function test.

## **1.4 Dry chemical powder fire-extinguishing systems**

**1.4.1** Ships in which the carriage of flammable products is intended shall be fitted with fixed dry chemical powder fire-extinguishing systems, approved by the Society based on IMO Circular MSC.1/Circ.1315 for the purpose of fire fighting on the deck in the cargo area, including any cargo liquid and vapour discharge and loading connections on deck and bow or stern cargo handling areas, as applicable.

Note 1: Dry chemical powder is to be based on potassium bicarbonate.

**1.4.2** The system shall be capable of delivering powder from at least two hand hose lines, or a combination of monitor/hand hose lines, to any part of the exposed cargo liquid and vapour piping, load/unload connection and exposed gas process units.

**1.4.3** The dry chemical powder fire-extinguishing system shall be designed with not less than two independent units. Any part required to be protected by [1.4.2] shall be capable of being reached from not less than two independent units with associated controls, pressurizing medium fixed piping, monitors or hand hose lines. For ships with a cargo capacity of less than 1,000 m<sup>3</sup>, only one such unit need be fitted. A monitor shall be arranged to protect any load/unload connection area and be capable of actuation and discharge both locally and remotely. The monitor is not required to be remotely aimed, if it can deliver the necessary powder to all required areas of coverage from a single position. One hose line shall be provided at both port- and starboard side at the end of the cargo area facing the accommodation and readily available from the accommodation.

**1.4.4** Powder systems are to be in accordance with the following requirements:

- a) Two powder units, even if mutually connected through a common main, may be considered independent on condition that non-return valves or other arrangements suitable to prevent powder from passing from one unit to the other are fitted.
- b) The powder units which constitute the system are to contain, in general, the same powder quantity and, when they are not grouped together in a single position, they are to be uniformly located over the area to be protected.
- c) Where powder units are grouped together in a single position or, in the case of ships having a cargo capacity less than 1000 m<sup>3</sup>, a single powder unit is installed, the said units are to be located aft of the cargo area.

**1.4.5** *The capacity of a monitor shall be not less than 10kg/s. Hand hose lines shall be non-kinkable and be fitted with a nozzle capable of on/off operation and discharge at a rate not less than 3.5 kg/s. The maximum discharge rate shall allow operation by one man. The length of a hand hose line shall not exceed 33m. Where fixed piping is provided between the powder container and a hand hose line or monitor, the length of piping shall not exceed that length which is capable of maintaining the powder in a fluidized state during sustained or intermittent use, and which can be purged of powder when the system is shut down. Hand hose lines and nozzles shall be of weather-resistant construction or stored in weather resistant housing or covers and be readily accessible.*

**1.4.6** *Hand hose lines shall be considered to have a maximum effective distance of coverage equal to the length of hose. Special consideration shall be given where areas to be protected are substantially higher than the monitor or hand hose reel locations.*

**1.4.7** *Ships fitted with bow/stern load/unload connections shall be provided with independent dry powder unit protecting the cargo liquid and vapour piping, aft or forward of the cargo area, by hose lines and a monitor covering the bow/stern load/unload complying with the requirements from [1.4.1] to [1.4.6].*

**1.4.8** *Ships intended for operation as listed in Ch 9, Sec 1, [2.1.10] shall be subject to special consideration.*

**1.4.9** *After installation, the pipes, valves, fittings and assembled systems shall be subjected to a tightness test and functional testing of the remote and local release stations. The initial testing shall also include a discharge of sufficient amounts of dry chemical powder to verify that the system is in proper working order. All distribution piping shall be blown through with dry air to ensure that the piping is free of obstructions.*

Testing arrangements are to involve the discharge using dry chemical powder from all monitors and hand hose lines on board but it is not required that there is a full discharge of the installed quantity of dry powder. This testing can also be used to satisfy the requirement that the piping is free of obstructions, in lieu of blowing through with dry air all the distribution piping. However, after the completion of this testing, the system, including all monitors and hand hose lines, are to be blown through with dry air but only for the purpose of the system subsequently being clear from any residues of dry chemical powder.

## **1.5 Enclosed spaces containing cargo handling equipment**

**1.5.1** In pump rooms and cargo compressor rooms, at least two portable extinguishers of a recognised type are to be fitted.

**1.5.2** *Enclosed spaces meeting the criteria of cargo machinery spaces in Ch 9, Sec 1, [4.1.11], and the cargo motor room within the cargo area of any ship, shall be provided with a fixed fire-extinguishing system complying with the provisions of the Pt C, Ch 4, Sec 15 and taking into account the necessary concentrations/application rate required for extinguishing gas fires.*

**1.5.3** Audible alarms fitted to warn of the release of fire extinguishing medium into pump rooms, are to be of the pneumatic type or electric type.

- a) In cases where the periodic testing of pneumatically operated alarms is required, CO<sub>2</sub> operated alarms should not be used owing to the possibility of the generation of static electricity in the CO<sub>2</sub> cloud. Air operated alarms may be used provided the air supply is clean and dry.
- b) When electrically operated alarms are used, the arrangements are to be such that the electric actuating mechanism is located outside the pump room except where the alarms are certified intrinsically safe.

**1.5.4** *Enclosed spaces meeting the criteria of cargo machinery spaces in Ch 9, Sec 3, [1.3], within the cargo area of ships that are dedicated to the carriage of a restricted number of cargoes, shall be protected by an appropriate fire-extinguishing system for the cargo carried.*

**1.5.5** *Turret compartments of any ship shall be protected by internal water spray, with an application rate of not less than 10 litre/m<sup>2</sup>/min of the largest projected horizontal surface. If the pressure of the gas flow through the turret exceeds 4 MPa, the application rate shall be increased to 20 litre/m<sup>2</sup>/min. The system shall be designed to protect all internal surfaces.*

Note 1: The sentence "shall be designed to protect all internal surfaces" should be interpreted as follows as follows:

- any horizontal internal surface (e.g. platform) is to be protected
- Additional nozzles are to be considered if necessary
- the surface of the internal surfaces has to be added to the largest projected horizontal surface in order to determine the required water capacity

## **1.6 Firefighter's outfits**

**1.6.1** Every ship carrying flammable products shall carry firefighter's outfits complying with the requirements of regulation II-2/10.10 of the SOLAS Convention, as in Tab 2.

**Table 2 :**

Total cargo capacity	Number of outfits
5,000 m <sup>3</sup> and below	4
Above 5,000 m <sup>3</sup>	5

**1.6.2** Additional requirements for safety equipment are given in Ch 9, Sec 14.

**1.6.3** Any breathing apparatus required as part of a firefighter's outfit shall be a self-contained compressed air-operated breathing apparatus having a capacity of at least 1,200 litres of free air.

# Section 12 Artificial Ventilation in the Cargo Area

## 1 General

### 1.1 Scope

**1.1.1** *The requirements of this Section replace the requirements of SOLAS regulations II-2/4.5.2.6 and 4.5.4.1, as amended.*

### 1.2 Spaces required to be entered during normal cargo handling operations

**1.2.1** *Electric motor rooms, cargo compressor and pump-rooms, spaces containing cargo handling equipment and other enclosed spaces where cargo vapours may accumulate shall be fitted with fixed artificial ventilation systems capable of being controlled from outside such spaces. The ventilation shall be run continuously to prevent the accumulation of toxic and/or flammable vapours, with a differential pressure monitoring device or flow monitoring device to indicate any loss of the required ventilating capacity. A warning notice requiring the use of such ventilation prior to entering shall be placed outside the compartment.*

**1.2.2** *Artificial ventilation inlets and outlets shall be arranged to ensure sufficient air movement through the space to avoid accumulation of flammable, toxic or asphyxiant vapours, and to ensure a safe working environment.*

**1.2.3** *The ventilation system shall have a capacity of not less than 30 changes of air per hour, based upon the total volume of the space. As an exception, non-hazardous cargo control rooms may have eight changes of air per hour.*

**1.2.4** *Where a space has an opening into an adjacent more hazardous space or area, it shall be maintained at an overpressure. It may be made into a less hazardous space or non-hazardous space by overpressure protection in accordance with recognized standards.*

**1.2.5** *Ventilation ducts, air intakes and exhaust outlets serving artificial ventilation systems shall be positioned in accordance with recognized standards.*

*Note 1: Refer to the recommendation published by the International Electrotechnical Commission, in particular, to publication IEC 60092-502:1999.*

*However, where the prescriptive requirements in the present Rules and IEC 60092-502 are not aligned, the prescriptive requirements in the present Rules take precedence and are to be applied.*

**1.2.6** *Ventilation ducts are to be arranged at a suitable height from the weather deck. This height is not to be less than 2,4 m for intake ducts.*

*Note 1: Hazardous areas for this purpose are those mentioned in [1.2.11] For other spaces which are gas-dangerous only due to their position, some relaxation may be granted.*

**1.2.7** *Ventilation ducts are to be fitted with metallic fire dampers provided with "open" and "closed" signs. These dampers are to be arranged in the open, in a readily accessible position.*

**1.2.8** *In particular, the discharges from ventilation systems which may contain hazardous vapours are to be located not less than 8 m from the nearest air intake or opening to accommodation, service and control station spaces or other safe spaces, and from all possible sources of ignition.*

**1.2.9** *Ventilation intakes and outlets and openings of accommodation spaces, control stations and other gas-safe spaces are to be located in a designated safe area and at least 3 m from any hazardous area.*

**1.2.10** *The air inlets and discharges of the ventilation systems are to be situated so that recirculation of the vented vapours does not occur and are to be arranged at a distance from each other in the horizontal direction of not less than 3 m.*

**1.2.11** *Ventilation ducts serving hazardous areas shall not be led through accommodation, service and machinery spaces or control stations, except as allowed in Ch 9, Sec 16.*

**1.2.12** *Electric motors' driving fans shall be placed outside the ventilation ducts that may contain flammable vapours. Ventilation fans shall not produce a source of ignition in either the ventilated space or the ventilation system associated with the space. For hazardous areas, ventilation fans and ducts, adjacent to the fans, shall be of non-sparking construction, complying with Pt C, Ch 4, Sec 1, [2.32], and as defined below:*

- *impellers or housing of non-metallic construction, with due regard being paid to the elimination of static electricity*
- *impellers and housing of non-ferrous materials*
- *impellers and housing of austenitic stainless steel, and*
- *ferrous impellers and housing with design tip clearance of not less than 13 mm.*

*Any combination of an aluminium or magnesium alloy fixed or rotating component and a ferrous fixed or rotating component, regardless of tip clearance, is considered a sparking hazard and Materials for non shall not be used in these places.*

**1.2.13** *The shafting penetration of motors driving fans through bulkheads and decks of dangerous spaces or through ventilation ducts is to be fitted with a gastight sealing device, of the oil- seal type or equivalent, deemed suitable by the Society.*

**1.2.14** *Where fans are required by this Section, full required ventilation capacity for each space shall be available after failure of any single fan, or spare parts shall be provided comprising a motor, starter spares and complete rotating element, including bearings of each type.*

**1.2.15** *Protection screens of not more than 13 mm square mesh shall be fitted to outside openings of ventilation ducts.*

**1.2.16** *Where spaces are protected by pressurization, the ventilation shall be designed and installed in accordance with recognized standards.*

*Note 1: Refer to the recommendation published by the International Electrotechnical Commission, in particular, to publication IEC 60092-502:1999.*

However, where the prescriptive requirements in the present Rules and IEC 60092-502 are not aligned, the prescriptive requirements in the present Rules take precedence and are to be applied.

### **1.3 Spaces not normally entered**

**1.3.1** Both fixed and portable systems are to guarantee the efficient ventilation of such spaces in relation to the relative density, in respect of the air, and to the toxicity of the gases transported. The type of portable fans and their connection to the spaces served are to be approved by the Society. In no case are portable electrical fans acceptable.

**1.3.2** *Enclosed spaces where cargo vapours may accumulate shall be capable of being ventilated to ensure a safe environment when entry into them is necessary. This shall be capable of being achieved without the need for prior entry.*

**1.3.3** *For permanent installations, the capacity of 8 air changes per hour shall be provided and for portable systems, the capacity of 16 air changes per hour.*

**1.3.4** *Fans or blowers shall be clear of personnel access openings, and shall comply with [1.2.12].*

# Section 13 Instrumentation and Automation Systems

## 1 General

### 1.1

**1.1.1** The instrumentation is to be of a type approved by the Society.

**1.1.2** Attention is drawn to the requirements of Ch 9, Sec 1, [6.2.4] regarding the satisfactory operation of the cargo control and monitoring system and of the level alarm system, that is to be ascertained during the first full loading and the subsequent first unloading of ships carrying liquefied natural gasses (LNG) in bulk.

**1.1.3** *Each cargo tank shall be provided with a means for indicating level, pressure and temperature of the cargo. Pressure gauges and temperature indicating devices shall be installed in the liquid and vapour piping systems, in cargo refrigeration installations.*

**1.1.4** *If loading and unloading of the ship is performed by means of remotely controlled valves and pumps, all controls and indicators associated with a given cargo tank shall be concentrated in one control position.*

**1.1.5** The following information and alarms are to be concentrated in the positions specified in this requirement:

- a) The following is to be transduced to the “cargo control room” and the “control position” as defined in Ch 9, Sec 3, [1.4.1]:
- the indication signalling the presence of water and/or liquid cargo in holds or interbarrier spaces
  - the cargo heater low temperature alarm required in Ch 9, Sec 4, [1.2.3]
  - the alarm signalling the presence of liquid cargo in the vent main as per in Ch 9, Sec 5, [2.2.4].
  - the indication of the hull temperature and the hull structure low temperature alarm required in [7.2.2].
  - the alarm signalling the automatic shutdown of electrically driven submerged pumps required in Ch 9, Sec 10, [1.4.10].
  - the indication of the cargo level and the cargo tank high level alarm required in [2.1.1].
  - the indication of the vapour space pressure and the vapour space pressure gauges of each cargo tank and associated high and low pressure alarms required in [4.1].
  - the gas detection equipment alarm required in [6.1.13]
  - the cargo compressor high temperature alarm required in Ch 9, Sec 17, [4.1.2] item b)
  - the alarm for automatic shutdown of the cargo compressor for high pressure or high temperature, as required in Ch 9, Sec 17, [16.1.4] item d)

When the cargo system is not remote controlled and therefore the aforesaid “control positions” are not required, the above-mentioned controls, information and alarms are to be located in a suitable, easily accessible location.

If this position is an enclosed space, it is to comply with the requirements in Ch 9, Sec 3, [1.3.7]. This position should preferably be located in the wheelhouse.

- b) Independently of the above, the following is to be transduced to the wheelhouse:
- 1) the alarm signalling the presence of water and/or liquid cargo in holds or interbarrier spaces
  - 2) the cargo heater low temperature alarm required in Ch 9, Sec 4, [1.2.3]
  - 3) the alarm signalling the presence of liquid cargo in the vent main as per Ch 9, Sec 5, [2.2.4]
  - 4) the indication of the pressure value in the vapour space of each cargo tank mentioned in [4.1]; such indication is to give the setting pressure value of the relief valve and the minimum allowable pressure value in the cargo tank concerned
  - 5) the high pressure and low pressure alarms, when required, for cargo tanks as per [4.1]
  - 6) the hull structure low temperature alarm required in [7.2.2]
  - 7) the gas detection equipment alarm required in [6.1.13]
  - 8) the cargo compressor high temperature alarm required in Ch 9, Sec 17, [4.1.2] item b)
  - 9) the alarm for automatic shutdown of the cargo compressor for high pressure or high temperature, as required in Ch 9, Sec 17, [16.1.4] item d)
- c) Where the cargo control room is located within the accommodation spaces and is readily accessible, the alarms in [3.1.5] may be grouped in a single audible and visual alarm except for the indication and alarms in [1.1.5] item b) 4), item b) 5) and item b) 7), which are to be independent from each other.
- d) The high level and high or low pressure audible and visual alarms for cargo tanks as per [3.1.1] and [3.1.4] and the alarm signalling the presence of liquid in the vent main are to be located in such a position as to be clearly heard and identifiable by the personnel in charge of loading operation control.

**1.1.6** Instruments shall be tested to ensure reliability under the working conditions, and recalibrated at regular intervals. Test procedures for instruments and the intervals between recalibration shall be in accordance with manufacturer's recommendations.

## **2 Level indicators for cargo tanks**

### **2.1 General**

**2.1.1** Each cargo tank shall be fitted with liquid level gauging device(s), arranged to ensure that a level reading is always obtainable whenever the cargo tank is operational. The device(s) shall be designed to operate throughout the design pressure range of the cargo tank and at temperatures within the cargo operating temperature range.

**2.1.2** Where only one liquid level gauge is fitted, it shall be arranged so that it can be maintained in an operational condition without the need to empty or gas-free the tank.

In order to assess whether or not only one level gauge is acceptable in relation to the aforesaid sentence, the expression "can be maintained" means that any part of the level gauge other than passive parts can be overhauled while the cargo tank is in service.

Note 1: Passive parts are those parts assumed not subject to failures under normal service conditions.

**2.1.3** Where level gauges containing cargo are arranged outside the tank they serve, means are to be provided to shut them off automatically in the event of failure.

**2.1.4** Cargo tank liquid level gauges may be of the following types, subject to special requirements for particular cargoes shown in Ch 9, Sec 19, Tab 1, column "Gauging":

- a) indirect devices, which determine the amount of cargo by means such as weighing or in-line flow metering
- b) closed devices which do not penetrate the cargo tank, such as devices using radio-isotopes or ultrasonic devices
- c) closed devices which penetrate the cargo tank, but which form part of a closed system and keep the cargo from being released, such as float type systems, electronic probes, magnetic probes and bubble tube indicators. If closed gauging device is not mounted directly onto the tank, it shall be provided with a shutoff valve located as close as possible to the tank, and
- d) restricted devices which penetrate the tank and, when in use, permit a small quantity of cargo vapour or liquid to escape to the atmosphere, such as fixed tube and slip tube gauges. When not in use, the devices shall be kept completely closed. The design and installation shall ensure that no dangerous escape of cargo can take place when opening the device. Such gauging devices shall be so designed that the maximum opening does not exceed 1.5 mm diameter or equivalent area, unless the device is provided with an excess flow valve.

## **3 Overflow control**

### **3.1 General**

**3.1.1** Except as provided in [3.1.5], each cargo tank shall be fitted with a high liquid level alarm operating independently of other liquid level indicators and giving an audible and visual warning when activated.

**3.1.2** The sensor for automatic closing of the loading valve for overflow control may be combined with the liquid level indicators required by [2.1.1].

**3.1.3** An additional sensor operating independently of the high liquid level alarm shall automatically actuate a shutoff valve in a manner that will both avoid excessive liquid pressure in the loading line and prevent the tank from becoming liquid full.

Note 1: The words 'to prevent the tank from becoming liquid full' in paragraph [3.1.3] have the following meaning:

At no time during the loading, transport or unloading of the cargo including fire conditions will the tank be more than 98% liquid full, except as permitted by Ch 9, Sec 15, [1.1.3]. These requirements, together with those of Ch 9, Sec 8, [2.1.20], are intended to ensure that the pressure relief valves remain in the vapour phase.

**3.1.4** The emergency shutdown valve referred to in 5.5 and Ch 9, Sec 18, [3] may be used for this purpose. If another valve is used for this purpose, the same information as referred to in Ch 9, Sec 18, [3.2.1], item c) shall be available on board. During loading, whenever the use of these valves may possibly create a potential excess pressure surge in the loading system, alternative arrangements such as limiting the loading rate shall be used.

**3.1.5** A high liquid level alarm and automatic shut-off of cargo tank filling need not be required, when the cargo tank:

- is a pressure tank with a volume not more than 200 m<sup>3</sup>, or
- is designed to withstand the maximum possible pressure during the loading operation, and such pressure is below that of the set pressure of the cargo tank relief valve.

**3.1.6** The position of the sensors in the tank shall be capable of being verified before commissioning. At the first occasion of full loading after delivery and after each dry-docking, testing of high-level alarms shall be conducted by raising the cargo liquid level in the cargo tank to the alarm point.

Note 1: The expression “each dry docking” is considered to be the survey of the outside of the ship’s bottom required for the renewal of the Cargo Ship Safety Construction Certificate and or the Cargo Ship Safety Certificate.

**3.1.7** All elements of the level alarms, including the electrical circuit and the sensor(s), of the high, and overflow alarms, shall be capable of being functionally tested. Systems shall be tested prior to cargo operation in accordance with IGC Code, 18.6.2.

**3.1.8** Where arrangements are provided for overriding the overflow control system, they shall be such that inadvertent operation is prevented. When this override is operated, continuous visual indication shall be given at the relevant control station(s) and the navigation bridge.

## **4 Pressure monitoring**

### **4.1 General**

**4.1.1** The vapour space of each cargo tank shall be provided with a direct reading gauge. Additionally, an indirect indication shall be provided at the control position required by [1.1.4]. Maximum and minimum allowable pressures shall be clearly indicated.

**4.1.2** A high-pressure alarm and, if vacuum protection is required as defined in Ch 9, Sec 8, [3], a low-pressure alarm shall be provided on the navigation bridge and at the control position required by [1.1.4]. Alarms shall be activated before the set pressures are reached. The low pressure alarm is also to be located in the cargo control room.

**4.1.3** For cargo tanks fitted with PRVs which can be set at more than one set pressure in accordance with Ch 9, Sec 8, [2.1.9], high-pressure alarms shall be provided for each set pressure.

**4.1.4** Each cargo-pump discharge line and each liquid and vapour cargo manifold shall be provided with at least one pressure indicator.

**4.1.5** Local-reading manifold pressure indication shall be provided to indicate the pressure between ship’s manifold valves and hose connections to the shore.

**4.1.6** Hold spaces and interbarrier spaces without open connection to the atmosphere shall be provided with pressure indication.

**4.1.7** All pressure indications provided shall be capable of indicating throughout the operating pressure range.

## **5 Temperature indicating devices**

### **5.1 General**

**5.1.1** Each cargo tank shall be provided with at least two devices for indicating cargo temperatures, one placed at the bottom of the cargo tank and the second near the top of the tank, below the highest allowable liquid level. The lowest temperature for which the cargo tank has been designed, as shown on the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk, shall be clearly indicated by means of a sign on or near the temperature indicating devices.

**5.1.2** The temperature indicating devices shall be capable of providing temperature indication across the expected cargo operating temperature range of the cargo tanks.

**5.1.3** Where thermowells are fitted, they shall be designed to minimize failure due to fatigue in normal service.

## **6 Gas detection**

### **6.1 General**

**6.1.1** Gas detection equipment shall be installed to monitor the integrity of the cargo containment, cargo handling and ancillary systems, in accordance with this section.

**6.1.2** A permanently installed system of gas detection and audible and visual alarms shall be fitted in:

- a) all enclosed cargo and cargo machinery spaces (including turrets compartments) containing gas piping, gas equipment or gas consumers
- b) other enclosed or semi-enclosed spaces where cargo vapours may accumulate, including interbarrier spaces and hold spaces for independent tanks other than type C tanks
- c) airlocks
- d) spaces in gas-fired internal combustion engines, referred to in Ch 9, Sec 16, [7.8.3]
- e) ventilation hoods and gas ducts required by Ch 9, Sec 16
- f) cooling/heating circuits, as required by Ch 9, Sec 7, [8.1.1], item d)
- g) inert gas generator supply headers, and
- h) motor rooms for cargo handling machinery.

In addition, the gas detection system is also to serve spaces adjacent to pump rooms and compressor rooms.

**6.1.3** Gas detection equipment shall be designed, installed and tested in accordance with recognized standards and shall be suitable for the cargoes to be carried in accordance with Ch 9, Sec 19, Tab 1, column "Vapour detection".

Note 1: IEC 60079-29-1 - Explosive atmospheres - Gas detectors - Performance requirements of detectors for flammable gases.

**6.1.4** Where indicated by an "A" in Ch 9, Sec 19, Tab 1, column "Vapour detection" ships certified for carriage of non-flammable products, oxygen deficiency monitoring shall be fitted in cargo machinery spaces and hold spaces for independent tanks other than type C tanks. Furthermore, oxygen deficiency monitoring equipment shall be installed in enclosed or semi-enclosed spaces containing equipment that may cause an oxygen-deficient environment such as nitrogen generators, inert gas generators or nitrogen cycle refrigerant systems.

Two oxygen sensors are to be positioned at appropriate locations in the space or spaces containing the inert gas system, in accordance with Pt C, Ch 4, Sec 15, [13.2.4], item e) 4), for all gas carriers, irrespective of the carriage of cargo indicated by an "A" in column "f" in Ch 9, Sec 19, Tab 1.

**6.1.5** In the case of toxic products or both toxic and flammable products, except when Ch 9, Sec 19, Tab 1, column "Special requirements" refers to Ch 9, Sec 17, [5.1.3], portable equipment can be used for the detection of toxic products as an alternative to a permanently installed system. This equipment shall be used prior to personnel entering the spaces listed in [6.1.2] and at 30-minute intervals while they remain in the space.

**6.1.6** In the case of gases classified as toxic products, hold spaces and interbarrier spaces shall be provided with a permanently installed piping system for obtaining gas samples from the spaces. Gas from these spaces shall be sampled and analysed from each sampling head location.

**6.1.7** Permanently installed gas detection shall be of the continuous detection type, capable of immediate response. Where not used to activate safety shutdown functions required by [6.1.9] and Ch 9, Sec 16, sampling type detection may be accepted.

**6.1.8** When sampling type gas detection equipment is used, the following requirements shall be met:

- the gas detection equipment shall be capable of sampling and analysing for each sampling head location sequentially at intervals not exceeding 30 min
- individual sampling lines from sampling heads to the detection equipment shall be fitted, and
- pipe runs from sampling heads shall not be led through non-hazardous spaces except as permitted by [6.1.9].

**6.1.9** The gas detection equipment may be located in a non-hazardous space, provided that the detection equipment such as sample piping, sample pumps, solenoids and analysing units are located in a fully enclosed steel cabinet with the door sealed by a gasket. The atmosphere within the enclosure shall be continuously monitored. At gas concentrations above 30% lower flammable limit (LFL) inside the enclosure, the gas detection equipment shall be automatically shut down.

Gas analysing units are to be in compliance with the requirements in Ch 7, Sec 6, [7.4].

**6.1.10** Where the enclosure cannot be arranged directly on the forward bulkhead, sample pipes shall be of steel or equivalent material and be routed on their shortest way. Detachable connections, except for the connection points for isolating valves required in [6.1.13] and analysing units, are not permitted.

**6.1.11** When gas sampling equipment is located in a non-hazardous space, a flame arrester and a manual isolating valve shall be fitted in each of the gas sampling lines. The isolating valve shall be fitted on the non-hazardous side. Bulkhead penetrations of sample pipes between hazardous and non-hazardous areas shall maintain the integrity of the division penetrated. The exhaust gas shall be discharged to the open air in a safe location.

**6.1.12** In every installation, the number and the positions of detection heads shall be determined with due regard to the size and layout of the compartment, the compositions and densities of the products intended to be carried and the dilution from compartment purging or ventilation and stagnant areas.

Sampling heads in cargo holds are not to be located in positions where bilge water may collect.

**6.1.13** Any alarms status within a gas detection system required by this section shall initiate an audible and visible alarm:

- on the navigation bridge
- at the relevant control station(s) where continuous monitoring of the gas levels is recorded, and
- at the gas detector readout location.

**6.1.14** In the case of flammable products, the gas detection equipment provided for hold spaces and interbarrier spaces that are required to be inerted shall be capable of measuring gas concentrations of 0% to 100% by volume.

**6.1.15** Alarms shall be activated when the vapour concentration by volume reaches the equivalent of 30% LFL in air.

**6.1.16** For membrane containment systems, the primary and secondary insulation spaces shall be able to be inerted and their gas content analysed individually.

Note 1: Gas Concentrations in the Insulation Spaces of Membrane LNG Carriers, March 2007 (published by SIGTTO).

The alarm in the secondary insulation space shall be set in accordance with [6.1.15], that in the primary space is set at a value approved by the Society.

**6.1.17** For other spaces described by [6.1.2], alarms shall be activated when the vapour concentration reaches 30% LFL and safety functions required by Ch 9, Sec 16 shall be activated before the vapour concentration reaches 60% LFL. The crankcases of internal combustion engines that can run on gas shall be arranged to alarm before 100% LFL.

**6.1.18** Gas detection equipment shall be so designed that it may readily be tested. Testing and calibration shall be carried out at regular intervals. Suitable equipment for this purpose shall be carried on board and be used in accordance with the manufacturer's recommendations. Permanent connections for such test equipment shall be fitted.

**6.1.19** Every ship shall be provided with at least two sets of portable gas detection equipment that meet the requirement of [6.1.3] or an acceptable national or international standard.

For ships intended to carry toxic and flammable gases, two sets for toxic gases and two sets for flammable gases are to be provided.

**6.1.20** A suitable instrument for the measurement of oxygen levels in inert atmospheres shall be provided.

## **7 Additional requirements for containment systems requiring a secondary barrier**

### **7.1 Integrity of barriers**

**7.1.1** Where a secondary barrier is required, permanently installed instrumentation shall be provided to detect when the primary barrier fails to be liquid-tight at any location or when liquid cargo is in contact with the secondary barrier at any location. This instrumentation shall consist of appropriate gas detecting devices according to [6]. However, the instrumentation need not be capable of locating the area where liquid cargo leaks through the primary barrier or where liquid cargo is in contact with the secondary barrier.

**7.1.2** Upon special approval, appropriate temperature indicating devices may be accepted by the Society instead of gas detecting devices when the cargo temperature is not lower than  $-55^{\circ}\text{C}$ .

### **7.2 Temperature indication devices**

**7.2.1** The number and position of temperature-indicating devices shall be appropriate to the design of the containment system and cargo operation requirements.

**7.2.2** When cargo is carried in a cargo containment system with a secondary barrier, at a temperature lower than  $-55^{\circ}\text{C}$ , temperature-indicating devices shall be provided within the insulation or on the hull structure adjacent to cargo containment systems. The devices shall give readings at regular intervals and, where applicable, alarm of temperatures approaching the lowest for which the hull steel is suitable.

**7.2.3** The temperatures are to be continuously recorded at regular intervals. Audible and visual alarms are to be automatically activated when the hull steel temperature approaches the lowest temperature for which the steel has been approved.

**7.2.4** If cargo is to be carried at temperatures lower than  $-55^{\circ}\text{C}$ , the cargo tank boundaries, if appropriate for the design of the cargo containment system, shall be fitted with a sufficient number of temperature-indicating devices to verify that unsatisfactory temperature gradients do not occur.

**7.2.5** For the purposes of design verification and determining the effectiveness of the initial cooldown procedure on a single or series of similar ships, one tank shall be fitted with devices in excess of those required in [7.2.1]. These devices may be temporary or permanent and only need to be fitted to the first ship, when a series of similar ships is built.

## 8 Automation systems

### 8.1 General

#### 8.1.1

*The requirements of this section shall apply where automation systems are used to provide instrumented control, monitoring/ alarm or safety functions required by this Code.*

**8.1.2** *Automation systems shall be designed, installed and tested in accordance with recognized standards.*

*Note 1: Refer to the recommendations for computer-based systems contained in the standard published by the International Electrotechnical Commission, IEC 60092-504:2001 "Electrical installations in ships - Special features - Control and instrumentation".*

**8.1.3** *Hardware shall be capable of being demonstrated to be suitable for use in the marine environment by type approval or other means.*

**8.1.4** *Software shall be designed and documented for ease of use, including testing, operation and maintenance.*

**8.1.5** *The user interface shall be designed such that the equipment under control can be operated in a safe and effective manner at all times.*

**8.1.6** *Automation systems shall be arranged such that a hardware failure or an error by the operator does not lead to an unsafe condition. Adequate safeguards against incorrect operation shall be provided.*

**8.1.7** *Appropriate segregation shall be maintained between control, monitoring/alarm and safety functions to limit the effect of single failures. This shall be taken to include all parts of the automation systems that are required to provide specified functions, including connected devices and power supplies.*

**8.1.8** *Automation systems shall be arranged such that the software configuration and parameters are protected against unauthorized or unintended change.*

**8.1.9** *A management of change process shall be applied to safeguard against unexpected consequences of modification. Records of configuration changes and approvals shall be maintained on board.*

**8.1.10** *Processes for the development and maintenance of integrated systems shall be in accordance with recognized standards. These processes shall include appropriate risk identification and management.*

*Note 1: Refer to the International Electrotechnical Commission standard ISO/IEC 15288:2008 Systems and software engineering - System life cycle processes, and ISO 17894:2005 Ships and marine technology - Computer applications - General principles for the development and use of programmable electronic systems in marine applications.*

## 9 System integration

### 9.1 General

**9.1.1** *Essential safety functions shall be designed such that risks of harm to personnel or damage to the installation or the environment are reduced to a level acceptable to the Society, both in normal operation and under fault conditions. Functions shall be designed to fail-safe. Roles and responsibilities for integration of systems shall be clearly defined and agreed by relevant parties.*

**9.1.2** *Functional requirements of each component subsystem shall be clearly defined to ensure that the integrated system meets the functional and specified safety requirements and takes account of any limitations of the equipment under control.*

**9.1.3** *Key hazards of the integrated system shall be identified using appropriate risk-based techniques.*

*Note 1: "Integrated system" means a combination of computer-based systems which are used for the control, monitoring/alarm and safety functions required for the carriage, handling and conditioning of cargo liquid and vapours and are interconnected in order to allow communication between computer-based systems and to allow centralized access to monitoring/alarm and safety information and/or command/control.*

**9.1.4** *The integrated system shall have a suitable means of reversonary control.*

**9.1.5** *Failure of one part of the integrated system shall not affect the functionality of other parts, except for those functions directly dependent on the defective part.*

**9.1.6** *Operation with an integrated system shall be at least as effective as it would be with individual stand-alone equipment or systems.*

**9.1.7** *The integrity of essential machinery or systems, during normal operation and fault conditions, shall be demonstrated.*

## Section 14 Personnel Protection

### 1 General

#### 1.1 Protective equipment

**1.1.1** Suitable protective equipment, including eye protection to a recognized national or international standard, shall be provided for protection of crew members engaged in normal cargo operations, taking into account the characteristics of the products being carried.

**1.1.2** Personal protective and safety equipment required in this Section shall be kept in suitable, clearly marked lockers located in readily accessible places.

**1.1.3** The compressed air equipment shall be inspected at least once a month by a responsible officer and the inspection logged in the ship's records. This equipment shall also be inspected and tested by a competent person at least once a year.

#### 1.2 First-aid equipment

**1.2.1** A stretcher that is suitable for hoisting an injured person from spaces below deck shall be kept in a readily accessible location.

**1.2.2** The ship shall have onboard medical first-aid equipment, including oxygen resuscitation equipment, based on the requirements of the Medical First Aid Guide (MFAG) for the cargoes listed on the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk shown in Appendix 2 of the IGC Code.

#### 1.3 Safety equipment

**1.3.1** Sufficient, but not less than three complete sets of safety equipment shall be provided in addition to the firefighter's outfits required by Ch 9, Sec 11, [1.6.1]. Each set shall provide adequate personal protection to permit entry and work in a gas-filled space. This equipment shall take into account the nature of the cargoes, listed on the International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk shown in Appendix 2 of the IGC Code.

**1.3.2** Each complete set of safety equipment shall consist of:

- a) one self-contained positive pressure air-breathing apparatus incorporating full face mask, not using stored oxygen and having a capacity of at least 1,200 litre of free air. Each set shall be compatible with that required by Ch 9, Sec 11, [1.6.1]
- b) protective clothing, boots and gloves to a recognized standard
- c) steel-cored rescue line with belt, and
- d) explosion-proof lamp.

**1.3.3** An adequate supply of compressed air shall be provided and shall consist of:

- a) at least one fully charged spare air bottle for each breathing apparatus required by [1.3.1]
- b) an air compressor of adequate capacity capable of continuous operation, suitable for the supply of high-pressure air of breathable quality, and
- c) a charging manifold capable of dealing with sufficient spare breathing apparatus air bottles for the breathing apparatus required by [1.3.1].

#### 1.4 Personal protection requirements for individual products

**1.4.1** Requirements of this section shall apply to ships carrying products for which those paragraphs are listed in Ch 9, Sec 19, Tab 1 column "Special requirements".

**1.4.2** Suitable respiratory and eye protection for emergency escape purposes shall be provided for every person on board, subject to the following:

- a) filter-type respiratory protection is unacceptable
- b) self-contained breathing apparatus shall have at least a duration of service of 15 min, and
- c) emergency escape respiratory protection shall not be used for fire fighting or cargo-handling purposes and shall be marked to that effect.

**1.4.3** One or more suitably marked decontamination showers and eyewash stations shall be available on deck, taking into account the size and layout of the ship. The showers and eyewashes shall be operable in all ambient conditions.

**1.4.4** The showers and eye wash are to be fitted with a heating system, or other suitable installation, in order to avoid any ice formation in their piping.

**1.4.5** *The protective clothing required under [1.3.2], item b), shall be gastight.*

# Section 15 Filling Limits for Cargo Tanks

## 1 General

### 1.1 Definitions

#### 1.1.1 Filling limit

*Filling limit (FL) means the maximum liquid volume in a cargo tank relative to the total tank volume when the liquid cargo has reached the reference temperature.*

#### 1.1.2 Loading limit

*Loading limit (LL) means the maximum allowable liquid volume relative to the tank volume to which the tank may be loaded.*

#### 1.1.3 Reference temperature

*Reference temperature means (for the purposes of this Section only):*

- a) *when no cargo vapour pressure/temperature control, as referred to in Ch 9, Sec 7, is provided, the temperature corresponding to the vapour pressure of the cargo at the set pressure of the PRVs, and*
- b) *when a cargo vapour pressure/temperature control, as referred to in Ch 9, Sec 7, is provided, the temperature of the cargo upon termination of loading, during transport or at unloading, whichever is the greatest.*

#### 1.1.4 Ambient design temperature for unrestricted service

*Ambient design temperature for unrestricted service means sea temperature of 32°C and air temperature of 45°C. However, lesser values of these temperatures may be accepted by the Society for ships operating in restricted areas or on voyages of restricted duration, and account may be taken in such cases of any insulation of the tanks. Conversely, higher values of these temperatures may be required for ships permanently operating in areas of high-ambient temperature.*

## 1.2 General requirements

**1.2.1** *The maximum filling limit of cargo tanks shall be so determined that the vapour space has a minimum volume at reference temperature allowing for:*

- *tolerance of instrumentation such as level and temperature gauges*
- *volumetric expansion of the cargo between the PRV set pressure and the maximum allowable rise stated in Ch 9, Sec 8, [4], and*
- *an operational margin to account for liquid drained back to cargo tanks after completion of loading, operator reaction time and closing time of valves, see Ch 9, Sec 5, [5] and Ch 9, Sec 18, [3.2.1], item d).*

## 1.3 Default filling limit

**1.3.1** *The default value for the filling limit (FL) of cargo tanks is 98% at the reference temperature. Exceptions to this value shall meet the requirements of [1.4].*

## 1.4 Determination of increased filling limit

**1.4.1** *A filling limit greater than the limit of 98% specified in [1.3] may be permitted under the trim and list conditions specified in Ch 9, Sec 8, [2.1.20], providing:*

- a) *no isolated vapour pockets are created within the cargo tank*
- b) *the PRV inlet arrangement shall remain in the vapour space, and*
- c) *allowances need to be provided for:*
  - *volumetric expansion of the liquid cargo due to the pressure increase from the MARVS to full flow relieving pressure in accordance with Ch 9, Sec 8, [4.1].*
  - *an operational margin of minimum 0,1% of tank volume, and*
  - *tolerances of instrumentation such as level and temperature gauges.*

**1.4.2** *In no case shall a filling limit exceeding 99.5% at reference temperature be permitted.*

**1.4.3** *The PRV inlet, as defined in [1.4.1], item b), is to be remain in the vapour space at a minimum distance of 40% of the diameter of the suction funnel measured at the centre of the funnel above the liquid level under conditions of 15° list and 0,015L trim.*

**1.4.4** The following method may be used to determine the allowance defined in [1.4.1], item c). The Society may accept other methods to determine the allowance provided the method meets an equivalent level of safety.

The parameters specified under [1.4.1], item c) may be expressed by the expansion factor  $\alpha_T$ , in %, to be determined as follows:

$$\alpha_T = \sqrt{\alpha_1^2 + \alpha_2^2} + \alpha_3 + \alpha_4$$

where:

$\alpha_1$  : Relative increase in liquid volume, in %, due to tolerance of level gauges:

$$\alpha_1 = \frac{dV}{dh} \times \frac{\Delta h}{V} \times 100$$

where:

$dV/dh$  : Variation of tank volume per metre filling height at the filling height  $h$ , in  $m^3/m$

$h$  : Filling height, in m, at the filling limit FL to be investigated (FL>98%)

$V$  : Accepted total tank volume, in  $m^3$

$\Delta h$  : Max. total tolerance of level gauges, in m

$\alpha_2$  : Relative increase in liquid volume, in %, due to the tolerance of temperature gauges:

$$\alpha_2 = \beta \Delta T$$

where:

$\beta$  : volumetric thermal expansion coefficient at reference temperature, in  $\%/^{\circ}K$

$\Delta T$  : max. tolerance of temperature gauge, in  $^{\circ}K$

$\alpha_3$  : Expansion of cargo volume, in %, due to pressure rise when pressure relief valves are relieving at maximum flow rate:

$$\alpha_3 = 100 \left( \frac{\rho_{PRV}}{\rho_{PRV1,2}} - 1 \right)$$

where:

$\rho_{PRV}$  : cargo density at reference conditions (corresponding to the temperature of the cargo at set opening pressure of the pressure relief valve (PRV))

$\rho_{PRV1,2}$  : cargo density corresponding to the temperature of the cargo at 1,2 times the set opening pressure of the pressure relief valve (PRV)

$\alpha_4$  : Operational margin of 0,1%.

## 1.5 Maximum loading unit

**1.5.1** The maximum loading limit (LL) to which a cargo tank may be loaded shall be determined by the following formula:

$$LL = FL \times \frac{\rho_R}{\rho_L}$$

where:

$LL$  : loading limit as defined in [1.1.2], expressed in percentage

$FL$  : filling limit as specified in [1.3] or [1.4], expressed in percentage

$\rho_R$  : relative density of cargo at the reference temperature, and

$\rho_L$  : relative density of cargo at the loading temperature.

**1.5.2** The Society may allow type C tanks to be loaded according to the formula in [1.5.1] with the relative density  $\rho_R$  provided that the tank vent system has been approved in accordance with Ch 9, Sec 8, [2.1.21]:

Note 1:  $\rho_R$  is the relative density of cargo at the highest temperature that the cargo may reach upon termination of loading, during transport, or at unloading, under the ambient design temperature conditions described in [1.1.4].

This paragraph does not apply to products requiring a type 1G ship.

## 1.6 Information to be provided to the Master

**1.6.1** A document shall be provided to the ship, specifying the maximum allowable loading limits for each cargo tank and product, at each applicable loading temperature and maximum reference temperature. The information in this document shall be approved by the Society.

**1.6.2** Pressures at which the PRVs have been set shall also be stated in the document.

**1.6.3** A copy of the above document shall be permanently kept on board by the master.

## Section 16 Use of Cargo as Fuel

### 1 General

#### 1.1

**1.1.1** Except as provided for in [9], methane (LNG) is the only cargo whose vapour or boil-off gas may be utilized in machinery spaces of category A, and, in these spaces, it may be utilized only in systems such as boilers, inert gas generators, internal combustion engines, gas combustion unit and gas turbines.

**1.1.2** Liquefied gas carriers using LPG as fuel are to comply with the requirements of Article [9].

### 2 Use of cargo vapour as fuel

#### 2.1 General

**2.1.1** This section addresses the use of cargo vapour as fuel in systems such as boilers, inert gas generators, internal combustion engines, gas combustion units and gas turbines.

**2.1.2** For vaporized LNG, the fuel supply system shall comply with the requirements of [4.1], [4.2] and [4.3].

**2.1.3** For vaporized LNG, gas consumers shall exhibit no visible flame and shall maintain the uptake exhaust temperature below 535°C.

### 3 Arrangement of spaces containing gas consumers

#### 3.1 General

**3.1.1** Spaces in which gas consumers are located shall be fitted with a mechanical ventilation system that is arranged to avoid areas where gas may accumulate, taking into account the density of the vapour and potential ignition sources. The ventilation system shall be separated from those serving other spaces.

**3.1.2** Gas detectors shall be fitted in these spaces, particularly where air circulation is reduced. The gas detection system shall comply with the requirements of Ch 9, Sec 13.

**3.1.3** Electrical equipment located in the double wall pipe or duct specified in [4.3] shall comply with the requirements of Ch 9, Sec 10.

**3.1.4** All vents and bleed lines that may contain or be contaminated by gas fuel shall be routed to a safe location external to the machinery space and be fitted with a flame screen.

In case of high pressure gas supply, means are to be taken to manage the large gas influx without release to atmosphere.

### 4 Gas fuel supply

#### 4.1 General

**4.1.1** The requirements of this section shall apply to gas fuel supply piping outside of the cargo area. Fuel piping shall not pass through accommodation spaces, service spaces, electrical equipment rooms or control stations. The routing of the pipeline shall take into account potential hazards, due to mechanical damage, in areas such as stores or machinery handling areas.

**4.1.2** Gas piping is to be installed in accordance with the requirements of Ch 9, Sec 5, [2.2].

**4.1.3** Gas piping is to be suitably earthed and in accordance with the requirement of Ch 9, Sec 5, [7.4.1].

**4.1.4** Piping, valves and fittings are to be hydrostatically tested, after assembly on board, to 1,5 times the working pressure but to not less than 7 bar. Subsequently, they are to be pneumatically tested to ascertain that all the joints are perfectly tight. The outer pipe or duct of double wall gas-fuel piping systems are to be in accordance with the requirement of Ch 9, Sec 5, [13.5.4].

**4.1.5** Provision shall be made for inerting and gas-freeing that portion of the gas fuel piping systems located in the machinery space.

**4.1.6 Classes of gas fuel piping systems**

a) Purpose of the classes of piping systems

Piping systems are subdivided into three classes, denoted as class I, class II and class III, for the purpose of acceptance of materials, selection of joints, heat treatment, welding, pressure testing and the certification of fittings.

b) Determination of the classes of piping systems

Piping classes I, II and III are to be determined in accordance with the provisions of:

- Tab 1 for gas fuel piping
- Tab 2 for all vent pipes and open ended lines, including:
  - discharge lines from thermal relief valves (see Ch 9, Sec 5, [5.3.3])
  - vent lines from the gas supply lines to consumers (see [4.6.1])
  - purging lines from engines and other gas consumers.

**Table 1 : Classes of gas fuel piping systems**

Design conditions		Class of the gas piping		
Design pressure	Design temperature	Single wall arrangement	Double wall arrangement	
			Inner pipe	Outer pipe (1)
p = 10 bar (2)	any	Class I	Class II	Class II
p > 10 bar	any	Class I	Class I	Class II

(1) The design pressure of the outer pipe or duct of fuel systems is to comply with Ch 9, Sec 5, [4.1.4]  
 (2) The design pressure is not to be taken less than 10 bar. See Ch 9, Sec 5, [4.1.1]

**Table 2 : Classes of vent pipes and bleed lines**

Design conditions		Class of the gas vent piping		
Vent pipe design pressure	Vent pipe design temperature	Single wall arrangement	Double wall arrangement	
			Inner pipe	Outer pipe (1)
p = 5 bar (2)	any	Class III	Class III	Class III
p > 5 bar and p ≤ 10 bar (3)	any	Class II	Class III	Class III
P > 10 bar (3)	any	Class I	Class II	Class III

(1) The design pressure of the outer pipe or duct of vent pipes or open ended lines is to comply with Ch 9, Sec 5, [4.1.4]  
 (2) The design pressure of the vent pipes or open ended lines is not to be taken less than 5 bar. See Ch 9, Sec 5, [4.1.1]  
 (3) The design pressure of the vent pipes or open ended lines is not to be less than the maximum expected pressure, which is to be justified

**4.2 Leak detection**

**4.2.1** Continuous monitoring and alarms shall be provided to indicate a leak in the piping system in enclosed spaces and shut down the relevant gas fuel supply.

**4.3 Routeing of fuel supply pipes**

**4.3.1** Fuel piping may pass through or extend into enclosed spaces other than those mentioned [4.1], provided it fulfils one of the following conditions:

- a) it is of a double-wall design with the space between the concentric pipes pressurized with inert gas at a pressure greater than the gas fuel pressure. The master gas fuel valve, as required by [4.6], closes automatically upon loss of inert gas pressure, or
- b) it is installed in a pipe or duct equipped with mechanical exhaust ventilation having a capacity of at least 30 air changes per hour and is arranged to maintain a pressure less than the atmospheric pressure. The mechanical ventilation is in accordance with Ch 9, Sec 12, as applicable. The ventilation is always in operation when there is fuel in the piping and the master gas fuel valve, as required by [4.6], closes automatically if the required air flow is not established and maintained by the exhaust ventilation system. The inlet or the duct may be from a non-hazardous machinery space, and the ventilation outlet is in a safe location.

**4.3.2** The gas valve unit rooms are to be:

- a) gastight toward other enclosed spaces
- b) equipped with mechanical exhaust ventilation having a capacity of at least 30 air changes per hour and arranged to maintain a pressure less than the atmospheric pressure, and
- c) able to withstand the maximum built-up pressure arising in the room in case of a gas pipe rupture, as documented by suitable calculations taking into account the ventilation arrangements.

#### **4.4 Requirements for gas fuel supply with pressure greater than 1 MPa**

**4.4.1** *Fuel delivery lines between the high-pressure fuel pumps/compressors and consumers shall be protected with a double-walled piping system capable of containing a high pressure line failure, taking into account the effects of both pressure and low temperature. A single-walled pipe in the cargo area up to the isolating valve(s) required by [4.6] is acceptable.*

**4.4.2** *The arrangement in [4.3.1], item b) may also be acceptable providing the pipe or trunk is capable of containing a high pressure line failure, according to the requirements of [4.7] and taking into account the effects of both pressure and possible low temperature and providing both inlet and exhaust of the outer pipe or trunk are in the cargo area.*

**4.4.3** High pressure gas piping systems are to be checked for sufficient constructive strength by carrying out stress analysis taking into account the stresses due to the weight of the piping system including acceleration load, when significant, internal pressure and loads induced by hog and sag of the ship (see also Ch 9, Sec 5, [11.4.1]).

In fuel gas piping systems of design pressure greater than the critical pressure, the tangential membrane stress of straight section of pipe or ducting is to be in accordance with requirement [11.4.1].

**4.4.4** All valves and expansion joints used in high pressure gas fuel supply lines are to be of an approved type.

**4.4.5** The possibility of fatigue failure of the high pressure gas piping due to vibration is to be considered.

**4.4.6** The possibility of pulsation of gas fuel supply pressure caused by the high pressure gas compressor is to be considered.

**4.4.7** Gas fuel piping may pass through or extend into machinery spaces or gas-safe spaces other than accommodation spaces, service spaces and control stations provided that they fulfil one of the following conditions:

- a) The system complies with [4.3.1], and in addition, with items 1) to 3) below:
  - 1) The pressure in the space between concentric pipes is monitored continuously. Alarm is to be issued and the automatic valves specified in [4.5.1] (hereafter referred to as “interlocked gas valves”) and the master gas fuel valves specified in [4.6] (hereafter referred to as “master gas valves”) are to be closed before the pressure drops to below the inner pipe pressure (however, an interlocked gas valve connected to the vent outlet is to be opened).
  - 2) The construction and strength of the outer pipes are to comply with the requirements of Ch 9, Sec 5.
  - 3) It is to be so arranged that the inside of the gas fuel supply piping system between the master gas valve and the engine is automatically purged with inert gas when the master gas valve is closed; or
- b) The system complies with [4.3.1], and, in addition, with items 1) to 4) below:
  - 1) The materials, construction and strength of protection pipes or ducts and mechanical ventilation systems are to be sufficiently durable against bursting and rapid expansion of high pressure gas in the event of gas pipe burst.
  - 2) The capacity of mechanical ventilating systems is to be determined considering the flow rate of gas fuel and construction and arrangement of protective pipes or ducts, as deemed appropriate by the Society.
  - 3) The air intakes of mechanical ventilating systems are to be provided with non-return devices effective for gas fuel leaks. However, if a gas detector is fitted at the air intakes, this requirement may be dispensed with.
  - 4) The number of flange joints of protective pipes or ducts is to be minimised; or
- c) Alternative arrangements to those given in a) and b) will be specially considered by the Society based upon an equivalent level of safety.

**4.4.8** Joints on the entire length of the gas fuel supply lines are to be butt-welded joints with full penetration and to be fully radiographed, except where specially approved by the Society.

**4.4.9** Pipe joints other than welded joints at the locations specifically approved by the Society are to comply with the appropriate standards recognised by the Society, or with joints whose structural strength has been verified through test analysis as deemed appropriate by the Society.

**4.4.10** For all butt-welded joints of high pressure gas fuel supply lines, post-weld heat treatment is to be performed depending on the kind of material.

## **4.5 Gas consumer isolation**

**4.5.1** *The supply piping of each gas consumer unit shall be provided with gas fuel isolation by automatic double block and bleed, vented to a safe location, under both normal and emergency operation. The automatic valves shall be arranged to fail to the closed position on loss of actuating power. In a space containing multiple consumers, the shutdown of one shall not affect the gas supply to the others.*

**4.5.2** The automatic double block and bleed indicated in [4.5.1] are to be capable of being manually operated.

**4.5.3** It is to be possible to operate the valves indicated in [4.5.1] locally and from each control platform. They are to close automatically under the following service conditions:

- a) whenever the gas pressure varies by more than 10% or, in the case of supercharged engines, if the differential pressure between gas and charging air is no longer constant
- b) in the event of one of the following fault situations:
  - 1) gas supply to boiler burners
    - insufficient air supply for complete combustion of the gas
    - extinguishing of the pilot burner for an operating burner, unless the gas supply line to every individual burner is equipped with a quick-closing valve that automatically cuts off the gas
    - low pressure of the gas
  - 2) gas supply to internal combustion engines
    - failure of supply to pilot fuel injection pump
    - drop of engine speed below the lowest service speed.

## **4.6 Spaces containing gas consumers**

**4.6.1** *It shall be possible to isolate the gas fuel supply to each individual space containing a gas consumer(s) or through which fuel gas supply piping is run, with an individual master valve, which is located within the cargo area. The isolation of gas fuel supply to a space shall not affect the gas supply to other spaces containing gas consumers if they are located in two or more spaces, and it shall not cause loss of propulsion or electrical power.*

**4.6.2** *If the double barrier around the gas supply system is not continuous due to air inlets or other openings, or if there is any point where single failure will cause leakage into the space, the individual master valve for the space shall operate under the following circumstances:*

- a) automatically, by:
  - gas detection within the space
  - leak detection in the annular space of a double-walled pipe
  - leak detection in other compartments inside the space, containing single-walled gas piping; in particular the GVU compartment
  - loss of ventilation in the annular space of a double-walled pipe, and
  - loss of ventilation in other compartments inside the space, containing single-walled gas piping, in particular the GVU compartment and
- b) manually, from within the space and at least one remote location.

**4.6.3** *If the double barrier around the gas supply system is continuous, an individual master valve located in the cargo area may be provided for each gas consumer inside the space. The individual master valve shall operate under the following circumstances:*

- a) automatically, by:
  - leak detection in the annular space of a double-walled pipe served by that individual master valve
  - leak detection in other compartments containing single-walled gas piping that is part of the supply system served by the individual master valve, and
  - loss of ventilation or loss of pressure in the annular space of a double-walled pipe, and
- b) manually, from within the space and at least one remote location.

## **4.7 Piping and ducting construction**

**4.7.1** *Gas fuel piping in machinery spaces shall comply with Ch 9, Sec 5, [1] to Ch 9, Sec 5, [9], as applicable. The piping shall, as far as practicable, have welded joints. Those parts of the gas fuel piping that are not enclosed in a ventilated pipe or duct according to [4.3], and are on the weather decks outside the cargo area, shall have full penetration butt-welded joints and shall be fully radiographed.*

## **4.8 Gas detection**

**4.8.1** Gas detection systems provided in accordance with the requirements of this Section shall activate the alarm at 30% LFL and shut down the master gas fuel valve required by [7.5] at not more than 60% LFL (see Ch 9, Sec 13, [6.1.17]).

## **5 Gas fuel plant and related storage tanks**

### **5.1 Provision of gas fuel**

**5.1.1** All equipment (heaters, compressors, vaporizers, filters, etc.) for conditioning the cargo and/or cargo boil off vapour for its use as fuel, and any related storage tanks, shall be located in the cargo area. If the equipment is in an enclosed space, the space shall be ventilated according to Ch 9, Sec 12, [1.2] and be equipped with a fixed fire-extinguishing system, according to Ch 9, Sec 11, [1.5], and with a gas detection system according to Ch 9, Sec 13, [6], as applicable.

**5.1.2** Means for purging of flammable gases before opening are to be provided in the equipment for making up gas.

**5.1.3** Where the equipment (heaters, compressors, filters) for making up the gas for its use as fuel and the storage tanks are located on the weather deck, they are to be suitably protected from atmospheric agents and the sea.

### **5.2 Remote stops**

**5.2.1** All rotating equipment utilized for conditioning the cargo for its use as fuel shall be arranged for manual remote stop from the engine-room. Additional remote stops shall be located in areas that are always easily accessible, typically cargo control room, navigation bridge and fire control station.

**5.2.2** The fuel supply equipment shall be automatically stopped in the case of low suction pressure or fire detection. Unless expressly provided otherwise, the requirements of Ch 9, Sec 18, [3] need not apply to gas fuel compressors or pumps when used to supply gas consumers.

- a) The compressors are to be capable of being remotely stopped from an always and easily accessible, non-dangerous position in the open, and also from the engine room.
- b) In addition, the compressors are to be capable of automatically stopping when the suction pressure reaches a certain value depending on the setting pressure of the vacuum relief valves of the cargo tanks.
- c) The automatic shutdown device of the compressors is to have a manual resetting.

### **5.3 Compressors**

#### **5.3.1 Miscellaneous requirements**

- a) Low pressure piston-type compressors are to be fitted with relief valves discharging to a position in the open, such as not to give rise to hazards.
- b) Volumetric compressors are to be fitted with pressure/vacuum relief valves discharging into the suction line of the compressor.
- c) The size of the pressure relief valves is to be determined in such a way that, with the delivery valve kept closed, the maximum pressure does not exceed the maximum working pressure by more than 10%.
- d) The compressors are to be automatically stopped by the emergency shutdown system of the cargo valves.
- e) The compressors are to be fitted with shut-off valves and flame screens on both the suction and delivery sides.

### **5.4 Heating and cooling mediums**

**5.4.1** If the heating or cooling medium for the gas fuel conditioning system is returned to spaces outside the cargo area, provisions shall be made to detect and alarm the presence of cargo/cargo vapour in the medium. Any vent outlet shall be in a safe position and fitted with an effective flame screen of an approved type.

- a) Operation of the heaters is to be automatically regulated depending on the gas temperature at the heater outlet.
- b) Before it is returned to the machinery space, the heating medium (steam or hot water) is to go through a degassing tank located in the cargo area.
- c) The vent outlet is to be in a safe position, having regards of source of ignition and fitted with a flame screen.

### **5.5 Piping and pressure vessels**

**5.5.1** Piping or pressure vessels fitted in the gas fuel supply system shall comply with Ch 9, Sec 5

## 6 Special requirements for main boilers

### 6.1 Arrangements

6.1.1 *Each boiler shall have a separate exhaust uptake.*

6.1.2 *Each boiler shall have a dedicated forced draught system. A crossover between boiler force draught systems may be fitted for emergency use providing that any relevant safety functions are maintained.*

6.1.3 Boilers are to be located as high as possible in boiler spaces and are to be of the membrane wall type or equivalent, so as to create a space with forced air circulation between the membrane wall and the boiler casing.

6.1.4 *Combustion chambers and uptakes of boilers shall be designed to prevent any accumulation of gaseous fuel.*

6.1.5 The Society may, at its discretion, require gas detectors to be fitted in those combustion chamber areas where gas could accumulate, as well as the provision of suitable air nozzles.

### 6.2 Combustion equipment

6.2.1 *The burner systems shall be of dual type, suitable to burn either: oil fuel or gas fuel alone, or oil and gas fuel simultaneously.*

6.2.2 *Burners shall be designed to maintain stable combustion under all firing conditions.*

6.2.3 *An automatic system shall be fitted to change over from gas fuel operation to oil fuel operation without interruption of the boiler firing, in the event of loss of gas fuel supply.*

6.2.4 *Gas nozzles and the burner control system shall be configured such that gas fuel can only be ignited by an established oil fuel flame, unless the boiler and combustion equipment is designed and approved by the Society to light on gas fuel.*

### 6.3 Safety

6.3.1 *There shall be arrangements to ensure that gas fuel flow to the burner is automatically cut-off, unless satisfactory ignition has been established and maintained.*

6.3.2 *On the pipe of each gas-burner, a manually operated shut-off valve shall be fitted.*

6.3.3 *Provisions shall be made for automatically purging the gas supply piping to the burners, by means of an inert gas, after the extinguishing of these burners.*

6.3.4 A mechanical device is to be installed to prevent the gas valve from opening until the air and the fuel oil controls are in the ignition position. A flame screen, which may be incorporated in the burner, is to be fitted on the pipe of each gas burner.

6.3.5 *The automatic fuel changeover system required by [6.2.3] shall be monitored with alarms to ensure continuous availability.*

6.3.6 *Arrangements shall be made that, in case of flame failure of all operating burners, the combustion chambers of the boilers are automatically purged before relighting.*

6.3.7 *Arrangements shall be made to enable the boilers to be manually purged.*

## 7 Special requirements for gas-fired internal combustion engines

### 7.1 General

7.1.1 *Dual fuel engines are those that employ gas fuel (with pilot oil) and oil fuel. Oil fuels may include distillate and residual fuels. Gas only engines are those that employ gas fuel only.*

### 7.2 Gas fuel supply to engines with fuel injection pressure greater than 1 MPa

7.2.1 Flame arresters are to be provided at the inlet to the gas supply manifold for the engine.

7.2.2 Arrangements are to be made so that the gas supply to the engine can be shut off manually from the starting platform or any other control position.

7.2.3 The arrangement and installation of the gas piping are to provide the necessary flexibility for the gas supply piping to accommodate the oscillating movements of the engines without risk of fatigue failure.

7.2.4 The connecting of gas line and protection pipes or ducts as per [4.2.1] to the gas fuel injection valves is to provide complete coverage by the protection pipe or ducts.

### **7.3 Shut-off of gas fuel supply with pressure greater than 1 MPa**

#### **7.3.1 Fuel supply shut-off**

In addition to the causes specified in [4.5.1], supply of gas fuel to engines is to be shut-off by the interlocked gas valves in the event of the following abnormalities:

- a) abnormality specified in Pt C, Ch 1, App 2
- b) engine stops due to any cause.

#### **7.3.2 Master gas valve shut-off**

In addition to the causes specified in [4.6], the master gas valve is to be closed in the event of any of the following:

- a) the oil mist detector or bearing temperature detector specified in Pt C, Ch 1, App 2 detects abnormality
- b) any kind of gas fuel leakage is detected
- c) abnormality specified in Pt C, Ch 1, App 2.

#### **7.3.3 Automatic operation**

The master gas valve is to close automatically upon activation of the interlocked gas valves.

### **7.4 Emergency stop of dual fuel engines with fuel injection pressure greater than 1 MPa**

**7.4.1** Dual fuel engines are to be stopped before the gas concentration detected by the gas detectors specified in [3.1.2] reaches 60% of the lower flammable limit.

### **7.5 Requirements on dual fuel engines**

**7.5.1** Specific requirements on internal combustion engines supplied by gas are given in Pt C, Ch 1, App 2.

### **7.6 Arrangements**

**7.6.1** *When gas is supplied in a mixture with air through a common manifold, flame arrestors shall be installed before each cylinder head.*

**7.6.2** *Each engine shall have its own separate exhaust.*

**7.6.3** *The exhausts shall be configured to prevent any accumulation of unburnt gaseous fuel.*

**7.6.4** *Unless designed with the strength to withstand the worst case overpressure due to ignited gas leaks, air inlet manifolds, scavenge spaces, exhaust system and crank cases shall be fitted with suitable pressure relief systems. Pressure relief systems shall lead to a safe location, away from personnel.*

A suitable pressure relief system for air inlet manifolds, scavenge spaces and exhaust system is to be provided unless designed to accommodate the worst-case overpressure due to ignited gas leaks or justified by the safety concept of the engine. A detailed evaluation regarding the hazard potential of overpressure in air inlet manifolds, scavenge spaces and exhaust system is to be carried out and reflected in the safety concept of the engine.

In the case of crankcases, the explosion relief valves, as required by Regulation 27.4 of SOLAS Chapter II-1 as amended by IMO resolutions up to MSC.436(99), are to be considered suitable for the gas operation of the engine. For engines not covered by said Regulation, a detailed evaluation regarding the hazard potential of fuel gas accumulation in the crankcase is to be carried out.

**7.6.5** *Each engine shall be fitted with vent systems independent of other engines for crankcases, sumps and cooling systems.*

### **7.7 Combustion equipment**

**7.7.1** *Prior to admission of gas fuel, correct operation of the pilot oil injection system on each unit shall be verified.*

**7.7.2** *For a spark ignition engine, if ignition has not been detected by the engine monitoring system within an engine specific time after opening of the gas supply valve, this shall be automatically shut off and the starting sequence terminated. It shall be ensured that any unburnt gas mixture is purged from the exhaust system.*

**7.7.3** *For dual-fuel engines fitted with a pilot oil injection system, an automatic system shall be fitted to change over from gas fuel operation to oil fuel operation with minimum fluctuation of the engine power.*

**7.7.4** *In the case of unstable operation on engines with the arrangement in [7.7.3] when gas firing, the engine shall automatically change to oil fuel mode.*

### **7.8 Safety**

**7.8.1** *During stopping of the engine, the gas fuel shall be automatically shut off before the ignition source.*

**7.8.2** *Arrangements shall be provided to ensure that there is no unburnt gas fuel in the exhaust gas system prior to ignition.*

**7.8.3** Crankcases, sumps, scavenge spaces and cooling system vents shall be provided with gas detection (see Ch 9, Sec 13, [6.1.17]).

**7.8.4** Provision shall be made within the design of the engine to permit continuous monitoring of possible sources of ignition within the crank case. Instrumentation fitted inside the crankcase shall be in accordance with the requirements of Ch 9, Sec 10.

**7.8.5** Means shall be provided to monitor and detect poor combustion or misfiring that may lead to unburnt gas fuel in the exhaust system during operation. In the event that it is detected, the gas fuel supply shall be shut down. Instrumentation fitted inside the exhaust system shall be in accordance with the requirements of Ch 9, Sec 10.

## **8 Special requirements for gas turbine**

### **8.1 Arrangements**

**8.1.1** Each turbine shall have its own separate exhaust.

**8.1.2** The exhausts shall be appropriately configured to prevent any accumulation of unburnt gas fuel.

**8.1.3** Unless designed with the strength to withstand the worst case overpressure due to ignited gas leaks, pressure relief systems shall be suitably designed and fitted to the exhaust system, taking into consideration explosions due to gas leaks. Pressure relief systems within the exhaust uptakes shall be lead to a non-hazardous location, away from personnel.

### **8.2 Combustion equipment**

**8.2.1** An automatic system shall be fitted to change over easily and quickly from gas fuel operation to oil fuel operation with minimum fluctuation of the engine power.

### **8.3 Safety**

**8.3.1** Means shall be provided to monitor and detect poor combustion that may lead to unburnt gas fuel in the exhaust system during operation. In the event that it is detected, the gas fuel supply shall be shut down.

**8.3.2** Each turbine shall be fitted with an automatic shutdown device for high exhaust temperatures.

## **9 Alternative fuels and technologies**

### **9.1 General**

**9.1.1** If acceptable to the Society, other cargo gases may be used as fuel, providing that the same level of safety as natural gas in this Code is ensured.

**9.1.2** The use of cargoes identified as toxic products shall not be permitted.

**9.1.3** For cargoes other than LNG, the fuel supply system shall comply with the requirements of [4.1], [4.2], [4.3] and [5], as applicable, and shall include means for preventing condensation of vapour in the system.

**9.1.4** Liquefied gas fuel supply systems shall comply with [4.5].

**9.1.5** In addition to the requirements of [4.3.1], item b), both ventilation inlet and outlet shall be located outside the machinery space. The inlet shall be in a non-hazardous area and the outlet shall be in a safe location.

# Section 17 Special Requirements

## 1 General

### 1.1 Application

**1.1.1** *The requirements of this Section are applicable where reference thereto is made in Ch 9, Sec 19, Tab 1, column “Special requirements”.*

*These requirements are additional to the general requirements of this Chapter.*

## 2 Materials of construction

### 2.1 General

**2.1.1** *Materials that may be exposed to cargo during normal operations shall be resistant to the corrosive action of the gases. In addition, the following materials of construction for cargo tanks and associated pipelines, valves, fittings and other items of equipment normally in direct contact with the cargo liquid or vapour shall not be used for certain products as specified in Ch 9, Sec 19, Tab 1, column “Special requirements”:*

- a) *mercury, copper and copper-bearing alloys, and zinc*
- b) *copper, silver, mercury, magnesium and other acetylide-forming metals*
- c) *aluminium and aluminium-bearing alloys*
- d) *copper, copper alloys, zinc and galvanized steel*
- e) *aluminium, copper and alloys of either, and*
- f) *copper and copper-bearing alloys with greater than 1% copper.*

*Materials “exposed to cargo” are those constituting systems, cargo appliances or arrangements which are in contact with (liquid or vapour) cargo in normal operating conditions.*

## 3 Independent tanks

### 3.1 General

**3.1.1** *Products shall be carried in independent tanks only.*

**3.1.2** *Products shall be carried in type C independent tanks, and the requirements of Ch 9, Sec 7, [1.1.2] shall apply. The design pressure of the cargo tank shall take into account any padding pressure or vapour discharge unloading pressure.*

## 4 Refrigeration systems

### 4.1 General

**4.1.1** *Only the indirect system described in Ch 9, Sec 7, [3.1.3], item b) shall be used.*

**4.1.2** *For a ship engaged in the carriage of products that readily form dangerous peroxides, recondensed cargo shall not be allowed to form stagnant pockets of uninhibited liquid. This may be achieved either by:*

- a) *using the indirect system described in Ch 9, Sec 7, [3.1.3], item b), with the condenser inside the cargo tank, or*
- b) *using the direct system or combined system described in Ch 9, Sec 7, [3.1.3], item a) and in Ch 9, Sec 7, [3.1.3], item c) respectively, or the indirect system described in Ch 9, Sec 7, [3.1.3], item b) with the condenser outside the cargo tank, and designing the condensate system to avoid any places in which liquid could collect and be retained. Where this is impossible, inhibited liquid shall be added upstream of such a place.*

**4.1.3** *If the ship is to consecutively carry products as specified in [4.1.2] with a ballast passage between, all uninhibited liquid shall be removed prior to the ballast voyage. If a second cargo is to be carried between such consecutive cargoes, the reliquefaction system shall be thoroughly drained and purged before loading the second cargo. Purging shall be carried out using either inert gas or vapour from the second cargo, if compatible. Practical steps shall be taken to ensure that polymers or peroxides do not accumulate in the cargo system.*

## 5 Cargoes requiring type 1G ship

### 5.1 General

- 5.1.1** All butt-welded joints in cargo piping exceeding 75 mm in diameter shall be subject to 100% radiography.
- 5.1.2** Gas sampling lines shall not be led into or through non-hazardous areas. Alarms referred to in Ch 9, Sec 13, [6.1.2] shall be activated when the vapour concentration reaches the threshold limiting value.
- 5.1.3** The alternative of using portable gas detection equipment in accordance with Ch 9, Sec 13, [6.1.5] shall not be permitted.
- 5.1.4** Cargo control rooms shall be located in a non-hazardous area and, additionally, all instrumentation shall be of the indirect type.
- 5.1.5** Personnel shall be protected against the effects of a major cargo release by the provision of a space within the accommodation area that is designed and equipped to the satisfaction of the Society.
- 5.1.6** Notwithstanding the requirements in Ch 9, Sec 3, [1.2.5], access to forecastle spaces shall not be permitted through a door facing the cargo area, unless airlock in accordance with Ch 9, Sec 3, [1.6] is provided.
- 5.1.7** Notwithstanding the requirements in Ch 9, Sec 3, [1.2.13], access to control rooms and machinery spaces of turret systems shall not be permitted through doors facing the cargo area.

## 6 Exclusion of air from vapour spaces

### 6.1 General

- 6.1.1** Air shall be removed from cargo tanks and associated piping before loading and, then, subsequently excluded by:
- introducing inert gas to maintain a positive pressure. Storage or production capacity of the inert gas shall be sufficient to meet normal operating requirements and relief valve leakage. The oxygen content of inert gas shall, at no time, be greater than 0.2% by volume, or
  - control of cargo temperatures such that a positive pressure is maintained at all times.

## 7 Moisture control

### 7.1 General

**7.1.1** For gases that are non-flammable and may become corrosive or react dangerously with water, moisture control shall be provided to ensure that cargo tanks are dry before loading and that, during discharge, dry air or cargo vapour is introduced to prevent negative pressures. For the purposes of this paragraph, dry air is air that has a dew point of  $-45^{\circ}\text{C}$  or below at atmospheric pressure.

## 8 Inhibition

### 8.1 General

**8.1.1** Care shall be taken to ensure that the cargo is sufficiently inhibited to prevent self-reaction (e.g. polymerization or dimerization) at all times during the voyage. Ships shall be provided with a certificate from the manufacturer stating:

- name and amount of inhibitor added
  - As an alternative to the addition of inhibited liquid, it may be accepted that, at the end of each refrigeration period, the liquid is completely removed from the refrigeration system by means of vapour from compressors or by means of inert gas. In such case, the following wording is to be entered on the Certificate of Fitness:  
"At the end of each refrigeration period, the liquid is to be completely removed from the refrigeration system by means of vapour from compressors or by means of inert gas."
  - On the cargo compressor delivery side, a temperature switch is to be fitted, set at a suitable temperature, depending on the characteristics of the product carried (e.g.  $60^{\circ}\text{C}$  for butadiene), giving a visual and audible alarm on the navigation bridge and in the cargo control station, if any, which causes the compressor to stop when such temperature is exceeded.
- date inhibitor was added and the normally expected duration of its effectiveness
- any temperature limitations affecting the inhibitor, and
- the action to be taken should the length of the voyage exceed the effective lifetime of the inhibitors.

## 9 Flame screens on vent outlets

### 9.1 General

**9.1.1** When carrying a cargo referenced to this section, cargo tank vent outlets shall be provided with readily renewable and effective flame screens or safety heads of an approved type. Due attention shall be paid in the design of flame screens and vent heads, to the possibility of the blockage of these devices by the freezing of cargo vapour or by icing up in adverse weather conditions. Flame screens shall be removed and replaced by protection screens, in accordance with Ch 9, Sec 8, [2.1.18], when carrying cargoes not referenced to this section.

## 10 Maximum allowable quantity of cargo per tank

### 10.1 General

**10.1.1** When carrying a cargo referenced to this section, the quantity of the cargo shall not exceed 3,000 m<sup>3</sup> in any one tank.

## 11 Cargo pumps and discharge arrangements

### 11.1 General

**11.1.1** The vapour space of cargo tanks equipped with submerged electric motor pumps shall be inerted to a positive pressure prior to loading, during carriage and during unloading of flammable liquids.

**11.1.2** The cargo shall be discharged only by deepwell pumps or by hydraulically operated submerged pumps. These pumps shall be of a type designed to avoid liquid pressure against the shaft gland.

**11.1.3** Inert gas displacement may be used for discharging cargo from type C independent tanks, provided the cargo system is designed for the expected pressure.

## 12 Ammonia

### 12.1 General

**12.1.1** Anhydrous ammonia may cause stress corrosion cracking in containment and process systems made of carbon-manganese steel or nickel steel. To minimize the risk of this occurring, measures detailed in [12.1.2] to [12.1.8] shall be taken, as appropriate.

**12.1.2** Where carbon-manganese steel is used, cargo tanks, process pressure vessels and cargo piping shall be made of fine-grained steel with a specified minimum yield strength not exceeding 355 N/mm<sup>2</sup>, and with an actual yield strength not exceeding 440 N/mm<sup>2</sup>. One of the following constructional or operational measures shall also be taken:

- a) lower strength material with a specified minimum tensile strength not exceeding 410 N/mm<sup>2</sup> shall be used, or
- b) cargo tanks, etc., shall be post-weld stress relief heat treated, or
- c) carriage temperature shall be maintained, preferably at a temperature close to the product's boiling point of – 33°C, but in no case at a temperature above – 20°C, or
- d) the ammonia shall contain not less than 0.1% w/w water, and the master shall be provided with documentation confirming this.

**12.1.3** If carbon-manganese steels with higher yield properties are used other than those specified in [12.1.2], the completed cargo tanks, piping, etc., shall be given a post-weld stress relief heat treatment.

**12.1.4** Process pressure vessels and piping of the condensate part of the refrigeration system shall be given a post-weld stress relief heat treatment when made of materials mentioned in [12.1.1].

**12.1.5** The tensile and yield properties of the welding consumables shall exceed those of the tank or piping material by the smallest practical amount.

**12.1.6** Nickel steel containing more than 5% nickel and carbon-manganese steel, not complying with the requirements of [12.1.2] and [12.1.3], are particularly susceptible to ammonia stress corrosion cracking and shall not be used in containment and piping systems for the carriage of this product.

**12.1.7** Nickel steel containing not more than 5% nickel may be used, provided the carriage temperature complies with the requirements specified in [12.1.2], item c).

**12.1.8** To minimize the risk of ammonia stress corrosion cracking, it is advisable to keep the dissolved oxygen content below 2.5 ppm w/w. This can best be achieved by reducing the average oxygen content in the tanks prior to the introduction of liquid ammonia to less than the values given as a function of the carriage temperature *T* in Tab 1:

Table 1 : Oxygen content

T (°C)	O <sub>2</sub> (% v/v)
– 30 and below	0,90
– 20	0,50
– 10	0,28
0	0,16
10	0,10
20	0,05
30	0,03

**Note 1:** Oxygen percentages for intermediate temperatures may be obtained by direct interpolation

## 13 Chlorine

### 13.1 Cargo containment system

**13.1.1** The capacity of each tank shall not exceed 600 m<sup>3</sup> and the total capacity of all cargo tanks shall not exceed 1200 m<sup>3</sup>.

**13.1.2** The tank design vapour pressure shall not be less than 1,35 MPa (see Ch 9, Sec 7, [1.1.2] and [3.1.2]).

**13.1.3** Parts of tanks protruding above the upper deck shall be provided with protection against thermal radiation, taking into account total engulfment by fire.

**13.1.4** Each tank shall be provided with two PRVs. A bursting disc of appropriate material shall be installed between the tank and the PRVs. The rupture pressure of the bursting disc shall be 0,1 MPa lower than the opening pressure of the pressure relief valve, which shall be set at the design vapour pressure of the tank but not less than 1,35 MPa gauge. The space between the bursting disc and the relief valve shall be connected through an excess flow valve to a pressure gauge and a gas detection system. Provisions shall be made to keep this space at or near the atmospheric pressure during normal operation.

Chlorine discharge from pressure relief valves is to be led to an absorption device deemed suitable by the Society.

**13.1.5** Outlets from PRVs shall be arranged in such a way as to minimize the hazards on board the ship as well as to the environment. Leakage from the relief valves shall be led through the absorption plant to reduce the gas concentration as far as possible. The relief valve exhaust line shall be arranged at the forward end of the ship to discharge outboard at deck level with an arrangement to select either port or starboard side, with a mechanical interlock to ensure that one line is always open.

**13.1.6** The Society and the port Administration may require that chlorine is carried in a refrigerated state at a specified maximum pressure.

### 13.2 Cargo piping systems

**13.2.1** Cargo discharge shall be performed by means of compressed chlorine vapour from shore, dry air or another acceptable gas, or fully submerged pumps. Cargo discharge compressors on board ships shall not be used for this. The pressure in the vapour space of the tank during discharging shall not exceed 1,05 MPa gauge.

**13.2.2** The design pressure of the cargo piping system shall be not less than 2,1 MPa gauge. The internal diameter of the cargo pipes shall not exceed 100 mm. Only pipe bends shall be accepted for compensation of pipeline thermal movement. The use of flanged joints shall be restricted to a minimum and, when used, the flanges shall be of the welding neck type with tongue and groove.

**13.2.3** A welding neck type flange deemed suitable is shown in Fig 1 as an example.

Figure 1 : Suitable neck type flange

**13.2.4**

Relief valves of the cargo piping system shall discharge to the absorption plant, and the flow restriction created by this unit shall be taken into account when designing the relief valve system (see Ch 9, Sec 8, [4.3] and Ch 9, Sec 8, [4.4]).

**13.3 Materials**

**13.3.1** The cargo tanks and cargo piping systems shall be made of steel suitable for the cargo and for a temperature of  $-40^{\circ}\text{C}$ , even if a higher transport temperature is intended to be used.

**13.3.2** The tanks shall be thermally stress relieved. Mechanical stress relief shall not be accepted as an equivalent.

**13.4 Instrumentation: safety devices**

**13.4.1** The ship shall be provided with a chlorine absorbing plant with a connection to the cargo piping system and the cargo tanks. The absorbing plant shall be capable of neutralizing at least 2% of the total cargo capacity at a reasonable absorption rate.

**13.4.2** During the gas-freeing of cargo tanks, vapours shall not be discharged to the atmosphere.

**13.4.3** A gas detecting system shall be provided that is capable of monitoring chlorine concentrations of at least 1 ppm by volume. Sample points shall be located:

- near the bottom of the hold spaces
- in the pipes from the safety relief valves
- at the outlet from the gas absorbing plant
- at the inlet to the ventilation systems for the accommodation, service and machinery spaces and control stations, and
- on deck - at the forward end, midships and the after end of the cargo area. This is only required to be used during cargo handling and gas-freeing operations.

The gas detection system shall be provided with an audible and visual alarm with a set point of 5 ppm.

The gas detection system is to be permanently installed.

**13.4.4** Each cargo tank shall be fitted with a high-pressure alarm giving an audible alarm at a pressure equal to 1,05 MPa gauge.

**13.5 Personnel protection**

**13.5.1** The enclosed space required by [5.1.5] shall meet the following requirements:

- the space shall be easily and quickly accessible from the weather decks and from accommodation spaces by means of air locks, and shall be capable of being rapidly closed gastight
- one of the decontamination showers required by Ch 9, Sec 14, [1.4.3] shall be located near the weather deck airlock to the space
- the space shall be designed to accommodate the entire crew of the ship and be provided with a source of uncontaminated air for a period of not less than 4 h, and
- one set of oxygen therapy equipment shall be carried in the space.

In addition to the source of uncontaminated air, two complete and independent air breathing apparatuses, not employing oxygen supplies, each having a capacity of at least 1200 litres of non-compressed air and two sets of protective equipment, complete with gas-tight boots, gloves and eye protection, are to be provided. The above-mentioned equipment and clothing are to be kept in the space indicated above and are additional to those required in other parts of this Chapter.

**13.6 Filling limits for cargo tanks**

**13.6.1** The requirements of Ch 9, Sec 15, [1.1.3], item b) do not apply when it is intended to carry chlorine.

**13.6.2** When determining the filling limits of the cargo tanks for the transport of chlorine, the effect of the refrigeration plant is not to be considered.

**13.6.3** The chlorine content of the gas in the vapour space of the cargo tank after loading shall be greater than 80% by volume.

**14 Ethylene oxide**

**14.1 General**

**14.1.1** For the carriage of ethylene oxide, the requirements of [18] shall apply, with the additions and modifications as given in this sub-article.

**14.1.2** Deck tanks shall not be used for the carriage of ethylene oxide.

**14.1.3** Stainless steels types 416 and 442, as well as cast iron, shall not be used in ethylene oxide cargo containment and piping systems.

**14.1.4** Before loading, tanks shall be thoroughly and effectively cleaned to remove all traces of previous cargoes from tanks and associated pipework, except where the immediate prior cargo has been ethylene oxide, propylene oxide or mixtures of these products. Particular care shall be taken in the case of ammonia in tanks made of steel other than stainless steel.

**14.1.5** Ethylene oxide shall be discharged only by deepwell pumps or inert gas displacement. The arrangement of pumps shall comply with [18.1.15].

**14.1.6** Ethylene oxide shall be carried refrigerated only and maintained at temperatures of less than 30°C.

**14.1.7** PRVs shall be set at a pressure of not less than 0,55 MPa gauge. The maximum set pressure shall be specially approved by the Society.

**14.1.8** The protective padding of nitrogen gas, as required by [18.1.27], shall be such that the nitrogen concentration in the vapour space of the cargo tank will, at no time, be less than 45% by volume.

**14.1.9** Before loading, and at all times when the cargo tank contains ethylene oxide liquid or vapour, the cargo tank shall be inerted with nitrogen.

**14.1.10** The water-spray system required by [18.1.29] and that required by Ch 9, Sec 11, [1.3] shall operate automatically in a fire involving the cargo containment system.

**14.1.11** A jettisoning arrangement shall be provided to allow the emergency discharge of ethylene oxide in the event of uncontrollable self-reaction.

## **15 Separate piping systems**

### **15.1 General**

**15.1.1** Separate piping systems, as defined in Ch 9, Sec 1, [4.1.45], shall be provided.

## **16 Methyl acetylene-propadiene mixtures**

### **16.1 General**

**16.1.1** Methyl acetylene-propadiene mixtures shall be suitably stabilized for transport. Additionally, upper limits of temperatures and pressure during the refrigeration shall be specified for the mixtures.

**16.1.2** Examples of acceptable stabilized compositions are:

- Composition 1:
  - maximum methyl acetylene to propadiene molar ratio of 3 to 1
  - maximum combined concentration of methyl acetylene and propadiene of 65 mol%
  - minimum combined concentration of propane, butane, and isobutane of 24 mol%, of which at least one third (on a molar basis) shall be butanes and one third propane,
  - maximum combined concentration of propylene and butadiene of 10 mol%.
- Composition 2:
  - maximum methylacetylene and propadiene combined concentration of 30 mol%
  - maximum methyl acetylene concentration of 20 mol%
  - maximum propadiene concentration of 20 mol%
  - maximum propylene concentration of 45 mol%
  - maximum butadiene and butylenes combined concentration of 2 mol%
  - minimum saturated C4 hydrocarbon concentration of 4 mol%, and
  - minimum propane concentration of 25 mol%.

**16.1.3** Other compositions may be accepted, provided the stability of the mixture is demonstrated to the satisfaction of the Society.

**16.1.4** If a ship has a direct vapour compression refrigeration system, this shall comply with the following requirements, subject to pressure and temperature limitations depending on the composition. For the example compositions given in [16.1.2], the following features shall be provided:

- a) vapour compressor that does not raise the temperature and pressure of the vapour above 60°C and 1,75 MPa gauge during its operation, and that does not allow vapour to stagnate in the compressor while it continues to run

- b) discharge piping from each compressor stage or each cylinder in the same stage of a reciprocating compressor shall have:
- 1) two temperature-actuated shutdown switches set to operate at 60°C or less
  - 2) a pressure-actuated shutdown switch set to operate at 1,75 MPa gauge or less, and
  - 3) a safety relief valve set to relieve at 1,8 MPa gauge or less;
- c) the relief valve required by [16.1.4], item b), 3). shall vent to a mast meeting the requirements of Ch 9, Sec 8, [2.1.10], Ch 9, Sec 8, [2.1.14] and Ch 9, Sec 8, [2.1.18] and shall not relieve into the compressor suction line, and
- d) an alarm that sounds in the cargo control position and in the navigation bridge when a high-pressure switch, or a high-temperature switch, operates.

**16.1.5** The piping system, including the cargo refrigeration system, for tanks to be loaded with methyl acetylene-propadiene mixtures shall be either independent (as defined in Ch 9, Sec 1, [4.1.28]) or separate (as defined in Ch 9, Sec 1, [4.1.45]) from piping and refrigeration systems for other tanks. This segregation shall apply to all liquid and vapour vent lines and any other possible connections, such as common inert gas supply lines.

## **17 Nitrogen**

### **17.1 General**

**17.1.1** Materials of construction and ancillary equipment such as insulation shall be resistant to the effects of high oxygen concentrations caused by condensation and enrichment at the low temperatures attained in parts of the cargo system. Due consideration shall be given to ventilation in areas where condensation might occur, to avoid the stratification of oxygen-enriched atmosphere.

## **18 Propylene oxide and mixtures of ethylene oxide-propylene oxide with ethylene oxide content of not more than 30% by weight**

### **18.1 General**

**18.1.1** Products transported under the provisions of this sub-article shall be acetylene-free.

**18.1.2** Unless cargo tanks are properly cleaned, these products shall not be carried in tanks that have contained as one of the three previous cargoes any product known to catalyse polymerization, such as:

- anhydrous ammonia and ammonia solutions
- amines and amine solutions, and
- oxidizing substances (e.g. chlorine).

**18.1.3** Before loading, tanks shall be thoroughly and effectively cleaned to remove all traces of previous cargoes from tanks and associated pipework, except where the immediate prior cargo has been propylene oxide or ethylene oxide-propylene oxide mixtures. Particular care shall be taken in the case of ammonia in tanks made of steel other than stainless steel.

**18.1.4** In all cases, the effectiveness of cleaning procedures for tanks and associated pipework shall be checked, by suitable testing or inspection, to ascertain that no traces of acidic or alkaline materials remain that might create a hazardous situation in the presence of these products.

**18.1.5** Tanks shall be entered and inspected prior to each initial loading of these products to ensure freedom from contamination, heavy rust deposits and any visible structural defects. When cargo tanks are in continuous service for these products, such inspections shall be performed at intervals of not more than two years.

**18.1.6** Tanks for the carriage of these products shall be of steel or stainless steel construction.

**18.1.7** Tanks that have contained these products may be used for other cargoes after thorough cleaning of tanks and associated pipework systems by washing or purging.

**18.1.8** All valves, flanges, fittings and accessory equipment shall be of a type suitable for use with these products and shall be constructed of steel or stainless steel in accordance with recognized standards. Disc or disc faces, seats and other wearing parts of valves shall be made of stainless steel containing not less than 11% chromium.

**18.1.9** Gaskets shall be constructed of materials which do not react with, dissolve in, or lower the auto-ignition temperature of, these products and which are fire-resistant and possess adequate mechanical behaviour. The surface presented to the cargo shall be polytetrafluoroethylene (PTFE) or materials giving a similar degree of safety by their inertness. Spirally-wound stainless steel with a filler of PTFE or similar fluorinated polymer may be accepted, if approved by the Society.

**18.1.10** Insulation and packing, if used, shall be of a material which does not react with, dissolve in, or lower the auto-ignition temperature of, these products.

- 18.1.11** The following materials are generally found unsatisfactory for use in gaskets, packing and similar uses in containment systems for these products and would require testing before being approved:
- neoprene or natural rubber, if it comes into contact with the products
  - asbestos or binders used with asbestos, and
  - materials containing oxides of magnesium, such as mineral wools.
- 18.1.12** Filling and discharge piping shall extend to within 100 mm of the bottom of the tank or any sump.
- 18.1.13** The products shall be loaded and discharged in such a manner that venting of the tanks to atmosphere does not occur. If vapour return to shore is used during tank loading, the vapour return system connected to a containment system for the product shall be independent of all other containment systems.
- 18.1.14** During discharging operations, the pressure in the cargo tank shall be maintained above 0,007 MPa gauge.
- 18.1.15** The cargo shall be discharged only by deepwell pumps, hydraulically operated submerged pumps or inert gas displacement. Each cargo pump shall be arranged to ensure that the product does not heat significantly if the discharge line from the pump is shut off or otherwise blocked.
- 18.1.16** Tanks carrying these products shall be vented independently of tanks carrying other products. Facilities shall be provided for sampling the tank contents without opening the tank to atmosphere.
- 18.1.17** Cargo hoses used for transfer of these products shall be marked "FOR ALKYLENE OXIDE TRANSFER ONLY".
- 18.1.18** Hold spaces shall be monitored for these products. Hold spaces surrounding type A and type B independent tanks shall also be inerted and monitored for oxygen. The oxygen content of these spaces shall be maintained below 2% by volume. Portable sampling equipment is satisfactory.
- 18.1.19** Prior to disconnecting shore lines, the pressure in liquid and vapour lines shall be relieved through suitable valves installed at the loading header. Liquid and vapour from these lines shall not be discharged to atmosphere.
- 18.1.20** Tanks shall be designed for the maximum pressure expected to be encountered during loading, carriage or unloading of cargo.
- 18.1.21** Tanks for the carriage of propylene oxide with a design vapour pressure of less than 0.06 MPa, and tanks for the carriage of ethylene oxide-propylene oxide mixtures with a design vapour pressure of less than 0.12 MPa, shall have a cooling system to maintain the cargo below the reference temperature. The reference temperatures are referred to in Ch 9, Sec 15, [1.1.3].
- 18.1.22** Pressure relief valve settings shall not be less than 0,02 MPa gauge; and for type C independent tanks not greater than 0,7 MPa gauge for the carriage of propylene oxide and not greater than 0,53 MPa gauge for the carriage of ethylene oxide-propylene oxide mixtures.
- 18.1.23** The piping system for tanks to be loaded with these products shall be completely separate from piping systems for all other tanks, including empty tanks, and from all cargo compressors. If the piping system for the tanks to be loaded with these products is not independent, as defined in Ch 9, Sec 1, [4.1.28], the required piping separation shall be accomplished by the removal of spool pieces, valves, or other pipe sections and the installation of blank flanges at these locations. The required separation applies to all liquid and vapour piping, liquid and vapour vent lines and any other possible connections such as common inert gas supply lines.
- 18.1.24** The products shall be transported only in accordance with cargo handling plans approved by the Society. Each intended loading arrangement shall be shown on a separate cargo handling plan. Cargo handling plans shall show the entire cargo piping system and the locations for installation of the blank flanges needed to meet the above piping separation requirements. A copy of each approved cargo handling plan shall be kept on board the ship. The International Certificate of Fitness for the Carriage of Liquefied Gases in Bulk shall be endorsed to include references to the approved cargo handling plans.
- 18.1.25** Before each initial loading of these products, and before every subsequent return to such service, certification verifying that the required piping separation has been achieved shall be obtained from a responsible person acceptable to the port Administration and carried on board the ship. Each connection between a blank flange and pipeline flange shall be fitted with a wire and seal by the responsible person to ensure that inadvertent removal of the blank flange is impossible.
- 18.1.26** The maximum allowable loading limits for each tank shall be indicated for each loading temperature that may be applied, in accordance with Ch 9, Sec 15, [1.5].
- 18.1.27** The cargo shall be carried under a suitable protective padding of nitrogen gas. An automatic nitrogen make-up system shall be installed to prevent the tank pressure falling below 0,007 MPa gauge in the event of product temperature fall due to ambient conditions or malfunctioning of refrigeration system. Sufficient nitrogen shall be available on board to satisfy the demand of the automatic pressure control. Nitrogen of commercially pure quality (99.9% by volume) shall be used for padding. A battery of nitrogen bottles, connected to the cargo tanks through a pressure reduction valve, satisfies the intention of the expression "automatic" in this context.

**18.1.28** *The cargo tank vapour space shall be tested prior to and after loading to ensure that the oxygen content is 2% by volume or less.*

**18.1.29** *A water-spray system of sufficient capacity shall be provided to blanket effectively the area surrounding the loading manifold, the exposed deck piping associated with product handling and the tank domes. The arrangement of piping and nozzles shall be such as to give a uniform distribution rate of 10 litre/m<sup>2</sup>/min. The arrangement shall ensure that any spilled cargo is washed away.*

**18.1.30** *The water-spray system shall be capable of local and remote manual operation in case of a fire involving the cargo containment system. Remote manual operation shall be arranged such that the remote starting of pumps supplying the water-spray system and remote operation of any normally closed valves in the system can be carried out from a suitable location outside the cargo area, adjacent to the accommodation spaces and readily accessible and operable in the event of fire in the areas protected.*

**18.1.31** *When ambient temperatures permit, a pressurized water hose ready for immediate use shall be available during loading and unloading operations, in addition to the above water-spray requirements.*

## **19 Vinyl chloride**

### **19.1 General**

**19.1.1** *In cases where polymerization of vinyl chloride is prevented by addition of an inhibitor, Article [8] is applicable. In cases where no inhibitor has been added, or the inhibitor concentration is insufficient, any inert gas used for the purposes of Article [6] shall contain no more oxygen than 0,1% by volume. Before loading is started, inert gas samples from the tanks and piping shall be analysed. When vinyl chloride is carried, a positive pressure shall always be maintained in the tanks and during ballast voyages between successive carriages.*

## **20 Mixed C4 cargoes**

### **20.1 General**

**20.1.1** *Cargoes that may be carried individually under the requirements of this Code, notably butane, butylenes and butadiene, may be carried as mixtures subject to the provisions of this section. These cargoes may variously be referred to as "Crude C4", "Crude butadiene", "Crude steam-cracked C4", "Spent steam-cracked C4", "C4 stream", "C4 raffinate", or may be shipped under a different description. In all cases, the material safety data sheets (MSDS) shall be consulted as the butadiene content of the mixture is of prime concern as it is potentially toxic and reactive. While it is recognized that butadiene has a relatively low vapour pressure, if such mixtures contain butadiene they shall be regarded as toxic and the appropriate precautions applied.*

**20.1.2** *If the mixed C4 cargo shipped under the terms of this section contains more than 50% (mole) of butadiene, the inhibitor precautions in [8] shall apply.*

**20.1.3** *Unless specific data on liquid expansion coefficients is given for the specific mixture loaded, the filling limit restrictions of Ch 9, Sec 15 shall be calculated as if the cargo contained 100% concentration of the component with the highest expansion ratio.*

## **21 Carbon dioxide: high purity**

### **21.1 General**

**21.1.1** *Interpretation and application for ships carrying liquefied carbon dioxide in bulk are given in Tab 2.*

**21.1.2** *Uncontrolled pressure loss from the cargo can cause "sublimation" and the cargo will change from the liquid to the solid state. The precise "triple point" temperature of a particular carbon dioxide cargo shall be supplied before loading the cargo, and will depend on the purity of that cargo, and this shall be taken into account when cargo instrumentation is adjusted. The set pressure for the alarms and automatic actions described in this section shall be set to at least 0,05 MPa above the triple point for the specific cargo being carried. The "triple point" for pure carbon dioxide occurs at 0,5 MPa gauge and – 54.4°C.*

**21.1.3** *There is a potential for the cargo to solidify in the event that a cargo tank relief valve, fitted in accordance with Ch 9, Sec 8, [2], fails in the open position. To avoid this, a means of isolating the cargo tank safety valves shall be provided and the requirements of Ch 9, Sec 8, [2.1.11], item b) do not apply when carrying this carbon dioxide. Discharge piping from safety relief valves shall be designed so they remain free from obstructions that could cause clogging. Protective screens shall not be fitted to the outlets of relief valve discharge piping, so the requirements of Ch 9, Sec 8, [2.1.18] do not apply.*

**21.1.4** *Discharge piping from safety relief valves are not required to comply with Ch 9, Sec 8, [2.1.12], but shall be designed so they remain free from obstructions that could cause clogging. Protective screens shall not be fitted to the outlets of relief valve discharge piping, so the requirements of Ch 9, Sec 8, [2.1.18] do not apply.*

**21.1.5** Cargo tanks shall be continuously monitored for low pressure when a carbon dioxide cargo is carried. An audible and visual alarm shall be given at the cargo control position and on the bridge. If the cargo tank pressure continues to fall to within 0.05 MPa of the “triple point” for the particular cargo, the monitoring system shall automatically close all cargo manifold liquid and vapour valves and stop all cargo compressors and cargo pumps. The emergency shutdown system required by Ch 9, Sec 18, [3] may be used for this purpose.

**21.1.6** All materials used in cargo tanks and cargo piping system shall be suitable for the lowest temperature that may occur in service, which is defined as the saturation temperature of the carbon dioxide cargo at the set pressure of the automatic safety system described in [21.1.2].

**21.1.7** Cargo hold spaces, cargo compressor rooms and other enclosed spaces where carbon dioxide could accumulate shall be fitted with continuous monitoring for carbon dioxide build-up. This fixed gas detection system replaces the requirements of Ch 9, Sec 13, [6], and hold spaces shall be monitored permanently even if the ship has type C cargo containment.

**22 Carbon dioxide: reclaimed quality**

**22.1 General**

**22.1.1** Specific relaxations may apply for ships carrying liquefied carbon dioxide (reclaimed quality) in bulk, as detailed in Tab 2.

**22.1.2** The requirements of [21] also apply to this cargo. In addition, the materials of construction used in the cargo system shall also take account of the possibility of corrosion, in case the reclaimed quality carbon dioxide cargo contains impurities such as water, sulphur dioxide, etc., which can cause acidic corrosion or other problems.

**Table 2 : Possible relaxations for ships carrying liquefied carbon dioxide in bulk**

Reference	Relaxations
Ch 9, Sec 3, [1.1.3]	A single A-0 bulkhead is sufficient.
Ch 9, Sec 5, [7.4]	Electrical bonding of piping and tanks is not required.
Ch 9, Sec 10	Certified safe electrical equipment is not required.
Ch 9, Sec 11	This entire Section is not applicable.
Ch 9, Sec 12, [1.2.12]	Safe placing and safe construction of electrical fan motors is not required.
Ch 9, Sec 12, [1.2.15]	Protection screens in vent ducts are not required.
Ch 9, Sec 13, [6]	Only Ch 9, Sec 13, [6.1.13] and Ch 9, Sec 13, [6.1.14] are applicable.
Ch 9, Sec 18, [3.3]	Fusible elements in the emergency shutdown system are not required.

# Section 18 Operating Requirements

## 1 General

### 1.1

**1.1.1** This Section contains only the provisions of IGC Code article 18.10, as the other provisions of Chapter 18 of the IGC Code are operating requirements which are not within the scope of classification.

## 2 Cargo operating manual

### 2.1 General

**2.1.1** *The ship shall be provided with copies of suitably detailed cargo system operation manuals approved by the Society such that trained personnel can safely operate the ship with due regard to the hazards and properties of the cargoes that are permitted to be carried.*

Note 1: As required in Ch 9, Sec 1, [5], the cargo operating manual is to be submitted for approval in order to check that all documents listed in [2.1.2] are included in the cargo operating manual.

**2.1.2** *The content of the manuals shall include, but not be limited to:*

- *overall operation of the ship from dry-dock to dry-dock, including procedures for cargo tank cooldown and warm-up, transfer (including ship-to-ship transfer), cargo sampling, gas-freeing, ballasting, tank cleaning and changing cargoes;*
- *cargo temperature and pressure control systems;*
- *cargo system limitations, including minimum temperatures (cargo system and inner hull), maximum pressures, transfer rates, filling limits and sloshing limitations;*
- *nitrogen and inert gas systems;*
- *firefighting procedures: operation and maintenance of firefighting systems and use of extinguishing agents;*
- *special equipment needed for the safe handling of the particular cargo;*
- *fixed and portable gas detection;*
- *control, alarm and safety systems;*
- *emergency shutdown systems;*
- *procedures to change cargo tank pressure relief valve set pressures in accordance with Ch 9, Sec 8, [2.1.10] and Ch 9, Sec 4, [3.3.2]; and*
- *emergency procedures, including cargo tank relief valve isolation, single tank gas-freeing and entry and emergency ship-to-ship transfer operations.*

## 3 Cargo emergency shutdown (ESD) system

### 3.1 General

**3.1.1** *A cargo emergency shutdown system shall be fitted to stop cargo flow in the event of an emergency, either internally within the ship, or during cargo transfer to ship or shore. The design of the ESD system shall avoid the potential generation of surge pressures within cargo transfer pipe work (see [3.2.1]).*

**3.1.2** *Auxiliary systems for conditioning the cargo that use toxic or flammable liquids or vapours shall be treated as cargo systems for the purposes of ESD. Indirect refrigeration systems using an inert medium, such as nitrogen, need not be included in the ESD function.*

**3.1.3** *The ESD system shall be activated by the manual and automatic initiations listed in Tab 1. Any additional initiations shall only be included in the ESD system if it can be shown that their inclusion does not reduce the integrity and reliability of the system overall.*

**3.1.4** *Ship's ESD systems shall incorporate a ship-shore link in accordance with recognized standards.*

Note 1: ISO 28460:2010 Petroleum and natural gas industries - Installation and equipment for liquefied natural gas - Ship-to-shore interface and port operations.

**3.1.5** *A functional flow chart of the ESD system and related systems shall be provided in the cargo control station and on the navigation bridge.*

**Table 1 : ESD functional arrangements**

Initiation	Shutdown action							
	Pumps		Compressor systems				Valves	Link
	Cargo pumps and cargo booster pumps	Spray / stripping pumps	Vapour return compressors	Fuel gas compressors	Reliquefaction plant (3), including condensate return pumps, if fitted	Gas combustion unit	ESD valves	Signal to ship / shore link (4)
Emergency push buttons (see [3.3.1])	F	F	F	see (6)	F	F	F	F
Fire detection on deck or in compressor house (1) (see [3.3.2])	F	F	F	F	F	F	F	F
High level in cargo tank (12)	F	F	F	see (5) see (6)	see (5) see (7)	see (5)	see (10)	F
Signal from ship / shore link (see [3.1.4])	F	F	F	see (6)	see (7)	NA	F	NA
Loss of motive power to ESD valves (2)	F	F	F	see (6)	see (7)	NA	F	F
Main electric power failure ("blackout")	see (11)	see (11)	see (11)	see (11)	see (11)	see (11)	F	F
Level alarm override (13)	see (8)	see (8) see (9)	F	see (5)	see (5)	see (5)	F	F

- (1) Fusible plugs, electronic point temperature monitoring or area fire detection may be used for this purpose on deck.
  - (2) Failure of hydraulic, electric or pneumatic power for remotely operated ESD valve actuators.
  - (3) Indirect refrigeration systems which form part of the reliquefaction plant do not need to be included in the ESD function if they employ an inert medium such as nitrogen in the refrigeration cycle.
  - (4) Signal need not indicate the event initiating ESD.
  - (5) These items of equipment can be omitted from these specific automatic shutdown initiators, provided the equipment inlets are protected against cargo liquid ingress.
  - (6) If the fuel gas compressor is used to return cargo vapour to shore, it shall be included in the ESD system when operating in this mode.
  - (7) If the reliquefaction plant compressors are used for vapour return/shore line clearing, they shall be included in the ESD system when operating in that mode.
  - (8) The override system permitted by Ch 9, Sec 13, [3.1.8] may be used at sea to prevent false alarms or shutdowns. When level alarms are overridden, operation of cargo pumps and the opening of manifold ESD valves shall be inhibited except when high-level alarm testing is carried out in accordance with Ch 9, Sec 13, [3.1.6] (see [3.3.4]).
  - (9) Cargo spray or stripping pumps used to supply forcing vaporizer may be excluded from the ESD system only when operating in that mode.
  - (10) The sensors referred to in Ch 9, Sec 13, [3.1.3] may be used to close automatically the tank filling valve for the individual tank where the sensors are installed, as an alternative to closing the ESD valve as referred to in [3.2.3]. If this option is adopted, activation of the full ESD system shall be initiated when the high-level sensors in all the tanks to be loaded have been activated.
  - (11) These items of equipment shall be designed not to restart upon recovery of main electric power and without confirmation of safe conditions.
  - (12) see Ch 9, Sec 13, [3.1.3] and Ch 9, Sec 13, [3.1.4]
  - (13) see Ch 9, Sec 13, [3.1.8]
- Note 1:** F = Functional requirement; NA = Not applicable.
- Note 2:** In applying the second sentence of (8), a hardware system such as an electric or mechanical interlocking device is to be provided to prevent inadvertent operation of cargo pumps and inadvertent opening of manifold ESD valves.

## **3.2 ESD valve requirements**

### **3.2.1 General**

- a) The term ESD valve means any valve operated by the ESD system.
- b) ESD valves shall be remotely operated, be of the fail-closed type (closed on loss of actuating power), be capable of local manual closure and have positive indication of the actual valve position. As an alternative to the local manual closing of the ESD valve, a manually operated shut-off valve in series with the ESD valve shall be permitted. The manual valve shall be located adjacent to the ESD valve. Provisions shall be made to handle trapped liquid should the ESD valve close while the manual valve is also closed.

The cargo stations in way of which the fusible elements are to be fitted are to be intended as the loading and unloading manifolds.

- c) ESD valves in liquid piping systems shall close fully and smoothly within 30 s of actuation. Information about the closure time of the valves and their operating characteristics shall be available on board, and the closing time shall be verifiable and repeatable.
- d) The closing time of the valve, in second, referred to in Ch 9, Sec 13, [3.1.1] to Ch 9, Sec 13, [3.1.4] (i.e. time from shutdown signal initiation to complete valve closure) shall not be greater than  $3600 U / LR$ , where
- $U$  : Ullage volume at operating signal level, in  $m^3$
- $LR$  : Maximum loading rate agreed between ship and shore facility, in  $m^3/h$ .

The loading rate shall be adjusted to limit surge pressure on valve closure to an acceptable level, taking into account the loading hose or arm, the ship and the shore piping systems, where relevant.

### **3.2.2 ESD valves of fail-closed type**

When ESD valve is actuated by hydraulic or pneumatic system, the following is to be complied with:

- a) Audible and visible alarm is to be given in the event of loss of pressure that causes activation of fail-closed action. The alarm is to be provided in a normally manned control station (e.g. Cargo Control Room and/or the navigation bridge, etc.).
- b) The following conditions are also to be complied with to ensure the fail-closed action:
- Failure of hydraulic or pneumatic system is not to lead to loss of fail-closed functionality (i.e. activated by spring or weight); or
  - Hydraulic or pneumatic system for fail-closed action is to be arranged with stored power and separated from normal valve operation.

### **3.2.3 Ship-shore and ship-ship manifold connections**

One ESD valve shall be provided at each manifold connection. Cargo manifold connections not being used for transfer operations shall be blanked with blank flanges rated for the design pressure of the pipeline system.

### **3.2.4 Cargo system valves**

If cargo system valves as defined in Ch 9, Sec 5, [5] are also ESD valves within the meaning of [3], then the requirements of [3] shall apply.

## **3.3 ESD system controls**

**3.3.1** As a minimum, the ESD system shall be capable of manual operation by a single control on the bridge and either in the control position required by Ch 9, Sec 13, [1.1.4] or the cargo control room, if installed, and no less than two locations in the cargo area.

**3.3.2** The ESD system shall be automatically activated on detection of a fire on the weather decks of the cargo area and/or cargo machinery spaces. As a minimum, the method of detection used on the weather decks shall cover the liquid and vapour domes of the cargo tanks, the cargo manifolds and areas where liquid piping is dismantled regularly. Detection may be by means of fusible elements designed to melt at temperatures between 98°C and 104°C, or by area fire detection methods.

**3.3.3** Cargo machinery that is running shall be stopped by activation of the ESD system in accordance with the cause and effect matrix in Tab 1.

**3.3.4** The ESD control system shall be configured so as to enable the high-level testing required in Ch 9, Sec 13, [3.1.6] to be carried out in a safe and controlled manner. For the purpose of the testing, cargo pumps may be operated while the overflow control system is overridden. Procedures for level alarm testing and re-setting of the ESD system after completion of the high-level alarm testing shall be included in the operation manual.

## **3.4 Additional shutdowns**

**3.4.1** The requirements of Ch 9, Sec 8, [3.1.1], item a), to protect the cargo tank from external differential pressure may be fulfilled by using an independent low pressure trip to activate the ESD system, or, as minimum, to stop any cargo pumps or compressors.

**3.4.2** *An input to the ESD system from the overflow control system required by Ch 9, Sec 13, [3] may be provided to stop any cargo pumps or compressors' running at the time a high level is detected, as this alarm may be due to inadvertent internal transfer of cargo from tank to tank.*

### **3.5 Pre-operations testing**

**3.5.1** *Cargo emergency shutdown and alarm systems involved in cargo transfer shall be checked and tested before cargo handling operations begin.*

### **3.6 Testing**

**3.6.1** Ship operators should periodically verify that the ESD valves onboard their vessels function correctly. The test results are to be recorded.

Also, as part of the check on the integrity of the cargo containment system, the ESD valves are to be pressure tested and internally inspected. Pressure testing at the same pressure as working pressure is recommended to be conducted every 5 years.

Note 1: The instruction manual produced by the ESD valve manufacturer providing information on installing, servicing and reassembly of the valves should be retained onboard the ship.

# Section 19 Summary of Minimum Requirements

## 1 General

### 1.1 Explanatory notes to the summary of minimum requirements

#### 1.1.1 Product name

The product name shall be used in the shipping document for any cargo offered for bulk shipments. Any additional name may be included in brackets after the product name. In some cases, the product names are not identical with the names given in previous issues of the Code.

#### 1.1.2 Ship type

- Ship type 1G (see Ch 9, Sec 2, [1.1.2], item a))
- Ship type 2G (see Ch 9, Sec 2, [1.1.2], item b))
- Ship type 2PG (see Ch 9, Sec 2, [1.1.2], item c))
- Ship type 3G (see Ch 9, Sec 2, [1.1.2], item d)).

#### 1.1.3 Independent tank type C required

Type C independent tank (see Ch 9, Sec 4, [10]).

#### 1.1.4 Tank environmental control

- Inert : Inerting (see Ch 9, Sec 9, [1.4])  
 Dry : Drying (see Ch 9, Sec 17, [7])  
 – : No special requirements under the Code.

#### 1.1.5 Vapour detection

- F : Flammable vapour detection  
 T : Toxic vapour detection  
 F + T : Flammable and toxic vapour detection  
 A : Asphyxiant.

#### 1.1.6 Gauging

- I : Indirect or closed (see Ch 9, Sec 13, [2.1.4], item a) and Ch 9, Sec 13, [2.1.4], item b))  
 R : Indirect, closed or restricted (from Ch 9, Sec 13, [2.1.4], item a) to Ch 9, Sec 13, [2.1.4], item d))  
 C : Indirect or closed (from Ch 9, Sec 13, [2.1.4], item a) to Ch 9, Sec 13, [2.1.4], item c)).

#### 1.1.7 Special requirements

When specific reference is made to Ch 9, Sec 14 and/or to Ch 9, Sec 17, these requirements shall be additional to the requirements in any other column.

#### 1.1.8 Refrigerant gases

Non-toxic and non-flammable gases.

#### 1.1.9

Unless otherwise specified, gas mixtures containing less than 5% total acetylenes may be transported with no further requirements than those provided for the major components.

## 2 Additional information on products

### 2.1

#### 2.1.1 Tab 2 lists some additional information for those products which are listed in Tab 1.

The list shown in Tab 2 gives properties for pure products. The specific gravity to be taken into account for the design of a ship might be altered considering the actual properties of the commercial product.

Information on temperature classes and explosion groups for electrical equipment in connection with the products to be carried is indicated in Ch 9, Sec 10, Tab 1.

Table 1 : Summary of minimum requirements

Product name	Ship type	Independent tank type C required	Control of vapour space within cargo tanks	Vapour detection	Gauging	Special requirements
Acetaldehyde	2G/2PG	-	Inert	F + T	C	Ch 9, Sec 14, [1.4.3], Ch 9, Sec 14, [1.3.3], item a), Ch 9, Sec 17, [4.1.1], Ch 9, Sec 17, [6.1.1], item a)
Ammonia, anhydrous	2G/2PG	-	-	T	C	Ch 9, Sec 14, [1.4], Ch 9, Sec 17, [2.1.1], item a), Ch 9, Sec 17, [12]
Butadiene (all isomers)	2G/2PG	-	-	F + T	C	Ch 9, Sec 14, [1.4], Ch 9, Sec 17, [2.1.1], item b), Ch 9, Sec 17, [4.1.2], Ch 9, Sec 17, [4.1.3], Ch 9, Sec 17, [6], Ch 9, Sec 17, [8]
Butane (all isomers)	2G/2PG	-	-	F	R	
Butane-propane mixture	2G/2PG	-	-	F	R	
Butylenes (all isomers)	2G/2PG	-	-	F	R	
Carbon Dioxide (high purity)	3G	-	-	A	R	Ch 9, Sec 17, [21]
Carbon Dioxide (Reclaimed quality)	3G	-	-	A	R	Ch 9, Sec 17, [22]
Chlorine	1G	Yes	Dry	T	I	Ch 9, Sec 14, [1.4], Ch 9, Sec 17, [3.1.2], Ch 9, Sec 17, [4.1.1], Ch 9, Sec 17, [5], Ch 9, Sec 17, [7], Ch 9, Sec 17, [9], Ch 9, Sec 17, [13]
Diethyl ether (1)	2G/2PG	-	Inert	F + T	C	Ch 9, Sec 14, [1.4.2], Ch 9, Sec 14, [1.4.3], Ch 9, Sec 17, [2.1.1], item f), Ch 9, Sec 17, [3.1.1], Ch 9, Sec 17, [6.1.1], item a), Ch 9, Sec 17, [9], Ch 9, Sec 17, [10], Ch 9, Sec 17, [11.1.2], Ch 9, Sec 17, [11.1.3]
Dimethylamine	2G/2PG	-	-	F + T	C	Ch 9, Sec 14, [1.4], Ch 9, Sec 17, [2.1.1], item a)
Dimethyl Ether	2G/2PG	-	-	F + T	C	
Ethane		-	-	F	R	
Ethyl Chloride	2G/2PG	-	-	F + T	C	
Ethylene	2G	-	-	F	R	
Ethylene oxide	1G	Yes	Inert	F + T	C	Ch 9, Sec 14, [1.4], Ch 9, Sec 17, [2.1.1], item b), Ch 9, Sec 17, [3.1.2], Ch 9, Sec 17, [4.1.1], Ch 9, Sec 17, [6.1.1], item a), Ch 9, Sec 17, [6.1.1], item a), Ch 9, Sec 17, [14]
Ethylene oxide-propylene oxide mixtures with ethylene oxide content of not more than 30% by weight (1)	2G/2PG	-	Inert	F + T	C	Ch 9, Sec 14, [1.4.3], Ch 9, Sec 17, [3.1.1], Ch 9, Sec 17, [4.1.1], Ch 9, Sec 17, [6.1.1], item a), Ch 9, Sec 17, [9], Ch 9, Sec 17, [10], Ch 9, Sec 17, [18]
Isoprene (1) (all isomers)	2G/2PG	-	-	F	R	Ch 9, Sec 14, [1.4.3], Ch 9, Sec 17, [8], Ch 9, Sec 17, [9], Ch 9, Sec 17, [11.1.1]
Isoprene (part refined) (1)	2G/2PG	-	-	F	R	Ch 9, Sec 14, [1.4.3], Ch 9, Sec 17, [8], Ch 9, Sec 17, [9], Ch 9, Sec 17, [11.1.1]
Isopropylamine (1)	2G/2PG	-	-	F + T	C	Ch 9, Sec 14, [1.4.2], Ch 9, Sec 14, [1.4.3], Ch 9, Sec 17, [2.1.1], item d), Ch 9, Sec 17, [9], Ch 9, Sec 17, [10], Ch 9, Sec 17, [11.1.1], Ch 9, Sec 17, [15]
Methane (LNG)	2G	-	-	F	C	

(1) This cargo is also covered by the IBC Code.

Product name	Ship type	Independent tank type C required	Control of vapour space within cargo tanks	Vapour detection	Gauging	Special requirements
Methyl acetylene-propadiene mixtures	2G/2PG	-	-	F	R	Ch 9, Sec 17, [16]
Methyl bromide	1G	Yes	-	F + T	C	Ch 9, Sec 14, [1.4], Ch 9, Sec 17, [2.1.1], item c), Ch 9, Sec 17, [3.1.2], Ch 9, Sec 17, [4.1.1], Ch 9, Sec 17, [5]
Methyl chloride	2G/2PG	-	-	F + T	C	Ch 9, Sec 17, [2.1.1], item c)
Mixed C4 Cargoes	2G/2PG	-	-	F + T	C	Ch 9, Sec 14, [1.4], Ch 9, Sec 17, [2.1.1], item b), Ch 9, Sec 17, [4.1.2], Ch 9, Sec 17, [4.1.3], Ch 9, Sec 17, [6], Ch 9, Sec 17, [20]

# Section 20 Hull Scantling

## 1 General

### 1.1 Application

1.1.1 The requirements in this Section apply to the hull structure, with the exception of the independent tank structure and tank supports, which are to be in compliance with Ch 9, Sec 4.

## 2 Flooding for ships with independent tanks

### 2.1 General

2.1.1 The net scantling of structural elements subject to flooding pressure is to be checked using the formula given in Pt B, Ch 7, Sec 4, Pt B, Ch 7, Sec 5 and Pt B, Ch 7, Sec 6, considering a still water bending moment of  $0,5 M_{sw-max}$  and a draught corresponding to the deepest equilibrium waterline in damage condition for transverse bulkhead.

At early stage of design, when damage stability calculations are not available, calculation with draft corresponding to  $0,8 D$  without heel may be considered.

## 3 Finite element model

### 3.1 General

3.1.1 For the checking of the scantlings of primary supporting members, a three-dimensional finite element model is required. The check is to be made in accordance with Part B, Chapter 8, taking into account the structural modeling principles given in [3.2].

### 3.2 Structural modeling

#### 3.2.1 Modeling principles

The following primary supporting members are to be modeled:

- outer shell, inner bottom, main deck, trunk deck, longitudinal and transverse bulkhead plating
- double-bottom longitudinal girders
- double-side horizontal stringers
- deck longitudinal girders
- transverse web frames with main frames if relevant
- primary supporting members of transverse bulkheads.

#### 3.2.2 Model extension for units with independent tanks

For units with independent tanks, the structural model is to include the primary supporting members of the hull (see a)) and the tanks with their supporting members and key systems.

The cargo tank model is to include the following primary members:

- shell plating
- bulkhead plating, including wash bulkheads if any
- bottom plating
- top plating
- transverse web frames
- horizontal stringers
- girders.

#### 3.2.3 Modeling of supports and keys

The cargo tanks are linked to the hold by the following supports and keys, acting in one direction:

- vertical supports (Z direction)
- antipitching keys (X direction), used also as anticollision keys
- antirolling keys (Y direction)
- antiflotation keys (Z direction).

They can be modeled by either linear elements (bar, flexible mounts, springs), or non-linear elements (gap elements).

When linear elements are used to model keys and supports not allowing tension loads, they are to be deleted when in tension. Stiffness of these linear and/or non-linear elements is to be representative of the actual stiffness of the supports and keys.

**3.2.4 Stiffness of supports and keys for independent tanks**

The axial stiffness of elements used for the modeling of supports and keys of independent tanks is to be calculated taking into account the stiffness of:

- the support in way of tank
- the spacer
- the support in way of hull.

The stiffness of the pad located between the lower and upper parts of the support may be calculated as follows:

$$K = E S / h$$

where:

- K : Stiffness of the pad, in N/mm
- E : Young modulus of the pad, in N/mm<sup>2</sup>
- S : Sectional area of the pad, in mm<sup>2</sup>
- h : Height of the pad, in mm.

The stiffness of the gap or spring element is to be taken as:  $K_{element} = K / N_{elements}$

with:

$N_{elements}$  : Number of elements used in the pad modeling.

**3.2.5 Size of the elements**

The mesh size should be equal to the spacing of the longitudinal ordinary stiffeners. Each of these longitudinal stiffeners is to be modeled. The aspect ratio of the elements should be as close to 1,0 as possible.

**3.3 Load combinations for direct strength analysis**

**3.3.1** The loading conditions and associated draughts, SWBM and dynamic load cases to be applied on the finite element model are described in Tab 1.

Additional loading conditions defined in the loading manual may be considered when deemed necessary.

**Table 1 : Loading conditions and associated draughts and SWBM for FEM model**

Loading conditions	Type A and type C independent tanks		Membrane tanks		Dynamic load case
	Draught	SWBM	Draught	SWBM	
Homogeneous	T <sub>SC</sub>	M <sub>SW-S</sub>	T <sub>SC</sub>	M <sub>SW-S</sub>	All
Ballast	T <sub>BAL</sub>	M <sub>SW-H</sub>	T <sub>BAL</sub>	M <sub>SW-H</sub>	
Alternate: Full/Empty/Full	0,9T <sub>SC</sub>	0,7M <sub>SW-H</sub>	0,9T <sub>SC</sub>	0,9M <sub>SW-H</sub>	
Alternate: Empty/Full/Empty	0,8T <sub>SC</sub>	0,7M <sub>SW-S</sub>	0,75T <sub>SC</sub>	0,9M <sub>SW-S</sub>	
<b>Note 1:</b>					
M <sub>SW-S</sub> : Design SWBM in sagging conditions					
M <sub>SW-H</sub> : Design SWBM in hogging conditions.					

**3.4 Yielding strength criteria**

**3.4.1** Yielding strength criteria for primary supporting members are defined in Pt B, Ch 7, Sec 6.

Yielding strength criteria for supporting members and keys systems are defined in Ch 9, Sec 4, [7.4] and Ch 9, Sec 4, [7.5].

**3.5 Buckling check**

**3.5.1** Buckling strength criteria for primary supporting members are defined in Pt B, Ch 9, Sec 1.

**4 Membrane tanks**

**4.1 General**

**4.1.1** The net scantlings of plating and ordinary stiffeners of membrane tanks are to be not less than those obtained from Part B, Chapter 7.

The hull girder loads and internal pressure to be considered are to be calculated according to Part B, Chapter 5, where the dynamic pressure is to be multiplied by 1,25.

Specific allowable hull girder stresses and/or deflections, indicated by the cargo containment Designer, are to be taken into account for the determination of the hull scantlings.

**4.1.2** The net scantlings of primary supporting members of membrane tanks are to be not less than those obtained from Part B, Chapter 7, where the hull girder loads and the internal pressure are to be calculated according to Part B, Chapter 5.

**4.1.3** Moreover, the net scantlings of plating, ordinary stiffeners and primary supporting members of membrane tanks are to be not less than those obtained from Articles [2] to [3].

## **4.2 Sloshing loads**

**4.2.1** The net thicknesses of plating subject to sloshing pressure are to be checked using the formula given in Pt B, Ch 7, Sec 4, [4] with  $P_{sl}$  to be taken equal to  $P_{sl}$  given in Ch 9, App 1, [2.2].

No buckling check is required.

Areas to be checked for sloshing pressure are defined in Ch 9, App 1, [2.2].

**4.2.2** The net section modulus of ordinary stiffeners subject to sloshing pressure, including longitudinals, are to be checked using the formulae given in Pt B, Ch 7, Sec 5, [1.3] with  $P_{sl}$  to be taken equal to  $P_{sl}$  given Ch 9, App 1, [2.2].

Areas to be checked for sloshing pressure are defined in Ch 9, App 1, [2.2].

No buckling check is required.

## **4.3 Collision loads**

**4.3.1** The structure of the tank is to be checked for collision loads using the pressure defined in Ch 9, App 1, [4.1.1] and criteria defined in Ch 9, Sec 4, [8.4.3].

# **5 Structural details**

## **5.1 General**

**5.1.1** The specific requirements in Pt B, Ch 13, Sec 5, [2] for ships with the service notation **liquefied gas carrier** are to be complied with.

## **5.2 Local structural strength analysis**

### **5.2.1 Screening criteria**

For all details specific to liquefied gas carriers which are to be evaluated by screening according to Pt B, Ch 13, Sec 5, [2.4], the screening criteria as defined in Pt B, Ch 8, App 2, [1.2.3] is to be checked with:

- $\lambda_{sc} = \lambda_y$
- $\lambda_{scperm} = 0,95\lambda_{yperm}$

where:

- $\lambda_y$  : Standard mesh yield utilisation factor, as defined in Pt B, Ch 8, App 1, [5.2.3]
- $\lambda_{yperm}$  : Standard mesh permissible yield utilisation factor, as defined in Pt B, Ch 8, App 1, [5.2.3]

## **5.3 Connections of inner bottom with transverse cofferdam bulkheads**

**5.3.1** The thickness and material properties of the supporting floors are to be at least equal to those of the cofferdam bulkhead plating.

**5.3.2** Vertical webs fitted within the cofferdam bulkhead are to be aligned with the double bottom girders.

**5.3.3** Manholes in double bottom floors aligned with the cofferdam bulkhead plating are to be located as low as practicable and at mid-distance between two adjacent longitudinal girders.

# Appendix 1      Guidance for Calculation of Pressures and Accelerations

## 1 Guidance to detailed calculation of internal pressure for static design purpose

### 1.1 Calculation of dynamic liquid pressure

**1.1.1** This Appendix provides guidance for the calculation of the associated dynamic liquid pressure for the purpose of static design calculations. This pressure may be used for determining the internal pressure referred to in Ch 9, Sec 4, [3.3.2], item e), where:

- $(P_{gd})_{max}$ , in MPa, is the associated liquid pressure determined using the maximum design accelerations.
- $(P_{gd}^{site})_{max}$ , in MPa, is the associated liquid pressure determined using site specific accelerations.
- $P_{eq}$ , in MPa, should be the greater of  $P_{eq1}$  and  $P_{eq2}$  calculated as follows:

$$P_{eq1} = P_o + (P_{gd})_{max}$$

$$P_{eq2} = P_h + (P_{gd}^{site})_{max}$$

**1.1.2** The internal liquid pressures are those created by the resulting acceleration of the centre of gravity of the cargo due to the motions of the ship referred to in Ch 9, Sec 4, [3.4.2]. The value of internal liquid pressure  $P_{gd}$ , in MPa, resulting from combined effects of gravity and dynamic accelerations should be calculated as follows:

$$P_{gd} = a_{\beta} Z_{\beta} \frac{\rho}{1,02 \times 10^5}$$

where:

$a_{\beta}$  : Dimensionless acceleration (i.e. relative to the acceleration of gravity), resulting from gravitational and dynamic loads, in an arbitrary direction  $\beta$  (see Fig 1).

For large tanks, an acceleration ellipsoid taking account of transverse vertical and longitudinal accelerations, should be used.

Methods for the calculation of acceleration in upright ship conditions and inclined ship conditions are given in [1.2]

$Z_{\beta}$  : Largest liquid height (m) above the point where the pressure is to be determined measured from the tank shell in the  $\beta$  direction (see Fig 2).

The liquid heights  $Z_{\beta}$  are to be calculated in accordance with Fig 4 at each calculation point of the tank.

At each calculation point, the maximum internal pressure  $(P_{gd})_{max}$  is to be obtained for the  $\beta$  direction which gives the maximum value of  $P_{gd}$  (see Fig 3).

Tank domes considered to be part of the accepted total tank volume shall be taken into account when determining  $Z_{\beta}$ , unless the total volume of tank domes  $V_d$  does not exceed the following value:

$$V_d = V_t \frac{100 - FL}{FL}$$

with:

$V_t$  : Tank volume without any domes

$FL$  : Filling limit according to Ch 9, Sec 15.

$\rho$  : Maximum cargo density, in  $\text{kg/m}^3$ , at the design temperature.

Where the maximum mass density of the liquid carried is not given, the following values are to be considered:

- $\rho_L = 0,50 \text{ t/m}^3 = 500 \text{ kg/m}^3$  for methane
- $\rho_L$  according to Ch 9, Sec 19, Tab 2 for other products.

The direction that gives the maximum value  $(P_{gd})_{max}$  or  $(P_{gd}^{site})_{max}$  should be considered. The above formula applies only to full tanks.

Equivalent calculation procedures may be applied.

Figure 1 : Acceleration ellipsoid

$a_\beta$  resulting acceleration (static and dynamic) in arbitrary direction  $\beta$   
 $a_x$  longitudinal component of acceleration  
 $a_y$  transverse component of acceleration  
 $a_z$  vertical component of acceleration

At 0,05L from FP

Figure 2 : Determination of internal pressure heads

Figure 3 : Determination of internal pressure for pressure points 1, 2 and 3

Figure 4 : Determination of liquid height  $Z_{\beta}$  for pressure points 1, 2 and 3

## 1.2 Calculation of acceleration components

### 1.2.1 Guidance formulae for acceleration components

The following formulae are given as guidance for the components of acceleration due to ship's motions corresponding to a probability level of  $10^{-8}$  in the North Atlantic and apply to ships with a length exceeding 50 m and at or near their service speed:

- vertical acceleration, as defined in Ch 9, Sec 4, [3.4.2]:

$$a_z = \pm a_0 \sqrt{1 + \left(5,3 - \frac{45}{L_0}\right)^2 \left(\frac{x}{L_0} + 0,05\right)^2 \left(\frac{0,6}{C_B}\right)^{1,5} + \left(\frac{0,6 y K^{1,5}}{B}\right)^2}$$

- transverse acceleration, as defined in Ch 9, Sec 4, [3.4.2]:

$$a_y = \pm a_0 \sqrt{0,6 + 2,5 \left(\frac{x}{L_0} + 0,05\right)^2 + K \left(1 + 0,6 K \frac{z}{B}\right)^2}$$

- longitudinal acceleration, as defined in Ch 9, Sec 4, [3.4.2]:

$$a_x = \pm a_0 \sqrt{0,06 + A^2 - 0,25 A}$$

where:

$$a_0 = 0,2 \frac{V}{\sqrt{L_0}} + \frac{34 - \frac{600}{L_0}}{L_0}$$

$L_0$  : Length of the ship for determination of scantlings as defined in recognized standards, in m

$C_B$  : Block coefficient

$B$  : Greatest moulded breadth of the ship, in m

$x$  : Longitudinal distance, in m, from amidships to the centre of gravity of the tank with contents;  $x$  is positive forward of amidships, negative aft of amidships

$y$  : Transverse distance, in m, from centreline to the centre of gravity of the tank with contents

$z$  : Vertical distance, in m, from the ship's actual waterline to the centre of gravity of tank with contents;  $z$  is positive above and negative below the waterline

$K$  :  $K = 1$  in general.

For particular loading conditions and hull forms, determination of  $K$  according to the following formula may be necessary:

$$K = 13 GM / B$$

where:

$$K \geq 1$$

$GM$  : metacentric height, in m

$$A = \left( 0,7 - \frac{L_0}{1200} + 5 \frac{z}{L_0} \right) \left( \frac{0,6}{C_B} \right)$$

$V$  : Service speed, in knots

$a_x, a_y, a_z$  : Maximum dimensionless accelerations (i.e. relative to the acceleration of gravity) in the respective directions. They are considered as acting separately for calculation purposes, and  $a_z$  does not include the component due to the static weight,  $a_y$  includes the component due to the static weight in the transverse direction due to rolling and  $a_x$  includes the component due to the static weight in the longitudinal direction due to pitching. The accelerations derived from the above formulae are applicable only to ships at or near their service speed, not while at anchor or otherwise near stationary in exposed locations.

**1.2.2 Accelerations for type C tanks**

The inertial internal liquid pressure is to be calculated considering the ship in the following mutually exclusive conditions:

a) Upright ship conditions

In these conditions, the ship encounters waves which produce ship motions in the X-Z plane, i.e. surge, heave and pitch.

The dimensionless acceleration  $a_\beta$  is to be obtained, for an arbitrary direction  $\beta$ , in accordance with Fig 5, in which the wave longitudinal and vertical accelerations  $a_x$  and  $a_z$ , respectively, are calculated from the formula in [1.2.1].

b) Inclined ship conditions

In these conditions, the ship encounters waves which produce ship motions in the X-Y and Y-Z planes, i.e. sway, heave, roll and yaw.

The dimensionless acceleration  $a_\beta$  is to be obtained, for an arbitrary direction  $\beta$ , in accordance with Fig 6, in which the wave transverse and vertical accelerations  $a_y$  and  $a_z$ , respectively, are calculated from the formula in [1.2.1].

**Figure 5 : Dimensionless acceleration in upright ship condition**

Figure 6 : Dimensionless acceleration in inclined ship condition

### 1.2.3 Accelerations for type A tanks

The inertial liquid pressure is to be calculated considering ship accelerations in the three directions.

The dimensionless acceleration  $a_\beta$  is to be obtained, for an arbitrary direction  $(\beta_x, \beta_y)$ , in accordance with Fig 1, in which the wave longitudinal, transverse and vertical accelerations  $a_x$ ,  $a_y$  and  $a_z$ , respectively, are calculated from the formula in [1.2.1].

Note 1: For analysis based on three-dimensional models, several load cases are to be considered. For each load case, the pressures are to be calculated for each finite element of the tank boundary with a given direction  $(\beta_x, \beta_y)$ .

The choice and number of load cases considered is to be to the satisfaction of the Society with respect to maximising the inertial liquid pressure on each element of the tank boundary.

## 2 Internal pressure for integral tanks and membrane tanks

### 2.1 General

2.1.1 The inertial internal liquid pressure is to be calculated according to Pt B, Ch 5, Sec 6.

### 2.2 Sloshing pressure and tank areas to be checked

2.2.1 The sloshing pressure is to be considered with regards to the number and size of membrane tanks.

The sloshing pressure in membrane tanks of ships having a total capacity over 180 000 m<sup>3</sup> is to be specially considered by the Society.

The ship structural members, i.e. plating, stiffeners and primary supporting members, supporting the membrane tanks are to be checked against the sloshing pressure defined in [2.2.2] for the tanks areas defined in [2.2.3].

2.2.2 The standard filling levels for membrane tanks of ships having a capacity less than 180 000 m<sup>3</sup> are to be taken as follows:

- Full load condition:  
The liquid height in the cargo tank is comprised between 70% of the cargo tank height to 98% of the cargo tank volume.
- Ballast condition:  
The liquid height in the cargo tank is comprised between 0% and 10% of the cargo tank height. In case of specific arrangement and tank dimensions, the value of 10% may be adapted on case by case basis.

For the standard filling levels, the sloshing pressure  $P_{sl}$ , in kN/m<sup>2</sup>, is to be obtained from the following formula:

$$P_{sl} = P_{wi} + P_{pv}$$

where:

$P_{wi}$  : Quasi static pressure, in kN/m<sup>2</sup>, taken equal to 240 kN/m<sup>2</sup>

If duly justified (for example by numerical analysis and/or model tests), another value of  $P_{wi}$  can be considered by the Society

$P_{pv}$  : Design vapour pressure, in kN/m<sup>2</sup>, not taken less than 25 kN/m<sup>2</sup>

**2.2.3** The areas of the tanks to be checked for sloshing are described in Fig 7.

For small tanks, the dimensions of those areas may be adapted on a case-by-case basis.

**Figure 7 : Areas to be checked for sloshing**

### 3 Guidance to detailed calculation of pressure for a static heel angle of 30°

#### 3.1 Internal pressure calculation

##### 3.1.1 Calculation of the highest point of each tank for 30° heel

The components of accelerations to be used for this calculation are the following:

- Positive roll angle case:

$$a_y = g \sin \frac{\pi}{6}$$

$$a_z = (-g) \cos \frac{\pi}{6}$$

- Negative roll angle case:

$$a_y = (-g) \sin \frac{\pi}{6}$$

$$a_z = (-g) \cos \frac{\pi}{6}$$

##### 3.1.2 Calculation of internal pressure

This highest point is then be used as a reference for calculation of internal pressure as following:

$$P_{gd} = \rho g [a_y (y - y_H) + a_z (z - z_H)]$$

where  $y_H$  and  $z_H$  are the coordinates of the highest point.

#### 3.2 Sea pressure calculation

**3.2.1** The sea pressure is calculated as above:

- Positive roll angle:

$$P_s = \rho g \left[ y \sin \frac{\pi}{6} + (T - z) \cos \frac{\pi}{6} \right]$$

- Negative roll angle:

$$P_s = \rho g \left[ (-y) \sin \frac{\pi}{6} + (T - z) \cos \frac{\pi}{6} \right]$$

## **4 Calculation of dynamic pressure for collision loads**

### **4.1 General**

**4.1.1** The dynamic pressure resulting from collision loads defined in Ch 9, Sec 4, [3.5.2] is the following:

$$P_w = \rho_1 a_x |x - x_B|$$

where:

$\rho_1$  : Maximum cargo density, in kg/m<sup>3</sup>, at the design temperature

$x$  : X co-ordinate, in m, at the point considered

• for the case of forward acceleration:

$a_x$  : Longitudinal acceleration, in m/s<sup>2</sup>, equal to:  $a_x = 0.5 g$

$x_B$  : X co-ordinate, in m, of aft bulkhead of the tank.

• for the case of aftward acceleration:

$a_x$  : Longitudinal acceleration, in m/s<sup>2</sup>, equal to:  $a_x = 0.25 g$

$x_B$  : X co-ordinate, in m, of fore bulkhead of the tank.

# Appendix 2 Correspondances between Part D, Chapter 9 and the IGC Code

## 1 General

### 1.1

1.1.1 Tab 1 to Tab 18 provide correspondances between the provisions of the IGC Code and those of the present Chapter.

**Table 1 : Equivalences between Part D, Chapter 9 and Chapter 1 of the IGC Code**

Ref. in IGC Code, Chapter 1	Ref. in Part D, Chapter 9	Ref. in IGC Code, Chapter 1	Ref. in Part D, Chapter 9	Ref. in IGC Code, Chapter 1	Ref. in Part D, Chapter 9

# Part D

## Service Notations

---

### CHAPTER 10

## TANKERS

---

- Section 1      General
- Section 2      Hull and Stability
- Section 3      Machinery and Cargo Systems

# Section 1                      General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **tanker**, as defined in Pt A, Ch 1, Sec 2, [4.4.7].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**1.1.3** The liquid cargoes which are allowed to be carried by ships having the service notation **tanker** are specified in Ch 7, App 4.

**Table 1 : Applicable requirements**

## Section 2 Hull and Stability

### 1 General

#### 1.1 Documents to be submitted

1.1.1 In addition to the documentation requested in Part B, the following information are to be submitted:

- indication of the type of cargoes, including cargo temperatures and densities.

### 2 General arrangement

#### 2.1 Compartment arrangement

##### 2.1.1 General

Tankers may be built with independent or integral cargo tanks.

##### 2.1.2 Integral tanks

Cofferdams are to be fitted between cargo tanks and compartments intended for liquids likely to alter edible liquids carried.

Tanks are to be separated from any compartment containing heat sources by cofferdams or duly heat-insulated bulkheads.

##### 2.1.3 Arrangement of tanks

In general, each tank is to be fitted with:

- a graduated metal gauge rod or any other equivalent sounding device
- an inspection door of adequate size fitted with a watertight metal cover secured by wing bolts or any other device offering equivalent safety
- an expansion system intended to avoid any excessive pressure and any risk of overflow due to a rise in temperature or occasional fermentation; the expansion capacity is to be about 0,5% of the tank cubic capacity
- a drain well that may be suppressed where precautions are taken to improve the running of liquids towards the suction pipes.

### 3 Stability

#### 3.1 Intact stability

##### 3.1.1 General

The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.3] is to be in compliance with the requirements in Pt B, Ch 3, Sec 2.

In general, a representative sample of loading conditions intended to be used for the ship is also to be submitted. The additional loading conditions are also to be in compliance with the requirements of Pt B, Ch 3, Sec 2.

### 4 Design loads

#### 4.1 Loading conditions for longitudinal strength assessment

4.1.1 In addition to the requirements in Pt B, Ch 5, Sec 8, still water loads are to be calculated for the following loading conditions:

- partial loading conditions
- light and heavy ballast conditions
- mid-voyage conditions relating to tank cleaning or other operations where, at the Society's discretion, these differ significantly from the ballast conditions.

#### 4.2 Load combinations for direct strength analysis

##### 4.2.1 Applicable general load combinations

The load combinations defined in Ch 7, Sec 3, [4.3] are to be considered.

## **5 Hull scantlings**

### **5.1 Strength check with respect to stresses due to the temperature gradient**

**5.1.1** Direct calculations of stresses induced in the hull structures by the temperature gradient are to be performed for ships intended to carry cargoes at temperatures exceeding 90°C. In these calculations, the water temperature is to be assumed equal to 0°C.

The calculations are to be submitted to the Society for review.

**5.1.2** The stresses induced in the hull structures by the temperature gradient are to comply with the checking criteria in Part B, Chapter 7.

## **6 Scantlings of independent tank structures**

### **6.1 General**

**6.1.1** Ships designed with independent cargo tanks are to comply with the applicable provisions of Part D, Chapter 7.

## **7 Supports of independent tanks**

### **7.1 General**

**7.1.1** Ships designed with independent cargo tanks are to comply with the applicable provisions of Part D, Chapter 7.

## **8 Other structures**

### **8.1 Machinery space**

#### **8.1.1 Extension of the hull structures within the machinery space**

Longitudinal bulkheads carried through cofferdams are to be extended within the machinery space and be used preferably as longitudinal bulkheads for liquid cargo tanks. In any case, such extension is to be compatible with the shape of the structures of the double bottom, deck and platforms of the machinery space.

## **9 Construction and testing**

### **9.1 Special structural details**

**9.1.1** The specific requirements in Pt B, Ch 13, Sec 5, [2] for ships with the service notation **tanker** are to be complied with.

## Section 3 Machinery and Cargo Systems

### 1 General

#### 1.1 Documents to be submitted

1.1.1 The documents listed in Tab 1 are to be submitted for approval.

### 2 Piping systems

#### 2.1 General

##### 2.1.1 Materials

- a) Materials used for piping systems are to comply with the provisions of Pt C, Ch 1, Sec 10, [2.1].
- b) Attention is drawn to any national standards or regulations which might restrict the use of materials in contact with edible substances.

##### 2.1.2 Independence of piping systems

- a) The cargo piping system is to be entirely separated from other piping systems serving the ship.
- b) In the case of carriage of edible substances, arrangements are to be made to avoid any inadvertent contamination of the cargo. In particular, the filling and discharge connections serving the cargo tanks are to be located remote from those serving the machinery piping systems.

##### 2.1.3 Passage of pipes through tanks

Cargo tanks containing edible substances are not to be passed through by pipes conveying other liquids.

#### 2.2 Cargo piping and pumping

##### 2.2.1 Cargo pumps

At least two cargo pumps are to be provided for transferring the cargo.

##### 2.2.2 Level gauging systems

Level gauging systems of tanks containing edible substances are to be so designed as to avoid any contamination of the cargo.

#### 2.3 Air pipes

##### 2.3.1

- a) Air pipes of cargo tanks are to be fitted with automatic closing appliances. Refer to Pt C, Ch 1, Sec 10, [9.1].
- b) Air pipes of tanks containing edible substances are to be led as far as practicable from:
  - air pipes of sewage or flammable oil tanks
  - machinery ventilation outlets.

#### 2.4 Refrigerating installations

##### 2.4.1

- a) Where the cargo needs to be kept refrigerated for conservation purposes, the refrigerating installation is to comply with the applicable provisions of Part F, Chapter 7.
- b) Provisions are to be made to avoid any contamination of the cargo by the refrigeration fluid.

#### 2.5 Cargo tank cleaning systems

2.5.1 Adequate means are to be provided for cleaning the cargo tanks.

#### 2.6 Additional requirements for ships carrying category Z substances

2.6.1 Tankers carrying category Z substances are to comply with the provisions of Ch 7, Sec 4, [9.2.2].

**Table 1 : Documents to be submitted**

No.	Description of the document <b>(1)</b>
1	Diagram of the cargo piping system
2	Diagram of the cargo tank venting system
3	Diagram of the cargo tank level gauging system
4	Diagram of the cargo tank cleaning system
5	Diagram of the bilge and ballast systems serving the cargo spaces
6	Diagram of the cargo heating and refrigerating systems
<b>(1)</b> Diagrams are also to include, where applicable: <ul style="list-style-type: none"><li>• the (local and remote) control and monitoring systems and automation systems</li><li>• the instructions for the operation and maintenance of the piping system concerned (for information).</li></ul>

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **passenger ship**, as defined in Pt A, Ch 1, Sec 2, [4.5.2].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**1.1.3** For ships having to comply with the provisions of SOLAS Ch II-1 reg 8-1 and SOLAS Ch II-2 reg 21 and 22, the service notation **passenger ship** is to be completed by the additional service feature **SRTP** according to requirements of NR598 Implementation of Safe Return to Port and Orderly Evacuation.

**1.1.4** Additional guidance for arrangement and structural assessment is provided in NI 640 Structural Assessment of Passenger Ships.

**Table 1 : Applicable requirements**

# Section 2 Ship Arrangement

## 1 General

### 1.1 Definitions

#### 1.1.1 Deepest subdivision load line

*Deepest subdivision load line is the waterline which corresponds to the summer load line of the ship.*

#### 1.1.2 Passenger spaces

Passenger spaces are those spaces which are provided for the accommodation and use of passengers, excluding baggage, store, provision and mail rooms.

In all cases volumes and areas are to be calculated to moulded lines.

## 2 General arrangement design

### 2.1 Openings in watertight boundaries below the bulkhead deck

#### 2.1.1 Openings in machinery spaces

*Not more than one door apart from the doors to shaft tunnels may be fitted in each watertight bulkhead within spaces containing the main and auxiliary propulsion machinery including boilers serving the needs of propulsion. Where two or more shafts are fitted the tunnels are to be connected by an inter-communicating passage. Only one door is to be provided between the machinery space and the tunnel spaces where two shafts are fitted and only two doors where there are more than two shafts. All these doors are to be of the sliding type and are to be so located as to have their sills as high as practicable. The hand gear for operating these doors from above the bulkhead deck is to be situated outside the spaces containing the machinery.*

*Portable plates on bulkheads are not permitted except in machinery spaces. The Society may permit not more than one power-operated sliding watertight door larger than 1,20 m to be substituted for these portable plates in each watertight bulkhead, provided these doors are intended to remain closed during navigation except in the case of urgent necessity at the discretion of the master. These doors need not meet the requirements of [2.3.3] e) regarding complete closure by hand-operated gear in 90 seconds.*

#### 2.1.2 Openings in cargo spaces

- a) *Watertight doors complying with the requirements of [2.3.1] may be fitted in watertight bulkheads dividing cargo spaces on 'tween decks. Such doors may be hinged, rolling or sliding doors but are not to be remotely controlled. They are to be fitted at the highest level and as far from the shell plating as practicable, but in no case are the outboard vertical edges to be situated at a distance from the shell plating which is less than one fifth of the breadth of the ship, such distance being measured at right angles to the centreline at the level of the deepest subdivision load line.*
- b) *The doors accessible during the voyage are to be fitted with a device which prevents unauthorised opening. When it is proposed to fit such doors, the number and arrangements are to receive the special consideration of the Society.*

#### 2.1.3 Openings in passenger ships carrying goods vehicles and accompanying personnel

*This requirement applies to passenger ships designed or adapted for the carriage of goods vehicles and accompanying personnel where the total number of persons on board, other than passengers as defined in Pt A, Ch 1, Sec 2, [4.5.2], exceeds 12.*

*If in such a ship the total number of passengers which include personnel accompanying vehicles does not exceed:*

$$N = 12 + \frac{A}{25}$$

where:

*N : Maximum number of passengers for which the ship is certified*

*A : Total deck area, in m<sup>2</sup>, of spaces available for the stowage of goods vehicles,*

*and where the clear height at the stowage position and at the entrance to such spaces is not less than 4 m, the provisions of [2.1.2] in respect of watertight doors apply except that the doors may be fitted at any level in watertight bulkheads dividing cargo spaces.*

*Additionally, indicators are required on the navigating bridge to show automatically when each door is closed and all door fastenings are secured.*

### **2.1.4 Trunks and tunnels**

Where trunkways or tunnels for access from crew accommodation to the stokehold, for piping, or for any other purpose are carried through watertight bulkheads, they are to be watertight and in accordance with the requirements of Pt B, Ch 4, Sec 5, [10.5]. The access to at least one end of each such tunnel or trunkway, if used as a passage at sea, is to be through a trunk extending watertight to a height sufficient to permit access above the bulkhead deck. The access to the other end of the trunkway or tunnel may be through a watertight door. Such trunkways or tunnels are not to extend through the first subdivision bulkhead abaft the collision bulkhead.

Where trunkways in connection with refrigerated cargo and ventilation or forced draught trunks are carried through more than one watertight bulkhead, the means of closure at such openings are to be operated by power and be capable of being closed from a central position situated above the bulkhead deck.

Where a ventilation trunk passing through a structure penetrates a watertight area of the bulkhead deck, the trunk is to be capable of withstanding the water pressure that may be present within the trunk, after having taken into account the maximum heel angle during flooding, in accordance with Ch 12, Sec 3, [2.3.5].

### **2.1.5 Additional requirements**

In addition to [2.1.1], [2.1.2], [2.1.3], and [2.1.4], the requirements reported in [2.3.3] are to be complied with.

## **2.2 Openings in bulkheads above the bulkhead deck**

### **2.2.1 General**

The internal watertight subdivision arrangements to limit the entry and spread of water above the bulkhead deck is to be in accordance with the design arrangements necessary for compliance with the stability requirements in Part B, Chapter 3. Where pipes, scuppers, electric cables, etc. are carried through internal watertight boundaries that are immersed at any intermediate or final stage of flooding in damage cases that contribute to the attained subdivision index A, arrangements are to be made to ensure their watertight integrity.

Doors in internal watertight subdivision arrangements above the bulkhead deck, and also above the worst intermediate or final stage of flooding waterlines, are to be capable of preventing the passage of water when immersed in the required range of positive stability for any damage cases contributing to the attained subdivision index A. These doors may remain open provided they can be remotely closed from the navigation bridge. They are to be always ready to be immediately closed.

The coamings of all openings in the exposed weather deck are to be of ample height and strength and are to be provided with efficient means for expeditiously closing them weathertight. Freeing ports, open rails and scuppers are to be fitted as necessary for rapidly cleaning the weather deck of water under all weather conditions.

Sidescuttles, gangway, cargo and fuelling ports and other means for closing openings in the shell plating above the bulkhead deck are to be of efficient design and construction and of sufficient strength (see Pt B, Ch 11, Sec 12) having regard to the spaces in which they are fitted and their positions relative to the deepest subdivision load line.

Efficient inside deadlights, so arranged that they can be easily and effectively closed and secured watertight, are to be provided for all sidescuttles to spaces below the first deck above the bulkhead deck.

### **2.2.2 Open end of air pipes**

Air pipes terminating within a superstructure which are not fitted with watertight means of closure are to be considered as unprotected openings when applying Pt B, Ch 3, App 3, [1.6.11].

### **2.2.3 Additional requirements**

In addition to [2.2.1] and [2.2.2], the requirements reported in [2.3.4] are to be complied with.

## **2.3 Doors**

### **2.3.1 Requirements for doors**

The requirements relevant to the operating systems for doors complying with the prescriptions in [2.3.2] and [2.3.3] are specified in Tab 1 for doors of internal watertight bulkheads and Tab 2 for doors of external watertight boundaries below equilibrium or intermediate waterplane.

### **2.3.2 Construction of watertight doors**

The design, materials and construction of all watertight doors are to be to the satisfaction of the Society.

Such doors are to be suitably marked to ensure that they may be properly used to provide maximum safety.

The frames of vertical watertight doors are to have no groove at the bottom in which dirt might lodge and prevent the door closing properly.

**2.3.3 Doors in watertight bulkheads below the bulkhead deck**

- a) Watertight doors, except as provided in [2.1.2] item a) and [2.1.3], are to be power operated sliding doors complying with the requirements of items e) to l).
- b) The means of operation whether by power or by hand of any power-operated sliding watertight door are to be capable of closing the door with the ship listed to 15° either way. Consideration is to also be given to the forces which may act on either side of the door as may be experienced when water is flowing through the opening applying a static head equivalent to a water height of at least 1 m above the sill on the centreline of the door.
- c) Watertight door controls, including hydraulic piping and electrical cables, are to be kept as close as practicable to the bulkhead in which the doors are fitted, in order to minimise the likelihood of them being involved in any damage which the ship may sustain. The positioning of watertight doors and their controls are to be such that if the ship sustains damage within one fifth of the breadth of the ship, such distance being measured at right angles to the centreline at the level of the deepest subdivision load line, the operation of the watertight doors clear of the damaged portion of the ship is not impaired.
- d) Each power-operated sliding watertight door:
- is to move vertically or horizontally;
  - is to be normally limited to a maximum clear opening width of 1,20 m. The Society may permit larger doors only to the extent considered necessary for the effective operation of the ship provided that other safety measures, including the following, are taken into consideration:
    - special consideration is to be given to the strength of the door and its closing appliances in order to prevent leakages;
    - the door is to be located outside the damage zone B/5.
  - is to be fitted with the necessary equipment to open and close the door using electrical power, hydraulic power, or any other form of power that is acceptable to the Society;
  - is to be provided with an individual hand-operated mechanism. It is to be possible to open and close the door by hand at the door itself from either side and, in addition, close the door from an accessible position above the bulkhead deck with an all round crank motion or some other movement providing the same degree of safety acceptable to the Society. Direction of rotation or other movement is to be clearly indicated at all operating positions. The time necessary for the complete closure of the door, when operating by hand gear, may not exceed 90 s with the ship in the upright position. Visual indicators to show whether the door is open or closed are to be provided at the accessible position above the bulkhead deck.
  - is to be provided with controls for opening and closing the door by power from both sides of the door and also for closing the door by power from the central operating console required in item n);
  - is to be provided with an audible alarm, distinct from any other alarm in the area, which is to sound whenever the door is closed remotely by power and which is to sound for at least 5 s but no more than 10 s before the door begins to move and is to continue sounding until the door is completely closed. In the case of remote hand operation it is sufficient for the audible alarm to sound only when the door is moving. Additionally, in passenger areas and areas of high ambient noise, the Society may require the audible alarm to be supplemented by an intermittent visual signal at the door;
  - is to have an approximately uniform rate of closure under power. The closure time, from the time the door begins to move to the time it reaches the completely closed position, is to in no case be less than 20 s or more than 40 s with the ship in the upright position.
- e) The electrical power required for power-operated sliding watertight doors is to be supplied from the emergency switchboard either directly or by a dedicated distribution board situated above the bulkhead deck. The associated control, indication and alarm circuits are to be supplied from the emergency switchboard either directly or by a dedicated distribution board situated above the bulkhead deck and be capable of being automatically supplied by a transitional source of emergency electrical power in the event of failure of either the main or emergency source of electrical power.

The transitional source of emergency electrical power is to consist of an accumulator battery suitably located for use in an emergency which is to operate without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage and be of sufficient capacity and so arranged as to supply power automatically, in the event of failure of either the main or emergency source of electrical power, to control, indication and alarm circuits at least for half an hour.

- f) Power-operated sliding watertight doors are to have either:
- a centralised hydraulic system with two independent power sources each consisting of a motor and pump capable of simultaneously closing all doors. In addition, there are to be for the whole installation hydraulic accumulators of sufficient capacity to operate all the doors at least three times, i.e. closed-open-closed, against an adverse list of 15°. This operating cycle is to be capable of being carried out when the accumulator is at the pump cut-in pressure. The fluid used is to be chosen considering the temperatures liable to be encountered by the installation during its service. The power operating system is to be designed to minimise the possibility of having a single failure in the hydraulic piping adversely affect the operation of more than one door. The hydraulic system is to be provided with a low-level alarm for hydraulic fluid reservoirs serving the power-operated system and a low gas pressure group alarm or other effective means of monitoring loss of stored energy in hydraulic accumulators. These alarms are to be audible and visual and are to be situated on the central operating console at the navigating bridge; or

- an independent hydraulic system for each door with each power source consisting of a motor or pump capable of opening and closing the door. In addition, there is to be a hydraulic accumulator of sufficient capacity to operate the door at least three times, i.e. closed-open-closed, against an adverse list of 15°. This operating cycle is to be capable of being carried out when the accumulator is at the pump cut-in pressure. The fluid used is to be chosen considering the temperatures liable to be encountered by the installation during its service. A low gas pressure group alarm or other effective means of monitoring loss of stored energy in hydraulic accumulators is to be provided at the central operating console required in item m). Loss of stored energy indication at each local operating position is to also be provided; or
- an independent electrical system and motor for each door with each power source consisting of a motor capable of opening and closing the door. The power source is to be capable of being automatically supplied by the transitional source of emergency electrical power in the event of failure of either the main or emergency source of electrical power and with sufficient capacity to operate the door at least three times, i.e. closed-open-closed, against an adverse list of 15°. The transitional source of emergency electrical power is to consist of an accumulator battery suitably located for use in an emergency which is to operate without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage and be of sufficient capacity and so arranged as to supply power automatically, in the event of failure of either the main or emergency source of electrical power, to watertight doors, but not necessarily all of them simultaneously, unless an independent source of stored energy is provided.

For the systems specified above, provision is to be made as follows:

Power systems for power-operated watertight sliding doors are to be separate from any other power system. A single failure in the electrical or hydraulic power-operated systems excluding the hydraulic actuator is not to prevent the hand operation of any door.

- g) Control handles are to be provided at each side of the bulkhead at a minimum height of 1,6 m above the floor and are to be so arranged as to enable persons passing through the doorway to hold both handles in the open position without being able to set the power closing mechanism in operation accidentally. The direction of movement of the handles in opening and closing the door is to be in the direction of door movement and is to be clearly indicated.
- h) As far as practicable, electrical equipment and components for watertight doors are to be situated above the bulkhead deck and outside hazardous areas and spaces.
- i) The enclosures of electrical components necessarily situated below the bulkhead deck are to provide suitable protection against the ingress of water.
- j) Electric power, control, indication and alarm circuits are to be protected against faults in such a way that a failure in one door circuit is not to cause a failure in any other door circuit. Short-circuits or other faults in the alarm or indicator circuits of a door are not to result in a loss of power operation of that door. Arrangements are to be such that leakage of water into the electrical equipment located below the bulkhead deck is not to cause the door to open.
- k) A single electrical failure in the power operating or control system of a power-operated sliding watertight door is not to result in a closed door opening. Availability of the power supply is to be continuously monitored at a point in the electric circuit as near as practicable to each of the motors required in g). Loss of any such power supply is to activate an audible and visual alarm at the central operating console required in item m).
- l) Failure of the normal power supply of the required alarms are to be indicated by an audible and visual alarm at the central operating console required in item m).
- m) A central operating console for all power-operated sliding watertight doors is to be located in the safety centre in accordance with Pt C, Ch 4, Sec 14. If the safety centre is located in a separate space adjacent to the navigation bridge, a central operating console is also to be located on the navigation bridge.

The central operating console is to have a "master mode" switch with two modes of control:

- a "local control" mode which is to allow any door to be locally opened and locally closed after use without automatic closure, and
- a "doors closed" mode which is to automatically close any door that is open in not more than 60 s with the ship in an upright position. The "doors closed" mode is to permit doors to be opened locally and is to automatically reclose the doors upon release of the local control mechanism.

The "master mode" switch is to normally be in the "local control" mode. The "doors closed" mode is to only be used in an emergency or for testing purposes.

- n) The central operating console is to be provided with a diagram showing the location of each power-operated sliding watertight door, with visual indicators to show whether each door is open or closed. A red light is to indicate a door is fully open and a green light is to indicate a door is fully closed. When the door is closed remotely the red light is to indicate the intermediate position by flashing. The indicating circuit is to be independent of the control circuit for each door. Indication is also to be provided to the onboard stability computer, if installed.
- o) It is not to be possible to remotely open any door from the central operating console.
- p) All watertight doors are to be kept closed during navigation. Certain watertight doors may be permitted to remain open during navigation only if considered absolutely necessary; that is, being open is determined essential to the safe and effective operation of the ship's machinery or to permit passengers normally unrestricted access throughout the passenger area. Such

determination is to be made by the Society only after careful consideration of the impact on ship operations and survivability. A watertight door permitted to remain thus open is to be clearly indicated in the ship's stability information and the damage control documentation and is always to be ready for immediate closure.

- q) All watertight doors, including sliding doors, operated by hydraulic door actuators, either a central hydraulic unit or an independent hydraulic unit for each door is to be provided with a low fluid level alarm or low gas pressure alarm, as applicable or some other means of monitoring loss of stored energy in the hydraulic accumulators. This alarm is to be both audible and visible and is to be located on the central operating console required in item n).
- r) Signboard/instructions are to be placed in way of the door advising how to act when the door closed.

**2.3.4 Doors in bulkheads above the bulkhead deck**

a) General

Doors are to be capable of being opened and closed by hand locally from both sides of the doors with the ship listed to 15° to either side.

Position indicators are to be provided on the bridge to show that the doors are open or closed and that the dogs are fully and properly engaged.

Where the doors also serve as fire doors they are to be provided with position indicators at the fire control station and audible alarms as required for fire doors, as well as for weathertight doors. Where two doors are fitted they must be capable of independent operation remotely and from both sides of each door.

b) Doors normally closed at sea

In addition to a), doors not required for frequent access while at sea are to be kept normally closed and may be of either hinged or sliding type.

Doors kept normally closed are to have local operation from both sides of the doors and are to be labelled on both sides: "to be kept closed at sea".

c) Doors normally open at sea

Where fitted in public spaces for the passage of passengers and crew, the doors may be kept normally open at sea and may be either hinged or sliding type.

In addition to a), doors kept normally open at sea are to have local power operation from both sides of the door and remote closing from the bridge. Operation of these doors is to be similar to that specified in Pt C, Ch 4, Sec 5 where, using a "master mode" switch on the bridge, local control can override the remote closing feature after which the door is automatically remotely reclosed upon release of the local control mechanism.

Doors kept normally open at sea are to have audible alarms, distinct from any other alarm in the area, which sound whenever the doors are closed remotely. The alarms are to sound for at least 5 s but not more than 10 s before the doors begins to move and continue sounding until the doors are completely closed. In passenger areas and areas of high ambient noise, the audible alarms are to be supplemented by visual signals at both sides of the doors.

d) Failure of the normal power supply of the required alarms are to be indicated by an audible and visual alarm.

e) All watertight doors, including sliding doors, operated by hydraulic door actuators, either a central hydraulic unit or an independent hydraulic unit for each door is to be provided with a low fluid level alarm or low gas pressure alarm, as applicable or some other means of monitoring loss of stored energy in the hydraulic accumulators. This alarm is to be both audible and visible and is to be located on the central operating console required in item n).

f) Signboard/instructions are to be placed in way of the door advising how to act when the door closed.

**Table 1 : Doors in internal watertight bulkheads of passenger ships**

Position relative to bulkhead deck	Frequency of use while at sea	Type (1)	Remote closure	Remote indication	Audible or visual alarm	Notice
Below	Used (2)	POS	X	X	X (local)	
	Permanently closed (3) (4)	S, H				X
At or above	Used	POS, POH	X	X	X (local)	
	Used (5)	S, H		X		X
	Used (Doors giving access to below ro-ro deck)	S, H		X	X (remote)	X
	Permanently closed (3) (5)	S, H		X	X (remote)	X

- (1) POS : Power operated, sliding or rolling
- POH : Power operated, hinged
- S : Sliding or rolling
- H : Hinged

(2) See SOLAS II-1/22.3 and IMO MSC.1/Circ.1564

(3) Doors are to be fitted with a device which prevents unauthorized opening.

(4) Passenger ships which have to comply with [2.1.3] require an indicator on the navigation bridge to show automatically when each door is closed and all doors fastenings are secured.

(5) If hinged, this door is to be of single action type.

**Table 2 : Doors in external watertight boundaries below equilibrium or intermediate waterplane**

Position relative to bulkhead deck	Frequency of use while at sea	Type (1)	Remote closure	Remote indication	Audible or visual alarm	Notice
Below	Permanently closed (2)	S, H				X
At or above	Normally closed (3)	S, H		X		X
	Normally closed (Doors giving access to below ro-ro deck)	S, H		X	X (remote)	X
	Permanently closed (2)	S, H		X	X (remote)	X
<p>(1) S : Sliding or rolling                      H : Hinged</p> <p>(2) Doors are to be fitted with a device which prevents unauthorized opening.</p> <p>(3) If hinged, this door is to be of single action type.</p>						

**2.4 Ballast compartment arrangement**

**2.4.1** *Water ballast is not to be, in general, carried in tanks intended for fuel oil. In ships in which it is not practicable to avoid putting water in fuel oil tanks, oily-water separating equipment to the satisfaction of the Society is to be fitted, or other alternative means, such as discharge to shore facilities, acceptable to the Society is to be provided for disposing of the oily-water ballast (see Pt C, Ch 1, Sec 10, [7]).*

**2.5 Machinery compartment arrangement**

**2.5.1** When longitudinal bulkheads are fitted in the machinery space, adequate self-operating arrangements are to be provided in order to avoid excessive heel after damage.

Where such arrangements are cross-flooding systems, their area is to be calculated in accordance with the requirements in Ch 11, App 1 In addition, such systems are to comply with the criteria for the maximum time necessary to cross flood according to Ch 11, Sec 3, [2.3.5], item a).

## Section 3 Hull and Stability

### 1 General

#### 1.1 Documents to be submitted

1.1.1 In addition to the documentation requested in Pt B, Ch 1, Sec 4, the following documents are to be submitted:

- Stability documentation as specified in Article [2]
- Plan of design loads on deck as specified in [4.1].

### 2 Stability

#### 2.1 Definitions

##### 2.1.1 Deepest subdivision draught

The deepest subdivision draught ( $d_s$ ) is the waterline which corresponds to the summer load line draught of the ship.

##### 2.1.2 Light service draught

Light service draught ( $d_l$ ) is the service draught corresponding to the lightest anticipated loading and associated tankage, including, however, such ballast as may be necessary for stability and/or immersion.

##### 2.1.3 Partial subdivision draught

The partial subdivision draught ( $d_p$ ) is the light service draught plus 60% of the difference between the light service draught and the deepest subdivision draught.

##### 2.1.4 Subdivision length $L_s$

The subdivision length  $L_s$  is the greatest projected moulded length of that part of the ship at or below deck or decks limiting the vertical extent of flooding with the ship at the deepest subdivision draught.

##### 2.1.5 Machinery space

Machinery spaces are spaces between the watertight boundaries of a space containing the main and auxiliary propulsion machinery, including boilers, generators and electric motors primarily intended for propulsion. In the case of unusual arrangements, the Society may define the limits of the machinery spaces.

##### 2.1.6 Other definitions

Mid-length is the mid point of the subdivision length of the ship.

Aft terminal is the aft limit of the subdivision length.

Forward terminal is the forward limit of the subdivision length.

Breadth  $B$  is the greatest moulded breadth, in m, of the ship at or below the deepest subdivision draught.

Draught  $d$  is the vertical distance, in m, from the moulded baseline at mid-length to the waterline in question.

Permeability  $\mu$  of a space is the proportion of the immersed volume of that space which can be occupied by water.

#### 2.2 Intact stability

##### 2.2.1 General

Every passenger ship regardless of size is to be inclined upon its completion. The lightship displacement and the longitudinal, transverse and vertical position of its centre of gravity shall be determined. The Master is to be supplied with such information satisfactory to the Society as is necessary to enable him by rapid and simple processes to obtain accurate guidance as to the stability of the ship under varying conditions of service. A copy of the stability information is to be furnished to the Society.

Where any alterations are made to a ship so as to materially affect the stability information supplied to the Master, amended stability information is to be provided. If necessary the ship is to be re-inclined.

##### 2.2.2 Periodical lightweight check

At periodical intervals not exceeding five years, a lightweight survey is to be carried out on all passenger ships to verify any changes in lightship displacement and longitudinal centre of gravity. The ship is to be re-inclined whenever, in comparison with the approved stability information, a deviation from the lightship displacement exceeding 2% or a deviation of the longitudinal centre of gravity exceeding 1% of  $L_{LL}$  is found, or anticipated.

**2.2.3 Standard requirements**

In addition to Pt B, Ch 3, Sec 2, [2], the requirements in [2.2.4] to [2.2.6] are to be complied with for the loading conditions defined in Pt B, Ch 3, App 2, [1.2.1] and Pt B, Ch 3, App 2, [1.2.9].

**2.2.4 Crowding of passengers**

The angle of heel on account of crowding of passengers to one side as defined below may not exceed 10°:

- a minimum weight of 75 kg is to be assumed for each passenger except that this value may be increased subject to the approval of the Society. In addition, the mass and distribution of the luggage is to be approved by the Society;
- the height of the centre of gravity for passengers is to be assumed equal to:
  - 1,0 m above deck level for passengers standing upright. Account may be taken, if necessary, of camber and sheer of deck; and
  - 0,3 m above the seat in respect of seated passengers.
- passengers and luggage are to be considered to be in the spaces normally at their disposal;
- passengers without luggage are to be considered as distributed to produce the most unfavourable combination of passenger heeling moment and/or initial metacentric height, which may be obtained in practice. In this connection, a value higher than four persons per square metre is not necessary.

**2.2.5 Maximum turning angle**

The angle of heel on account of turning may not exceed 10° when calculated using the following formula:

$$M_R = 0,02 \frac{V_0^2}{L_S} \Delta \left( KG - \frac{T_1}{2} \right)$$

where:

- $M_R$  : Heeling moment, in t.m
- $V_0$  : Service speed, in m/s
- $T_1$  : Mean draught, in m
- $KG$  : Height of centre of gravity above keel, in m.

**2.2.6** Where anti-rolling devices are installed in a ship, the Society is to be satisfied that the above criteria can be maintained when the devices are in operation.

**2.3 Damage stability for ships where SDS notation has been required**

**2.3.1 General**

The requirements of this Section are to be applied to passenger ships in conjunction with the exploratory notes as set out by the IMO Resolution MSC 429(98).

**2.3.2 Required subdivision index R**

The required subdivision index R of a passenger ship according to the total number of persons on board is defined in Tab 1. These regulations are intended to provide ships with a minimum standard of subdivision. In addition to these requirements, the requirements of [2.3.12] are to be complied with.

**Table 1 : Required subdivision index R**

Total number of persons on board N	R
$N < 400$	0,722
$400 \leq N \leq 1350$	$N / 7580 + 0,66923$
$1350 < N \leq 6000$	$0,0369 \ln (N + 89,048) + 0,579$
$N > 6000$	$1 - (852,5 + 0,03875 N) / (N + 5000)$

**2.3.3 Attained subdivision index A**

The attained subdivision index A is to be calculated in accordance with Pt B, Ch 3, App 3, [1.4].

The attained subdivision index A is not to be less than the required subdivision index R. In addition, the partial indices  $A_s$ ,  $A_p$  and  $A_L$  are not to be less than 0,9 R.

**2.3.4 Calculation of the factor  $p_i$**

The factor  $p_i$  is to be calculated in accordance with Pt B, Ch 3, App 3, [1.5].

**2.3.5 Calculation of the factor  $s_i$**

The factor  $s_i$  is to be determined for each case of assumed flooding, involving a compartment or group of compartments, in accordance with the following notations and the provisions in this regulation.

- $\theta_e$  : The equilibrium heel in any stage of flooding, in degrees

- $\theta_v$  : The angle, in any stage of flooding, where the righting lever becomes negative, or the angle at which an opening incapable of being closed weathertight becomes submerged  
 In applying this criterion, openings which are incapable of being closed weathertight include ventilators that have to remain open to supply air to the engine room or emergency generator room for the effective operation of the ship.
- $GZ_{max}$  : The maximum positive righting lever, in metres, up to the angle  $\theta_v$
- Range : The Range of positive righting levers, in degrees, measured from the angle  $\theta_e$ . The positive range is to be taken up to the angle  $\theta_v$ .

Flooding stage is any discrete step during the flooding process, including the stage before equalization (if any) until final equilibrium has been reached.

The factor  $s_p$ , for any damage case at any initial loading condition,  $d_p$ , shall be obtained from the formula:

$$s_i = \min[s_{intermediate,i}, (s_{final,i} \cdot s_{mom,i})]$$

where:

$s_{intermediate,i}$ : The probability to survive all intermediate flooding stages until the final equilibrium stage, and is calculated in accordance with item a)

$s_{final,i}$  : The probability to survive in the final equilibrium stage of flooding. It is calculated in accordance with item b)

$s_{mom,i}$  : The probability to survive heeling moments, and is calculated in accordance with item c)

a) Calculation of  $s_{intermediate}$ :

The factor  $s_{intermediate,i}$  is to be taken as the least of the  $s$ -factors obtained from all flooding stages including the stage before equalization, if any, and is to be calculated as follows:

$$s_{intermediate,i} = \left[ \frac{GZ_{max}}{0,05} \cdot \frac{Range}{7} \right]^{\frac{1}{4}}$$

where  $GZ_{max}$  is not to be taken as more than 0,05 m and Range as not more than 7°.

$s_{intermediate,i} = 0$ , if the intermediate heel angle exceeds 15°.

Where cross-flooding fittings are required, the time for equalization is not to exceed 10 min. The time for equalization is to be calculated in accordance with Ch 11, App 1

b) Calculation of  $s_{final}$ :

The factor  $s_{final,i}$  is to be obtained from the formula:

$$s_{final,i} = K \left[ \frac{GZ_{max}}{TGZ_{max}} \cdot \frac{Range}{TRange} \right]^{\frac{1}{4}}$$

where:

$GZ_{max}$  is not to be taken as more than  $TGZ_{max}$

Range is not to be taken as more than  $T_{Range}$

$TGZ_{max}$  is taken equal to:

- $TGZ_{max} = 0,20$  m for ro-ro passenger ships each damage case that involves a ro-ro space
- $TGZ_{max} = 0,12$  m otherwise

$T_{Range}$  is taken equal to:

- $T_{Range} = 20^\circ$  for ro-ro passenger ships each damage case that involves a ro-ro space,
- $T_{Range} = 16^\circ$  otherwise

$K$  is taken equal to:

- $K = 1$  if  $\theta_e \leq \theta_{min}$
- $K = 0$  if  $\theta_e \geq \theta_{max}$
- $K = \sqrt{\frac{\theta_{max} - \theta_e}{\theta_{max} - \theta_{min}}}$  otherwise

where:

$\theta_{min}$  is equal to 7°

$\theta_{max}$  is equal to 15°.

c) Calculation of  $s_{mom}$ :

The factor  $s_{mom,i}$  is to be calculated at the final equilibrium from the formula:

$$s_{mom,i} = \frac{(GZ_{max} - 0,04) \text{ Displacement}}{M_{heel}}$$

where:

$$s_{mom,i} \leq 1$$

Displacement is the intact displacement at the respective draught ( $d_s, d_p, d_l$ )

$M_{heel}$  is the maximum assumed heeling moment as calculated as follows:

$$M_{heel} = \max[M_{passengers}, M_{wind}, M_{survivalcraft}]$$

where heeling moments  $M_{passenger}$ ,  $M_{wind}$  and  $M_{survivalcraft}$  are calculated in [2.3.11].

**2.3.6 Equalization arrangements**

Unsymmetrical flooding is to be kept to a minimum consistent with the efficient arrangements. Where it is necessary to correct large angles of heel, the means adopted shall, where practicable, be self-acting, but in any case where controls to equalization devices are provided they are to be operable from above the bulkhead deck. These fittings together with their controls are to be acceptable to the Society. Suitable information concerning the use of equalization devices are to be supplied to the master of the ship.

Tanks and compartments taking part in such equalization are to be fitted with air pipes or equivalent means of sufficient cross-section to ensure that the flow of water into the equalization compartments is not delayed.

**2.3.7 Cases where  $s_i$  is to be equal to zero**

The factor  $s_i$  is to be taken as zero in those cases where the final waterline, taking into account sinkage, heel and trim, immerses:

- the lower edge of openings through which progressive flooding may take place and such flooding is not accounted for in the calculation of factor  $s_i$ . Such openings are to include air-pipes, ventilators and openings which are closed by means of weathertight doors or hatch covers, but the openings closed by means of watertight manhole covers and flush scuttles, small watertight hatch covers, remotely operated sliding watertight doors, side scuttles of the non-opening type as well as watertight access doors and hatch covers required to be kept closed at sea need not be considered.
- any part of the bulkhead deck considered a horizontal evacuation route.

The factor  $s_i$  is to be taken as zero if, taking into account sinkage, heel and trim, any of the following occur in any intermediate stage or in the final stage of flooding:

- immersion of any vertical escape hatch in the bulkhead deck intended for compliance with the applicable requirements of Pt C, Ch 4, Sec 8
- any controls intended for the operation of watertight doors, equalization devices, valves on piping or on ventilation ducts intended to maintain the integrity of watertight bulkheads from above the bulkhead deck become inaccessible or inoperable
- immersion of any part of piping or ventilation ducts located within the assumed extent of damage and carried through a watertight boundary if this can lead to the progressive flooding of compartment not assumed as flooded.

**2.3.8 Calculation of the factor  $v_i$**

Where horizontal watertight boundaries are fitted above the waterline under consideration the  $s$ -value calculated for the lower compartment or group of compartments is to be obtained by multiplying the value as determined in [2.3.5] by the reduction factor  $v_m$  defined below, which represents the probability that the spaces above the horizontal subdivision will not be flooded.

The factor  $v_i$  is to be calculated in accordance with Pt B, Ch 3, App 3, [1.6.10] and Pt B, Ch 3, App 3, [1.6.11].

**2.3.9 Contribution  $dA$  to the index A**

The contribution  $dA$  to the index A is to be calculated in accordance with Pt B, Ch 3, App 3, [1.6.12].

**2.3.10 Permeability**

For the purpose of the subdivision and damage stability calculations of the regulations, the permeability of each general compartment or part of a compartment is to be according to Tab 2.

Other figures for permeability may be used if substantiated by calculations.

**Table 2 : Values of permeability**

Spaces	Permeability
Appropriated to stores	0,60
Occupied by accommodation or voids	0,95
Occupied by machinery	0,85
Intended for liquids	0 or 0,95 <b>(1)</b>
<b>(1)</b> whichever results in the more severe requirements.	

**2.3.11 Inclining moments**

The following inclining moments are to be taken into account:

a) *Moment due to the crowding of passengers:*

$M_{passenger}$  is the maximum assumed heeling moment resulting from movement of passengers, and is to be obtained as follows:

$$M_{passenger} = (0,075 N_p) (0,45 B) \text{ (tm)}$$

where:

- $N_p$  : Maximum number of passengers permitted to be on board in the service condition corresponding to the deepest subdivision draught under consideration; and
- $B$  : Breadth of the ship.

Alternatively, the heeling moment may be calculated assuming the passengers are distributed with 4 persons per square metre on available deck areas towards one side of the ship on the decks where muster stations are located and in such a way that they produce the most adverse heeling moment. In doing so, a weight of 75 kg per passenger is to be assumed.

b) Moment due to launching of all fully loaded davit-launched survival craft on one side:

$M_{\text{Survivalcraft}}$  is the maximum assumed heeling moment due to the launching of all fully loaded davit-launched survival craft on one side of the ship. It shall be calculated using the following assumptions:

- all lifeboats and rescue boats fitted on the side to which the ship has heeled after having sustained damage are to be assumed to be swung out fully loaded and ready for lowering.
- for lifeboats which are arranged to be launched fully loaded from the stowed position, the maximum heeling moment during launching is to be taken.
- a fully loaded davit-launched liferaft attached to each davit on the side to which the ship has heeled after having sustained damage is to be assumed to be swung out ready for lowering.
- persons not in the life-saving appliances which are swung out are not to provide either additional heeling or righting moment.
- life-saving appliances on the side of the ship opposite to the side to which the ship has heeled are to be assumed to be in a stowed position.

c) Moment due to wind pressure:

$M_{\text{wind}}$  is the maximum assumed wind force acting in a damage situation:

$$M_{\text{wind}} = (P A Z) / 9,806 \cdot 10^3 \text{ (tm)}$$

- $P$  : Wind pressure  
 $P = 120 \text{ N/m}^2$

$A$  : Projected lateral area above waterline

$z$  : Distance from centre of lateral projected area above waterline to  $T/2$ ; and

$T$  : Ship's draught,  $d_1$ .

**2.3.12 Special requirements concerning stability**

A passenger ship intended to carry 400 or more persons is to have watertight subdivision abaft the collision bulkhead so that  $s_i = 1$  for a damage involving all the compartments with  $0.08L$  measured from the forward perpendicular for the three loading conditions used to calculate the attained subdivision index  $A$ . If the attained subdivision index  $A$  is calculated for different trims, this requirement shall also be satisfied for those loading conditions.

A passenger ship intended to carry 36 or more persons is to be capable of withstanding damage along the side shell to an extent specified below. Compliance with this regulation is to be achieved by demonstrating that  $s_i$ , as defined in [2.3.5], is not less than 0,9 for the three loading conditions used to calculate the attained subdivision index  $A$ . If the attained subdivision index  $A$  is calculated for different trims, this requirement is also to be satisfied for those loading conditions.

The damage extent to be assumed when demonstrating compliance with the above paragraph, is to be dependent on the total number of persons carried, and  $L$ , such that:

- the vertical extent of damage is to extend from the ships moulded baseline to a position up to 12,5 m above the position of the deepest subdivision draught as defined in [2.1], unless a lesser vertical extent of damage were to give a lower value of  $s_i$  in which case this reduced extent is to be used.
- where 400 or more persons are to be carried, a damage length of  $0,03 L$  but not less than 3 m is to be assumed at any position along the side shell, in conjunction with a penetration inboard of  $0,1 B$  but not less than 0,75 m measured inboard from the ship side, at right angles to the centreline at the level of the deepest subdivision draught.
- where less than 400 persons are carried, damage length is to be assumed at any position along the shell side between transverse watertight bulkheads provided that the distance between two adjacent transverse watertight bulkheads is not less than the assumed damage length. If the distance between adjacent transverse watertight bulkheads is less than the assumed damage length, only one of these bulkheads is to be considered effective for the purpose of demonstrating compliance with the criteria  $s_i \geq 0,9$ .
- where 36 persons are carried, a damage length of  $0,015 L$  but not less than 3 m is to be assumed, in conjunction with a penetration inboard of  $0,05 B$  but not less than 0,75 m.
- where more than 36, but fewer than 400 persons are carried the values of damage length and penetration inboard, used in the determination of the assumed extent of damage, are to be obtained by linear interpolation between the values of damage length and penetration which apply for ships carrying 36 persons and 400 persons.

**2.3.13 Documents to be supplied**

The master is to be supplied with such information to the satisfaction of the Society as is necessary to enable him by rapid and simple processes to obtain accurate guidance as to the stability of the ship under varying conditions of service. A copy of the stability information shall be furnished to the Society.

The information should include:

- curves or tables of minimum operational metacentric height (GM) and maximum permissible trim versus draught which assures compliance with the intact and damage stability requirements where applicable, alternatively corresponding curves or tables of the maximum allowable vertical centre of gravity (KG) and maximum permissible trim versus draught, or with the equivalents of either of these curves or tables.
- instructions concerning the operation of cross-flooding arrangements
- all other data and aids which might be necessary to maintain the required intact stability and stability after damage.

The intact and damage stability information specified above are to be presented as consolidated data and encompass the full operating range of draught and trim. Applied trim values shall coincide in all stability information intended for use on board. Information not required for determination of stability and trim limits should be excluded from this information.

If the damage stability is calculated in accordance with the present sub-article, a stability limit curve is to be determined using linear interpolation between the minimum required GM assumed for each of the three draughts  $d_s$ ,  $d_p$  and  $d_i$ . When additional subdivision indices are calculated for different trims, a single envelope curve based on the minimum values from this calculations is to be presented. When it is intended to develop curves of maximum permissible KG, it is to be ensured that the resulting maximum KG curves correspond with a linear variation of GM.

As an alternative to a single envelope curve, the calculations for additional trims may be carried out with one common GM for all of the trims assumed at each subdivision draught. The lowest values of each partial index  $A_s$ ,  $A_p$  and  $A_i$  across these trims shall then be used in the summation of the attained subdivision index A according to [2.3.3]. This will result in one GM limit curve based on the GM used at each draught. A trim limit diagram showing the assumed trim range shall be developed.

When curves or tables of minimum operational metacentric height (GM) or maximum allowable KG versus draught are not provided, the master is to ensure that the operating condition does not deviate from approved loading conditions, or verify by calculation that the stability requirements are satisfied for this loading condition.

### 2.3.14 Damage control documentation

Plans showing clearly for each deck and hold the boundaries of the watertight compartments, the openings therein with the means of closure and position of any controls thereof, and the arrangements for the correction of any list due to flooding are to be permanently exhibited for the guidance of the officer in charge of the ship. In addition, booklets containing the aforementioned information are to be made available to the officers of the ship.

Detailed description of the information to be included in the damage control documentation is reported in Pt B, Ch 3, Sec 3, [4].

## 3 Structure design principles

### 3.1 Hull structure

#### 3.1.1 Framing

In general, the strength deck and the bottom of passenger ships of more than 100 m in length are to be longitudinally framed. Where a transverse framing system is adopted for such ships, it is to be considered by the Society on a case-by-case basis.

## 4 Design loads

### 4.1 Loads on deck

#### 4.1.1 Plan of design loads on deck

A plan of design static loads on deck, including fork lift areas, axle loads and tyre print areas of wheeled loads, is to be provided for information.

All values displayed on this plan are to be at least equivalent to the values given by the present Rules for each kind of load.

### 4.2 Sea pressures

#### 4.2.1 Bow impact pressure

The bow impact pressure  $p_{Fi}$ , in kN/m<sup>2</sup>, is to be taken as obtained in Pt B, Ch 5, Sec 5, [4.3.1] considering the coefficient  $C_z$  calculated from the following formulae:

- for  $z \geq 21,5 H + T_{LC} - 11$ :

$$C_z = [10,75H - 0,5(z - T_{LC})] \left[ 0,82 - 0,09 \left( \frac{z - T_{LC}}{T_{LC}} \right) \right]$$

- for  $z < 21,5 H + T_{LC} - 11$ :

$$C_z = \left[ 4,5 - 0,5 \left( \frac{z - T_{LC}}{T_{LC}} \right) \right]$$

where:

- H : Wave parameter defined in Pt B, Ch 5, Sec 3, for a reference length calculated with:  
 $\alpha = 0,65 C_{W-LC}^{-1,3}$   
 $f_{\alpha} = 1,0$
- z : z co-ordinate, in m, of the calculation point, with respect to the reference co-ordinate system defined in Pt B, Ch 1, Sec 3, [2.6]

Other values of bow impact pressure may be considered by the Society on a case-by-case basis, provided that they are documented through model tests or full scale measurements.

## **5 Hull girder strength**

### **5.1 Basic criteria**

#### **5.1.1 Strength deck**

In addition to the requirements in Pt B, Ch 6, Sec 1, [1.3], the contribution of the hull structures up to the strength deck to the longitudinal strength is to be assessed through a finite element analysis of the whole ship in the following cases:

- when the size of openings in the side shell and/or longitudinal bulkheads located below the deck assumed by the Designer as the strength deck decrease significantly the capability of the plating to transmit shear forces to the strength deck.
- when the ends of superstructures which are required to contribute to longitudinal strength may be considered not effectively connected to the hull structures in way.

### **5.2 Global transverse strength**

**5.2.1** The behaviour of the ship primary structural members under racking effects due to transverse forces induced by transverse accelerations is to be investigated according to Pt B, Ch 7, App 1, or by means of a complete ship model under transverse accelerations load case according to NI640.

## **6 Hull scantlings**

### **6.1 Balcony doors**

#### **6.1.1 General**

Glazed sliding doors fitted on sides of superstructures are to comply with the following requirements:

- Pt B, Ch 11, Sec 12, [3.3] for the assessment of glass panes
- [6.1.2] for the structural testing of supporting frames.

#### **6.1.2 Supporting frame structural testing**

Strength test of balcony doors supporting frames is to be carried out according to the following procedure:

- the structural testing is to be carried out at twice the design pressure defined in Pt B, Ch 5, Sec 5, [5]
- the door assembly, its supporting frame and supporting structure are to be same as, or deemed representative of the ship actual arrangement
- the pressure is to be applied uniformly on the door entire external area
- the glass panel may be alternatively replaced by a steel plate, of reduced thickness in order to represent equivalent flexural stiffness of the glass
- the pressure is to be maintained for not less than 5 minutes
- visual inspection is to be carried out after testing, without damage nor deformation.

## Section 4 Machinery and Cargo System

### 1 Bilge system

#### 1.1 General

##### 1.1.1

- a) *The bilge pumping system required in Pt C, Ch 1, Sec 10, [6] shall be capable of operation under all practicable conditions after a casualty, whether the ship is upright or listed. For this purpose, wing suctions shall generally be fitted except in narrow compartments at the end of the ship where one suction may be sufficient. In compartments of unusual form, additional suctions may be required.*
- b) *Arrangements shall be made whereby water in the compartment may find its way to the suction pipes.*
- c) *Where, for particular compartments, the Society is satisfied that the provisions of drainage may be undesirable, it may allow such provision to be dispensed with if damage stability calculations carried out in accordance with Ch 11, Sec 3, [2] show that the survival capability of the ship will not be impaired.*

#### 1.2 Bilge pumps

##### 1.2.1 Number and capacity of bilge pumps

- a) a) *At least three power pumps shall be fitted connected to the bilge main, one of which may be driven by the propulsion machinery. Where the bilge pump numeral is 30 or more, one additional independent power pump shall be provided.*

*The bilge pump numeral shall be calculated as follows:*

- *when  $P_1$  is greater than  $P$ :*

*bilge pump numeral =*

$$72 \left[ \frac{M + 2P_1}{V + P_1 - P} \right]$$

- *in other cases:*

*bilge pump numeral =*

$$72 \left[ \frac{M + 2P}{V} \right]$$

*where:*

*L : Length of the ship (metres), as defined in Pt B, Ch 1, Sec 3, [2.1.1]*

*M : Volume of the machinery space (cubic metres), as defined in Ch 11, Sec 3, [2.1.5], that is below the bulkhead deck; with the addition thereto of the volume of any permanent oil fuel bunkers which may be situated above the inner bottom and forward of, or abaft, the machinery space*

*P : Whole volume of the passenger and crew spaces below the bulkhead deck (cubic metres), which are provided for the accommodation and use of passengers and crew, excluding baggage, store and provision rooms*

*V : Whole volume of the ship below the bulkhead deck (cubic metres).*

*$P_1 = K \cdot N$*

*where:*

*N : Number of passengers for which the ship is to be certified*

*$K = 0,056 L$*

*However, where the value of  $K \cdot N$  is greater than the sum of  $P$  and the whole volume of the actual passenger spaces above the bulkhead deck, the figure to be taken as  $P_1$  is that sum or two-thirds  $K \cdot N$ , whichever is the greater.*

- b) *Each of the above pumps is to have a capacity not less than that required in Pt C, Ch 1, Sec 10, [6.7.4].*

- c) *For use of ejectors in lieu of bilge pumps, see Pt C, Ch 1, Sec 10, [6.7.2].*

##### 1.2.2 Location of bilge pumps

*Where practicable, the power bilge pumps shall be placed in separate watertight compartments and so arranged or situated that these compartments will not be flooded by the same damage. If the main propulsion machinery, auxiliary machinery and boilers are in two or more watertight compartments, the pumps available for bilge service shall be distributed as far as is possible throughout these compartments.*

### **1.2.3 Availability of pumps**

*On a ship of 91,5 m in length and upwards or having a criterion numeral of 30 or more, as stated in Ch 11, Sec 3, [2.3.6], the arrangements shall be such that at least one power bilge pump will be available for use in all flooding conditions which the ship is required to withstand, and in all flooding conditions derived from consideration of minor damages as specified in Ch 11, Sec 3, [2.3.12], as follows:*

- a) *one of the required bilge pumps shall be an emergency pump of a reliable submersible type having a source of power situated above the bulkhead deck, or*
- b) *the bilge pumps and their sources of power shall be so distributed throughout the length of the ship that at least one pump in an undamaged compartment will be available.*

### **1.2.4 Draining capability**

*With the exception of additional pumps which may be provided for peak compartments only, each required bilge pump shall be so arranged as to draw water from any space required to be drained.*

## **1.3 Direct bilge suction**

### **1.3.1**

- a) *In passenger ships subject to subdivision regulations, independent power bilge pumps situated in machinery and/or boiler spaces shall have direct suctions from these spaces, except that not more than two such suctions shall be required in any one space.*
- b) *Where two or more such suctions are provided in one compartment, there shall be at least one on each side of the ship.*
- c) *The Society may require independent power bilge pumps situated in other spaces to have separate direct suctions.*

## **1.4 Control location**

### **1.4.1**

- a) *The spindles of the sea inlet and direct suction valves shall extend well above the engine room platform.*
- b) *Where the circulating pumps are driven by electric motors, their starting equipment shall be located at, or above, the level of the motors.*

## **1.5 Provision against bilge system damage**

### **1.5.1 Damage to the bilge system**

*Provision shall be made to prevent the compartment served by any bilge suction pipe being flooded in the event of the pipe being severed or otherwise damaged by collision or grounding in any other compartment. For this purpose, where the pipe is at any part situated nearer the side of the ship than one fifth of the breadth of the ship (measured at right angles to the centreline at the level of the deepest subdivision load line), or is in a duct keel, a non-return valve shall be fitted to the pipe in the compartment containing the open end. The deepest subdivision load line shall be taken as the deepest subdivision draught.*

### **1.5.2 Operation in the case of flooding**

- a) *Distribution boxes, cocks and valves in connection with the bilge pumping system shall be so arranged that, in the event of flooding, one of the bilge pumps may be operative on any compartment; in addition, damage to a pump or its pipe connecting to the bilge main outboard of a line drawn at one fifth of the breadth of the ship shall not put the bilge system out of action.*
- b) *If there is only one system of pipes common to all the pumps, the necessary valves for controlling the bilge suctions must be capable of being operated from above the bulkhead deck.*
- c) *Where in addition to the main bilge pumping system an emergency bilge pumping system is provided, it shall be independent of the main system and so arranged that a pump is capable of operating on any compartment under flooding condition; in that case only the valves necessary for the operation of the emergency system need be capable of being operated from above the bulkhead deck.*

### **1.5.3 Valve controls**

*All cocks and valves referred in [1.5.2] which can be operated from above the bulkhead deck shall have their controls at their place of operation clearly marked and shall be provided with means to indicate whether they are open or closed.*

## **1.6 Drainage and pumping arrangements for vehicle, special category and ro-ro spaces protected by fixed pressure water-spraying systems**

**1.6.1** *When fixed pressure water-spraying fire-extinguishing systems are fitted, in view of the serious loss of stability which could arise due to large quantities of water accumulating on the deck or decks during the operation of the fixed pressure water-spraying system, the following arrangements shall be provided:*

- a) *in the spaces above the bulkhead deck, scuppers shall be fitted so as to ensure that such water is rapidly discharged directly overboard, taking into account IMO Circular MSC.1/Circ.1320*

b)

- 1) *in ro-ro passenger ships, discharge valves for scuppers, fitted with positive means of closing operable from a position above the bulkhead deck in accordance with the requirements of the International Convention on Load Lines in force, shall be kept open while the ships are at sea*
  - 2) *any operation of valves referred to in 1) shall be recorded in the log-book*
- c) *in the spaces below the bulkhead deck, the Society may require pumping and drainage facilities to be provided additional to the requirements above and to those of Pt C, Ch 1, Sec 10. In such case, the drainage system shall be sized to remove no less than 125% of the combined capacity of both the water-spraying system pumps and the required number of fire hose nozzles. The drainage system valves shall be operable from outside the protected space at a position in the vicinity of the extinguishing system controls. Bilge wells shall be of sufficient holding capacity and shall be arranged at the side shell of the ship at a distance from each other of not more than 40 m in each watertight compartment.*

## **2 Ballast system**

### **2.1**

**2.1.1** *Water ballast should not in general be carried in tanks intended for fuel oil. In ships in which it is not practicable to avoid putting water in fuel oil tanks, oily-water separating equipment to the satisfaction of the Society shall be fitted, or other alternative means, such as discharge to shore facilities shall be provided for disposing of the oily-water ballast.*

## **3 Miscellaneous requirements**

### **3.1 Steering gear**

**3.1.1** For steering gear arrangements without auxiliary means for steering, see Ch 15, Sec 4, [24.3.2].

### **3.2 Oil-level gauges**

**3.2.1** For oil-level gauges, see Pt C, Ch 1, Sec 10, [11.6.7].

### **3.3 Watertight doors**

**3.3.1** For watertight doors, see Ch 11, Sec 2.

## Section 5 Electrical Installations

### 1 General

#### 1.1 Documentation to be submitted

**1.1.1** The documentation dealing with the electrical system for watertight door and fire door systems as requested in Pt C, Ch 2, Sec 1, Tab 1, Pt B, Ch 1, Sec 4, Tab 1 and Pt C, Ch 4, Sec 1, Tab 1 is to be submitted for approval.

#### 1.2 Electrical distribution and protection

**1.2.1** *In a passenger ship, distribution systems shall be so arranged that fire in any main vertical zone as defined in Part C, Chapter 4 will not interfere with services essential for safety in any other such zone.*

*This requirement will be met if main and emergency feeders passing through any such zone are separated both vertically and horizontally as widely as is practicable.*

**1.2.2** For generators arranged to operate in parallel and for individually operating generators, arrangements are to be made to disconnect automatically the excess load when the generators are overloaded in such a way as to prevent a sustained loss of speed. The operation of such device is to activate a visual and audible alarm.

#### 1.3 Flooding detection systems for passenger ships carrying 36 or more persons

**1.3.1** *A flooding detection system for watertight spaces below the bulkhead deck is to be provided based on IMO MSC.1/Circ.1291.*

## 2 Emergency source of electrical power and emergency installations

### 2.1 General

**2.1.1** *A self-contained emergency source of electrical power shall be provided.*

**2.1.2** *Provided that suitable measures are taken for safeguarding independent emergency operation under all circumstances, the emergency generator may be used, exceptionally, and for short periods, to supply non-emergency circuits.*

Exceptionally, whilst the vessel is at sea, is understood to mean conditions such as:

- a) blackout situation
- b) dead ship situation
- c) routine use for testing
- d) short-term parallel operation with the main source of electrical power for the purpose of load transfer.

Unless instructed otherwise by the Society, the emergency generator may be used during lay time in port for the supply of the ship mains, provided the requirements of Pt C, Ch 2, Sec 3, [2.4] are complied with.

**2.1.3** *The electrical power available shall be sufficient to supply all those services that are essential for safety in an emergency, due regard being paid to such services as may have to be operated simultaneously.*

**2.1.4** *The emergency source of electrical power shall be capable, having regard to starting currents and the transitory nature of certain loads, of supplying simultaneously at least the services stated in [2.2.3] for the period specified, if they depend upon an electrical source for their operation.*

**2.1.5** *The transitional source of emergency electrical power, where required, is to be of sufficient capacity to supply at least the services stated in [2.2.7] for the periods specified therein, if they depend upon an electrical source for their operation.*

**2.1.6** *An indicator shall be mounted in a suitable place on the main switchboard or in the machinery control room to indicate when the batteries constituting either the emergency source of electrical power or the transitional source of emergency electrical power referred to in Pt C, Ch 2, Sec 3, [2.3.15] and Pt C, Ch 2, Sec 3, [2.3.16] are being discharged.*

**2.1.7** If the services which are to be supplied by the transitional source receive power from an accumulator battery by means of semiconductor converters, means are to be provided for supplying such services also in the event of failure of the converter (e.g. providing a bypass feeder or a duplication of converter).

**2.1.8** *Where electrical power is necessary to restore propulsion, the capacity of the emergency source shall be sufficient to restore propulsion to the ship in conjunction to other machinery as appropriate, from a dead ship condition within 30 min. after blackout.*

For the purpose of this requirement only, the dead ship condition and blackout are both understood to mean a condition under which the main propulsion plant, boilers and auxiliaries are not in operation and in restoring the propulsion, no stored energy for starting the propulsion plant, the main source of electrical power and other essential auxiliaries is to be assumed available. It is assumed that means are available to start the emergency generator at all times.

The emergency generator and other means needed to restore the propulsion are to have a capacity such that the necessary propulsion starting energy is available within 30 minutes of blackout/dead ship condition as defined above. Emergency generator stored starting energy is not to be directly used for starting the propulsion plant, the main source of electrical power and/or other essential auxiliaries (emergency generator excluded).

For steam ships, the 30 minute time limit given in SOLAS can be interpreted as the time from blackout/dead ship condition defined above to light-off of the first boiler.

**2.1.9** *Provision shall be made for the periodical testing of the complete emergency system and shall include the testing of automatic starting arrangements.*

**2.1.10** For starting arrangements of emergency generating sets, see Pt C, Ch 1, Sec 2, [3.1].

**2.1.11** *The emergency source of electrical power may be either a generator or an accumulator battery, which shall comply with the provisions of [2.1.12] or [2.1.13], respectively.*

**2.1.12** *Where the emergency source of electrical power is a generator, it shall be:*

- a) *driven by a suitable prime mover with an independent supply of fuel having a flashpoint (closed cup test) of not less than 43°C*
- b) *started automatically upon failure of the electrical supply to the emergency switchboard from the main source of electrical power and shall be automatically connected to the emergency switchboard; those services referred to in [2.2.7] shall then be transferred automatically to the emergency generating set. The automatic starting system and the characteristic of the prime mover shall be such as to permit the emergency generator to carry its full rated load as quickly as is safe and practicable, subject to a maximum of 45 s, and*
- c) *provided with a transitional source of emergency electrical power according to [2.1.14].*

**2.1.13** *Where the emergency source of electrical power is an accumulator battery, it shall be capable of:*

- a) *carrying the emergency electrical load without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage*
- b) *automatically connecting to the emergency switchboard in the event of failure of the main source of electrical power, and*
- c) *immediately supplying at least those services specified in [2.2.7].*

**2.1.14** *The transitional source of emergency electrical power required by [2.1.12] (c) shall consist of an accumulator battery which shall operate without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage and be so arranged as to supply automatically in the event of failure of either the main or emergency source of electrical power at least the services in [2.2.7] if they depend upon an electrical source for their operation.*

**2.1.15** Where the emergency and/or transitional source of power is an uninterruptible power system (UPS), it is to comply with the requirements of Pt C, Ch 2, Sec 6, [3].

## **2.2 Distribution of electrical power**

**2.2.1** *The emergency switch board shall be supplied during normal operation from the main switchboard by an interconnector feeder which shall be adequately protected at the main switchboard against overload and short-circuit and which is to be disconnected automatically at the emergency switchboard upon failure of the main source of electrical power.*

*Where the system is arranged for feedback operation, the interconnector feeder is also to be protected at the emergency switchboard at least against short-circuit.*

**2.2.2** *In order to ensure ready availability of the emergency source of electrical power, arrangements shall be made where necessary to disconnect automatically non-emergency circuits from the emergency switchboard to ensure that power shall be available to the emergency circuits.*

**2.2.3** The emergency source of electrical power shall be capable of supplying simultaneously at least the following services for the periods specified hereafter, if they depend upon an electrical source for their operation:

- a) for a period of 36 hours, emergency lighting:
  - 1) at every muster and embarkation station and over the sides
  - 2) in alleyways, stairways and exits giving access to the muster and embarkation stations
  - 3) in all service and accommodation alleyways, stairways and exits, personnel lift cars
  - 4) in the machinery spaces and main generating stations including their control positions
  - 5) in all control stations, machinery control rooms, and at each main and emergency switchboard
  - 6) at all stowage positions for firemen's outfits
  - 7) at the steering gear, and
  - 8) at the fire pump, the sprinkler pump and the emergency bilge pump referred to in (d) below and at the starting position of their motors
- b) for a period of 36 hours:
  - 1) the navigation lights and other lights required by the International Regulations for Preventing Collisions at Sea in force, and
  - 2) the VHF radio installation required by Regulation IV/7.1.1 and IV/7.1.2 of SOLAS 1974 as amended, and, if applicable:
    - the MF radio installation required by Regulations IV/9.1.1, IV/9.1.2, IV/10.1.2 and IV/10.1.3
    - the ship earth station required by Regulation IV/10.1.1, and
    - the MF/HF radio installation required by Regulations IV/11.1.1 and IV/11.1.2
- c) for a period of 36 hours:
  - 1) all internal communication equipment required in an emergency (see [2.2.4])
  - 2) the shipborne navigational equipment as required by Regulation V/12; where such provision is unreasonable or impracticable the Society may waive this requirement for ships of less than 5,000 gross tonnage
  - 3) the fire detection and fire alarm system, the fire door holding and release system, and
  - 4) intermittent operation of the daylight signalling lamp, the ship's whistle, the manually operated call points and all internal signals (see [2.2.5]) that are required in an emergency, unless such services have an independent supply for the period of 36 hours from an accumulator battery suitably located for use in an emergency
- d) for a period of 36 hours:
  - 1) one of the fire pumps required by the relevant provisions of Part C, Chapter 4
  - 2) the automatic sprinkler pump, if any, and
  - 3) the emergency bilge pump and all the equipment essential for the operation of electrically powered remote controlled bilge valves
- e) for the period of time required in Pt C, Ch 1, Sec 14, [2], the steering gear if required to be so supplied
- f) for a period of half an hour:
  - 1) any watertight doors required by Regulation II-1/13 to be power operated together with their indicators and warning signals
  - 2) the emergency arrangements to bring the lift cars to deck level for the escape of persons. The passenger lift cars may be brought to deck level sequentially in an emergency.

**2.2.4** Internal communication equipment required in an emergency generally includes:

- a) the means of communication between the navigating bridge and the steering gear compartment
- b) the means of communication between the navigating bridge and the position in the machinery space or control room from which the engines are normally controlled
- c) the means of communication which is provided between the officer of the watch and the person responsible for closing any watertight door which is not capable of being closed from a central control station
- d) the public address system or other effective means of communication throughout the accommodation, public and service spaces
- e) the means of communication between the navigating bridge and the main fire control station.

**2.2.5** Internal signals required in an emergency generally include:

- a) general alarm
- b) watertight door indication
- c) fire door indication.

**2.2.6** In a ship engaged regularly in voyages of short duration, i.e. voyages where the route is no greater than 20 nautical miles offshore or where the vessel has a class notation "Coastal Service", the Society if satisfied that an adequate standard of safety would be attained may accept a lesser period than the 36-hour period specified in [2.2.3] (b) to (e) but not less than 12 hours.

**2.2.7** The transitional source of emergency electrical power required is to supply at least the following services if they depend upon an electrical source for their operation:

a) for half an hour:

- 1) the lighting required by [2.2.3] (b1) and Pt C, Ch 2, Sec 3, [3.6.7] (a)
- 2) all services required by [2.2.3] (c1, 3 and 4) unless such services have an independent supply for the period specified from an accumulator battery suitably located for use in an emergency

b) it is also to supply power to close the watertight doors as required by Regulation II-1/13.7.3.3, but not necessarily all of them simultaneously, unless an independent temporary source of stored energy is provided. Power to the control, indication and alarm circuits as required by Regulation II-1/13.7.2, for half an hour.

## **2.3 Low-location lighting**

**2.3.1** Passenger ships are to be provided with a low-location lighting (LLL) system in accordance with Pt C, Ch 4, Sec 8, [2.2.3].

Where LLL is satisfied by electric illumination, it is to comply with the following requirements.

**2.3.2** The LLL system is to be connected to the emergency switchboard and is to be capable of being powered either by the main source of electrical power, or by the emergency source of electrical power for a minimum period of 60 minutes after energising in an emergency.

**2.3.3** The power supply arrangements to the LLL are to be arranged so that a single fault or a fire in any one fire zone or deck does not result in loss of the lighting in any other zone or deck. This requirement may be satisfied by the power supply circuit configuration, use of fire-resistant cables complying with IEC Publication 60331: Fire characteristics of electrical cables, and/or the provision of suitably located power supply units having integral batteries adequately rated to supply the connected LLL for a minimum period of 60 minutes.

**2.3.4** Single lights and lighting assemblies are to be designed or arranged so that any single fault or failure in a light or lighting assembly, other than a short-circuit, will not result in a break in visible delineation exceeding 1 metre.

**2.3.5** Light and lighting assemblies are to be flame-retardant as a minimum, to have an ingress protection of at least IP55 and to meet the type test requirements as specified in Pt C, Ch 3, Sec 6, Tab 1.

**2.3.6** The LLL system is to be capable of being manually activated by a single action from the continuously manned central control station. It may, additionally, be continuously operating or be switched on automatically, e.g. by the presence of smoke within the space(s) being served.

**2.3.7** When powered, the systems are to achieve the following minimum luminance:

- for any planar source: 10 cd/m<sup>2</sup> from the active parts in a continuous line of 15 mm minimum width
- for any point source: 35 mcd in the typical track directions of approach and viewing which is to be considered:
  - for sources which are required to be viewed from a horizontal position, i.e. deck mounted or horizontally bulkhead mounted fittings, within a 60° cone having its centre located 30° from the horizontal mounting surface of the point source and in line with the track direction, see Fig 1
  - for sources which are required to be viewed vertically, i.e. the vertical LLL marking up to the door handles, within a 60° cone having its centre located perpendicular to the mounting service of the point source, see Fig 2.

Spacing between sources is not to exceed 300 mm.

**2.3.8** The lights or lighting assemblies are to be continuous except as interrupted by constructional constraints, such as corridors or cabin doors etc., are to provide a visible delineation along the escape route and, where applicable, are to lead to the exit door handles. Interruption of the LLL system due to constructional constraints is not to exceed 2 metres.

**2.3.9** The lighting is to be provided on at least one side of the corridor or stairway. In corridors and stairways in excess of 2 metres width, lighting is to be provided on both sides.

**2.3.10** In corridors the lighting is to be installed either on the bulkhead within 300 mm of the deck or, alternatively, on the deck within 150 mm of the bulkhead.

**2.3.11** In stairways the lighting is to be installed within 300 mm above the steps such that each step may be readily identified from either above or below that step. The top and bottom steps are to be further identified to show that there are no further steps.

Figure 1 :

Figure 2 :

### 3 General emergency alarm and public address systems

#### 3.1 General emergency alarm system

**3.1.1** An electrically operated bell or klaxon or other equivalent warning system installed in addition to the ship's whistle or siren for sounding the general emergency alarm signal is to comply with the following requirements.

**3.1.2** The general emergency alarm system is to be supplemented by either a public address system complying with the requirements in [3.2] or other suitable means of communication.

**3.1.3** The entertainment sound system is to be automatically turned off when the general alarm system is activated.

**3.1.4** The system is to be continuously powered and is to have an automatic change-over to a standby power supply in case of loss of the normal power supply.

An alarm is to be given in the event of failure of the normal power supply.

**3.1.5** The system is to be powered by means of two circuits, one from the ship's main supply and the other from the emergency source of electrical power required by [2.1] and [2.2].

**3.1.6** The system is to be capable of operation from the navigation bridge and, except for the ship's whistle, also from other strategic points.

Note 1: Other strategic points are taken to mean those locations, other than the navigation bridge, from where emergency situations are intended to be controlled and the general alarm system can be activated. A fire control station or a cargo control station is normally to be regarded as strategic points.

**3.1.7** The alarm is to continue to function after it has been triggered until it is manually turned off or is temporarily interrupted by a message on the public address system.

**3.1.8** The alarm system is to be audible throughout all the accommodation and normal crew working spaces and on all open decks.

**3.1.9** The minimum sound pressure level for the emergency alarm tone in interior and exterior spaces is to be 80 dB (A) and at least 10 dB (A) above ambient noise levels existing during normal equipment operation with the ship underway in moderate weather.

**3.1.10** In cabins without a loudspeaker installation, an electronic alarm transducer, e.g. a buzzer or similar, is to be installed.

**3.1.11** The sound pressure level at the sleeping position in cabins and in cabin bathrooms is to be at least 75 dB (A) and at least 10 dB (A) above ambient noise levels.

**3.1.12** For cables used for the general emergency alarm system, see Pt C, Ch 2, Sec 3, [9.6.1], Pt C, Ch 2, Sec 11, [5.2.1] and Pt C, Ch 2, Sec 11, [5.2.5].

**3.1.13** Electrical cables and apparatus for the general emergency alarm system and their power supply are to be arranged so that the loss of the system in any one area due to localised fire is minimised.

**3.1.14** Where the fire alarm to summon the crew operated from the navigating bridge or fire control station is part of the ship's general alarm system, it is to be capable of being sounded independently of the alarm in the passenger spaces.

## **3.2 Public address system**

**3.2.1** The public address system is to be one complete system consisting of a loudspeaker installation which enables simultaneous broadcast of messages from the navigation bridge, and at least one other location on board for use when the navigation bridge has been rendered unavailable due to the emergency, to all spaces where crew members or passengers, or both, are normally present (accommodation and service spaces and control stations and open decks), and to assembly stations (i.e. muster stations).

In spaces such as under deck passageways, bosun's locker, hospital and pump room, the public address system may not be required.

**3.2.2** The public address system is to be arranged to operate on the main source of electrical power, the emergency source of electrical power and transitional sources of electrical power as required by Pt C, Ch 2, Sec 3, [2.3] and Pt C, Ch 2, Sec 3, [3.6].

**3.2.3** The controls of the system on the navigation bridge are to be capable of interrupting any broadcast on the system from any other location on board.

**3.2.4** Where an individual loudspeaker has a device for local silencing, an override arrangement from the control station(s), including the navigating bridge, is to be in place.

**3.2.5** The system is not to require any action by the addressee.

**3.2.6** It is to be possible to address crew accommodation and work spaces separately from passenger spaces.

**3.2.7** In addition to any function provided for routine use aboard the ship, the system is to have an emergency function control at each control station which:

- a) is clearly indicated as the emergency function
- b) is protected against unauthorised use
- c) automatically overrides any other input system or program, and
- d) automatically overrides all volume controls and on/off controls so that the required volume for the emergency mode is achieved in all spaces.

**3.2.8** The system is to be installed with regard to acoustically marginal conditions, so that emergency announcements are clearly audible above ambient noise in all spaces where crew members or passengers, or both, are normally present (accommodation and service spaces and control stations and open decks), and at assembly stations (i.e. muster stations).

**3.2.9** With the ship underway in normal conditions, the minimum sound pressure level for broadcasting emergency announcements is to be:

- a) in interior spaces 75 dB (A) and at least 20 dB (A) above the speech interference level, and
- b) in exterior spaces 80 dB (A) and at least 15 dB (A) above the speech interference level.

Evidence of this level is to be shown with test result in open sea or equivalent quay measurement with appropriate correction factor.

**3.2.10** The system is to be arranged to prevent feed-back or other interference.

**3.2.11** The system is to be arranged to minimise the effect of a single failure so that the emergency messages are still audible (above ambient noise levels) also in the event of failure of any one circuit or component.

**3.2.12** Each loudspeaker is to be individually protected against short-circuits.

**3.2.13** For cables used for the public address system, see Pt C, Ch 2, Sec 3, [9.6.1], Pt C, Ch 2, Sec 11, [5.2.1] and Pt C, Ch 2, Sec 11, [5.2.5].

**3.2.14** All areas of each fire zone are to be served by at least two dedicated loops of flame-retardant cables which are to be sufficiently separated throughout their length and supplied by two separate and independent amplifiers.

**3.2.15** A temperature alarm is to be provided in the public address cabinets in case of forced air cooling.

### **3.3 Combined general emergency alarm - public address system**

**3.3.1** Where the public address system is the only means for sounding the general emergency alarm signal and the fire alarm, in addition to the requirements of [3.1] and [3.2], the following are to be satisfied:

- the system automatically overrides any other input system when an emergency alarm is required.
- the system automatically overrides any volume control provided to give the required output for the emergency mode when an emergency alarm is required.
- the system is arranged to minimise the effect of a single failure so that the alarm signal is still audible (above ambient noise levels) also in the event of failure of any one circuit or component, by means of the use of more than one device for generating an electronic sound signal.

## **4 Installation**

### **4.1 Section and distribution boards**

**4.1.1** Cubicles and cupboards in areas which are accessible to any passenger are to be lockable.

## **5 Type approved components**

### **5.1**

**5.1.1** Components for Low-Location Lighting systems (LLL) in passenger ship escape routes are to be type approved or in accordance with [5.1.2].

**5.1.2** Case-by-case approval based on submission of adequate documentation and execution of tests may also be granted at the discretion of the Society.

# Appendix 1 Calculation Method for Cross-Flooding Arrangements

## 1 Calculation method for cross-flooding arrangements

### 1.1 Definitions

#### 1.1.1 Definitions

$\Sigma k$  : Sum of friction coefficients in the considered cross-flooding arrangement

$S$  : Cross-section area, in  $m^2$ , of the cross-flooding pipe or duct. If the cross-section area is not circular, then:

$$S_{\text{equiv}} = \frac{\pi D_{\text{equiv}}^2}{4}$$

where:

$$D_{\text{equiv}} = \frac{4A}{p}$$

$A$  : actual cross-section area

$p$  : actual cross-section perimeter

$\theta_0$  : Angle, in degree, before commencement of cross-flooding. This assumes that the cross-flooding device is fully flooded but that no water has entered into the equalizing compartment on the opposite side of the damage

$\theta_f$  : Heel angle, in degree, at final equilibrium  
 $\theta_f \leq \theta$

$\theta$  : Any angle of heel between the commencement of cross-flooding and the final equilibrium at a given time

$W_f$  : Volume, in  $m^3$ , of water which is used to bring the ship from commencement of cross-flooding  $\theta_0$  to final equilibrium  $\theta_f$

$W_\theta$  : Volume, in  $m^3$ , of water which is used to bring the ship from any angle of heel  $\theta$  to the final equilibrium  $\theta_f$

$H_0$  : Head of water, in m, before commencement of cross-flooding, with the same assumption as for  $\theta_0$

$H_\theta$  : Head of water, in m, when any angle of heel  $\theta$  is achieved

$h_f$  : Final head of water, in m, after cross-flooding

( $h_f = 0$ , when the level inside the equalizing compartment is equal to the free level of the sea).

### 1.2 Cross-flooding area

#### 1.2.1 Cross-flooding area calculation

The cross-flooding area  $S$ , in  $m^2$ , can be calculated from the following formula:

$$S = \frac{2W_f}{T_f F} \cdot \frac{\left(1 - \sqrt{\frac{h_f}{H_0}}\right)}{\sqrt{2gH_0}} \cdot \frac{1}{\left(1 - \frac{h_f}{H_0}\right)}$$

#### 1.2.2 Calculation of time

$T_f$  : Time required from commencement of cross flooding  $\theta_0$  to the final equilibrium  $\theta_f$

$T_\theta$  : Time required to bring the ship from any angle of heel  $\theta$  to the final equilibrium  $\theta_f$

$$T_\theta = \frac{2W_\theta}{S \cdot F} \cdot \frac{\left(1 - \sqrt{\frac{h_f}{H_\theta}}\right)}{\sqrt{2gH_\theta}} \cdot \frac{1}{\left(1 - \frac{h_f}{H_\theta}\right)}$$

$T$  : Time required from commencement of cross flooding  $\theta_0$  until any angle of heel  $\theta$  is achieved:

$$T = T_f - T_\theta$$

#### 1.2.3 Dimensionless factor F

The dimensionless factor of reduction of speed through an equalization device, being a function of bends, valves, etc., in the cross-flooding system is to be calculated as follows:

$$F = \frac{1}{\sqrt{\sum k}}$$

where *F* is not to be taken as more than 1.

Values for *k* can be obtained from [1.2.4] or other appropriate sources.

**1.2.4 Factor of reduction k**

The factor of reduction is to be calculated depending on the following cases:

- Case 1: 90° circular bend
- Case 2: radius bend R/D = 2
- Case 3: mitre bend
- Case 4: 90° double mitre bend
- Case 5: pipe inlet
- Case 6: pipe outlet
- Case 7: non-return valve
- Case 8: pipe friction losses
- Case 9: gate valve
- Case 10: butterfly valve
- Case 11: disc valve.

Case 1: 90° CIRCULAR BEND (see Fig 1)

The factor *k* is defined in Tab 1.

**Figure 1 : 90° CIRCULAR BEND**

**Table 1 : Values of factor k**

R/D	2	3	4	5	6	7
k	.30	.26	.23	.20	.18	.17

Case 2: RADIUS BEND R/D = 2 (see Fig 2)

The factor *k* is defined in Tab 2.

**Figure 2 : RADIUS BEND R/D = 2**

**Table 2 : Values of factor k**

α°	15	30	45	60	75	90
k	.06	.12	.18	.24	.27	.30

Case 3: MITRE BEND (see Fig 3)

The factor *k* is defined in Tab 3.

**Figure 3 : MITRE BEND**

**Table 3 : Values of factor k**

$\alpha^\circ$	5	15	30	45	60	90
k	.02	.06	.17	.32	.68	1.26

Case 4: 90°DOUBLE MITRE BEND (see Fig 4)  
The factor k is defined in Tab 4.

**Figure 4 : 90° DOUBLE MITRE BEND**

**Table 4 : Values of factor k**

L/D	1	2	3	4	5	6
k	.41	.40	.43	.46	.46	.44

Case 5: PIPE INLET (see Fig 5)  
The factor k is defined in Tab 5.

**Figure 5 : PIPE INLET**

**Table 5 : Values of factor k**

t/D	.01	.02	.03	.04	.05	$\geq .05$
k	.83	.68	.53	.46	.44	.43

Case 6: PIPE OUTLET (see Fig 6)  
k = 1.0

**Figure 6 : PIPE OUTLET**

Case 7: NON-RETURN VALVE (see Fig 7)

$k = 0.5$

The value of  $k$  actually increases with decrease in Froude number, particularly below speeds of 2m/sec.

**Figure 7 : NON-RETURN VALVE**

Case 8: PIPE FRICTION LOSSES

The coefficient above is a mean value and does in fact vary as Reynold's number (i.e. varies with  $V$  for constant  $D$  and  $\nu$ ) as well as with relative roughness.

$k = 0.02/D$  per unit length

Case 9: GATE VALVE (see Fig 8)

$k = 0.3$

**Figure 8 : GATE VALVE**

Case 10: BUTTERFLY VALVE (see Fig 9)

$k = 0.8$

**Figure 9 : BUTTERFLY VALVE**

Case 11: DISC VALVE (see Fig 10)

$k = 6.0$

**Figure 10 : DISC VALVE**

**1.2.5 Cross-flooding through successive devices**

If the same flow crosses successive flooding devices of cross-section  $S_1, S_2, S_3, \dots$  having corresponding friction coefficients  $k_1, k_2, k_3, \dots$ , then the total  $k$  coefficient referred to  $S_1$  is:

$$\sum k = k_1 + k_2 \frac{S_1^2}{S_2^2} + k_3 \frac{S_1^2}{S_3^2} \dots$$

**1.2.6 Different flooding devices not crossed by the same volume**

If different flooding devices are not crossed by the same volume, each  $k$  coefficient is to be multiplied by the square of the ratio of the volume crossing the device and the volume crossing the reference section (which will be used for the time calculation):

$$\sum k = k_1 + k_2 \frac{S_1^2}{S_2^2} \cdot \frac{W_2^2}{W_1^2} + k_3 \frac{S_1^2}{S_3^2} \cdot \frac{W_3^2}{W_1^2} \dots$$

### 1.2.7 Cross flooding through devices in parallel

For cross-flooding through devices in parallel that lead to the same space, equalisation time is to be calculated assuming that:

$$SF = S_1F_1 + S_2F_2 + \dots$$

with:

$$F = \frac{1}{\sqrt{\sum k}}$$

for each device of cross section  $S_i$ .

### 1.2.8 Air pipe venting criteria

In arrangements where the total air pipe sectional area is 10% or more of the cross-flooding sectional area, the restrictive effect of any air back pressure may be neglected in the cross-flooding calculations. The air pipe sectional area is to be taken as the minimum or the net sectional area of any automatic closing devices, if that is less.

In arrangements where the total air pipe sectional area is less than 10% of the cross-flooding sectional area, the restrictive effect of air back pressure is to be considered in the cross-flooding calculations. The following method may be used for this purpose:

The  $k$  coefficient used in the calculation of cross-flooding time is to take into account the drop of head in the air pipe. This can be done using an equivalent coefficient  $k_e$ , which is calculated according to the following formula:

$$k_e = k_w + k_a \frac{\rho_a}{\rho_w} \cdot \left(\frac{S_w}{S_a}\right)^2$$

where:

$k_w$  :  $k$  coefficient for the cross-flooding arrangement (water)

$k_a$  :  $k$  coefficient for the air pipe

$\rho_a$  : Air density

$\rho_w$  : Water density

$S_w$  : Cross-section area of the cross-flooding device (water)

$S_a$  : Cross-section of air pipe

### 1.2.9 Alternatives

As an alternative to the provisions above, and for arrangements other than those shown in [1.2.4], direct calculation using computational fluid dynamics (CFD), time-domain simulations or model testing may also be used.

### 1.2.10 Examples

- Cross-flooding through a series of structural ducts with 1 manhole (see Fig 11 and Fig 12)

- if  $0 < L_i < 1$ :

$$k = 0,2748 L_i + 0,0313$$

- if  $1 \leq L_i \leq 4$ :

$$k = -0,0986 L_i^3 + 0,6873 L_i^2 - 1,0212 L_i + 0,7386$$

- if  $L_i > 4$ :

$$k = 1,34$$

- Cross-flooding through a series of structural ducts with 2 manholes (see Fig 13)

- if  $0 < L_i < 1$ :

$$k = 0,4045 L_i + 0,0627$$

- if  $1 \leq L_i \leq 4$ :

$$k = 0,0424 L_i^3 + 0,3593 L_i^2 - 1,1401 L_i - 0,356$$

- if  $L_i > 4$ :

$$k = 1,17$$

Note 1:  $k$  is the friction coefficient related to each space between two adjacent girders.  $k$  is evaluated with effective cross-section area therefore in calculations use the real cross-section area  $A$  and not  $S_{equiv}$ . The pressure loss for entrance in the first manhole is already computed in the calculation, and  $k = 1$  has to be added to take into account the outlet losses.

# Part D

## Service Notations

---

## CHAPTER 12

# RO-RO PASSENGER SHIPS

---

Section 1	General
Section 2	Ship Arrangement
Section 3	Hull and Stability
Section 4	Electrical Installations

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **ro-ro passenger ship**, as defined in Pt A, Ch 1, Sec 2, [4.5.3].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**1.1.3** For ships having to comply with the provisions of SOLAS Ch II-1 reg 8-1 and SOLAS Ch II-2 reg 21 and 22, the service notation **ro-ro passenger ship** is to be completed by the additional service feature **SRTP** according to requirements of NR598 Implementation of Safe Return to Port and Orderly Evacuation.

**1.1.4** Additional guidance for arrangement and structural assessment is provided in NI640 Structural Assessment of Passenger Ships.

**Table 1 : Applicable requirements**

Item		Ships having the navigation notation <b>unrestricted navigation</b>	Ships having a navigation notation other than <b>unrestricted navigation</b>

# Section 2 Ship Arrangement

## 1 General

### 1.1 Definitions

#### 1.1.1 Deepest subdivision load line

*Deepest subdivision load line is the waterline which corresponds to the summer load line of the ship.*

#### 1.1.2 Ro-ro cargo spaces

*Ro-ro cargo spaces are spaces not normally subdivided in any way and normally extending to either a substantial length or the entire length of the ship in which motor vehicles with fuel in their tanks for their own propulsion and/or goods (packaged or in bulk, in or on rail or road cars, vehicles, including road or rail tankers, trailers, containers, pallets, demountable tanks or in or on similar stowage units or other receptacles) can be loaded and unloaded normally in a horizontal direction.*

#### 1.1.3 Special category spaces

*Special category spaces are those enclosed vehicle spaces above and below the bulkhead deck, into and from which vehicles can be driven and to which passengers have access. Special category spaces may be accommodated on more than one deck provided that the total overall clear height for vehicles does not exceed 10 m.*

## 2 General arrangement design

### 2.1 Number and disposition of transverse watertight bulkheads

**2.1.1** Where there are less transverse bulkheads than those specified in Pt B, Ch 2, Sec 1, [2.1] or where the distance between them is considered excessive by the Society, ships are to be fitted with a system of partial bulkheads, side transverse frames and deck transverses such as to provide equivalent transverse strength.

### 2.2 Openings in watertight boundaries below the bulkhead deck

#### 2.2.1 Openings in machinery spaces

*Not more than one door apart from the doors to shaft tunnels may be fitted in each watertight bulkhead within spaces containing the main and auxiliary propulsion machinery including boilers serving the needs of propulsion. Where two or more shafts are fitted the tunnels are to be connected by an inter-communicating passage. Only one door is to be provided between the machinery space and the tunnel spaces where two shafts are fitted and only two doors where there are more than two shafts. All these doors are to be of the sliding type and are to be so located as to have their sills as high as practicable. The hand gear for operating these doors from above the bulkhead deck is to be situated outside the spaces containing the machinery.*

*Portable plates on bulkheads are not permitted except in machinery spaces. The Society may permit not more than one power-operated sliding watertight door larger than 1,20 m to be substituted for these portable plates in each watertight bulkhead, provided these doors are intended to remain closed during navigation except in the case of urgent necessity at the discretion of the master. These doors need not meet the requirements of [2.3.3] e) regarding complete closure by hand-operated gear in 90 seconds.*

#### 2.2.2 Openings in cargo spaces

*Watertight doors complying with the requirements of [2.3.1] may be fitted in watertight bulkheads dividing cargo spaces on 'tween decks. Such doors may be hinged, rolling or sliding doors but are not to be remotely controlled. They are to be fitted at the highest level and as far from the shell plating as practicable, but in no case are the outboard vertical edges to be situated at a distance from the shell plating which is less than one fifth of the breadth of the ship, such distance being measured at right angles to the centreline at the level of the deepest subdivision load line.*

*The doors accessible during the voyage are to be fitted with a device which prevents unauthorised opening. When it is proposed to fit such doors, the number and arrangements are to receive the special consideration of the Society.*

#### 2.2.3 Openings in ships carrying goods vehicles and accompanying personnel

*This requirement applies to passenger ships designed or adapted for the carriage of goods vehicles and accompanying personnel where the total number of persons on board, other than passengers as defined in Pt A, Ch 1, Sec 2, [4.5.2], exceeds 12.*

*If in such a ship the total number of passengers which include personnel accompanying vehicles does not exceed:*

$$N = 12 + \frac{A}{25}$$

where:

*N* : The maximum number of passengers for which the ship is certified

*A* : The total deck area, in m<sup>2</sup>, of spaces available for the stowage of goods vehicles,

and where the clear height at the stowage position and at the entrance to such spaces is not less than 4 m, the provisions of [2.2.2] in respect of watertight doors apply except that the doors may be fitted at any level in watertight bulkheads dividing cargo spaces.

Additionally, indicators are required on the navigating bridge to show automatically when each door is closed and all door fastenings are secured.

#### **2.2.4 Trunks and tunnels**

Where trunkways or tunnels for access from crew accommodation to the machinery space, for piping, or for any other purpose are carried through watertight bulkheads, they are to be watertight and in accordance with the requirements of Pt B, Ch 4, Sec 5, [10.5]. The access to at least one end of each such tunnel or trunkway, if used as a passage at sea, is to be through a trunk extending watertight to a height sufficient to permit access above the bulkhead deck. The access to the other end of the trunkway or tunnel may be through a watertight door. Such trunkways or tunnels are not to extend through the first subdivision bulkhead abaft the collision bulkhead.

Where trunkways in connection with refrigerated cargo and ventilation or forced draught trunks are carried through more than one watertight bulkhead, the means of closure at such openings are to be operated by power and be capable of being closed from a central position situated above the bulkhead deck.

Where a ventilation trunk passing through a structure penetrates a watertight area of the bulkhead deck, the trunk is to be capable of withstanding the water pressure that may be present within the trunk, after having taken into account the maximum heel angle during flooding, in accordance with Ch 12, Sec 3, [2.3.5].

#### **2.2.5 Additional requirements**

In addition to [2.2.1], [2.2.2], [2.2.3], and [2.2.4], the requirements reported in [2.3.3] are to be complied with.

### **2.3 Doors**

#### **2.3.1 Requirements for doors**

The requirements relevant to the operating systems for doors complying with the prescriptions in [2.3.2] and [2.3.3] are specified in Tab 1 for doors of internal watertight bulkheads and Tab 2 for doors of external watertight boundaries below equilibrium or intermediate waterplane.

#### **2.3.2 Construction of watertight doors**

The design, materials and construction of all watertight doors are to be to the satisfaction of the Society.

Such doors are to be suitably marked to ensure that they may be properly used to provide maximum safety.

The frames of vertical watertight doors are to have no groove at the bottom in which dirt might lodge and prevent the door closing properly.

#### **2.3.3 Doors in watertight bulkheads below the bulkhead deck**

- a) Watertight doors, except as provided in [2.2.2] paragraph 1 and [2.2.3], are to be power operated sliding doors complying with the requirements of items e) to l)
- b) The means of operation whether by power or by hand of any power-operated sliding watertight door are to be capable of closing the door with the ship listed to 15° either way. Consideration is to also be given to the forces which may act on either side of the door as may be experienced when water is flowing through the opening applying a static head equivalent to a water height of at least 1 m above the sill on the centreline of the door.
- c) Watertight door controls, including hydraulic piping and electrical cables, are to be kept as close as practicable to the bulkhead in which the doors are fitted, in order to minimise the likelihood of them being involved in any damage which the ship may sustain. The positioning of watertight doors and their controls are to be such that if the ship sustains damage within one fifth of the breadth of the ship, such distance being measured at right angles to the centreline at the level of the deepest subdivision load line, the operation of the watertight doors clear of the damaged portion of the ship is not impaired.
- d) Each power-operated sliding watertight door:
  - is to move vertically or horizontally;
  - is to be normally limited to a maximum clear opening width of 1,20 m. The Society may permit larger doors only to the extent considered necessary for the effective operation of the ship provided that other safety measures, including the following, are taken into consideration:
    - special consideration is to be given to the strength of the door and its closing appliances in order to prevent leakages;
    - the door is to be located outside the damage zone B/5;
  - is to be fitted with the necessary equipment to open and close the door using electrical power, hydraulic power, or any other form of power that is acceptable to the Society;

- is to be provided with an individual hand-operated mechanism. It is to be possible to open and close the door by hand at the door itself from either side and, in addition, close the door from an accessible position above the bulkhead deck with an all round crank motion or some other movement providing the same degree of safety acceptable to the Society. Direction of rotation or other movement is to be clearly indicated at all operating positions. The time necessary for the complete closure of the door, when operating by hand gear, may not exceed 90 s with the ship in the upright position. Visual indicators to show whether the door is open or closed are to be provided at the accessible position above the bulkhead deck.
  - is to be provided with controls for opening and closing the door by power from both sides of the door and also for closing the door by power from the central operating console required in item m);
  - is to be provided with an audible alarm, distinct from any other alarm in the area, which is to sound whenever the door is closed remotely by power and which is to sound for at least 5 s but no more than 10 s before the door begins to move and is to continue sounding until the door is completely closed. In the case of remote hand operation it is sufficient for the audible alarm to sound only when the door is moving. Additionally, in passenger areas and areas of high ambient noise, the Society may require the audible alarm to be supplemented by an intermittent visual signal at the door;
  - is to have an approximately uniform rate of closure under power. The closure time, from the time the door begins to move to the time it reaches the completely closed position, is to in no case be less than 20 s or more than 40 s with the ship in the upright position.
- e) The electrical power required for power-operated sliding watertight doors is to be supplied from the emergency switchboard either directly or by a dedicated distribution board situated above the bulkhead deck. The associated control, indication and alarm circuits are to be supplied from the emergency switchboard either directly or by a dedicated distribution board situated above the bulkhead deck and be capable of being automatically supplied by a transitional source of emergency electrical power in the event of failure of either the main or emergency source of electrical power.

The transitional source of emergency electrical power is to consist of an accumulator battery suitably located for use in an emergency which is to operate without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage and be of sufficient capacity and so arranged as to supply power automatically, in the event of failure of either the main or emergency source of electrical power, to control, indication and alarm circuits at least for half an hour.

- f) Power-operated sliding watertight doors are to have either:
- a centralised hydraulic system with two independent power sources each consisting of a motor and pump capable of simultaneously closing all doors. In addition, there are to be for the whole installation hydraulic accumulators of sufficient capacity to operate all the doors at least three times, i.e. closed-open-closed, against an adverse list of 15°. This operating cycle is to be capable of being carried out when the accumulator is at the pump cut-in pressure. The fluid used is to be chosen considering the temperatures liable to be encountered by the installation during its service. The power operating system is to be designed to minimise the possibility of having a single failure in the hydraulic piping adversely affect the operation of more than one door. The hydraulic system is to be provided with a low-level alarm for hydraulic fluid reservoirs serving the power-operated system and a low gas pressure group alarm or other effective means of monitoring loss of stored energy in hydraulic accumulators. These alarms are to be audible and visual and are to be situated on the central operating console at the navigating bridge; or
  - an independent hydraulic system for each door with each power source consisting of a motor or pump capable of opening and closing the door. In addition, there is to be a hydraulic accumulator of sufficient capacity to operate the door at least three times, i.e. closed-open-closed, against an adverse list of 15°. This operating cycle is to be capable of being carried out when the accumulator is at the pump cut-in pressure. The fluid used is to be chosen considering the temperatures liable to be encountered by the installation during its service. A low gas pressure group alarm or other effective means of monitoring loss of stored energy in hydraulic accumulators is to be provided at the central operating console required in item n). Loss of stored energy indication at each local operating position is to also be provided; or
  - an independent electrical system and motor for each door with each power source consisting of a motor capable of opening and closing the door. The power source is to be capable of being automatically supplied by the transitional source of emergency electrical power in the event of failure of either the main or emergency source of electrical power and with sufficient capacity to operate the door at least three times, i.e. closed-open-closed, against an adverse list of 15°.

The transitional source of emergency electrical power is to consist of an accumulator battery suitably located for use in an emergency which is to operate without recharging while maintaining the voltage of the battery throughout the discharge period within 12% above or below its nominal voltage and be of sufficient capacity and so arranged as to supply power automatically, in the event of failure of either the main or emergency source of electrical power, to watertight doors, but not necessarily all of them simultaneously, unless an independent source of stored energy is provided.

For the systems specified above, provision is to be made as follows:

Power systems for power-operated watertight sliding doors are to be separate from any other power system. A single failure in the electrical or hydraulic power-operated systems excluding the hydraulic actuator is not to prevent the hand operation of any door.

- g) Control handles are to be provided at each side of the bulkhead at a minimum height of 1,6 m above the floor and are to be so arranged as to enable persons passing through the doorway to hold both handles in the open position without being able to set the power closing mechanism in operation accidentally. The direction of movement of the handles in opening and closing the door is to be in the direction of door movement and is to be clearly indicated.
- h) As far as practicable, electrical equipment and components for watertight doors are to be situated above the bulkhead deck and outside hazardous areas and spaces.
- i) The enclosures of electrical components necessarily situated below the bulkhead deck are to provide suitable protection against the ingress of water.
- j) Electric power, control, indication and alarm circuits are to be protected against faults in such a way that a failure in one door circuit is not to cause a failure in any other door circuit. Short-circuits or other faults in the alarm or indicator circuits of a door are not to result in a loss of power operation of that door. Arrangements are to be such that leakage of water into the electrical equipment located below the bulkhead deck is not to cause the door to open.
- k) A single electrical failure in the power operating or control system of a power-operated sliding watertight door is not to result in a closed door opening. Availability of the power supply is to be continuously monitored at a point in the electric circuit as near as practicable to each of the motors required in g). Loss of any such power supply is to activate an audible and visual alarm at the central operating console required in item m).
- l) Failure of the normal power supply of the required alarms are to be indicated by an audible and visual alarm at the central operating console required in item m).
- m) A central operating console for all power-operated sliding watertight doors is to be located in the safety centre in accordance with Pt C, Ch 4, Sec 14. If the safety centre is located in a separate space adjacent to the navigation bridge, a central operating console is also to be located on the navigation bridge.

The central operating console is to have a "master mode" switch with two modes of control:

- a "local control" mode which is to allow any door to be locally opened and locally closed after use without automatic closure, and
- a "doors closed" mode which is to automatically close any door that is open in not more than 60 s with the ship in an upright position. The "doors closed" mode is to permit doors to be opened locally and is to automatically reclose the doors upon release of the local control mechanism.

The "master mode" switch is to normally be in the "local control" mode. The "doors closed" mode is to only be used in an emergency or for testing purposes.

- n) The central operating console is to be provided with a diagram showing the location of each power-operated sliding watertight door, with visual indicators to show whether each door is open or closed. A red light is to indicate a door is fully open and a green light is to indicate a door is fully closed. When the door is closed remotely the red light is to indicate the intermediate position by flashing. The indicating circuit is to be independent of the control circuit for each door. Indication is also to be provided to the onboard stability computer, if installed.
- o) It is not to be possible to remotely open any door from the central operating console.
- p) All watertight doors are to be kept closed during navigation. Certain watertight doors may be permitted to remain open during navigation only if considered absolutely necessary; that is, being open is determined essential to the safe and effective operation of the ship's machinery or to permit passengers normally unrestricted access throughout the passenger area. Such determination is to be made by the Society only after careful consideration of the impact on ship operations and survivability. A watertight door permitted to remain thus open is to be clearly indicated in the ship's stability information and the damage control documentation and is always to be ready for immediate closure.
- q) All watertight doors, including sliding doors, operated by hydraulic door actuators, either a central hydraulic unit or an independent hydraulic unit for each door is to be provided with a low fluid level alarm or low gas pressure alarm, as applicable or some other means of monitoring loss of stored energy in the hydraulic accumulators. This alarm is to be both audible and visible and is to be located on the central operating console required in item n).
- r) Signboard/instructions are to be placed in way of the door advising how to act when the door closed.

#### **2.3.4 Doors in bulkheads above the bulkhead deck**

##### **a) General**

Doors are to be capable of being opened and closed by hand locally from both sides of the doors with the ship listed to 15° to either side.

Position indicators are to be provided on the bridge to show that the doors are open or closed and that the dogs are fully and properly engaged.

Where the doors also serve as fire doors they are to be provided with position indicators at the fire control station and audible alarms as required for fire doors, as well as for weathertight doors. Where two doors are fitted they must be capable of independent operation remotely and from both sides of each door.

b) *Doors normally closed at sea*

*In addition to a), doors not required for frequent access while at sea are to be kept normally closed and may be of either hinged or sliding type.*

*Doors kept normally closed are to have local operation from both sides of the doors and are to be labelled on both sides: "to be kept closed at sea".*

c) *Doors normally open at sea*

*Where fitted in public space for the passage of passengers and crew, the doors may be kept normally open at sea and may be either hinged or sliding type.*

*In addition to a), doors kept normally open at sea are to have local power operation from both sides of the door and remote closing from the bridge. Operation of these doors is to be similar to that specified in Pt C, Ch 4, Sec 5 where, using a "master mode" switch on the bridge, local control can override the remote closing feature after which the door is automatically remotely reclosed upon release of the local control mechanism.*

*Doors kept normally open at sea are to have audible alarms, distinct from any other alarm in the area, which sound whenever the doors are closed remotely. The alarms are to sound for at least 5 s but not more than 10 s before the doors begins to move and continue sounding until the doors are completely closed. In passenger areas and areas of high ambient noise, the audible alarms are to be supplemented by visual signals at both sides of the doors.*

d) *Failure of the normal power supply of the required alarms are to be indicated by an audible and visual alarm.*

e) *The following doors, located above the bulkhead deck, are to be provided with adequate means of closure and locking devices according to a) and b) above and the requirements of Pt B, Ch 11, Sec 8, [4]:*

- *cargo loading doors in the shell or the boundaries of enclosed superstructures,*
- *bow visors fitted in the shell or the boundaries of enclosed superstructures,*
- *cargo loading doors in the collision bulkhead,*
- *weathertight ramps forming an alternative closure to those previously defined.*

f) *All watertight doors, including sliding doors, operated by hydraulic door actuators, either a central hydraulic unit or an independent hydraulic unit for each door is to be provided with a low fluid level alarm or low gas pressure alarm, as applicable or some other means of monitoring loss of stored energy in the hydraulic accumulators. This alarm is to be both audible and visible and is to be located on the central operating console required in item n).*

g) *Signboard/instructions are to be placed in way of the door advising how to act when the door closed.*

### **2.3.5 Watertight doors above the freeboard deck**

The scantlings of the watertight doors above the freeboard deck in ro-ro spaces are to be checked in accordance with the structural requirements of Part B, Chapter 7 for watertight structure in flooded conditions.

## **2.4 Openings in bulkheads above the bulkhead deck**

### **2.4.1 General**

*The internal watertight subdivision arrangements to limit the entry and spread of water above the bulkhead deck is to be in accordance with the design arrangements necessary for compliance with the stability requirements in Part B, Chapter 3. Where pipes, scuppers, electric cables, etc. are carried through internal watertight boundaries that are immersed at any intermediate or final stage of flooding in damage cases that contribute to the attained subdivision index A, arrangements are to be made to ensure their watertight integrity.*

*Doors in internal watertight subdivision arrangements above the bulkhead deck, and also above the worst intermediate or final stage of flooding waterlines, are to be capable of preventing the passage of water when immersed in the required range of positive stability for any damage cases contributing to the attained subdivision index A. These doors may remain open provided they can be remotely closed from the navigation bridge. They are to be always ready to be immediately closed.*

*The coamings of all openings in the exposed weather deck are to be of ample height and strength and are to be provided with efficient means for expeditiously closing them weathertight. Freeing ports, open rails and scuppers are to be fitted as necessary for rapidly cleaning the weather deck of water under all weather conditions.*

*Sidescuttles, gangway, cargo and fuelling ports and other means for closing openings in the shell plating above the bulkhead deck are to be of efficient design and construction and of sufficient strength (see Pt B, Ch 11, Sec 12) having regard to the spaces in which they are fitted and their positions relative to the deepest subdivision load line.*

*Efficient inside deadlights, so arranged that they can be easily and effectively closed and secured watertight, are to be provided for all sidescuttles to spaces below the first deck above the bulkhead deck.*

### **2.4.2 Watertight integrity from the ro-ro deck (bulkhead deck) to spaces below**

*All access from the ro-ro deck that leads to spaces below the bulkhead deck are to have a lowest point which is not less than 2.5 m above the bulkhead deck, unless the access is covered by the provisions of [2.4.3].*

**2.4.3 Vehicle ramps and other accesses**

Where vehicle ramps are installed to give access to spaces below the bulkhead deck, their openings are to be closed weathertight to prevent ingress of water below, and fitted with alarms and open/close indicators on the navigation bridge. The means of closure are to be watertight if the deck is intended as a watertight horizontal boundary for compliance with stability requirements. The Society may permit the fitting of particular accesses to spaces below the bulkhead deck provided they are necessary for the essential working of the ship, e.g. the movement of machinery and stores, subject to such accesses being made watertight, fitted with alarms and open/close indicators on the navigation bridge.

**2.4.4 Open end of air pipes**

Air pipes terminating within a superstructure which are not fitted with watertight means of closure are to be considered as unprotected openings when applying Pt B, Ch 3, App 3, [1.6.11].

**2.4.5 Additional requirements**

In addition to [2.4.1], [2.4.2], [2.4.3] and [2.4.4], the requirements in [2.3.4] are to be complied with.

**Table 1 : Doors in internal watertight bulkheads of ro-ro passenger ships**

Position relative to bulkhead deck	Frequency of use while at sea	Type (1)	Remote closure	Remote indication	Audible or visual alarm	Notice
Below	Used (2)	POS	X	X	X (local)	
	Permanently closed (3) (4)	S, H				X
At or above	Used	POS, POH	X	X	X (local)	
	Used (5)	S, H		X		X
	Used (Doors giving access to below ro-ro deck)	S, H		X	X (remote)	X
	Permanently closed (3) (5)	S, H		X	X (remote)	X

(1) POS : Power operated, sliding or rolling  
 POH : Power operated, hinged  
 S : Sliding or rolling  
 H : Hinged

(2) See SOLAS II-1/22.3 and IMO MSC.1/Circ.1564

(3) Doors are to be fitted with a device which prevents unauthorized opening

(4) Passenger ships which have to comply with [2.2.3] require an indicator on the navigation bridge to show automatically when each door is closed and all doors fastenings are secured.

(5) If hinged, this door is to be of single action type.

**Table 2 : Doors in external watertight boundaries below equilibrium or intermediate waterplane**

Position relative to bulkhead deck	Frequency of use while at sea	Type (1)	Remote closure	Remote indication	Audible or visual alarm	Notice
Below	Permanently closed (2)	S, H				X
At or above	Normally closed (3)	S, H		X		X
	Normally closed (Doors giving access to below ro-ro deck)	S, H		X	X (remote)	X
	Permanently closed (2)	S, H		X	X (remote)	X

(1) S : Sliding or rolling  
 H : Hinged

(2) Doors are to be fitted with a device which prevents unauthorized opening

(3) If hinged, this door is to be of single action type.

**2.5 Integrity of the hull and superstructure, damage prevention and control**

**2.5.1** Indicators are to be provided on the navigation bridge for all shell doors, loading doors and other closing appliances which, if left open or not properly secured, could, in the opinion of the Society, lead to flooding of a special category space or ro-ro cargo space. The indicator system is to be designed on the fail-safe principle and is to show by visual alarms if the door is not fully closed or if any of the securing arrangements are not in place and fully locked and by audible alarms if such door or closing appliances become open or the securing arrangements become unsecured. The indicator panel on the navigation bridge is to be equipped with a mode selection function "harbour/sea voyage" so arranged that an audible alarm is given on the navigation bridge if the ship leaves harbour with the bow doors, inner doors, stern ramp or any other side shell doors not closed or any closing device not in the correct position. The power supply for the indicator system is to be independent of the power supply for operating and securing the doors.

The sensors of the indicator system are to be protected from water, ice formation and mechanical damage.

The indication panel is to be provided with a lamp test function. It is not to be possible to turn off the indicator light.

**2.5.2** *Television surveillance and a water leakage detection system are to be arranged to provide an indication to the navigation bridge and to the engine control station of any leakage through inner and outer bow doors, stern doors or any other shell doors which could lead to flooding of special category spaces or ro-ro cargo spaces.*

**2.5.3** *Special category spaces and ro-ro cargo spaces are to be continuously patrolled or monitored by effective means, such as television surveillance, so that any movement of vehicles in adverse weather conditions and unauthorised access by passengers thereto can be detected during navigation.*

**2.5.4** *Documented operating procedures for closing and securing all shell doors, loading doors and other closing appliances which, if left open or not properly secured, could, in the opinion of the Society, lead to flooding of a special category space or ro-ro cargo space, are to be kept on board and posted at an appropriate place. The operating procedures may be included in the stability information or in the damage control booklet.*

**2.5.5** A closing indicator is to be fitted for the inner bow doors which constitute a prolongation of the collision bulkhead above the bulkhead deck as requested in [2.5.1].

## **2.6 Ballast compartment arrangement**

**2.6.1** *Water ballast is not to, in general, be carried in tanks intended for fuel oil. In ships in which it is not practicable to avoid putting water in fuel oil fuel, oily-water separating equipment to the satisfaction of the Society is to be fitted, or other alternative means, such as discharge to shore facilities, acceptable to the Society is to be provided for disposing of the oily-water ballast (see Pt C, Ch 1, Sec 10, [7]).*

## **2.7 Machinery compartment arrangement**

**2.7.1** When longitudinal bulkheads are fitted in the machinery space, adequate self-operating arrangements are to be provided in order to avoid excessive heel after damage.

Where such arrangements are cross-flooding systems, their area is to be calculated in accordance with the requirements in Ch 11, App 1. In addition, such systems are to comply with the criteria for the maximum time necessary to cross flood according to Ch 12, Sec 3, [2.3.5], item a).

## **2.8 Passenger spaces in ro-ro ships**

**2.8.1** No passenger spaces are permitted within the enclosed ro-ro decks.

# Section 3 Hull and Stability

## 1 General

### 1.1 Documents to be submitted

1.1.1 In addition to the documentation requested in Part B, the following documents are to be submitted:

- operating and maintenance manual (see Pt B, Ch 11, Sec 6 and Pt B, Ch 11, Sec 7) of bow and stern doors and ramps
- plan of design loads on deck as specified in [4.1.1]
- plan of arrangement of motor vehicles, railway cars and/or other types of vehicles which are intended to be carried and indicating securing and load bearing arrangements
- characteristics of motor vehicles, railways cars and/or other types of vehicles which are intended to be carried: (as applicable) axle load, axle spacing, number of wheels per axle, wheel spacing, size of tyre print

## 2 Stability

### 2.1 Definitions

#### 2.1.1 Deepest subdivision draught

The deepest subdivision draught ( $d_s$ ) is the waterline which corresponds to the summer load line draught of the ship.

#### 2.1.2 Light service draught

Light service draught ( $d_L$ ) is the service draught corresponding to the lightest anticipated loading and associated tankage, including, however, such ballast as may be necessary for stability and/or immersion.

#### 2.1.3 Partial subdivision draught

The partial subdivision draught ( $d_p$ ) is the light service draught plus 60% of the difference between the light service draught and the deepest subdivision draught.

#### 2.1.4 Subdivision length $L_s$

The subdivision length  $L_s$  is the greatest projected moulded length of that part of the ship at or below deck or decks limiting the vertical extent of flooding with the ship at the deepest subdivision draught.

#### 2.1.5 Machinery space

Machinery spaces are spaces between the watertight boundaries of a space containing the main and auxiliary propulsion machinery, including boilers, generators and electric motors primarily intended for propulsion. In the case of unusual arrangements, the Society may define the limits of the machinery spaces.

#### 2.1.6 Other definitions

Mid-length is the mid point of the subdivision length of the ship.

Aft terminal is the aft limit of the subdivision length.

Forward terminal is the forward limit of the subdivision length.

Breadth  $B$  is the greatest moulded breadth, in m, of the ship at or below the deepest subdivision draught.

Draught  $d$  is the vertical distance, in m, from the moulded baseline at mid-length to the waterline in question.

Permeability  $\mu$  of a space is the proportion of the immersed volume of that space which can be occupied by water.

### 2.2 Intact stability

#### 2.2.1 General

Every passenger ship regardless of size is to be inclined upon its completion. The lightship displacement and the longitudinal, transverse and vertical position of its centre of gravity shall be determined. The Master is to be supplied with such information satisfactory to the Society as is necessary to enable him by rapid and simple processes to obtain accurate guidance as to the stability of the ship under varying conditions of service. A copy of the stability information is to be furnished to the Society.

Where any alterations are made to a ship so as to materially affect the stability information supplied to the Master, amended stability information is to be provided. If necessary the ship is to be re-inclined.

**2.2.2 Periodical lightweight check**

At periodical intervals not exceeding five years, a lightweight survey is to be carried out on all passenger ships to verify any changes in lightship displacement and longitudinal centre of gravity. The ship is to be re-inclined whenever, in comparison with the approved stability information, a deviation from the lightship displacement exceeding 2% or a deviation of the longitudinal centre of gravity exceeding 1% of L is found, or anticipated.

**2.2.3 Standard requirements**

In addition to Pt B, Ch 3, Sec 2, [2], the requirements in [2.2.4] to [2.2.6] are to be complied with for the loading conditions defined in Pt B, Ch 3, App 2, [1.2.1] and Pt B, Ch 3, App 2, [1.2.9].

**2.2.4 Crowding of passengers**

The angle of heel on account of crowding of passengers to one side as defined below may not exceed 10°:

- a minimum weight of 75 kg is to be assumed for each passenger except that this value may be increased subject to the approval of the Society. In addition, the mass and distribution of the luggage is to be approved by the Society;
- the height of the centre of gravity for passengers is to be assumed equal to:
  - 1,0 m above deck level for passengers standing upright. Account may be taken, if necessary, of camber and sheer of deck; and
  - 0,3 m above the seat in respect of seated passengers.
- passengers and luggage are to be considered to be in the spaces normally at their disposal;
- passengers without luggage are to be considered as distributed to produce the most unfavourable combination of passenger heeling moment and/or initial metacentric height, which may be obtained in practice. In this connection, a value higher than four persons per square metre is not necessary.

**2.2.5 Maximum turning angle**

The angle of heel on account of turning may not exceed 10° when calculated using the following formula:

$$M_R = 0,02 \frac{V_0^2}{L_S} \Delta \left( KG - \frac{T_1}{2} \right)$$

where:

- $M_R$  : Heeling moment, in t.m
- $V_0$  : Service speed, in m/s
- $T_1$  : Mean draught, in m
- $KG$  : Height of centre of gravity above keel, in m.

**2.2.6** Where anti-rolling devices are installed in a ship, the Society is to be satisfied that the above criteria can be maintained when the devices are in operation.

**2.2.7 Stability booklet for ro-ro ships**

The stability booklet of ro-ro ships is to contain information concerning the importance of securing and maintaining all closure watertight integrity, due to the rapid loss of stability which may result when water enters the vehicle deck and the fact capsizing can rapidly occur.

**2.3 Damage stability for ships where SDS notation has been required**

**2.3.1 General**

The requirements of this Section are to be applied to passenger ships in conjunction with the exploratory notes as set out by the IMO Resolution MSC 429(98).

**2.3.2 Required subdivision index R**

The required subdivision index R of a passenger ship according to the total number of persons on board is defined in Tab 1.

These regulations are intended to provide ships with a minimum standard of subdivision. In addition to these requirements, the requirements of [2.3.12] are to be complied with.

**Table 1 : Required subdivision index R**

Total number of persons on board N	R
N < 400	0,722
400 ≤ N ≤ 1350	N / 7580 + 0,66923
1350 < N ≤ 6000	0,0369 Ln (N + 89,048) + 0,579
N > 6000	1 - (852,5 + 0,03875 N) / (N + 5000)

### 2.3.3 Attained subdivision index A

The attained subdivision index A is to be calculated in accordance with Pt B, Ch 3, App 3, [1.4].

The partial indices  $A_s$ ,  $A_p$  and  $A_L$  are not to be less than 0,9 R.

### 2.3.4 Calculation of the factor $p_i$

The factor  $p_i$  is to be calculated in accordance with Pt B, Ch 3, App 3, [1.5].

### 2.3.5 Calculation of the factor $s_i$

The factor  $s_i$  is to be determined for each case of assumed flooding, involving a compartment or group of compartments, in accordance with the following notations and the provisions in this regulation.

$\theta_e$  : The equilibrium heel angle in any stage of flooding, in degrees

$\theta_v$  : The angle, in any stage of flooding, where the righting lever becomes negative, or the angle at which an opening incapable of being closed weathertight becomes submerged

In applying this criterion, openings which are incapable of being closed weathertight include ventilators that have to remain open to supply air to the engine room or emergency generator room for the effective operation of the ship.

$GZ_{max}$  : The maximum positive righting lever, in metres, up to the angle  $\theta_v$

Range : The Range of positive righting levers, in degrees, measured from the angle  $\theta_e$ . The positive range is to be taken up to the angle  $\theta_v$

Flooding stage is any discrete step during the flooding process, including the stage before equalization (if any) until final equilibrium has been reached.

The factor  $s_{i'}$  for any damage case at any initial loading condition,  $d_{i'}$ , shall be obtained from the formula:

$$s_i = \min[s_{intermediate,i}, (s_{final,i} \cdot s_{mom,i})]$$

where:

$s_{intermediate,i}$ : The probability to survive all intermediate flooding stages until the final equilibrium stage, and is calculated in accordance with item a)

$s_{final,i}$  : The probability to survive in the final equilibrium stage of flooding. It is calculated in accordance with item b)

$s_{mom,i}$  : The probability to survive heeling moments, and is calculated in accordance with item c)

a) Calculation of  $s_{intermediate}$ :

The factor  $s_{intermediate,i}$  is to be taken as the least of the  $s$ -factors obtained from all flooding stages including the stage before equalization, if any, and is to be calculated as follows:

$$s_{intermediate,i} = \left[ \frac{GZ_{max}}{0,05} \cdot \frac{Range}{7} \right]^{\frac{1}{4}}$$

where  $GZ_{max}$  is not to be taken as more than 0,05 m and Range as not more than 7°.

$s_{intermediate} = 0$ , if the intermediate heel angle exceeds 15°.

Where cross-flooding fittings are required, the time for equalization is not to exceed 10 min. The time for equalization is to be calculated in accordance with Ch 11, App 1

b) Calculation of  $s_{final}$ :

The factor  $s_{final,i}$  is to be obtained from the formula:

$$s_{final,i} = K \left[ \frac{GZ_{max}}{TGZ_{max}} \cdot \frac{Range}{T_{Range}} \right]^{\frac{1}{4}}$$

where:

$GZ_{max}$  is not to be taken as more than  $TGZ_{max}$

Range is not to be taken as more than  $T_{Range}$

$TGZ_{max}$  is taken equal to:

- $TGZ_{max} = 0,20$  m for ro-ro passenger ships each damage case that involves a ro-ro space
- $TGZ_{max} = 0,12$  m otherwise

$T_{Range}$  is taken equal to:

- $T_{Range} = 20^\circ$  for ro-ro passenger ships each damage case that involves a ro-ro space,
- $T_{Range} = 16^\circ$  otherwise

K is taken equal to:

- $K = 1$  if  $\theta_e \leq \theta_{min}$
- $K = 0$  if  $\theta_e \geq \theta_{max}$

$$K = \sqrt{\frac{\theta_{max} - \theta_e}{\theta_{max} - \theta_{min}}} \quad \text{otherwise}$$

where:

$\theta_{min}$  is equal to 7°

$\theta_{max}$  is equal to 15°.

c) Calculation of  $s_{mom}$ :

The factor  $s_{mom,i}$  is to be calculated at the final equilibrium from the formula:

$$s_{mom,i} = \frac{(GZ_{max} - 0,04) \text{ Displacement}}{M_{heel}}$$

where:

$$s_{mom,i} \leq 1$$

Displacement is the intact displacement at the respective draught ( $d_s, d_p, d_l$ )

$M_{heel}$  is the maximum assumed heeling moment as calculated as follows:

$$M_{heel} = \max[M_{passenger}, M_{wind}, M_{survivalcraft}]$$

where heeling moments  $M_{passenger}$ ,  $M_{wind}$  and  $M_{survivalcraft}$  are calculated in [2.3.11].

### 2.3.6 Equalization arrangements

Unsymmetrical flooding is to be kept to a minimum consistent with the efficient arrangements. Where it is necessary to correct large angles of heel, the means adopted shall, where practicable, be self-acting, but in any case where controls to equalization devices are provided they are to be operable from above the bulkhead deck. These fittings together with their controls are to be acceptable to the Society. Suitable information concerning the use of equalization devices are to be supplied to the master of the ship.

Tanks and compartments taking part in such equalization are to be fitted with air pipes or equivalent means of sufficient cross-section to ensure that the flow of water into the equalization compartments is not delayed.

### 2.3.7 Cases where $s_i$ is to be equal to zero

The factor  $s_i$  is to be taken as zero in those cases where the final waterline, taking into account sinkage, heel and trim, immerses:

- the lower edge of openings through which progressive flooding may take place and such flooding is not accounted for in the calculation of factor  $s_i$ . Such openings are to include air-pipes, ventilators and openings which are closed by means of weathertight doors or hatch covers, but the openings closed by means of watertight manhole covers and flush scuttles, small watertight hatch covers, remotely operated sliding watertight doors, side scuttles of the non-opening type as well as watertight access doors and hatch covers required to be kept closed at sea need not be considered.
- any part of the bulkhead deck considered a horizontal evacuation route.

The factor  $s_i$  is to be taken as zero if, taking into account sinkage, heel and trim, any of the following occur in any intermediate stage or in the final stage of flooding:

- immersion of any vertical escape hatch in the bulkhead deck intended for compliance with the applicable requirements of Pt C, Ch 4, Sec 8
- any controls intended for the operation of watertight doors, equalization devices, valves on piping or on ventilation ducts intended to maintain the integrity of watertight bulkheads from above the bulkhead deck become inaccessible or inoperable
- immersion of any part of piping or ventilation ducts located within the assumed extent of damage and carried through a watertight boundary if this can lead to the progressive flooding of compartment not assumed as flooded.

### 2.3.8 Calculation of the factor $v_i$

Where horizontal watertight boundaries are fitted above the waterline under consideration the  $s$ -value calculated for the lower compartment or group of compartments is to be obtained by multiplying the value as determined in [2.3.5] by the reduction factor  $v_m$  defined below, which represents the probability that the spaces above the horizontal subdivision will not be flooded.

The factor  $v_i$  is to be calculated in accordance with Pt B, Ch 3, App 3, [1.6.10] and Pt B, Ch 3, App 3, [1.6.11].

### 2.3.9 Contribution dA to the index A

The contribution dA to the index A is to be calculated in accordance with Pt B, Ch 3, App 3, [1.6.12].

### 2.3.10 Permeability

For the purpose of the subdivision and damage stability calculations of the regulations, the permeability of each general compartment or part of a compartment is to be according to Tab 2.

Other figures for permeability may be used if substantiated by calculations.

The permeability of the Ro-Ro spaces is to be as per Tab 3.

Table 2 : Values of permeability

Spaces	Permeability
Appropriated to stores	0,60
Occupied by accommodation or voids	0,95
Occupied by machinery	0,85
Intended for liquids	0 or 0,95 <b>(1)</b>
<b>(1)</b> whichever results in the more severe requirements.	

Table 3 : Permeability of Ro-Ro spaces

Permeability at draught:		
$d_s$	$d_p$	$d_L$
0,90	0,90	0,95

### 2.3.11 Inclining moments

The following inclining moments are to be taken into account:

a) *Moment due to the crowding of passengers:*

$M_{passenger}$  is the maximum assumed heeling moment resulting from movement of passengers, and is to be obtained as follows:

$$M_{passenger} = (0,075 N_p) (0,45 B) \text{ (tm)}$$

where:

$N_p$  : Maximum number of passengers permitted to be on board in the service condition corresponding to the deepest subdivision draught under consideration; and

$B$  : Breadth of the ship.

Alternatively, the heeling moment may be calculated assuming the passengers are distributed with 4 persons per square metre on available deck areas towards one side of the ship on the decks where muster stations are located and in such a way that they produce the most adverse heeling moment. In doing so, a weight of 75 kg per passenger is to be assumed.

b) *Moment due to launching of all fully loaded davit-launched survival craft on one side:*

$M_{survivalcraft}$  is the maximum assumed heeling moment due to the launching of all fully loaded davit-launched survival craft on one side of the ship. It shall be calculated using the following assumptions:

- all lifeboats and rescue boats fitted on the side to which the ship has heeled after having sustained damage are to be assumed to be swung out fully loaded and ready for lowering
- for lifeboats which are arranged to be launched fully loaded from the stowed position, the maximum heeling moment during launching is to be taken
- a fully loaded davit-launched liferaft attached to each davit on the side to which the ship has heeled after having sustained damage is to be assumed to be swung out ready for lowering
- persons not in the life-saving appliances which are swung out are not to provide either additional heeling or righting moment
- life-saving appliances on the side of the ship opposite to the side to which the ship has heeled are to be assumed to be in a stowed position.

c) *Moment due to wind pressure:*

$M_{wind}$  is the maximum assumed wind force acting in a damage situation:

$$M_{wind} = (P A Z) / 9,806 \cdot 10^3 \text{ (tm)}$$

$P$  : Wind pressure

$$P = 120 \text{ N/m}^2$$

$A$  : Projected lateral area above waterline

$z$  : Distance from centre of lateral projected area above waterline to  $T/2$ ; and

$T$  : Ship's draught,  $d_1$ .

### 2.3.12 Special requirements concerning stability

A passenger ship intended to carry 400 or more persons is to have watertight subdivision abaft the collision bulkhead so that  $s_i = 1$  for a damage involving all the compartments with 0.08L measured from the forward perpendicular for the three loading conditions used to calculate the attained subdivision index A. If the attained subdivision index A is calculated for different trims, this requirement shall also be satisfied for those loading conditions.

A passenger ship intended to carry 36 or more persons is to be capable of withstanding damage along the side shell to an extent specified below. Compliance with this regulation is to be achieved by demonstrating that  $s_i$ , as defined in [2.3.5], is not less than

0,9 for the three loading conditions used to calculate the attained subdivision index A. If the attained subdivision index A is calculated for different trims, this requirement is also to be satisfied for those loading conditions.

The damage extent to be assumed when demonstrating compliance with the above paragraph, is to be dependent on the total number of persons carried, and  $L$ , such that:

- the vertical extent of damage is to extend from the ships moulded baseline to a position up to 12,5 m above the position of the deepest subdivision draught as defined in Ch 11, Sec 3, [2.1], unless a lesser vertical extent of damage were to give a lower value of  $s_i$  in which case this reduced extent is to be used.
- where 400 or more persons are to be carried, a damage length of  $0,03 L_s$  but not less than 3 m is to be assumed at any position along the side shell, in conjunction with a penetration inboard of  $0,1 B$  but not less than 0,75 m measured inboard from the ship side, at right angles to the centreline at the level of the deepest subdivision draught.
- where less than 400 persons are carried, damage length is to be assumed at any position along the shell side between transverse watertight bulkheads provided that the distance between two adjacent transverse watertight bulkheads is not less than the assumed damage length. If the distance between adjacent transverse watertight bulkheads is less than the assumed damage length, only one of these bulkheads is to be considered effective for the purpose of demonstrating compliance with the criteria  $s_i \geq 0,9$ .
- where 36 persons are carried, a damage length of  $0,015 L_s$  but not less than 3 m is to be assumed, in conjunction with a penetration inboard of  $0,05 B$  but not less than 0,75 m.
- where more than 36, but fewer than 400 persons are carried the values of damage length and penetration inboard, used in the determination of the assumed extent of damage, are to be obtained by linear interpolation between the values of damage length and penetration which apply for ships carrying 36 persons and 400 persons.

### 2.3.13 Documents to be supplied

The master is to be supplied with such information to the satisfaction of the Society as is necessary to enable him by rapid and simple processes to obtain accurate guidance as to the stability of the ship under varying conditions of service. A copy of the stability information shall be furnished to the Society.

The information should include:

- curves or tables of minimum operational metacentric height (GM) and minimum permissible trim versus draught which assures compliance with the intact and damage stability requirements where applicable, alternatively corresponding curves or tables of the maximum allowable vertical centre of gravity (KG) and maximum permissible trim versus draught, or with the equivalents of either of these curves or tables.
- instructions concerning the operation of cross-flooding arrangements
- all other data and aids which might be necessary to maintain the required intact stability and stability after damage.

The intact and damage stability information specified above are to be presented as consolidated data and encompass the full operating range of draught and trim. Applied trim values shall coincide in all stability information intended for use on board. Information not required for determination of stability and trim limits should be excluded from this information.

If the damage stability is calculated in accordance with the present sub-article, a stability limit curve is to be determined using linear interpolation between the minimum required GM assumed for each of the three draughts  $d_s$ ,  $d_p$  and  $d_l$ . When additional subdivision indices are calculated for different trims, a single envelope curve based on the minimum values from this calculations is to be presented. When it is intended to develop curves of maximum permissible KG, it is to be ensured that the resulting maximum KG curves correspond with a linear variation of GM.

As an alternative to a single envelope curve, the calculations for additional trims may be carried out with one common GM for all of the trims assumed at each subdivision draught. The lowest values of each partial index  $A_s$ ,  $A_p$  and  $A_l$  across these trims shall then be used in the summation of the attained subdivision index A according to [2.3.3]. This will result in one GM limit curve based on the GM used at each draught. A trim limit diagram showing the assumed trim range shall be developed.

When curves or tables of minimum operational metacentric height (GM) or maximum allowable KG versus draught are not provided, the master is to ensure that the operating condition does not deviate from approved loading conditions, or verify by calculation that the stability requirement are satisfied for this loading condition.

### 2.3.14 Damage control documentation

Plans showing clearly for each deck and hold the boundaries of the watertight compartments, the openings therein with the means of closure and position of any controls thereof, and the arrangements for the correction of any list due to flooding are to be permanently exhibited for the guidance of the officer in charge of the ship. In addition, booklets containing the aforementioned information are to be made available to the officers of the ship.

Detailed description of the information to be included in the damage control documentation is reported in Pt B, Ch 3, Sec 3, [4].

## 3 Structure design principles

### 3.1 General

**3.1.1** Wood sheathing is recommended for caterpillar trucks and unusual vehicles.

It is recommended that a piece of wood of suitable thickness should be fitted under each crutch in order to distribute the mass over the plate and the nearest stiffeners.

### 3.2 Hull structure

#### 3.2.1 Framing

In general, the strength deck and the bottom are to be longitudinally framed.

Where a transverse framing system is adopted for such ships, it is to be considered by the Society on a case by case basis.

#### 3.2.2 Side structures

Where decks are fitted with ramp openings adjacent to the ship's side, special consideration is to be given to the supports for the side framing.

## 4 Design loads

### 4.1 Loads on deck

#### 4.1.1 Plan of design loads on deck

A plan of design static loads on deck, including fork lift areas, axle loads and any tyre print areas of wheeled loads, is to be provided for information.

All values displayed on this plan are to be at least equivalent to the values given by the present Rules for each kind of load.

### 4.2 Lowest 0,5 m of bulkheads forming vertical division along escape routes

**4.2.1** The still water and inertial pressures transmitted to the structures *belonging to lowest 0,5 m of bulkheads and other partitions forming vertical divisions along escape routes* are to be obtained, in kN/m<sup>2</sup>, as specified in Pt B, Ch 5, Sec 6, [6.1], where the value  $p_{dl-s}$  is to be taken not less than 1,5 kN/m<sup>2</sup> to allow them to be used as walking surfaces from the side of the escape route with the ship at large angles of heel.

## 5 Hull girder strength

### 5.1 Basic criteria

#### 5.1.1 Strength deck

In addition to the requirements in Pt B, Ch 6, Sec 1, [1.3], the contribution of the hull structures up to the strength deck to the longitudinal strength is to be assessed through a finite element analysis of the whole ship in the following cases:

- when the size of openings in the side shell and/or longitudinal bulkheads located below the deck assumed by the Designer as the strength deck decrease significantly the capability of the plating to transmit shear forces to the strength deck
- when the ends of superstructures which are required to contribute to longitudinal strength may be considered not effectively connected to the hull structures in way.

### 5.2 Global transverse strength

**5.2.1** The behaviour of the ship primary structural members under racking effects due to transverse forces induced by transverse accelerations is to be investigated according to Pt B, Ch 7, App 1, or by means of a complete ship model according to NI640 considering the loading conditions and load cases defined in Pt B, Ch 7, App 1, [4.1.2].

## 6 Hull scantlings

### 6.1 Plating

#### 6.1.1 Lowest 0,5 m of bulkheads forming vertical division along escape routes

The net thickness of plating belonging to the lowest 0,5 m of bulkheads and other partitions forming vertical divisions along escape routes is to be obtained according to Pt B, Ch 7, Sec 4, where the loads are defined in [4.2.1].

## **6.2 Ordinary stiffeners**

### **6.2.1 Lowest 0,5 m of bulkheads forming vertical division along escape routes**

The net scantlings of ordinary stiffeners belonging to the lowest 0,5 m of bulkheads and other partitions forming vertical divisions along escape routes are to be obtained according to Pt B, Ch 7, Sec 5, where the loads are defined in [4.2.1].

## **6.3 Primary supporting members**

### **6.3.1 Double bottom structures**

In ships where pillars are widely spaced and transmit very high loads to the double bottom, the net scantlings of double bottom structures are to be considered by the Society on a case-by-case basis, taking into account the results of direct calculations.

Where deemed necessary, on the basis of the above results, additional floors and bottom girders may be required.

### **6.3.2 Lowest 0,5 m of bulkheads forming vertical division along escape routes**

The net scantlings of primary supporting members belonging to the lowest 0,5 m of bulkheads and other partitions forming vertical divisions along escape routes are to be obtained according to Pt B, Ch 7, Sec 6, where the loads are defined in [4.2.1].

## **7 Other structures**

### **7.1 Superstructures and deckhouses**

**7.1.1** *Where a ventilation trunk passing through a structure penetrates the bulkhead deck, the trunk is to be capable of withstanding the water pressure that may be present within the trunk, after having taken into account the maximum heeling angle allowable during intermediate stages of flooding, in accordance with the criteria in [2.3.5].*

**7.1.2** *Where all or part of the penetration of the bulkhead deck is on the main ro-ro deck, the trunk is to be capable of withstanding impact pressure due to internal water motions (sloshing) of water trapped in the ro-ro deck, to be calculated according to the applicable formulae in Pt B, Ch 5, Sec 6, [2].*

## **8 Construction and testing**

### **8.1 Special structural details**

**8.1.1** The specific requirements in Pt B, Ch 13, Sec 5, [2] for ships with the service notation **ro-ro passenger ship** are to be complied with.

## Section 4 Electrical Installations

### 1 General

#### 1.1 Applicable requirements

**1.1.1** In addition to the relevant requirements of Part C, Chapter 2 and Ch 11, Sec 5 and those contained in this Section, electrical installations in spaces intended for the carriage of motor vehicles with fuel in their tanks for their propulsion are to comply with those of Part C, Chapter 4.

#### 1.2 Documentation to be submitted

**1.2.1** In addition to the documentation requested in Pt C, Ch 2, Sec 1, Tab 1, the following are to be submitted for approval:

- a) plan of hazardous areas
- b) document giving details of types of cables and safety characteristics of the equipment installed in hazardous areas
- c) diagrams of indicator systems for shell doors, loading doors and similar appliances, television surveillance or water leakage detection systems
- d) diagrams of the supplies to the supplementary emergency lighting systems.

#### 1.3 Safety characteristics

**1.3.1** The explosion group and temperature class of electrical equipment of a certified safe type for use with explosive petrol-air mixtures are to be at least IIA and T3.

#### 1.4 Flooding detection systems for passenger ships carrying 36 or more persons

**1.4.1** *A flooding detection system for watertight spaces below the bulkhead deck is to be provided based on IMO MSC.1/Circ.1291.*

### 2 Supplementary emergency lighting

#### 2.1

**2.1.1** *In addition to the emergency lighting required in Ch 11, Sec 5, [2.2], on every passenger ship with ro-ro cargo spaces or special category spaces:*

- a) *all passenger public spaces and alleyways shall be provided with supplementary electric lighting that can operate for at least three hours when all other sources of electrical power have failed and under any condition of heel. The illumination provided shall be such that the approach to the means of escape can be readily seen. The source of power for the supplementary lighting shall consist of accumulator batteries located within the lighting units that are continuously charged, where practicable, from the emergency switchboard. Alternatively, any other means of lighting which is at least as effective may be accepted by the Society. The supplementary lighting shall be such that any failure of the lamp will be immediately apparent. Any accumulator battery provided shall be replaced at intervals having regard to the specified service life in the ambient conditions that they are subject to in service;*
- b) *a portable rechargeable battery operated lamp shall be provided in every crew space alleyway and recreational space and every working space which is normally occupied unless supplementary emergency lighting, as required in (a), is provided.*

### 3 Installation

#### 3.1 Installations in special category spaces situated above the bulkhead deck

**3.1.1** On any deck or platform, if fitted, on which vehicles are carried and on which explosive vapours might be expected to accumulate, except platforms with openings of sufficient size permitting penetration of petrol gases downwards, electrical equipment and cables are to be installed at least 450 mm above the deck or platform.

Electrical equipment is to be as stated in Pt C, Ch 2, Sec 3, [10.1.7] and electrical cables as stated in Pt C, Ch 2, Sec 3, [10.3.3].

**3.1.2** Where the installation of electrical equipment and cables at less than 450 mm above the deck or platform is deemed necessary for the safe operation of the ship, the electrical equipment is to be of a certified safe type as stated in Pt C, Ch 2, Sec 3, [10.1.6] and the electrical cables are to be as stated in Pt C, Ch 2, Sec 3, [10.3.2].

**3.1.3** Electrical equipment and cables in exhaust ventilation ducts are to be as stated in [3.1.2].

3.1.4 The requirements in this item are summarised in Tab 1.

**3.2 Installations in special category spaces situated below the bulkhead deck**

3.2.1 Any electrical equipment installed is to be as stated in Pt C, Ch 2, Sec 3, [10.1.6] and electrical cables are to be as stated in Pt C, Ch 2, Sec 3, [10.3.2].

3.2.2 Electrical equipment and cables in exhaust ventilation ducts are to be as stated in [3.2.1].

3.2.3 The requirements in this item are summarised in Tab 2.

**3.3 Installations in cargo spaces other than special category spaces intended for the carriage of motor vehicles**

3.3.1 The requirements for installations in special category spaces situated below the bulkhead deck, as stated in [3.2], apply.

3.3.2 All electric circuits terminating in cargo holds are to be provided with multipole linked isolating switches located outside the holds. Provision is to be made for locking in the off position.

This requirement does not apply to safety installations such as fire, smoke or gas detection systems.

**3.4 Protection of socket outlets in vehicle spaces**

3.4.1 The provisions of [3.4.2] to [3.4.7] are applicable to socket outlets with a rated current not exceeding 63A in AC installations and 16A in DC installations. Socket outlets with higher rated current will be subject to special consideration by the Society.

**Table 1 : Electrical equipment permitted in special category spaces above the bulkhead deck**

No.	Description of spaces	Electrical equipment	Hazardous area
1	Areas at less than 450 mm above the deck or platforms for vehicles, if fitted, without openings of sufficient size permitting penetration of petrol gases downward	Electrical equipment complying with one of the following types of protection may be considered: a) any type that may be considered for zone 0 b) certified intrinsically safe apparatus Ex(ib) c) simple electrical apparatus and components (e.g. thermocouples, photocells, strain gauges, junction boxes, switching devices), included in intrinsically-safe circuits of category "ib" not capable of storing or generating electrical power or energy in excess of limits stated in the relevant rules, and acceptable to the appropriate authority d) certified flameproof Ex(d) e) certified pressurised Ex(p) f) certified increased safety Ex(e) g) certified encapsulated Ex(m) h) certified sand filled Ex(q) i) certified specially Ex(s) j) cables sheathed with at least one of the following: • a non-metallic impervious sheath in combination with braiding or other metallic covering • copper or stainless steel sheath (for mineral insulated cables only)	Zone 1
2	Exhaust ventilation ducts	As stated under item 1.	Zone 1
3	<ul style="list-style-type: none"> <li>• areas above a height of 450 mm from the deck</li> <li>• areas above a height of 450 mm from each platform for vehicles, if fitted, without openings of sufficient size permitting penetration of petrol gases downward</li> <li>• areas above platforms for vehicles, if fitted, with openings of sufficient size permitting penetration of petrol gases downward</li> </ul>	Electrical equipment complying with one of the following types of protection may be considered: a) any type that may be considered for zone 1 b) tested specially for zone 2 (e.g. type "n" protection) c) pressurised, and acceptable to the appropriate authority d) encapsulated, and acceptable to the appropriate authority e) the type which ensures the absence of sparks and arcs and of "hot spots" during its normal operation. For installation, in compliance with Pt C, Ch 4, Sec 13, [2.2.2], a minimum class of protection IP55 is acceptable as an alternative f) cables sheathed with at least a non-metallic external impervious sheath	Zone 2

**Table 2 : Electrical equipment permitted in special category spaces below the bulkhead deck**

No	Description of spaces	Electrical equipment	Hazardous area
1	Special category spaces	Electrical equipment complying with one of the following types of protection may be considered: a) any type that may be considered for zone 0 b) certified intrinsically safe apparatus Ex(ib) c) simple electrical apparatus and components (e.g. thermocouples, photocells, strain gauges, junction boxes, switching devices), included in intrinsically-safe circuits of category "ib" not capable of storing or generating electrical power or energy in excess of limits stated in the relevant rules, and acceptable to the appropriate authority d) certified flameproof Ex(d) e) certified pressurised Ex(p) f) certified increased safety Ex(e) g) certified encapsulated Ex(m) h) certified sand filled Ex(q) i) certified specially Ex(s) j) cables sheathed with at least one of the following: <ul style="list-style-type: none"> <li>• a non-metallic impervious sheath in combination with braiding or other metallic covering</li> <li>• copper or stainless steel sheath (for mineral insulated cables only)</li> </ul>	Zone 1
2	Exhaust ventilation ducts	As stated under item 1	Zone 1

**3.4.2** A separate final sub-circuit is to be provided for each socket outlet. Each final sub-circuit is to be automatically disconnected in case of overcurrent, overload and earth fault (e.g. with an earth fault breaker).

**3.4.3** Socket outlets with a current rating above 16A are to be provided with a switch. The switch is to be so interlocked that the plug can only be inserted or withdrawn when the switch is in "off" position.

**3.4.4** The temperature rise on the live parts of socket outlets and plugs is not to exceed 30°C. Socket outlets and plugs are to be so constructed that they cannot readily short-circuited whether the plug is in or out, and so that a pin of the plug cannot be made to earth either pole of the socket outlet.

**3.4.5** The minimum required degree of protection for socket outlets installed in vehicle spaces is IP56.

**3.4.6** Socket-outlets and plugs with a specified degree of protection shall be provided with effective means to maintain the same degree of protection after the plug is removed from the socket-outlet.

Where a loose cover is used for this purpose, it shall be anchored to its socket-outlet, for example by means of a chain.

**3.4.7** Suitable means for phase inversion are to be available for 3-phase sockets.

## 4 Type approved components

### 4.1

**4.1.1** Accumulator lamps for the supplementary electric lighting, alarm systems for closing devices of openings and water leakage detection systems if of electronic type, and television surveillance systems are to be type approved or in accordance with [4.1.2].

**4.1.2** Case-by-case approval based on submission of adequate documentation and execution of tests may also be granted at the discretion of the Society.

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of one of the following service notations:

- **dredger**
- **hopper dredger**
- **hopper unit**
- **split hopper dredger**
- **split hopper unit**

as defined in Pt A, Ch 1, Sec 2, [4.13].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**1.1.3** The additional service feature **EOC** may be assigned in accordance with Pt A, Ch 1, Sec 2, [4.13.1] only to:

- ships greater than 90m in length assigned the service notation **dredger**
- ships greater than 65m in length assigned the service notation **hopper dredger**, **hopper unit**, **split hopper dredger** or **split hopper unit**.

**Table 1 : Applicable requirements**

### 1.2 Documents to be submitted

**1.2.1** The document listed in Tab 2 are to be submitted for approval, as applicable.

**1.2.2** The document listed in Tab 3 are to be submitted for information, as applicable.

**1.2.3** The following documents are also to be submitted for **split hopper dredger** and **split hopper unit**:

- Superstructure hinges and connections to the ship’s structure, including mass and location of the superstructure centre of gravity
- Structure of hydraulic jack spaces
- Deck hinges, including location of centre of buoyancy and of centre of gravity of each half-hull, mass of equipped half-hull, half mass of spoil or water, supplies for each half-hull and mass of superstructures supported by each half-hull
- Hydraulic jacks and connections to ship’s structure including operating pressure and maximum pressure of the hydraulic jacks (cylinder and rod sides) and corresponding forces
- Longitudinal chocks of bottom and deck
- Transverse chocks
- Hydraulic installation of jacks, with explanatory note.

**Table 2 : Documents to be submitted for approval**

No.	Description of the document
1	Construction of suction inlet tube
2	Gantry foundations
3	Bottom door and cylinder integrations

2	Design loads on all components of the dredging equipment

## Section 2 Hull and Stability

### Symbols

$a$	: Distance from the bottom to the sealing joint located at the lower part of the hopper well, in m
$b_p$	: Maximum breadth, in m, of the hopper well
$C$	: Wave coefficient, defined in Pt B, Ch 5, Sec 4
$d$	: Vertical distance, in m, from the calculation point to the filling level of the considered navigation or dredging situation (see [3.1.1])
$g$	: Gravity acceleration, in $m/s^2$ taken equal to $9,81 m/s^2$
$H_{Di}$	: Wave parameter corresponding to the dredging situation $i$ (see [3.1.1])
$h_{Di}$	: Distance, in m, from spoil level to base line (see Fig 7) when working in the dredging situation $i$ (see [3.1.1])
$k$	: Material factor for steel, defined in Pt B, Ch 4, Sec 1, [2.2]
$l_p$	: Maximum length, in m, of the hopper well
$n$	: Navigation coefficients, defined in Pt B, Ch 5, Sec 3, [1.1.2]
$n_{Di}$	: Navigation coefficient for the dredging situation $i$ (see [3.1.1])
$P_{Di}$	: Mass, in t, of the spoil contained in the hopper space for the dredging situation $i$ (see [3.1.1])
$R_{eH}$	: Minimum yield stress, in $N/mm^2$ , of the material
$R_m$	: Minimum ultimate tensile strength, in $N/mm^2$ , of the material.
$R_y$	: Minimum yield stress, in $N/mm^2$ , of the material, to be taken equal to $235/k N/mm^2$ , unless otherwise specified
$T_{Di}$	: Design draught, in m, corresponding to the dredging situation $i$ (see [3.1.1])
$T_{IF}$	: Navigation draught, in m, corresponding to the international freeboard
$V_{Di}$	: Volume of spoil contained in the hopper space for the dredging situation $i$ (see [3.1.1]), in $m^3$ (vertically limited to the lowest overflow level)
$\delta$	: Specific gravity of the mixture of sea water and spoil for the navigation situation, taken equal to 1,025
$\delta_i$	: Specific gravity of the mixture of sea water and spoil for the dredging situation $i$ (see [3.1.1]), taken equal to:
	$\delta_i = \frac{P_{Di}}{V_{Di}}$

## 1 Stability

### 1.1 Intact stability

#### 1.1.1 General

The intact stability of the ship is to be sufficient to comply with the criteria indicated in [1.1.3] for the operational loading conditions of Pt B, Ch 3, App 2, [1.2.10] and the calculation method described in [1.1.2].

#### 1.1.2 Calculation method

The calculation of the righting lever curves is to take into account:

- the change of trim due to heel
- the inflow of seawater or outflow of liquid cargo at the upper edge of the hopper coaming in the case of an open hopper
- the inflow of water at the lower edge of the overflow, located at cargo level or at the lowest possible position above cargo level, or at the lower edge of the lowest overflow ports or spillways.

#### 1.1.3 Intact stability criteria

The area under the righting lever curve is not to be less than

- 0,07 m.rad up to an angle of  $15^\circ$  when the maximum righting lever  $GZ_{max}$  occurs at  $15^\circ$
- 0,055 m.rad up to an angle of  $30^\circ$  when the maximum righting lever  $GZ_{max}$  occurs at  $30^\circ$  or above.

Where the maximum righting lever  $GZ_{max}$  occurs at angles of between  $15^\circ$  and  $30^\circ$ , the corresponding area under the righting lever curve is to be equal to or greater than  $A$ , where  $A$  is to be obtained, in m-rad by the following formula:

$$A = 0,055 + 0,001 (30^\circ - \theta_{max})$$

where

$\theta_{max}$  : angle of heel in degrees at which the righting lever curve reaches its maximum.

The area under the righting lever curve between:

- the angles of heel of 30° and 40°, or
- the angle of heel of 30° and the down-flooding angle  $\theta_r$ , if this angle is less than 40°,

is to be not less than 0,03 m.rad.

The righting lever GZ is to be at least 0,20 m at an angle of heel equal to or greater than 30°.

The maximum righting lever  $GZ_{max}$  should occur at an angle of heel not less than 15°.

The initial metacentric height  $GM_0$  as corrected for the free surface effect of the tanks and the hopper(s) containing liquids is not to be less than 0,15 m.

#### **1.1.4 Weather criterion at the international freeboard**

At the international freeboard, the dredger is to comply with the requirements of Pt B, Ch 3, Sec 2, [3.2] considering:

- the state of the cargo as a liquid
- 10% stores and fuel
- and the hopper(s) loaded with a homogeneous cargo up to the upper edge of the hopper coaming if the density of the cargo is not less than 1000 kg/m<sup>3</sup>; otherwise the hopper is considered to be partially loaded with a cargo of density equal to 1000 kg/m<sup>3</sup>.

#### **1.1.5 Weather criterion at the dredging freeboard**

At the dredging freeboard, the dredger is to comply with the requirements of Pt B, Ch 3, Sec 2, [3.2] considering a reduced wind pressure equal to 270 N/m<sup>2</sup> for the most severe of the loading conditions in Pt B, Ch 3, App 2, [1.2.10]. The most severe loading condition is defined as the loading condition where the area under the righting lever curve between 0° and 40° is the least.

#### **1.1.6 Dredgers with open hopper(s)**

When the height of the hopper coaming overflow edge above the dredging draught is less than the minimum bow height as specified in the International Load Line Convention 1966, the loading conditions in Pt B, Ch 3, App 2, [1.2.10] at the dredging draught are to take into account a layer of seawater on top of the cargo up to the overflow edge of the hopper coaming. However, if overflow ports or spillways of a size sufficient to enable a fast freeing of the water in the hopper on top of the cargo are fitted in the hopper coaming above the freeboard deck, the layer of sea water may be reduced up to the lower edge of the overflow ports or spillways.

The area of the overflow ports or spillways is to be at least equivalent to the area required by Regulation 24(1) of the International Convention on Load Lines, 1966.

#### **1.1.7 Dredgers with bottom doors or similar means**

Dredgers with bottom doors or similar means at port side and at starboard side are to comply with the following criteria considering an asymmetric discharging:

- the angle of equilibrium is not to exceed 25°
- the righting lever GZ within the 30° range beyond the angle of equilibrium is to be at least 0,10 m
- the range of stability is not to be less than 30°.

The dredger is assumed loaded up to the dredging draught with solid cargo of a density equal to 1900 kg/m<sup>3</sup>, when discharging, 20% of the total hopper load is assumed to be discharged only at one side of the longitudinal centreline of the hopper, horizontally equally distributed at the discharging side.

### **1.2 Damage stability where the additional class notation SDS has been requested**

#### **1.2.1 General**

When the dredger is assigned a dredging freeboard which is less than B/2, where B is the statutory freeboard as calculated in accordance with the International Convention on Load Lines 1966, the dredger is to comply with the requirements of Pt B, Ch 3, App 3, [1], modified by [1.2.2], [1.2.3] and [1.2.5]. The dredger may not be assigned a freeboard less than B/3.

#### **1.2.2 Calculation method of the righting lever curves**

The calculation of the righting lever curves is to take into account:

- the change of trim due to heel
- the inflow of seawater or outflow of cargo at the upper edge of the hopper coaming in the case of an open hopper
- the inflow of water at the lower edge of the overflow, located at the highest possible position or at the lower edge of the lowest overflow ports or spillways
- the sliding of the cargo in the hopper, in transverse and longitudinal direction, according to the following shifting law:
  - for  $\rho \leq 1400$  (liquid cargo):  
 $\theta_r = \theta_g$
  - for  $1400 < \rho < 2000$  (sliding cargo):  
 $\theta_r = \theta_g (2000 - \rho) / 600$

- for  $\rho \geq 2000$  (solid cargo):  
 $\theta_r = 0$

where:

- $\rho$  : Cargo density, in  $\text{kg/m}^3$
- $\theta_r$  : Angle of heel or angle of trim, in degrees
- $\theta_g$  : Shifting angle of the cargo, in degrees.

### 1.2.3 Progressive flooding

Internal and external progressive floodings are to be considered in accordance with the requirements of Pt B, Ch 3, Sec 3, [3.3].

### 1.2.4 The attained subdivision index $A_U$

The attained subdivision index  $A_U$  is to be calculated for the draught  $d_U$  and the corresponding initial trim assuming the dredger in the unloaded condition, i.e. loaded with 50% fuel and stores, no cargo in the hopper(s) and the hopper(s) in direct communication with the sea.

### 1.2.5 The attained subdivision index $A_L$

The attained subdivision index  $A_L$  is to be calculated assuming the dredger loaded at the dredging draught  $d_l$  with 50% fuel and stores, for each of the densities  $\rho_d$  and  $\rho_i$  defined by:

- The design density  $\rho_d$  corresponding to the dredging draught and obtained from the following formula:

$$\rho_d = M_2 / V_2$$

where:

- $M_2$  : Mass of cargo in the hopper when the dredger is loaded at the dredging draught with 50% fuel and stores
- $V_2$  : Volume of the hopper at the highest overflow position.

- Each density  $\rho_i$  greater than  $\rho_d$ , obtained from the following formula:

$$\rho_i = 2200 - 200 i$$

where  $i$  is equal to 0; 1; 2; 3; etc.

The damage stability calculations are to be performed taking into account the initial trim of the dredging draught, an assumed permeability of the cargo in the hopper equal to 0% and a permeability of the space above the cargo equal to 100%.

### 1.2.6 Damage stability criteria

The dredger is to comply with the following criteria:

$$A \geq R$$

$$A_U \geq 0,7 R$$

$$A_L \geq 0,7 R$$

where:

- $R$  : Required index as defined in Pt B, Ch 3, App 3, [1.3]
- $A_U$  : Attained subdivision index at the unloaded draught  $d_U$ , as defined in [1.2.4]
- $A_L$  : Attained subdivision index at the loaded draught  $d_l$  and for the cargo densities defined in [1.2.5].

## 2 Structure design principles

### 2.1 General

**2.1.1** The attention of Designers is drawn to the fact that structural arrangement of ships for dredging activities involves discontinuities and that particular care is to be taken to avoid cracks or fractures.

**2.1.2** Where dredgers are likely to work in association with hopper barges, the sheerstrake is to be protected, slightly below the deck, by a fender efficiently secured to the shell plating and extending over at least two thirds of the ship's length. Compensation is to be provided in way of the gangway port in raised deck, if fitted.

**2.1.3** Where dredgers are likely to work in association with hopper barges, the shell plating is to be protected by a fender extending from the load waterline to the lowest waterline.

Additional structural reinforcements are to be provided in way of fenders and submitted to the Society for approval.

**2.1.4** On bucket dredgers, in order to prevent dangerous flooding in the event of damage to the shell plating by metal debris (e.g. anchors), a watertight compartment is to be provided at the lower part of the caissons on either side of the bucket well in the area of the buckets. The compartment is to be of adequate size to allow surveys to be carried out.

**2.1.5** Reinforcements are to be provided at locations where the hull is heavily stressed, such as:

- beneath the suction pipe gantries
- in way of the gantry frame on bucket dredgers
- points where tow ropes are secured
- connections of piles, etc.

**2.1.6** Flat bottom areas, other than flat bottom area forward, where dynamic pressures due to the bottom impact might occur are to be examined by the Society on a case by case basis.

**2.1.7** Overflows are to be provided in the hopper spaces. Their sectional area is to be large enough, taking into account the density of the water-spoil mixture to be drained off.

The disposition and location of the overflows are to be such that:

- they prevent the maximum authorised draught from being exceeded during loading
- trim and stability are always in accordance with the reviewed loading conditions
- draining off is made without any overflowing on the decks.

**2.1.8** The corners of the cut-outs in the bottom plating are to be rounded and the radius is to be as large as possible, especially near the bottom doors.

The shape and the radius of cut-out corners are to be in accordance with Pt B, Ch 4, Sec 5 or NR600, Ch 2, Sec 1, as applicable.

**2.1.9** Where hopper barges and suction dredgers are intended for unrestricted navigation, it is recommended, as far as possible, that sidescuttles are not be fitted in the shell plating.

**2.1.10** The brackets are generally to be of a swept shape. A flange is to be fitted on the free edge if the length of this edge exceeds 60 times the web thickness.

**2.1.11** For ships with one of the service notations **split hopper dredger** or **split hopper unit**, where panting beams are provided as stated in Pt B, Ch 11, Sec 1, [2.3.5], stringers and web frames are to be fitted on the centreline bulkheads of the two half-hulls to take up the reactions.

## **2.2 Longitudinal members in the area of the hopper well**

**2.2.1** The scantlings of the midship region are generally to be kept over the full length of the hopper well.

**2.2.2** Attention is to be paid to the structural continuity of longitudinal members, especially coaming and hopper well bulkheads.

**2.2.3** The upper deck stringer plate is to extend to the longitudinal bulkhead over the full length of the hopper well.

**2.2.4** The fore and aft ends of longitudinal bulkheads of hopper spaces are to be extended by webs and brackets, with a size not less than one frame spacing (see Fig 1).

Openings in primary members in way of the transition are to be avoided.

A longitudinal effective coaming is to be extended via large brackets, the length of the bracket is to be equal to the height of the coaming. A suitable overlap between the coaming stay and bracket is to be provided. The bracket is to be full penetration welded to the deck.

**2.2.5** The fore and aft ends of the centreline cellular keel are to be extended by means of brackets and webs. The sloped plating of the cellular keel is to be extended behind the hopper end bulkheads for at least one frame spacing.

In areas where a double bottom is provided, the brackets may be arranged in accordance with Fig 2.

**2.2.6** The vertical sides of the trunks are to be extended beyond the end of the hopper spaces over a distance of at least 1,5 times their height.

**2.2.7** The Society may, on a case-by-case basis, require that longitudinal members of the double bottom structure are extended, by means of brackets, inside the side compartments bounding the hopper spaces.

**2.2.8** Arrangements other than those described in [2.2.4] to [2.2.7] are to be considered by the Society on a case-by-case basis.

Figure 1 : Longitudinal bulkhead extension outside of hopper spaces

Figure 2 : Integration of cellular keels

## 2.3 Transverse members in the area of the hopper well

### 2.3.1 Transverse primary supporting rings

Within the hopper well area, transverse primary supporting rings are to be provided and are to involve:

- deep floors inside hopper spaces
- side vertical primary supporting members
- hopper well vertical primary supporting members
- strong beams inside hopper spaces, at deck or trunk level
- where necessary, cross-ties connecting either the side vertical primary supporting members to the hopper well vertical primary supporting members or the floor to the hopper well vertical primary supporting members.

The spacing of the transverse rings is generally to be taken not greater than five frame spaces.

**2.3.2** The cellular keel is to be rigidly connected to the transverse rings required in [2.3.1].

**2.3.3** The upper part of the cellular keel may be connected to the deck or trunk structure by means of axial or inclined pillars in association with strong beams, or by a centerline wash bulkhead.

**2.3.4** The connection of hopper space floors with the longitudinal bulkheads and the cellular keel is to be arranged such that the continuity of the strength is ensured.

Where the floor is made of a box with sloping sides, particular attention is to be paid to the continuity of the lower flange. Fig 3 shows an example of possible connection.

**Figure 3 : Example of connection with floor made of box with sloping sides**

**2.3.5** The connection between the flanges of the strong beams and the adjacent structure is generally to be made by means of brackets having the thickness of these flanges and extending inside the adjacent structure.

**2.3.6** In general the sloped hopper well plating is to be supported by a deck or a stringer at the connection to the longitudinal vertical bulkhead. The welding at this location is to be full or partial penetration in the hopper well. Outside of the hopper well the welding may be fillet welding. Tensile stress in the fillet welds is to be less than  $0,5 R_y$ .

## 2.4 Arrangements relating to suction pipes

**2.4.1** Where a cut-out is necessary in the side shell plating to fit the suction pipe guides, continuity of members is to be restored, for example by means of knuckled plates as thick as the side shell plating and with a knuckle angle as small as possible.

The knuckles are to be stiffened by reinforced vertical primary supporting members and intercostal girders of the same web height (see Fig 4 and Fig 5)

The fillet welding between the web of vertical primary supporting members and the knuckled plates is not to be made onto the knuckles, but about 50 mm apart.

Figure 4 : Suction pipe guide arrangement for transversally stiffened vessel

Figure 5 : Suction pipe guide arrangement for longitudinally stiffened

**2.4.2** The suction pipe guides are to be fitted as far as possible from the hopper space ends or from any cut-out in the bottom or deck plating.

Deck plating is generally to be reinforced in way of suction pipe guides. Alternatively, strength of deck plating is to be justified by direct calculations for a knuckle angle greater than  $30^\circ$  on a case by case basis.

**2.4.3** In areas where, during suction pipe operations, the drag head and the joint may run against the hull, one or several of the following arrangements are generally to be provided:

- thickness plating in excess of thickness obtained according to Pt B, Ch 7, Sec 4 or NR600, Ch 4, Sec 3, as applicable, for bilge and side shell
- reinforcement of the structure by means of vertical primary supporting members, girders, intermediate frames or longitudinals, depending on the construction type
- fenders to be provided outside the hull; these fenders together with the bilge shape are not to impede the suction pipe operation
- cofferdam to be provided to limit the possible flooding of side compartments.

**2.4.4** The suction pipes are generally to be fitted with:

- auxiliary devices able to lift the suction pipe, in addition to the suction pipe gantries
- a sufficient number of attachment points on the suction pipe itself, to facilitate handling
- a load limiting device to avoid any overload, if the suction pipe is equipped with cutting teeth
- accessories fitted onto the suction pipe built in several parts to facilitate partial replacements in case of damage.

## 2.5 Areas subject to heavy wear

**2.5.1** Some parts of the structure subjected to heavy wear, such as longitudinal bulkheads of hopper spaces, may be protected or reinforced to avoid frequent replacement.

**2.5.2** If protection is provided by means of removable plates, called wear plates, attention is to be paid to avoid corrosion between the facing sides of these plates and the hopper space plating.

**2.5.3** If reinforcement is made by increasing the thickness, the section moduli may be determined taking into account the extra thickness, provided it is not considered as a voluntary addition  $t_{vol\_add}$  when applying requirements in Pt B, Ch 4, Sec 2.

If this extra thickness is disregarded in the section moduli calculation, it is to be considered as a voluntary addition  $t_{vol\_add}$  when applying requirements in Pt B, Ch 4, Sec 2 and is to be clearly indicated on the midship section drawing.

## 2.6 Reinforcements for grounding

**2.6.1** If grounding is considered for normal operation of the ship, the bottom plating and the bottom structure are to be reinforced as indicated in [2.6.2] to [2.6.5].

**2.6.2** Along the full length of the ship, in the area of flat bottoms, the bottom net thickness obtained according to Pt B, Ch 7, Sec 4 or NR600, Ch 4, Sec 3, as applicable, is to be increased by 2,5 mm.

**2.6.3** Where the ship has a transversely framed double bottom, floors are to be fitted at each frame space and associated with intercostal longitudinal girders, the mean spacing of which is to be not greater than 2,10 m.

Moreover, intercostal longitudinal ordinary stiffeners located at mid-spacing of bottom girders are to be provided.

**2.6.4** Where the ship has a longitudinally framed double bottom, the floor spacing may not exceed three frame spaces and the bottom girder spacing may not exceed three longitudinal ordinary stiffener spaces.

Intercostal transverse stiffeners are to be provided at mid-span of longitudinal ordinary stiffeners.

Floors are to be stiffened by vertical stiffeners having the same spacing as the longitudinal ordinary stiffeners.

**2.6.5** Where the ship is built with open hopper spaces (bottom doors provided on the bottom), reinforcements as required in [2.6.3] or [2.6.4] are to be provided within the side compartments, the cellular keel and, in general, within the limits of the flat bottom area.

## **2.7 Bolted structures**

**2.7.1** Where the dredger is made of several independent members connected by bolting, the connection is to be examined by the Society on a case-by-case basis.

## **3 Design loads**

### **3.1 General**

**3.1.1** Design loads are to be determined for the various load cases in the following situations:

- navigation situation
- each dredging situation  $i$ , with  $i$  chosen between 1 to  $x$ , where  $x$  is the number of operating area notations which are assigned to the ship according to Pt A, Ch 1, Sec 2, [5.3.2].

The navigation situation is associated with the following design parameters:

- Navigation draught  $T_{IF}$ , in m, corresponding to the international freeboard
- block coefficient at the considered loading condition  $C_{B-LC}$
- waterplane coefficient at the considered loading condition  $C_{W-LC}$
- wave parameter  $H$
- navigation coefficient  $n$
- roll radius  $k_r$  and metacentric height  $GM$  as per full load condition
- the hopper space(s) filled with water up to the load line

Each dredging situation  $i$  is associated with the following design parameters:

- design draughts  $T_{Di}$  in m

For ships assigned the service notation **split hopper dredger** or **split hopper unit**, the following design draughts have to be included, as a minimum, among the different design dredging draughts:

$T_{IF}$  : Draught when dredging at the international freeboard

$T_{WL}$  : Draught when dredging with well filled up to waterline

$T_{OL}$  : Draught when dredging with well filled with water up to the lowest overflow level

- still water bending moments and shear forces
- block coefficient at the considered loading condition  $C_{B-LC}$
- waterplane coefficient at the considered loading condition  $C_{W-LC}$
- wave parameter  $H_{Di}$ , calculated using the coefficients given in:
  - Tab 1 for ships assigned the operating area notation **unrestricted dredging area (T= x m)**,
  - Tab 2 for ships assigned the operating area notations defined in Pt A, Ch 1, Sec 2, Tab 3,
  - Tab 3 for ships assigned the additional service feature **EOC**, and granted with the operating area notations defined in Pt A, Ch 1, Sec 2, Tab 4

instead of the coefficients given for  $H$ , as defined in Pt B, Ch 5, Sec 3, [1.1.1]

- navigation coefficient  $n_{Di}$ , calculated using  $H_{Di}$  instead of  $H$ , as defined in Pt B, Ch 5, Sec 3, [1.1.2],
- Roll radius  $k_r$  and metacentric height  $GM$  as per full load condition
- spoil density  $\delta_i$  and hopper space filling level  $h_{Di}$ .

For ships assigned the additional class notation **split hopper dredger** or **split hopper unit**, the following values of  $h_{Di}$  have to be included, as a minimum:

$h_{IF}$  : Distance, in m, from spoil level to base line when dredging at the international freeboard (see Fig 7)

$h_{WL}$  : Distance, in m, from spoil level to base line when dredging with well filled up to waterline (see Fig 7)

$h_{OL}$  : Distance, in m, from the lowest overflow level to base line when dredging with well filled with water up to the lowest overflow level.

**3.1.2** For dredgers made of bolted structure, the Society may require the hull girder loads calculated with the maximum length of the unit when mounted to be applied to each individual element.

**Table 1 : Wave parameter  $H_{Di}$  coefficients for ships assigned the operating area notation unrestricted dredging area ( $T= x m$ )**

Operating area notation	Assessment	$A_0$	$A_1$	$e_1$	$A_2$	$e_2$	$L_c$	$h_{lu}$ (1)
<b>unrestricted dredging area (<math>T= x m</math>)</b>	Strength	1,00	1,50	2,20	0,45	1,70	486	–
	Fatigue	0,16	1,66	1,96	0,49	1,43	243	12,5

**Note 1:** ( $T= x m$ ) indicates the maximum allowable draught  $x$ , in m, corresponding to the values of  $T_{Di}$  defined in [3.1.1]  
**Note 2:** The operations area notation **unrestricted dredging area ( $T= x m$ )** is equivalent to the navigation notation **unrestricted navigation** when applying requirements of Part B.  
**(1)** Reference height for loading/unloading fatigue assessment, in m, to be considered for the calculation of  $f_{plu}$  according to Pt B, Ch 5, Sec 3

**Table 2 : Wave parameter  $H_{Di}$  coefficients for ships not assigned the additional service feature EOC**

Ship length	Operating area notation	Assessment	$A_0$	$A_1$	$e_1$	$A_2$	$e_2$	$L_c$	$h_{lu}$ (1)
≤ 110 m	<b>dredging ≤ 8 miles from shore or <math>H_s \leq 1,5 m</math> (<math>T= x m</math>)</b>	Strength	0,21	1,27	2,38	0,31	1,69	223	–
		Fatigue	0,09	1,96	2,13	0,38	1,14	143	2,5
	<b>dredging ≤ 15 miles from shore or <math>H_s \leq 2,5 m</math> (<math>T= x m</math>)</b>	Strength	0,46	1,44	2,46	0,37	1,79	308	–
		Fatigue	0,15	1,71	1,98	0,47	1,38	219	5,5
> 110 m and ≤ 150 m	<b>dredging ≤ 8 miles from shore or <math>H_s \leq 2,0 m</math> (<math>T= x m</math>)</b>	Strength	0,25	1,29	2,38	0,32	1,71	239	–
		Fatigue	0,10	1,90	2,10	0,38	1,20	158	3,0
	<b>dredging ≤ 15 miles from shore or <math>H_s \leq 3,0 m</math> (<math>T= x m</math>)</b>	Strength	0,49	1,48	2,46	0,39	1,75	321	–
		Fatigue	0,15	1,70	1,97	0,49	1,40	226	6,0
> 150 m	<b>dredging ≤ 8 miles from shore or <math>H_s \leq 2,0 m</math> (<math>T= x m</math>)</b>	Strength	0,25	1,29	2,38	0,32	1,71	239	–
		Fatigue	0,10	1,90	2,10	0,38	1,20	158	3,0
	<b>dredging ≤ 15 miles from shore or <math>H_s \leq 3,5 m</math> (<math>T= x m</math>)</b>	Strength	0,53	1,48	2,45	0,39	1,76	331	–
		Fatigue	0,16	1,69	1,96	0,49	1,41	230	6,5

**Note 1:**  $H_s$  : Maximum significant wave height, in m, associated to the operating area notation.  
**Note 2:** ( $T= x m$ ) indicates the maximum allowable draught  $x$ , in m, corresponding to the values of  $T_{Di}$  defined in [3.1.1]  
**(1)** Reference height for loading/unloading fatigue assessment, in m, to be considered for the calculation of  $f_{plu}$  according to Pt B, Ch 5, Sec 3

**Table 3 : Wave parameter  $H_{Di}$  coefficients for ships assigned the additional service feature EOC**

	Fatigue	0,16	1,69	1,96	0,49	1,41	231	6,5

**Note 1:** H<sub>s</sub> : Maximum significant wave height, in m, associated to the operating area notation.  
**Note 2:** (T= x m) indicates the maximum allowable draught x, in m, corresponding to the values of T<sub>Di</sub> defined in [3.1.1]  
(1) Reference height for loading/unloading fatigue assessment, in m, to be considered for the calculation of f<sub>plu</sub> according to Pt B, Ch 5, Sec 3.

### 3.2 Loading conditions

**3.2.1** In addition to the requirements in Pt B, Ch 5, Sec 4, as applicable, still water hull girder loads are to be calculated for the following loading conditions:

- homogeneous loading at maximum dredging draught if higher than the maximum service draught
- partial loading conditions
- any specified non-homogeneous loading condition, in particular where dredgers are fitted with several hopper spaces
- hopper space(s) filled with water up to the load line
- hopper space(s) filled with spoil at a draught corresponding to the international freeboard
- ballast navigation conditions, with empty hopper space(s), if applicable.

Calculation of the still water bending moment and shear force for any loading case corresponding to a special use of the ship may be required by the Society on a case-by-case basis. In particular, in the case of stationary dredgers, the still water bending moment distribution, where the suction pipe is horizontal, is to be submitted to the Society for approval.

### 3.3 Hull girder loads for dredgers, hopper dredgers and hopper units of more than 65 m in length

#### 3.3.1 Application

The provisions in [3.3.2] to [3.3.5] apply to ships with one of the service notations **dredger**, **hopper dredger** or **hopper unit** of more than 65 m in length.

#### 3.3.2 Vertical still water bending moments

In addition to the vertical still water bending moments M<sub>sw-max</sub> and M<sub>sw-min</sub> in navigation situation (see [3.1.1]) defined in Pt B, Ch 5, Sec 4, [2.2], the vertical still water bending moments in any of the dredging situations (see [3.1.1]) are also to be considered. The same value, provided by the designer for each dredging situation is to be given to both M<sub>sw-max,Di</sub> and M<sub>sw-min,Di</sub> associated respectively to hogging and sagging conditions.

If the design vertical still water bending moments in dredging situations are not defined at a preliminary design stage, at any hull transverse section, M<sub>sw-max,Di</sub> and M<sub>sw-min,Di</sub> in kN.m may be taken as:

$$M_{sw-max,Di} = f_{sw} \left( 190 \cdot \frac{1+n}{2} \cdot C \cdot L^2 \cdot B(C_B + 0,7) \cdot 10^{-3} - M_{wv-h-mid,Di} \right)$$

$$M_{sw-min,Di} = -f_{sw} \left( 190 \cdot \frac{1+n}{2} \cdot C \cdot L^2 \cdot B(C_B + 0,7) \cdot 10^{-3} + M_{wv-s-mid,Di} \right)$$

where:

$f_{sw}$  : Distribution factor along the ship length to be taken:

- equal to 1 from 0,35L to 0,65L and to 0 at the ship's ends for hopper dredgers with single hopper well. Intermediate values are to be obtained by linear interpolation
- as defined in Pt B, Ch 5, Sec 4, [2.2.3] for other cases

$M_{wv-h,mid,Di}$ : Vertical wave bending moment for strength assessment in the dredging situation  $i$  (see [3.1.1]), in hogging conditions, defined in [3.3.3] where  $F_M = 1$

$M_{wv-s,mid,Di}$ : Vertical wave bending moment for strength assessment in the dredging situation  $i$  (see [3.1.1]), in sagging conditions, defined in [3.3.3] where  $F_M = 1$

### 3.3.3 Vertical wave bending moments

In addition to the vertical wave bending moments  $M_{wv-h}$  and  $M_{wv-s}$  in navigation situation (see [3.1.1]) defined in Pt B, Ch 5, Sec 4, [3.1], the vertical wave bending moments in any of the dredging situations (see [3.1.1]) at any hull transverse section,  $M_{wv-h,Di}$  and  $M_{wv-s,Di}$  are to be obtained using definitions in Pt B, Ch 5, Sec 4, [3.1], replacing  $n$  by  $n_{Di}$  or  $H$  by  $H_{Di}$ .

### 3.3.4 Horizontal wave bending moments

In addition to the horizontal wave bending moment  $M_{wh}$  in navigation situation (see [3.1.1]) defined in Pt B, Ch 5, Sec 4, [3.3], the horizontal wave bending moments in any of the dredging situations (see [3.1.1]),  $M_{wh,Di}$  at any hull transverse section is to be obtained using definition in Pt B, Ch 5, Sec 4, [3.3], replacing  $H$  by  $H_{Di}$ .

### 3.3.5 Vertical wave shear forces

In addition to the vertical wave shear forces  $Q_{wv-pos}$  and  $Q_{wv-neg}$  in navigation situation (see [3.1.1]) defined in Pt B, Ch 5, Sec 4, [3.2], the vertical wave shear forces in any of the dredging situations (see [3.1.1]) at any hull transverse section  $Q_{wv-pos,Di}$  and  $Q_{wv-neg,Di}$  are to be obtained using definitions in Pt B, Ch 5, Sec 4, [3.2.1], replacing  $n$  by  $n_{Di}$ .

## 3.4 Hull girder loads for split hopper dredgers and split hopper units of more than 65 m in length

### 3.4.1 Application

The provisions in [3.4.2] to [3.4.8] apply to ships with one of the service notations **split hopper dredger** or **split hopper unit** of more than 65 m in length.

### 3.4.2 General

Horizontal bending moments are to be calculated assuming that the hopper well is simply supported at each end.

The clearance between the two half-hulls is to be large enough not to be suppressed when the hopper well is full up.

Details of the calculation of the necessary clearances are to be submitted to the Society for review.

However, the horizontal bending moments are generally to be calculated assuming that both ends of the hopper well are partly clamped, on condition that at deck and bottom level chocks are provided forward and aft of the well so that:

- the clearance between the two half-hulls is nil
- the chocks are long enough to withstand the end moments due to the horizontal forces developed along the hopper well.

### 3.4.3 Vertical still water bending moments

The vertical still water bending moments to be applied on one half-hull in navigation and dredging situations are to be taken equal respectively to half the vertical still water bending moments defined in [3.3.2].

### 3.4.4 Vertical wave bending moments

The vertical wave bending moments to be applied on one half-hull in navigation and dredging situations are to be taken equal respectively to half the vertical wave bending moments defined in [3.3.3]

### 3.4.5 Horizontal still water bending moments

The horizontal still water bending moments to be applied on one half-hull in navigation and dredging situations are to be obtained, in kN.m, from the formulae given in Tab 4, assuming that the hopper well is simply supported at each end.

If the hopper well may not be considered as simply supported at each end, the horizontal still water bending moments to be applied on one half-hull in navigation and dredging situations are to be determined on a case by case basis.

Table 4 : Split hopper dredgers and split hopper units - Horizontal still water bending moment on half-hulls

	$M_{sh-hh}$ , in kN.m	
	for portside half-hull:	for starboard half-hull:
Hopper well mid-section (1)	$\left(\frac{1}{8} + \frac{c_1}{2l_p}\right) p l_p^2$	$-\left(\frac{1}{8} + \frac{c_1}{2l_p}\right) p l_p^2$
Hopper well ends (1)	0	
(1) Between hopper well mid-section and ends, the value of the horizontal still water bending moment is to be obtained by linear interpolation.		
<b>Note 1:</b>		
$p$	: Load per metre, in kN/m, applied along the hopper well, defined in Tab 5 depending on the loading condition	
$c_1$	: Distance, in m, from deck hinges to ends of hopper well (see Fig 6).	

Figure 6 : Definitions of dimensions in hopper well area

Table 5 : Load per metre applied along the hopper well

Loading condition	$p$ , in kN/m
Navigation situation	0
Dredging with spoil loading corresponding to the international freeboard	$\frac{\delta_i(h_{IF} - a)^2 - 1,025(T_{IF} - a)^2}{2} g$
Dredging condition with well filled with water up to the waterline	0
Dredging condition with well filled with water up to the lowest weir level	$\frac{,025[(h_{OL} - a)^2 - (T_{OL} - a)^2]}{2} \xi$
Other dredging situations	$\frac{\delta_i(h_{Dj} - a)^2 - 1,025(T_{Dj} - a)^2}{2} g$
<b>Note 1:</b> See Fig 7 for the definitions of distances for calculation of the loads applied along the hopper well	

Figure 7 : Definitions of distances for calculation of the load applied along the hopper well

### 3.4.6 Horizontal wave bending moments

The horizontal wave bending moments to be applied on one half-hull in navigation and dredging situations are to be obtained, in kN.m, from the formulae given in Tab 6, assuming that the hopper well is simply supported at each end.

If the hopper well may not be considered as simply supported at each end, the horizontal still water bending moments to be applied on one half-hull in navigation and dredging situations are to be determined on a case by case basis.

**Table 6 : Split hopper dredgers and split hopper units - Horizontal wave bending moment on half-hulls**

	$M_{wh-hh}$ , in kN.m	
	Navigation situation	Dredging situations
Hopper well mid-section (1)	$\left[ T_{IF} + 0,079Cn \left( 2 \frac{\ell_D}{L} - 1 \right) (C_{B-LC} + 0,7) \right] \frac{M_{wv}}{B}$	$\left[ T_{Di} + 0,079Cn_{Di} \left( 2 \frac{\ell_D}{L} - 1 \right) (C_{B-LC} + 0,7) \right] \frac{M_{wv}}{B}$
Hopper well ends (1)	0	

(1) Between hopper well mid-section and ends, the value of the horizontal wave bending moment is to be obtained by linear interpolation.  
**Note 1:**  $M_{wv}$ : Vertical wave bending moment, in kN.m, in navigation or dredging situations, as applicable, in hogging or sagging conditions, as defined in [3.3.3].

**3.4.7 Combined still water and wave vertical bending moment**

In the midship area, the total vertical bending moment  $M_v$  to be applied on half-hull is to be obtained, in kN.m, from Tab 7.

At hopper well ends, the total bending moment  $M_v$  is to be determined in accordance with Tab 7 considering:

- for the still water vertical bending moment: the greater of the values at the fore and aft hopper well ends
- for the vertical wave bending moment: the longitudinal distribution defined in Pt B, Ch 5, Sec 4, Fig 2.

**Table 7 : Vertical bending moment applied on half-hull**

Condition	Vertical bending moment $M_v$ , in kN.m	
	Navigation situation	Dredging situation i
Hogging	$\frac{M_{sw-max} + M_{wv-h}}{2}$	$\frac{M_{sw-max,Di} + M_{wv-h,Di}}{2}$
Sagging	$\frac{M_{sw-min} + M_{wv-s}}{2}$	$\frac{M_{sw-min,Di} + M_{wv-s,Di}}{2}$

**Note 1:**

$M_{sw-max}, M_{sw-min}$  : Maximum and minimum still water vertical bending moment in navigation situation as defined in Pt B, Ch 5, Sec 4, [2.2]

$M_{wv-h}, M_{wv-s}$  : Wave vertical bending moment in navigation situation in hogging and sagging condition, respectively, defined in Pt B, Ch 5, Sec 4, [3.1]

$M_{sw-max, Di}, M_{sw-min, Di}$  : Maximum and minimum still water vertical bending moment in the dredging situation i, as defined in [3.3.2]

$M_{wv-h, Di}, M_{wv-s, Di}$  : Wave vertical bending moment in the dredging situation i, in hogging and sagging condition, respectively, defined in [3.3.3].

**3.4.8 Combined still water and wave horizontal bending moment**

The total horizontal bending moment  $M_H$  applied on half-hull at hopper well mid-section and at hopper well ends, in navigation and dredging situations, is to be obtained, in kN.m, from the following formula:

$$M_H = M_{sh-hh} + M_{wh-hh}$$

where:

$M_{sh-hh}$  : Horizontal still water bending moment, defined in [3.4.5] at hopper well mid-section and at hopper well ends, in navigation and dredging situations

$M_{wh-hh}$  : Horizontal wave bending moment, defined in [3.4.6] at hopper well mid-section and at hopper well ends, in navigation and dredging situations.

**3.4.9 Combined still water and wave vertical shear forces**

The combined still water and wave vertical shear forces may be taken as equally distributed between both half hulls.

**3.5 Internal pressures in hopper well**

**3.5.1 Pressures for the strength and fatigue assessments in navigation and dredging situations**

The internal pressure  $P_{in}$  due to the mixture of sea water and spoil acting on any load point of the hopper boundary, in kN/m<sup>2</sup>, is to be taken as:

$$P_{in} = P_s + P_w$$

where:

$P_s$  : Static pressure due to water and spoil in hopper, as defined in [3.5.2]

$P_w$  : Dynamic pressure due to water and spoil in hopper, as defined in [3.5.3]

**3.5.2 Still water pressure in hopper well**

The still water pressure  $P_S$  in the hopper well, in  $\text{kN/m}^2$ , is to be taken as follows:

$$P_S = g \delta_i K_D d$$

without being taken less than:

- 12  $\text{kN/m}^2$  for prescriptive strength assessment
- 0  $\text{kN/m}^2$  for direct strength analysis and fatigue assessment

where:

- $\delta_i$  : density, taken equal to:
- for the navigation situation (see [3.1.1]):  $\delta$
  - for each of dredging situation  $i$  (see [3.1.1]):  $\delta_i$
- $K_D$  : coefficient taken equal to:
- for the navigation situation:  
 $K_D = 1,0$
  - for each of dredging situation  $i$ :  
 $K_D = \cos^2\alpha + \phi\sin^2\alpha$   
where:  
 $\phi$  : friction coefficient, taken equal to:
    - for  $\delta_i < 1,4$ :  
 $\phi = 1,0$
    - for  $\delta_i \geq 1,4$ :  
 $\phi = 1,4/\delta_i$
- $\alpha$  : angle between the considered panel and horizontal plane

**3.5.3 Inertial pressure in hopper well**

The dynamic pressure  $P_{Wi}$  in the hopper well, in  $\text{kN/m}^2$ , is to be taken as follows:

- for the navigation situation:  
 $P_W = \delta [a_x (x_0 - x) + a_y (y_0 - y) + a_z (z_0 - z)]$
- for each of the dredging situations  $i$ :

$$P_{Wi} = \delta_i \left( \frac{a_x(x_G - x) + a_y(y_G - y)}{4} + a_z d K_D \right)$$

without being taken less than:

- 12  $\text{kN/m}^2$  for prescriptive strength assessment
- 0  $\text{kN/m}^2$  for direct strength analysis and fatigue assessment

where:

- $x_0$  : X coordinate, in m, of the reference point.  
 $y_0$  : Y coordinate, in m, of the reference point.  
 $z_0$  : Z coordinate, in m, of the reference point.

The reference point is to be taken as the point with the highest value of  $V_j$ , calculated for all the points that define the free spoil surface at the filling level of the considered navigation or dredging situation, as follows:

$$V_j = a_x (x_j - x_G) + a_y (y_j - y_G) + (a_z + g) (z_j - z_G)$$

where:

- $x_j$  : X coordinate, in m, of the point  $j$  on the free spoil surface at the filling level of the considered navigation or dredging situation;  
 $y_j$  : Y coordinate, in m, of the point  $j$  on the free spoil surface at the filling level of the considered navigation or dredging situation;  
 $z_j$  : Z coordinate, in m, of the point  $j$  on the free spoil surface at the filling level of the considered navigation or dredging situation.  
 $x_G, y_G, z_G$ : X, Y and Z coordinates, in m, of the volumetric centre of gravity of spoil with respect to the reference coordinate system defined in Pt B, Ch 1, Sec 3, [2.6.1], to be taken as follows:
  - $x_G, y_G$ : Volumetric centre of gravity of the hopper well
  - $z_G$ : vertical position at mid height of the spoil, measured at the centerline. $K_D$  : coefficient as defined in [3.5.2]

## 4 Hull girder strength of dredgers, hopper dredgers and hopper units

### 4.1 General

4.1.1 The hull girder strength of:

- ships of more than 90 m and assigned with the service notation **dredger**, and
- ships of more than 65 m and assigned with the service notation **hopper dredger** or **hopper unit**,

is to be checked for navigation situation and each of the dredging situations (see [3.1.1]) according to the criteria of Part B, Chapter 6, considering the still water and wave loads defined in [3.3].

4.1.2 For dredgers made of bolted structure, the Society may require the hull girder strength criteria to be applied to each individual element, considering the loads calculated according to [3.1.2].

### 4.2 Midship section modulus

4.2.1 In the determination of the midship section modulus according to Pt B, Ch 6, Sec 1, [1.4], account is to be taken of both 85% and 100% effectiveness of the sectional area of the cellular keel.

However the 85% and 100% effectiveness of the sectional area of the cellular keel may be replaced by the actual effectiveness of the cellular keel determined by a three dimensional finite element analysis.

4.2.2 Where cut-outs in the side shell are needed to fit the suction pipe guides, a section modulus calculation not taking account of the side shell plating may be required by the Society on a case-by-case basis, if the structural continuity is not correctly achieved.

## 5 Hull girder strength of split hopper dredgers and split hopper units

### 5.1 General

5.1.1 The yielding check of ships with one of the service notations **split hopper dredger** or **split hopper unit** and of more than 65 m in length is to be carried out for navigation situation and each of the dredging situations (see [3.1.1]) according to [5.2] to [5.4] considering:

- each half-hull as being subjected to independent bending
- the deck hinges and the hydraulic jacks acting as supports at the ends of the hopper well.

Both the vertical bending moment and horizontal bending moment acting within the well area are to be taken into account.

5.1.2 The hull section modulus, considered with the two half-hulls connected, is to be checked for navigation situation and each of the dredging situations (see [3.1.1]) according to the criteria of Pt B, Ch 6, Sec 1, [3], considering the still water and wave bending moments defined in [3.4]

See also [4.2] for the determination of the midship section modulus.

### 5.2 Definitions

#### 5.2.1 Co-ordinate system

The hull girder strength is defined with reference to the following co-ordinate system, as shown in Fig 8:

- G : Centre of gravity of the half-hull transverse section
- GY : Transverse axis, parallel to Y defined in Pt B, Ch 1, Sec 3, [2.6] and crossing through G
- GZ : Vertical axis, parallel to Z defined in Pt B, Ch 1, Sec 3, [2.6] and crossing through G
- Gy, Gz : Main axes of the half-hull transverse section, defined in [5.2.2].

Figure 8 : Half-hull co-ordinate system

**5.2.2 Main axes**

The main axes Gy and Gz are obtained from the axes GY and GZ by a rotation around the centre of gravity G of an angle  $\alpha$  obtained from the following formula:

$$\alpha = \frac{1}{2} \text{atan} \left( \frac{2I_{YZ}}{I_Z - I_Y} \right)$$

where:

- $I_Y$  : Net moment of inertia, in  $m^4$ , of the transverse section around the axis GY
- $I_Z$  : Net moment of inertia, in  $m^4$ , of the transverse section around the axis GZ
- $I_{YZ}$  : Net inertia product, in  $m^4$ , of the transverse section, in the reference (G, GY, GZ).

**5.2.3 Bending moments**

The bending moments  $M_y$  and  $M_z$  in relation to the main axes Gy and Gz, respectively, are to be obtained, in kN.m, from the following formulae:

$$M_y = M_V \cos \alpha + M_H \sin \alpha$$

$$M_z = -M_V \sin \alpha + M_H \cos \alpha$$

where:

- $M_V$  : Vertical bending moment defined in [3.4.7], in kN.m, to be considered in hogging and sagging conditions, for the navigation and dredging situations
- $M_H$  : Horizontal bending moment defined in [3.4.8], in kN.m, to be considered for the navigation and dredging situations
- $\alpha$  : Angle defined in [5.2.2].

As the main inertia axes of each half-hull are oblique, the bending of each half-hull is a deviated bending.

**5.3 Hull girder stress**

**5.3.1** At any point of the transverse section of each half-hull, the hull girder normal stresses are to be obtained, in  $N/mm^2$ , from the following formula:

$$\sigma_L = \left( z \frac{M_y}{I_{yM}} - y \frac{M_z}{I_{zM}} \right) 10^{-3}$$

where:

- $M_y, M_z$  : Bending moments, in kN.m, in hogging and sagging conditions, for the navigation and dredging situations (see [3.1.1]), defined in [5.2.3]
- $I_{yM}, I_{zM}$  : Net moments of inertia, in  $m^4$ , of the transverse section around its main axes
- $y, z$  : y and z coordinates, in m, of the calculation point with respect to the main axes Gy and Gz.

**5.3.2** In the case of partly clamped ends of the hopper well (see [3.4.2]), the hull girder normal stresses are to be calculated in the hopper well mid-section and at hopper well ends.

In this case, the stresses are also to be calculated in the midship area assuming the ends supported as regards the horizontal moment. This calculation relates to the beginning of the hopper well drainage by opening of the two half-hulls.

**5.3.3** In the case of supports at hopper well ends, the calculation of the hull girder normal stress is to be carried out in the hopper well mid-section.

**5.3.4** For each section of calculation, the most unfavourable combination of moments is to be considered.

## 5.4 Checking criteria

5.4.1 It is to be checked that the normal stresses calculated according to [5.3.1] are in compliance with the requirements in Pt B, Ch 6, Sec 1, [3.5.2].

## 6 Hull scantlings

### 6.1 General

6.1.1 Hull scantlings are to be checked according to the applicable requirements of Part B, Chapter 7 for the additional design load sets defined in Tab 8.

Note 1: the design load sets SEA-Di are to be considered in addition to the design load set SEA-1 when applying the criteria for rounded bilge plating in Pt B, Ch 7, Sec 4, [6.2.1] item b).

For ships with one of the service notations **split hopper dredger** or **split hopper unit**, and of more than 65 m in length, the hull girder normal stresses to be used in the application of requirements of Part B, Chapter 7 are defined in [6.2].

**Table 8 : Additional design load sets for dredgers**

Item	Design load set	Load component	Draught	Acceptance criteria	Design load scenario / Loading condition
Outer shell and exposed deck	SEA-Di	$P_{ex}, P_d$	$T_{Di}$	AC-2	Sea-going / Dredging situation i
Hopper wells of dredgers	HW-N	$P_{in} - P_{ex}$ (1)	$T_{IF}$	AC-2	Seagoing / Navigation situation
	HW-Di	$P_{in} - P_{ex}$ (1)	$T_{Di}$	AC-2	Seagoing / Dredging situation i
Exposed deck, internal decks or platforms	DL-Di (2)	$P_{dk}, F_U$	$T_{Di}$	AC-2	Sea-going / Dredging situation i

(1)  $P_{ex}$  is to be considered for external shell only.  
 (2) Distributed or concentrated loads only. Need not be combined with simultaneously occurring green sea pressure.

### 6.2 Hull girder normal stress for split hopper dredgers and split hopper units of more than 65 m in length

6.2.1 The hull girder normal stress  $\sigma_L$  to be considered for the strength and buckling check of plating, stiffeners and primary supporting members according to Part B, Chapter 7 and Part B, Chapter 9 is to be obtained as calculated in [5.3].

### 6.3 Minimum net thicknesses of plating

6.3.1 The net thickness of plating is to be not less than the greater of the following values:

- 5 mm
- thickness, in mm, obtained from Tab 9.

**Table 9 : Ships for dredging activities - Minimum net thicknesses of plating**

Plating	Minimum net thickness, in mm
Hopper well <ul style="list-style-type: none"> <li>• transverse and longitudinal bulkheads</li> <li>• cellular keel plating</li> </ul>	$2,7 + 0,034 L k^{1/2} + 0,0045 b$
Splash coaming	6

6.3.2 Where no protection is fitted on the deck areas where heavy items of dredging equipment may be stored for maintenance, the net thickness of the deck plating is to be not less than the value obtained, in mm, from the following formula:

$$t = 5,1 + 0,040 L k^{1/2} + 0,0045 b$$

### 6.4 Transverse vertically corrugated bulkheads

6.4.1 Transverse vertically corrugated bulkheads forming the boundary of hopper wells are to comply with the requirements in Pt B, Ch 7, Sec 6, [4.6] considering an internal spoil pressure P as calculated in [3.5] for the design load sets HW-N and HW-Di.

### 6.5 Well bulkhead and cellular keel platings

6.5.1 The net thickness of the longitudinal bulkhead above the deck or within 0,1D below the deck is to be not less than the net thickness of the strength deck abreast of the hatchways.

6.5.2 The net thickness of the transverse and longitudinal bulkhead of a dredge pipe well is to be determined as for the side shell net thickness.

## 6.6 Transversely framed bottoms

### 6.6.1 Floors

The scantlings of floors located inside large compartments, such as pump rooms, are to be obtained from a direct calculation, according to Pt B, Ch 7, Sec 6 as applicable, and taking into account the following assumptions:

- floors are simply supported at ends
- local discontinuities in strength, due to the presence of wells, are to be considered.

## 7 Fatigue

### 7.1 General

#### 7.1.1 Application

Loading and unloading fatigue assessment is to be performed according to the requirements of Pt B, Ch 10, Sec 1, [1.3] to all ships having a length equal to or greater than 150m or assigned with the additional service feature **EOC**, considering the requirements in [7.1.2] to [7.1.4].

#### 7.1.2 Loading conditions

Loading conditions representative of the intended operation:

- navigation,
- ballast,
- dredging situation (see [3.1.1]),

and the fraction of time spent in each condition are to be considered for fatigue analysis.

Tanks filling levels associated to each loading condition are to be specified.

#### 7.1.3 Still water loads for the fatigue assessment

The still water bending moment,  $M_{sw}$ , to be used for the fatigue assessment is to be taken:

- for the navigation and ballast conditions, as defined in Pt B, Ch 5, Sec 4, [2.1.3]
- for the dredging situations  $M_{sw}$  is to be taken equal to  $1,00 M_{sw-min,Di}$ .

#### 7.1.4 List of special structural details

The following details are to be assessed in addition to those listed in Pt B, Ch 13, Sec 5:

- Corners of bottom door openings
- Crane rail details (e.g. expansion joints)
- Splash coaming details (e.g. expansion joints)
- Connections of the cellular keel to the transverse boxes and the hopper end bulkheads
- Connections of transverse boxes to the side structure
- Other details may be considered as special structural details whenever deemed necessary by the Society.

## 8 Hopper dredgers and hopper units: checking of hopper well structure

### 8.1 General

**8.1.1** The requirements of Article [8] apply to ships with one of the service notations **hopper dredger** or **hopper unit**.

**8.1.2** At the ends of the hopper spaces, the transverse bulkheads are to extend over the full breadth of the ship. Where this is not the case, web rings with special scantlings are to be provided.

### 8.2 Floors, webs, trunks, strongbeams and girders

**8.2.1** Stresses in transverse primary members (such as floors, webs, trunks, strongbeams and girders) are to be obtained by a 2D or 3D beam model or FEM with the following assumptions:

- design loads as specified by the Designer
- load cases according to Pt B, Ch 5, Sec 2.

**8.2.2** Stresses obtained according to [8.2.1] need to be combined with hull girder longitudinal stresses obtained according to Pt B, Ch 6, Sec 1, [2].

**8.2.3** It is to be checked that stresses obtained according to [8.2.1] and [8.2.2] are not greater than the allowable stresses defined in Pt B, Ch 7, Sec 6, [5.1.4].

**8.2.4** Alternatively, the transverse strength of the hopper well structure can be calculated considering the guidance provided in Ch 13, App 1.

## 9 Split hopper dredgers and split hopper units: superstructure hinges

### 9.1 General

**9.1.1** For ships with one of the service notations **split hopper dredger** or **split hopper unit**, a check of the superstructure hinges according to [9.5] is to be carried out considering the forces defined in [9.4].

### 9.2 Arrangements

**9.2.1** Chocks able to withstand the longitudinal forces induced by the superstructures are generally to be fitted on the deck located below the superstructures.

**9.2.2** When the chocks are fitted on one side only, attention is to be paid to the longitudinal take over of forces by the hinges located on the side opposite to the chocks.

**9.2.3** Chocks are to be able to work when the half-hulls swing apart to discharge the spoil.

**9.2.4** Special attention is to be paid to the reinforcement below the deck in way of the hinges and chocks, as well as to the fixing of the hinge to the strength members of the superstructures.

The scantlings of these members are to be calculated considering the forces given in [9.4.3] applied at the level of the hinge pin.

**9.2.5** Generally, no cut-out is to be fitted immediately near to hinges or chocks.

### 9.3 Materials used for the hinges

#### 9.3.1 Grades of hull steel plates

In normal service conditions, the hull steel plates are to be of the grade defined in Tab 10.

Moreover, in low temperature service conditions, the choice of the steel grade is to be made with the Society on a case-by-case basis, according to the actual service conditions and to the design detail of the welded assembly.

**Table 10 : Material grade requirements for superstructure hinges**

Gross thickness, in mm	Normal strength steel	Higher strength steel
$t \leq 20$	A	AH
$20 < t \leq 25$	D	DH
$25 < t \leq 30$	E	DH
$t > 30$	E	EH

#### 9.3.2 Grades of steel castings and steel forgings

The steel grade of the steel castings and steel forgings is to be defined according to the service temperature of the part and to the weld location on the part.

#### 9.3.3 Grades of steel for hinge pins

The hinge pins are generally to be made of forged steel.

In addition to the rule checks defined in NR216 Materials and Welding, Chapter 5, a series of impact tests is to be carried out on three Charpy V test pieces and the minimum mean value of impact energy KVL is to be equal to or greater than 27 J at 0°C.

#### 9.3.4 Inspections and tests of weld connections

For welds concerning the main members of the hinges, non-destructive examinations are to be carried out along the full length of the joint:

- for butt welds: 100% radiographic and ultrasonic examination
- for fillet welds with deep penetration: 100% ultrasonic examination and 100% magnetic particle inspection or penetrant fluid test
- for fillet welds with small penetration: 100% magnetic particle inspection or penetrant fluid tests.

### 9.4 Forces

**9.4.1** The forces defined in [9.4.2] to [9.4.4] may be replaced by results from model tests or by representative calculations.

In such case, the method used and the assumed conditions for model tests or calculation are to be submitted to the Society for information.

**9.4.2** The forces  $F_x$ ,  $F_y$  and  $F_z$ , in kN, applied on superstructures in respectively x, y and z direction, are to be obtained as follows:

- for split hopper dredger/unit with a length  $L < 65$  m:

$$F_x = 0 ; F_y = F_T ; F_z = F_Z + F_V$$

with  $F_T$ ,  $F_Z$  and  $F_V$  to be calculated from the formulae in NR600, Ch 6, Sec 1, [13.4.4], item c), with  $M$ , in t, to be taken as the mass of the superstructures.

- for split hopper dredger/unit with a length  $L \geq 65$  m:

$F_x$ ,  $F_y$  and  $F_z$  to be calculated from the applicable formulae of  $F_{u-d}$ , as defined in Pt B, Ch 5, Sec 6, [6.2.1] and Pt B, Ch 5, Sec 6, Tab 11 with  $m_{u,r}$ , in t, to be taken as the mass of the superstructures.

**9.4.3** In the case of superstructures connected to the ship by means of two simple hinges and two hinges with connecting tie-rods (as shown in Fig 9 and Fig 10), the forces are to be obtained, in kN, from the following formulae:

- force in line with a tie-rod:

$$F = \frac{1}{\cos\beta} \left( \frac{1}{2} + \frac{\epsilon_L}{d_L} \right) \left[ \left( \frac{1}{2} - \frac{\epsilon_T}{d_T} \right) F_Z + \frac{d_V}{d_T} F_V \right]$$

- vertical force in a simple hinge:

$$F = \left( \frac{1}{2} + \frac{\epsilon_L}{d_L} \right) \left[ \left( \frac{1}{2} + \frac{\epsilon_T}{d_T} \right) F_Z + \frac{d_V}{d_T} F_V \right]$$

- transverse force in a hinge:

$$F = \left( \frac{1}{2} + \frac{\epsilon_L}{d_L} \right) \left[ \left( \frac{1}{2} - \frac{\epsilon_T}{d_T} \right) F_Z \tan\beta + \left( 1 - \frac{d_V}{d_T} \tan\beta \right) F_V \right]$$

- longitudinal force for each chock:

$$F = \frac{F_x}{n_B}$$

where:

- $\beta$  : Angle of tie-rods with respect to the vertical line, in degrees
- $d_T$  : Transverse distance between a simple hinge and a tie-rod hinge, in m
- $d_V$  : Vertical distance from the centre of gravity of the superstructures to the horizontal plane passing through the hinge centreline, in m
- $d_L$  : Longitudinal distance between the fore and aft hinges, in m
- $\epsilon_T$  : Transverse eccentricity of the centre of gravity of the superstructures (taken as positive if the centre of gravity is on the side of the simple hinges, and as negative otherwise), in m
- $\epsilon_L$  : Longitudinal eccentricity of the centre of gravity of the superstructures (positive), in m
- $n_B$  : Number of longitudinal chocks.

Where a longitudinal chock is provided on one side only, the hinges are to be able to withstand the longitudinal force  $F_x$ .

The distribution of forces in the case of other arrangements is to be examined by the Society on a case-by-case basis.

**Figure 9 : Connection between superstructure and ship - Transverse direction**

Figure 10 : Connection between superstructure and ship - Longitudinal direction

9.4.4 The force F to be considered for the check of the hinge scantlings is to be taken equal to:

- for a simple hinge:  
the resultant of the horizontal and vertical forces
- for a hinge with tie-rod:  
the force in the tie-rod centreline.

Moreover, the horizontal force in the hinges due to withstanding of the longitudinal force  $F_x$  in the case of a horizontal chock on one side only is to be considered alone.

### 9.5 Scantlings of the hinges

9.5.1 The hinges consist generally of two side straps and a centre eye connected by a pin, as shown in Fig 11.

The two main types of hinges are generally the following (see Tab 11):

- type I: welded assembly made of plates
- type II: welded assembly made of plates and of cast steel or forged steel parts.

The check of scantlings in [9.5.2] applies to the case of direct bearing of the pin on the side straps and the centre eye (see Fig 12) and to the case of load transfer by bearings (see Fig 13). In the second case, the designer is to demonstrate that the bearings can withstand the calculated forces.

Hinges whose manufacture is different from these two cases are to be examined by the Society on a case-by-case basis.

9.5.2 For the pins, centre eye and side straps of the hinges, the applied forces are to comply with the formulae given in Tab 12.

Figure 11 : Superstructure hinge arrangement

Table 11 : Type of hinges

Type I superstructure hinges	Type II superstructure hinges

Figure 12 : Superstructure hinges: case of direct bearing

Figure 13 : Superstructure hinges: case of load transfer by bearings

Table 12 : Scantling check of superstructures hinges

Case	Elements to be checked			
		Pins	Centre eye	Side straps
Direct bearing	$F < \frac{d_a^2 R_m}{5,76} 10^{-3}$ $F < \frac{2}{3} d_a t_0 R_{eH} 10^{-3}$	<ul style="list-style-type: none"> <li>if <math>t_0 &lt; d_a</math>:  <math>F &lt; \frac{d_a^3 R_m}{2D_C - t_0} 10^{-3}</math></li> <li>if <math>t_0 \geq d_a</math>:  <math>F &lt; \frac{d_a^3 R_m}{2D_C - 2t_0 + d_a} 10^{-3}</math></li> </ul>	$F < \frac{b_0 t_0 R_{eH}}{2,27} 10^{-3}$ $F < d_a t_0 R_{rad} 10^{-3}$	$F < \frac{b_c t_c R_{eH}}{1,14} 10^{-3}$ $F < 2 d_a t_c R_{rad} 10^{-3}$
Load transfer by bearings	$F < \frac{d_a^2 R_m}{5,76} 10^{-3}$ $F < \frac{2}{3} d_a t_3 R_{eH} 10^{-3}$	<ul style="list-style-type: none"> <li>if <math>t_3 &lt; d_a</math>:  <math>F &lt; \frac{d_a^3 R_m}{2D_{C1} - t_3} 10^{-3}</math></li> <li>if <math>t_3 \geq d_a</math>:  <math>F &lt; \frac{d_a^3 R_m}{2D_{C1} - 2t_3 + d_a} 10^{-3}</math></li> </ul>	$F < \frac{b_0 t_0 R_{eH}}{2,27} 10^{-3}$ $F < \frac{2}{3} d_{a0} t_1 R_{eH} 10^{-3}$	$F < \frac{b_c t_c R_{eH}}{1,14} 10^{-3}$ $F < \frac{4}{3} d_{ac} t_2 R_{eH} 10^{-3}$

**Note 1:**  
 $R_{rad}$  : Admissible radial pressure on the bearing, to be taken equal to 100 N/mm<sup>2</sup>.

## 10 Split hopper dredgers and split hopper units: decks hinges, hydraulic jack connections and chocks

### 10.1 General

**10.1.1** For ships with one of the service notations **split hopper dredger** or **split hopper unit**, the scantlings of the deck hinges and the hydraulic jack attachments connecting the two half-hulls are to be determined according to [10.5] or by direct calculation.

The loads to be considered are the result of the most unfavourable combination of simultaneous static and dynamic forces (see [10.3] and [10.4]), calculated for the loading conditions in [3.2.1].

**10.1.2** The locking devices of the two half-hulls, if any, are to be examined by the Society on a case-by-case basis.

### 10.2 Arrangements

**10.2.1** Transverse chocks to be used upon closing the two half-hulls are to be provided in the bottom area, preferably in way of the hydraulic cylinders. These chocks may consist of heavy plates inserted in the bottom plating. They are to be arranged to come into contact before the end of the stroke of the jack, upon closing.

Moreover, if the calculation of the longitudinal strength is carried out assuming the hopper well ends are partly fixed, transverse chocks are to be provided at deck level.

**10.2.2** Longitudinal chocks are to be provided at bottom and deck level, to prevent relative displacement of the two half-hulls. Deck longitudinal chocks must also act in the open position.

For units of a capacity less than 700 m<sup>3</sup>, longitudinal deck chocks need not be provided; in such case, one of the two deck hinges is to be designed to fulfil the function of a chock. The other hinge is then to have sufficient clearance.

### 10.3 Static forces

**10.3.1** The method of calculation in [10.3.2] to [10.3.9] enables the determination of the static forces in the hydraulic jack, in the chocks and in the deck hinges only if the following conditions are met:

- the total number of hydraulic jacks connecting the two half-hulls is even
- there are no superposed jacks in the same section
- there is a deck hinge at each end of the hopper well.

Any other arrangement is to be examined by the Society on a case-by-case basis.

**10.3.2** In the case of maximum loading corresponding to the dredging freeboard, the forces exerted on a half-hull to be considered to calculate the static forces in the hinges, transverse bottom chocks and jacks are shown in Fig 14 as well as their lever arm in relation to the deck hinge pins.

**10.3.3** The horizontal static forces to be considered are the following:

- horizontal hydrostatic buoyancy  $F_h$  on the full length of the well, in kN. This force takes into account the hydrostatic buoyancy due to the water located between the two half-hulls below the sealing joint situated at the lower part of the hopper well, taken equal to:

$$F_h = 5,026 (T_D - a)^2 \ell_p$$

- horizontal pressure of the spoil  $F_d$ , in kN, taken equal to:

$$F_d = 4,904 \delta (h_{Di} - a)^2 \ell_p$$

- force  $F_{CY}$  in each jack, in kN, equal to the greater of  $F_{MC}$  and  $F_p$
- force  $F_{CH}$  in each hinge, in kN, taken equal to:

$$F_{CH} = 0,5 \left[ F_h - F_d + n_1 \left( 1 - \frac{a_3}{a_4} \right) F_{CY} + \frac{M}{a_4} \right]$$

- force  $F_B$  in each bottom transverse chock, in kN, taken equal to:

$$F_B = \frac{n_1 a_3 F_{CY} - M}{n_2 a_4}$$

where:

$F_{MC}$  : Minimum force required to keep the dredger closed in the loading case considered, obtained from the following formula:

$$F_{MC} = M / n_1 a_3$$

For a tendency to close,  $F_{MC}$  is negative and is not to be taken into account to determine  $F_{CY}$

$F_p$  : Force in the jack corresponding to a pressure on the rod side equal to the maximum pressure  $P_p$  of the pumps and of their pressure limiting device

Figure 14 : Forces exerted on a half-hull

M : Moment with respect to the hinge chocks, positive for a tendency to open, negative in the opposite case, taken equal to:

$$M = -F_h a_1 + F_d a_2 + \frac{1}{2}(\Delta b_1 - \Delta_1 b_2 - Q b_3)$$

$n_1$  : Number of jacks

$n_2$  : Number of bottom transverse chocks

$\Delta, \Delta_1 \ell, Q$ : Vertical forces, defined in [10.3.4]

$a_1, a_2, a_3, a_4$ : Lever arms of horizontal forces, as shown in Fig 14

$b_1, b_2, b_3$ : Lever arms of vertical forces, as shown in Fig 14.

10.3.4 The vertical static forces to be considered are the following:

- vertical hydrostatic buoyancy  $\Delta/2$  on a half-hull, in kN
- weight  $\Delta_1 \ell / 2$  of the half-hull without spoil, in kN
- weight  $Q / 2$  of the half spoil loading, in kN

where:

$\Delta$  : Total displacement of the ship with spoil

$\Delta_1 \ell$  : Total displacement of the ship without spoil, including superstructures

$Q$  : Total weight of the spoil in the well.

The following relation between vertical static forces is to be verified:

$$\Delta = \Delta_1 \ell + Q$$

10.3.5 For every other loading case, the forces  $F_{CY}, F_{CH}$  and  $F_B$  are to be calculated according to [10.3.3], by replacing:

- $a_1, a_2, b_1, b_2, b_3, \Delta, \Delta_1 \ell$  and  $Q$  by the corresponding values for the loading case considered
- $T_{Di}, \delta_i$  and  $h_{Di}$  by values of external draught, density of water or spoils in the well and level inside the well for the loading case considered, i.e.:
  - in dredging condition, at the international freeboard:  $T_{IF}, \delta$  and  $h_{IF}$
  - in dredging condition, with the well filled up to the waterline:  $T_{WL}, 1,025$  and  $h_{WL}$  taken equal to  $T_{WL}$
  - in dredging condition, with well filled with water to the lowest weir level:  $T_{OL}, 1,025$  and  $h_{OL}$ .

10.3.6 If, in the maximum loading condition corresponding to the dredging freeboard or the international freeboard, densities of spoil higher than  $\delta$  may be considered with reduced heights (for constant mass of spoils), calculation of  $F_{CY}, F_{CH}$  and  $F_B$  is also to be carried according to [10.3.3], using the parameters corresponding to the maximum densities of spoil likely to be considered with draughts  $T_{Di}$  and  $T_{IF}$ .

10.3.7 The maximum static force  $F_s$ , actually developed by the jack, is the greatest of the values obtained for  $F_{CY}$  for the various loading cases and calculated according to [10.3.3], [10.3.5] and [10.3.6].

10.3.8 Where the hopper well ends are partly fixed, the end moments result in additional forces in the deck hinges, jacks, deck and bottom chocks, forward and aft of the well.

The distribution of these forces is to be determined by a direct calculation to be submitted to the Society for information.

**10.3.9** The Designer is to give the value of the horizontal lever arm  $b_2$  and the hull weight for the various loading cases as stated in [10.3.3]. In each case, the value to be taken into account is the most unfavourable one according to the distribution of the compartments, considering the tendency to open or to close.

However, the attention of the Owner and of the Designer is drawn to the fact that side tank ballasting can noticeably reduce the static forces necessary in the jacks to act against opening of the two half-hulls in the above operating conditions.

**10.4 Dynamic forces**

**10.4.1** The Designer is to give the dynamic forces applied on the deck hinges and on the hydraulic jack attachments by means of a calculation to be submitted to the Society for information.

**10.4.2** The dynamic forces are generally to be calculated by means of a long-term statistical analysis, under the conditions defined in Tab 13.

**Table 13 : Probability for the determination of dynamic forces**

Condition	Probability
Dredging and navigation with spoil, with sea state limited to $H_s = 3$ m (1)	$10^{-5}$ for jacks and hinges
Navigation without spoil, without limitation on sea state (2)	$10^{-7}$ for jacks $10^{-5}$ for hinges
<p>(1) <math>H_s</math> : Significant wave height, in m.                  (2) In sailing condition without spoil, a different probability level may be adopted for the calculation of dynamic forces on the cylinders, subject to the Society's agreement, when a device intended to restore the pressure to the cylinders after opening of the safety valves is fitted (see also [11.3.1]).  <b>Note 1:</b> The different calculation conditions are to be justified by the Designer.</p>	

**10.4.3** For each rule loading case, the results of the calculation are to give:

- the dynamic force  $F_{DCY}$  in each jack, in kN
- the horizontal dynamic force  $F_{DHC}$  in each hinge, in kN
- the vertical dynamic force  $F_{DVC}$  in each hinge, in kN.

**10.4.4** If loading cases other than those defined in [3] are considered, calculations for such additional cases are to be defined in agreement with the Society on a case-by-case basis.

**10.4.5** In the case of dredgers with a capacity of less than 700 m<sup>3</sup>, the dynamic forces in the jacks and hinges may be taken into account without long-term statistical calculations. The calculations for jacks and hinges are to be justified to the Society.

**10.4.6** For ships with one of the navigation notations **coastal area** or **sheltered area**, the dynamic forces in the cylinders and the hinges may be reduced by 10% in the case of navigation without spoil.

**10.5 Scantlings**

**10.5.1** The maximum total force in the jack is to be taken equal to the greatest value, from all the loading cases foreseen, obtained, in kN, from the following formula:

$$F_m = F_{CY} + F_{DCY}$$

The jack is to be capable of developing a force at least equal to  $F_m$ , at the setting pressure of the safety valve of the jack considered as isolated.

**10.5.2** The scantlings of the jack lugs are to comply with [9.5] considering the force  $F_m$  as determined in [10.5.1]. Cases where the force developed by the jack, at the setting pressure of the safety valve of the jack considered as isolated, is noticeably higher than  $F_m$  are to be examined by the Society on a case-by-case basis.

**10.5.3** The scantlings of the deck hinges are to comply with [9.5], considering the resultant of the total horizontal force and the total vertical force, obtained, in kN, from the following formula:

$$F_{Res} = \sqrt{(F_{CH} + F_{DCH})^2 + F_{DVC}^2}$$

**10.5.4** The scantling load of the transverse bottom chocks is to be defined in agreement with the Society.

**10.5.5** The scantlings of the longitudinal bottom chocks provided for in [10.3.2] are to be determined considering for each chock the force obtained, in kN, from the following formula:

$$F = 0,15 \frac{\Delta_m}{n_3}$$

where:

$\Delta_m$  : Maximum displacement of the ship, in kN, with the well loaded with spoil

$n_3$  : Total number of chocks (at deck and bottom).

The scantlings of the longitudinal deck chocks mentioned in [10.3.2] are to be determined considering for each chock the force obtained, in kN, from the following formula:

$$F = 0,15 \frac{\Delta_m}{n_4}$$

where:

$\Delta_n$  : Displacement of the ship with the well filled with water up to the waterline

$n_4$  : Number of longitudinal deck chocks.

The permissible shear stress for bottom and deck chocks is to be obtained, in N/mm<sup>2</sup>, from the following formula:

$$\tau = 0,9 \frac{R_{eH}}{\sqrt{3}}$$

For the calculation of the shear stress in the deck chocks, a reduced sectional area corresponding to the efficient sectional area of the chocks when the well is open is to be considered.

**10.5.6** The lugs of the jacks and the deck hinges may be calculated using a finite element model.

In such case, the finite element model and the applied loadings are to be preliminarily agreed upon by the Society.

The permissible stress is to be defined in agreement with the Society, depending on the finite element model and on the characteristics of the materials.

## **11 Split hopper dredgers and split hopper units: hydraulic jacks and associated piping systems**

### **11.1 General**

**11.1.1** For ships with one of the service notations **split hopper dredger** or **split hopper unit**, the check of hydraulic jacks and associated piping systems intended for closing the two half-hulls of the ship is to be carried out according to [11.1] to [11.6].

**11.1.2** Hydraulic jack design and construction are to be in accordance with the applicable requirements of Pt C, Ch 1, Sec 14, [2], while associated piping systems are generally to fulfil the relevant requirements of Pt C, Ch 1, Sec 10.

Materials used are to be in accordance with the applicable requirements of NR216 Materials and Welding.

### **11.2 Definitions**

**11.2.1** For the checking of hydraulic jacks and associated piping systems, the following definitions are to be considered:

$P_m$  : Pressure on the rod side of the jack resulting from the extreme foreseen ambient conditions corresponding to the maximum force  $F_{m,r}$ , defined in [10.5.1]

$P_C$  : Maximum pressure on the bottom side of the cylinder equal to the setting value of the safety valves protecting the bottom side of the cylinder

$P_p$  : Maximum pressure which can be delivered through the pumps and their associated pressure limiting devices

$P_S$  : Pressure on the rod side of the jack corresponding to the greatest of forces  $F_{S,r}$ , defined in [10.3.7], and  $F_{p,r}$ , defined in [10.3.3].

### **11.3 Arrangements**

**11.3.1** When large ships are concerned, the following arrangements are generally to be provided:

- for each hydraulic jack, a measuring system of the pressure in the cylinder is to be supplied
- this system, in addition to the indication of the pressure at the bridge and at the dredging room, is to comprise a visual and audible alarm at the same locations, to be activated when a certain limit is exceeded
- the measuring system, the alarm activating limit as well as the instructions to be followed after the alarm occurs are to be submitted to the Society for approval.

**11.3.2** Special attention is to be paid to protection against corrosion.

### **11.4 Scantling of jacks**

**11.4.1** For the pressure parts of hydraulic jacks made of steel, the permissible stress related to the loading conditions resulting in pressure  $P_p$  or  $P_S$  (whichever is the greater) acting on the cylinder rod side without pressure on the other side is to be taken as the smaller of  $R_{eH} / 1,8$  and  $R_m / 2,7$ .

The allowable stress applicable to the cylindrical envelope, for the loading conditions resulting in pressure  $P_m$ , may be taken as the smaller of  $R_{eH} / 1,5$  and  $R_m / 2,25$ .

**11.4.2** The scantlings of the jack end cover on the rod side are to be determined using  $P_m$  as design pressure.

The scantlings of the jack end cover on the bottom side as well as the mechanical connections (for example the bolts between the cover and the cylinder or between the piston and the rod) are to be based on  $F_m$ .

The calculations justifying the proposed scantlings and, as the case may be, the pre-stresses are to be submitted to the Society for information.

**11.4.3** The scantlings of the rod are to be based on  $F_m$  and on the smaller value of  $R_{eH} / 2$  and  $R_m / 2,4$ , for the mean permissible stress in traction. A calculation proving the adequate buckling strength of the rod is to be submitted to the Society for information.

**11.4.4** The scantlings of the lugs and the pins at each end of the hydraulic cylinder are to be based on  $F_m$ .

## **11.5 Inspection and testing**

**11.5.1** In addition to inspections required in [11.1.2], where applicable, welded joints connecting parts subject to the load  $F_m$  are to fulfil the requirements for class I pressure vessels or equivalent.

**11.5.2** Completed cylinders and attached piping up to and including the first isolating valve are to undergo, at works, a pressure test at the greater of the values  $1,4 P_s$  and  $1,2 P_m$  applied on the rod side and a pressure test at  $1,4 P_C$  on the bottom side for the fully extended position.

**11.5.3** The completed hydraulic circuit is to be subjected, on board, to pressure tests at  $1,4$  times the relevant maximum service pressure for normal conditions or static loads, for the part of the circuit considered.

## **11.6 Relief valve setting**

**11.6.1** At least one relief valve of appropriate capacity is to protect each part of the circuit which may be subject to overpressure due to external loads or due to pump action; in general, relief valves on the rod side of each cylinder or group of cylinders are to be set at  $P_{mv}$  while  $P_C$  applies to the bottom side for relief valve setting purposes.

Parts of the circuit possibly subject to overpressure from pumps only are to be protected by relief valves set at pressure  $P_p$ .

## **12 Rudders**

### **12.1 General**

**12.1.1** The rudder stock diameter obtained from Pt B, Ch 12, Sec 1, [4] is to be increased by 5%.

### **12.2 Additional requirements for split hopper dredgers and split hopper units**

**12.2.1** Each half-hull of ships with one of the service notations **split hopper unit** or **split hopper dredger** is to be fitted with a rudder complying with the requirements of Pt B, Ch 12, Sec 1.

**12.2.2** An automatic system for synchronising the movement of both rudders is to be fitted.

## **13 Equipment**

### **13.1 General**

**13.1.1** The requirements of this Article apply to ships having normal ship shape of the underwater part of the hull.

For ships having unusual ship shape of the underwater part of the hull, the equipment is to be considered by the Society on a case-by-case basis.

**13.1.2** The equipment obtained from [13.1.4] or [13.1.5] is independent of anchors, chain cables and ropes which may be needed for the dredging operations.

**13.1.3** The Equipment Number EN is to be obtained from the following formula:

$$EN = 1,5 (L B D)^{2/3}$$

When calculating EN, bucket ladders and gantries may not be included.

**13.1.4** For ships equal to or greater than 80 m in length and for ships with EN, calculated according to [13.1.3], equal to or greater than 795, the equipment is to be obtained from Pt B, Ch 12, Sec 4, [2], with EN calculated according to Pt B, Ch 12, Sec 4, [1] and not being taken less than 795, considering the following:

- to apply the formula, the displacement considered is that of the navigation draught, taking into account the cylinder housings and the free space between the two half-hulls
- the chain cable diameter is to be read off after moving to the next line below in the applicable Table.

**13.1.5** For ships other than those defined in [13.1.4], the equipment is to be obtained from Tab 14.

Where such ships are assigned one of the following navigation notations:

- **summer zone**
- **tropical zone**
- **coastal area,**

the equipment is to be obtained by consulting Tab 14 one line higher.

Where such ships are assigned the navigation notation **sheltered area**, the equipment is to be obtained by consulting Tab 14 two lines higher.

**Table 14 : Ships for dredging activities - Equipment**

Equipment number EN A < EN ≤ B		Stockless anchors		Stud link chain cables for anchors	
A	B	N	Mass per anchor, in kg	Total length, in m	Diameter, in mm
35	45	2	120	110,0	16,0
45	60	2	140	110,0	17,5
60	80	2	220	110,0	19,0
80	92	2	260	137,5	20,5
92	102	2	290	137,5	22
102	112	2	320	165,0	24
112	130	2	350	165,0	24
130	155	2	430	165,0	26
155	185	2	500	165,0	28
185	210	2	600	165,0	30
210	250	2	700	165,0	32
250	285	2	800	220,0	34
285	315	2	900	220,0	36
315	350	2	1000	220,0	38
350	385	2	1100	220,0	38
385	415	2	1200	220,0	40
415	450	2	1300	220,0	40
450	485	2	1400	220,0	42
485	515	2	1500	220,0	44
515	550	2	1600	220,0	46
550	585	2	1700	220,0	48
585	635	2	1800	275,0	48
635	685	2	2000	275,0	50
685	715	2	2100	275,0	52
715	750	2	2200	275,0	54
750	795	2	2300	275,0	54

**13.2 Additional requirements for split hopper dredgers and split hopper units**

**13.2.1** Arrangements of ships with one of the service notations **split hopper dredger** or **split hopper unit** are to be in accordance with [13.2.2] to [13.2.5].

**13.2.2** One chain locker and one complete mooring chain cable are generally to be provided for each half-hull.

**13.2.3** If the mass of the anchor permits, only one windlass needs to be provided on either of the half-hulls. In this case, in addition to the requirements in Pt B, Ch 12, Sec 4, [2], a chain stopper is to be fitted on the half-hull which is not equipped with a windlass.

**13.2.4** Fairleads or rollers are to be located in suitable places between the windlass and the hawse pipe so that the dropping and the housing of the anchor are satisfactorily ensured.

**13.2.5** Arrangements are to be made to avoid jamming of the cable during the opening and closing operations of the two half-hulls.

**13.3 Towlines and mooring lines**

**13.3.1** The towline and the mooring lines are given as a guidance, but are not required as a condition of classification.

**13.3.2** For ships equal to or greater than 80 m in length and ships with EN, calculated according to [13.1.3], greater than 795, the characteristics of towlines and mooring lines may be obtained from Pt B, Ch 12, Sec 4, [2] with EN calculated according to Pt B, Ch 12, Sec 4, [1], considering the displacement at navigation draught, taking into account the cylinder housings and the free space between the two half-hulls, the latter value of EN not being less than 795.

**13.3.3** For ships other than those defined in [13.3.2], the characteristics of towlines and mooring lines may be obtained from Tab 15.

**Table 15 : Ships for dredging activities - Towlines and mooring lines**

Equipment number EN A < EN ≤ B		Towline (1)		Mooring lines (1)		
A	B	Minimum length, in m	Breaking load, in kN	N	Length of each line, in m	Breaking load, in kN
35	45	120	88	2	90	59
45	60	120	93	2	90	64
60	80	120	98	2	90	68

685	715	160	465	4	160	170
715	750	160	490	4	160	175
750	795	180	515	4	160	180

**(1)** The towline and the mooring lines are given as a guidance, but are not required as a condition of classification.

## Section 3 Machinery and Dredging Systems

### 1 General

#### 1.1 Application

**1.1.1** This Section provides requirements for ships having the service notation **dredger, hopper dredger, hopper unit, split hopper unit** and **split hopper dredger**. These requirements are only applicable at the request of an Owner.

**1.1.2** This Section does not cover the other aspects of the system and equipment design, in particular in respect of their performance.

**1.1.3** The requirements for bottom doors and valves fitted on ships having the notation **hopper dredger, hopper unit, split hopper unit** and **split hopper dredger** are given in Ch 13, Sec 2.

### 2 Dredging system

#### 2.1 Attachment of dredging equipment to the hull

**2.1.1** The scantlings of the structure for attachment of the equipment intended for dredging operations (e.g. connection of the suction pipe to the hull, foundation of the suction pipe davits) are to be based on the service load of such equipment, as specified by the Designer.

In determining the above service load, the Designer is to take account of additional loads imposed by ship movements (in particular pitch and heave) in the most unfavourable sea and weather conditions expected during service.

### 3 Steering gear of split hopper dredgers and split hopper units

#### 3.1 General

**3.1.1** The rudder fitted to each half-hull of ships having the service notations **split hopper dredger** or **split hopper unit** (see Ch 13, Sec 2, [12.2.1]) is to be served by its own steering gear.

#### 3.2 Design of the steering gear

**3.2.1** The steering gear referred to in [3.1.1] is to consist of a control system and a power actuating system capable to operate the relevant rudder as required in Pt C, Ch 1, Sec 14, [2.2.1] or Ch 15, Sec 4, [24.3.1], as appropriate.

**3.2.2** An auxiliary steering gear or a duplicated power actuating system need not be fitted.

#### 3.3 Synchronisation

**3.3.1** An automatic system for synchronising the movement of both rudders is to be fitted. It is to comply with the provisions of Pt C, Ch 1, Sec 14, [3.2.2].

### 4 Testing of dredging equipment

#### 4.1 On board testing

##### 4.1.1 Ship trials

- a) Upon completion of construction, in addition to the conventional sea trials required in Pt C, Ch 1, Sec 18, specific tests may be required at the Society's discretion in relation to the particular service for which the ship is intended or the specific characteristics of machinery and equipment fitted on board.
- b) In particular, as regards propulsion and steering systems, tests may be required to check the manoeuvring capability and the speed of the ship whilst operating.

##### 4.1.2 Equipment trials

As far as the dredging system is concerned, tests are to be carried out to verify the proper operation of all relevant equipment in different sea and weather conditions, according to a specification submitted by the interested party.

# Appendix 1      Guidance on Calculation of Transverse Strength Hopper Well Structure

## 1 Hopper dredgers and hopper units: checking of hopper well structure

### 1.1 General

1.1.1 The requirements in Articles [1] to [5] apply to ships with one of the service notations **hopper dredger** or **hopper unit**.

## 2 Floors

### 2.1 General

2.1.1 The scantlings of floors of ships with open wells fitted with bottom doors are to be obtained from a direct calculation, according to Pt B, Ch 7, Sec 6 or NR600, Ch 4, Sec 5, [1.2] as applicable, taking into account the following assumptions:

- the span is equal to half the sum of the upper face plate length and the distance between lower ends of the hopper well sloped bulkheads
- the floors have fixed ends
- the floors are subject to the uniform and concentrated loads detailed in [2.3]
- the central box (cellular keel) is supported by the floors

However, where this box has sufficient dimensions and scantlings to support a part of the loads, this may be taken into account if a relevant calculation of grid type is submitted to the Society for information.

- in addition to the loads laid down in [2.3], the floor may support differential loads, for example when all the valves are not simultaneously opened, or compression loads when the well is empty
- the web cut-out section is deducted for the calculations of shear stresses and normal stresses (tension or compression)
- for the calculation of normal stresses and bending stresses, the face plate cross-section is taken into account only if these face plates are correctly offset on the adjacent structure

### 2.2 Different types of bottom and valves used

2.2.1 The different types of bottom doors and valves generally used, as well as the relevant symbols, are defined in Tab 1.

### 2.3 Load borne by floors

2.3.1 The loads borne by floors are a combination, according to the type of bottom doors, of the elementary loads [a], [b], [c], [d], [e] and [f], obtained, in kN, from the following formulae:

[a] : Uniform load of spoils, to be taken equal to:

$$Q_1 = g \delta (D + h_D) S_a \ell$$

[b] : External hydrostatic pressure, to be taken equal to:

$$Q_2 = g (T_D - 0,5 h_0) S_a \ell$$

In the course of calculations,  $P_r$  is the reduced pressure, evenly distributed, to be taken equal to:

$$P_r = \delta (D + h_D) - (T_D - 0,5 h_0)$$

The resultant load is to be taken equal to:

$$Q = Q_1 - Q_2 = g P_r S_a \ell$$

[c] : Load acting directly on a valve (to be deducted), to be taken equal to:

$$q = g P_r A_{bd}$$

This load is assumed to be evenly distributed along the length  $c_1$ . It is to be cut off from the load  $Q$ .

In the case of type 5 bottom doors (see Tab 1),  $q = 0$

[d] : Reactions  $R_2$  of the bottom doors on the floor (to be added), the absolute values and abscissae of which are indicated in Tab 2

Reactions  $R_1$  on the rods of the hydraulic jacks of bottom doors type 1, type 2 and type 3 (see Tab 1) are given in Tab 2 for further calculations but they are not borne by the floors

[e] : Axial force due to the lack of spoils in the volume occupied by the cellular keel (to be deducted), to be taken equal to:

$$F_1 = g \delta S_a A$$

[f] : Axial force due to a possible transmission of the resultant reaction  $R_1$  to the cellular keel, through a strong beam, an axial pillar or inclined pillars, to be taken equal to:

- with one axial pillar:

$$F_2 = 4 \frac{vR_1}{\ell_0}$$

- with two inclined pillars:

$$F_2 = 2 R_1$$

For determination of the scantlings of strong beams, girders and pillars,  $R_1$  is to be replaced by  $F_M$ , in kN, when calculating  $F_2$ , if  $F_M$  is higher than  $R_1$ ,  $F_M$  being the maximum force induced by the bottom door hydraulic jack.

where:

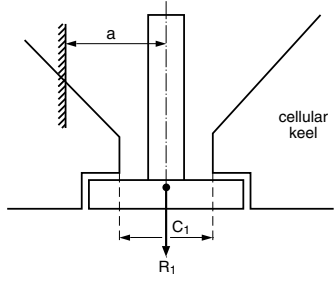

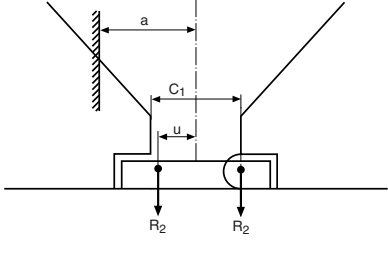

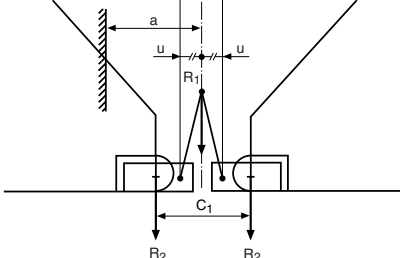

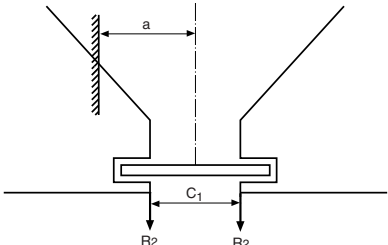

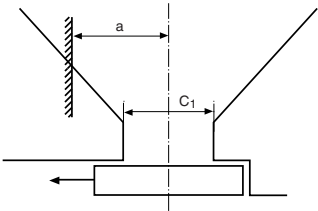

- $h_D$  : Distance, in m, from the highest weir level, corresponding to the draught  $T_D$ , to the deck-line ( $h_D$  is to be counted negatively where the level is located below the deck-line at side)
- $S_a$  : Transverse primary supporting ring spacing, in m
- $\ell$  : Stiffener span, in m  
In the case of floors, the span is equal to half the sum of the length of the upper flange plate and the distance between the lower ends of the sloping sides of the hopper space.
- $h_0$  : Ship relative motion, in m, taken equal to  $h_w$  as defined in Pt B, Ch 5, Sec 5 or to  $h_1$ , as defined in NR600, Ch 3, Sec 3, as applicable
- $A_{bd}$  : Whole sectional area, in  $m^2$ , of the bottom door whatever its type may be
- $A$  : Area, in  $m^2$ , enclosed by the contour of the cellular keel
- $v$  : Distance, in m, from the hydraulic jack centreline to the end of the strong beam span
- $\ell_0$  : Span, in m, of the strong beam bearing the reactions of the hydraulic jacks

## 2.4 Shear force diagrams

2.4.1 The shear force diagrams corresponding to each elementary load defined in [2.3] are given in Tab 3.

The total shear force, at abscissa X, equal to the algebraical sum of the elementary shear forces corresponding to each type of bottom doors, is indicated in Tab 4.

**Table 1 : Types of bottom doors and valves**

<p><b>Type 1</b> Bottom valve, centrally operated by a vertical shaft</p> 	<p><b>Type 2</b> Single bottom door, with hinges at one side (either cellular keel side or lower wing tank side) and operated by a vertical shaft at the other side</p> 	<p><b>Type 3</b> Double bottom doors, with hinges at both sides and operated by one central vertical shaft connected to the doors by means of two rods</p> 
<p><b>Type 4</b> Longitudinal sliding bottom doors</p> 	<p><b>Type 5</b> Transverse sliding bottom doors, guides being supported by floors</p> 	

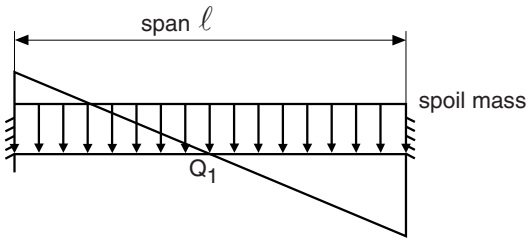

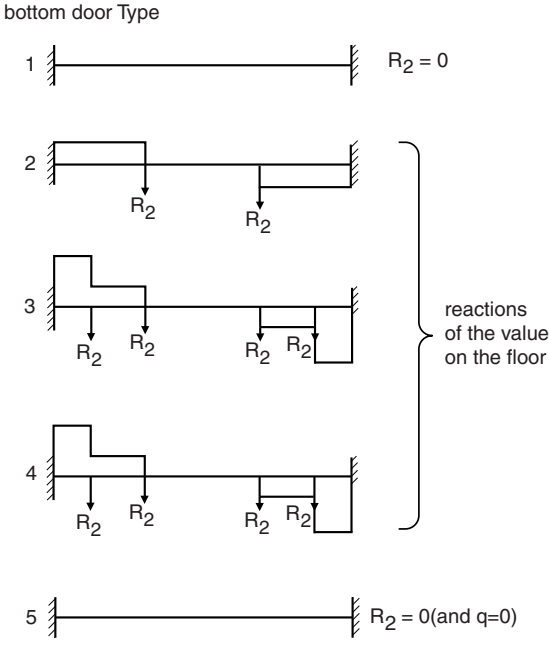

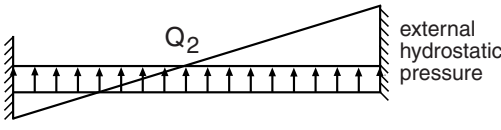

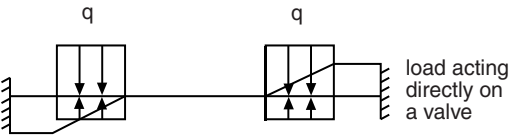

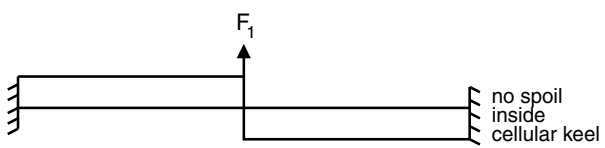

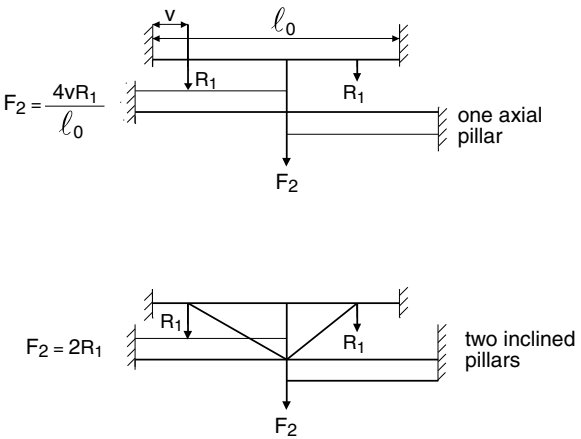

**Table 2 : Reactions  $R_1$  and  $R_2$  for elementary load [d]**

Bottom door type (see Tab 1)	Reactions $R_2$			Reactions $R_1$
	No.	Value, in kN	Abscissae	Value, in kN
Type 1		0		$g A_{bd} P_r$
Type 2	1	$g A_{bd} P_r \left( \frac{2u}{c_1 + 2u} \right)$	$(a + 0,5 c_1)$ or $(a - 0,5 c_1)$	$g A_{bd} P_r \left( \frac{c_1}{c_1 + 2u} \right)$
Type 3	2	$0,25 g A_{bd} P_r \left( \frac{c_1 - 4u}{c_1 - 2u} \right)$	$(a + 0,5 c_1)$ and $(a - 0,5 c_1)$	$0,5 g A_{bd} P_r \left( \frac{c_1}{c_1 - 2u} \right)$
Type 4	2	$0,5 g A_{bd} P_r$	$(a + 0,5 c_1)$ and $(a - 0,5 c_1)$	0
Type 5		0		0

**Note 1:**

- a : Distance, in m, from either end of the floor span to the centreline of the bottom door closest to that end
- $c_1$  : Width of a bottom door, in m
- u : Distance, in m, from the fixing point of the hydraulic jack rod (or of the two rod hydraulic jack) to the centreline of the bottom door.

**Table 3 : Shear force diagram**

<p><b>Elementary load [a] - Load <math>Q_1</math></b></p> 	<p><b>Elementary load [d] - Reactions <math>R_2</math></b></p> <p>bottom door Type</p> 
<p><b>Elementary load [b] - Load <math>Q_2</math></b></p> 	
<p><b>Elementary load [c] - Load q</b></p> 	
<p><b>Elementary load [e] - Force <math>F_1</math></b></p> 	<p><b>Elementary load [f] - Force <math>F_2</math></b></p> 

**Table 4 : Shear force values**

Bottom door type (see Tab 1)	Total shear force T(x) at abscissa X, in kN
Type 1	$T_0$
Type 2	$T_0 + R_2$
Type 3	$T_0 + 2 R_2$
Type 4	$T_0 + 2 R_2$
Type 5	$T_0 + q - 0,5 F_2$

**Note 1:**  
X : Distance, in m, from the cross-section under consideration to the end of the floor span  
 $T_0$  : Total shear force, in kN, at the left end of the span, to be taken equal to:  

$$T_0 = \frac{1}{2}(Q_1 - Q_2 - 2q - F_1 + F_2)$$

**2.5 Bending moments for each elementary load**

2.5.1 The bending moments for each elementary load defined in [2.3] are given in Tab 5, at span ends and at mid-span.

**2.6 Resultant bending moment**

2.6.1 The resultant bending moment is the sum of the elementary moments for each type of valve.

The total moment value at abscissa X is determined by deducting algebraically from the total moment value at the span ends the value of the area bounded by the total shear force curve.

**2.7 Normal load**

2.7.1 The normal load is to be obtained, in kN, from the following formula:

$$F_N = F_{N1} - F_{N2}$$

where:

$$F_{N1} = \frac{3,3S_a\delta}{2D - h_v}(D + h_D)^2(2D - h_D)$$

$$F_{N2} = \frac{3,3S_a}{2D - h_v}(T_D - 0,5h_0)^2(3D - T_D + 0,5h_0)$$

$h_v$  : Mean floor depth, in m.

**Table 5 : Values of bending moments**

Elementary load / Bottom valve type	Bending moment, in kN.m, at span ends	Bending moment, in kN.m, at mid-span	
[a]	$-\frac{Q_1\ell}{12}$	$\frac{Q_1\ell}{24}$	
[b]	$\frac{Q_2\ell}{12}$	$-\frac{Q_2\ell}{24}$	
[c]	$\frac{qa(\ell - a)}{\ell}$	$-\frac{qa^2}{\ell}$	
[d]	Type 1 or Type 5	0	
	Type 2	$-R_2 \frac{(2a + c_1)(2\ell - 2a - c_1)}{4\ell}$ (1)	$R_2 \frac{(2a + c_1)^2}{4\ell}$
	Type 3 or Type 4	$-R_2 \left[ \frac{4a(\ell - a) - c_1^2}{2\ell} \right]$	$R_2 \left[ \frac{4a^2 + c_1^2}{2\ell} \right]$
[e]	$\frac{F_1\ell}{8}$	$-\frac{F_1\ell}{8}$	
[f]	$-\frac{F_2\ell}{8}$	$\frac{F_2\ell}{8}$	

(1) Formula valid for a hinge on cellular keel. In the case of a hinge on lateral wing tank, replace  $(2a + c_1)$  with  $(2a - c_1)$

## 2.8 Differential opening valves

**2.8.1** In the case of a differential opening of the valves, the stresses induced by the bending moments and the shear forces are determined as follows:

- the upper flange is assumed to be simply supported at ends; its span  $\ell_s$  is measured between the longitudinal bulkhead and the cellular keel
- the lower flange is assumed to have fixed ends and its span is taken equal to  $c_1$
- the transverse section moduli of the flanges are determined with respect to a vertical axis located in the plane of the floor web
- for the upper flange, the transverse bending moment at mid-span is obtained, in kN.m, from the following formula:

$$M_s = 0,05 \delta h_v^2 [3 \ell_s^2 - (\ell_s - c_1)^2]$$

- for the upper flange, the maximum shear force at ends of span  $\ell_s$  is obtained, in kN.m, from the following formula:

$$T_s = 0,3 \delta h_v^2 (\ell_s + c_1)$$

- for the lower flange, the maximum bending moment and shear force at span ends are obtained, in kN.m, from the following formulae:

$$M_i = 1,33 \left( \frac{c_1}{\ell_s} \right)^2 M_s$$

$$T_i = 2 \left( \frac{c_1}{\ell_s} \right) T_s$$

## 2.9 Buckling of upper flange

**2.9.1** When the ship is to navigate with empty hopper space(s), the buckling of the upper flange is to be checked, using the formulae given in [3] for strong beams and assuming that:

$$F_R = \frac{-3,3 S_a}{2D - h_v} (T_2 + 0,5 h_0)^2 (3D - T_2 - 0,5 h_0) \frac{A_s}{A_v}$$

where:

- $T_2$  : Maximum draught for navigation with empty hopper space(s), in m
- $A_s$  : Sectional area, in cm<sup>2</sup>, of the upper flange
- $A_v$  : Sectional area, in cm<sup>2</sup>, of the floor, cut-outs in web deducted

## 3 Strong beams at deck level

### 3.1 Forces acting on strong beams

**3.1.1** Where strong beams are fitted at deck level, the forces acting on them are to be obtained, in kN, from the following formulae:

- tension force due to the spoil pressure onto the longitudinal bulkheads of the well:

$$F_T = \frac{1,6 \delta s (D + h_D)^2}{2D - h_v} [2(D + h_D) - 3h_v]$$

- compression force due to the external hydrostatic pressure:

$$F_{C1} = \frac{1,6 s (T_D - 0,5 h_0)^2}{2D - h_v} (2T_D - h_0 - 3h_v)$$

- compression force due to moment at floor ends:

$$F_{C2} = \frac{2M(0)}{2D - h_v}$$

- compression force due to floor reaction at span ends:

$$F_{C3} = \frac{d_1 + 2b_1}{2D - h_v} T(0)$$

where:

- $s$  : Spacing of strong beams, in m
- $d_1$  : Distance, in m, from the side plating to the longitudinal bulkhead of the hopper well
- $b_1$  : Distance, in m, between the fixed end of the floor and the hopper well longitudinal bulkhead or its extension

$M(0)$ ,  $T(0)$ : Total bending moment and shear force at fixed ends, determined, respectively, according to [2.5] and [2.4], for  $X = 0$ . For strong beams with a large web depth, the upper flange of which is located at deck level, the term  $D$  may be replaced by  $(D - 0,5 h_{WS})$ , where  $h_{WS}$  is the web depth, in m, of strong beams.

The resultant of the forces is to be obtained, in kN, from the following formula:

$$F_R = F_T - F_{C1} - F_{C2} - F_{C3}$$

$F_R$  is a tension load when positive, a compression load when negative.

### 3.2 Sectional area of strong beams

**3.2.1** The sectional area of strong beams, after deduction of possible cut-outs, is to be obtained, in cm<sup>2</sup>, from Tab 6.

**Table 6 : Sectional area of strong beams**

Condition	Sectional area $A_T$ , in cm <sup>2</sup>	
$F_R \geq 0$	0,08 $F_R$	
$F_R < 0$	when $\ell_F / r \leq 1,15$	$\left[ 0,085 + 0,064 \left( \frac{\ell_F}{r} \right)^2 \right] F_R$
	when $\ell_F / r > 1,15$	$0,1 \left( \frac{\ell_F}{r} \right)^2 F_R$
<p><b>Note 1:</b></p> <p><math>\ell_F</math> : Buckling length, in m, of the strong beam considered as fixed at ends, to be taken equal to <math>0,5\ell_0</math></p> <p><math>r</math> : Minimum gyration radius, in cm, to be taken equal to:</p> $r = \sqrt{\frac{I}{A_T}}$ <p><math>I</math> : Moment of inertia, in cm<sup>4</sup>, equal to the minimum of <math>I_{XX}</math> and <math>I_{YY}</math></p> <p><math>I_{XX}</math> : Moment of inertia, in cm<sup>4</sup>, with respect to the axis perpendicular to the plane of the web</p> <p><math>I_{YY}</math> : Moment of inertia, in cm<sup>4</sup>, with respect to the axis parallel to the plane of the web.</p>		

## 4 Brackets for trunks

### 4.1 General

**4.1.1** Brackets for trunks are to be provided in way of the strengthened transverse rings. They are to be securely fixed at their lower ends.

**4.1.2** In order to check the stresses according to [4.1.3], the value of the bending moment at the lower end, in kN.m, and the value of the corresponding shear stress, in kN, may be obtained, respectively, from the following formulae:

$$M_p = 1,64 \delta s h_T^3$$

$$T_p = 4,9 \delta s h_T^2$$

where:

$h_T$  : Height, in m, of the trunk above the deck-line.

**4.1.3** It is to be checked that the normal stress, in N/mm<sup>2</sup>, and the shear stress are, respectively, in compliance with the following formulae:

$$\sigma \leq 0,65 R_Y$$

$$\tau \leq 0,45 R_Y$$

## 5 Girders supporting the hydraulic cylinder in the hopper spaces (bottom door types 1, 2 and 3)

### 5.1

**5.1.1** In order to check the stresses according to [5.1.2], the local bending stress due to the cylinder reaction and the corresponding shear stress, in N/mm<sup>2</sup>, may be obtained, respectively, from the following formulae:

$$\sigma_{LX} = \frac{125F\ell}{w}$$

$$\tau_{XY} = \frac{5F}{A_a}$$

where:

$F$  : Maximum value, in kN, of  $R_1$  and  $F_M$  defined in [2.3]

$w$  : Girder web modulus, in cm<sup>3</sup>

$A_a$  : Girder web sectional area, in  $\text{cm}^2$ , possible cut-outs deducted.

**5.1.2** It is to be checked that the normal stress, in  $\text{N/mm}^2$ , and the shear stress are, respectively, in compliance with the following formulae:

$$\sigma \leq 0,65 R_y$$

$$\tau \leq 0,45 R_y$$

## NON-PROPELLED UNITS

---

- Section 1      General
- Section 2      Hull and Stability
- Section 3      Machinery Systems

# Section 1                      General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of one of the following notations applicable to no propulsion units, as defined in Pt A, Ch 1, Sec 2, [4.14]:

- service notations:
  - **barge**
  - **pontoon**
  - **pontoon-crane**
- additional service feature:
  - **no propulsion**

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**1.1.3** For ships dealt with in this Chapter and intended to carry only one type of cargo, the Society reserves the right to establish requirements and/or conditions additional to those contained in these Rules.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT
Ship arrangement	L ≥ 65 or 90 m <b>(1)</b>	• Part B	• NR566

## Section 2 Hull and Stability

### 1 General

#### 1.1 Application

##### 1.1.1 General

Unless otherwise specified, the requirements of this Section apply to ships with one of the service notations **barge**, **pontoon** and **pontoon - crane**.

Specific requirements which apply only to ships with the service notation **barge** or ships with the service notation **pontoon** or **pontoon- crane** are indicated.

Barges with the additional service feature **tug combined** are also to comply with the applicable additional requirements in Pt E, Ch 1, Sec 4

##### 1.1.2 Main characteristics of non-propelled units

The requirements of this Section are based on the following assumptions, relevant to the main characteristics of non-propelled units:

- the structural configuration and proportions of non-propelled units are similar to those of propelled ships
- the cargo is homogeneously distributed.

The scantlings of non-propelled units with unusual shapes and proportions or carrying cargoes which are not homogeneously distributed, such as containers or heavy loads concentrated in limited areas, are to be considered by the Society on a case-by-case basis, taking into account the results of direct calculations, to be carried out according to Pt B, Ch 8, Sec 1.

#### 1.2 Additional class notations for lifting appliances of ships with service notation pontoon - crane

1.2.1 For ships with service notation **pontoon - crane**, one of the following additional class notations, defined in Pt A, Ch 1, Sec 2, [6.12], is generally to be granted:

- **ALP** or (**ALP**) for lifting appliances intended to be used in harbours or similar sheltered areas
- **ALM** or (**ALM**) for lifting appliances intended to be used in offshore conditions.

Note 1: when the lifting appliance is provided to be used essentially in harbour conditions or similarly sheltered areas and exceptionally in offshore conditions, the additional class notation **ALP** or (**ALP**) is generally assigned. For the exceptional using in offshore conditions, the lifting capacity is reduced to a value in accordance with the considered sea conditions.

### 2 Stability

#### 2.1 Intact stability for ships with service notation pontoon or pontoon - crane

##### 2.1.1 Application

The requirements of this item apply to seagoing ships with one of the service notations **pontoon** and **pontoon - crane** with the following characteristics:

- *unmanned*
- *having a block coefficient not less than 0,9*
- *having a breadth/depth ratio greater than 3,0*
- *having no hatchways in the deck except small manholes closed with gasketed covers.*

##### 2.1.2 Trim and stability booklet

In addition to the information to be included in the trim and stability booklet specified in Pt B, Ch 3, App 2, [1.1], simplified stability guidance, such as a loading diagram, is to be submitted to the Society for approval, so that pontoons may be loaded in compliance with the stability criteria.

##### 2.1.3 Stability calculations

Stability calculations may be carried out according to the following criteria:

- *no account is to be taken of the buoyancy of deck cargo (except buoyancy credit for adequately secured timber)*
- *consideration is to be given to such factors as water absorption (e.g. timber), trapped water in cargo (e.g. pipes) and ice accretion*

- in carrying out wind heel calculations:
  - the wind pressure is to be constant and for general operations considered to act on a solid mass extending over the length of the cargo deck and to an assumed height above the deck
  - the centre of gravity of the cargo is to be assumed at a point mid-height of the cargo
  - the wind lever arm is to be taken from the centre of the deck cargo to a point at one half the draught
- calculations are to be carried out covering the full range of operating draughts
- the downflooding angle is to be taken as the angle at which an opening through which progressive flooding may take place is immersed. This would not be an opening closed by a watertight manhole cover or a vent fitted with an automatic closure.

#### **2.1.4 Intact stability criteria**

The following intact stability criteria are to be complied with, for the loading conditions specified in Pt B, Ch 3, App 2, [1.2.1] and Pt B, Ch 3, App 2, [1.2.2]:

- the area under the righting lever curve up to the angle of maximum righting lever is to be not less than 0,08 m-rad
- the static angle of heel due to a uniformly distributed wind load of 0,54 kPa (wind speed 30 m/s) may not exceed a heeling angle corresponding to half the freeboard for the relevant loading condition, where the lever of wind heeling moment is measured from the centroid of the windage area to half the draught
- The minimum range of stability is to be:
  - 20° for  $L < 100$  m
  - $20^\circ - 0,1^\circ (L - 100)$  for  $100 \leq L \leq 150$  m
  - 15° for  $L > 150$  m.

### **2.2 Additional intact stability criteria for ships with service notation pontoon - crane**

**2.2.1** Ships assigned with the service notation **pontoon-crane** are to comply with the stability criteria during lifting operations specified in Pt E, Ch 8, Sec 3, in addition to those in [2.1].

## **3 Structure design principles**

### **3.1 Hull structure**

#### **3.1.1 Framing of ships with one of the service notations pontoon and pontoon - crane**

In general, ships with one of the service notations **pontoon** and **pontoon - crane** are to be longitudinally framed.

#### **3.1.2 Supports for docked non-propelled units**

Adequate supports are to be fitted on the longitudinal centreline in order to carry loads acting on the structure when the non-propelled units are in dry dock.

#### **3.1.3 Truss arrangement supporting deck loads**

Where truss arrangements are used as supports of the deck loads, including top and bottom girders in association with pillars and diagonal bracing, the diagonal members are generally to have angles of inclination with the horizontal of about 45° and cross-sectional area of about 50% that of the adjacent pillars.

Where pillar arrangements are used without diagonal bracing, the scantlings of primary members can generally not be determined by means of isolated beam structural models.

### **3.2 Lifting appliances**

#### **3.2.1 Crane or derrick position during navigation**

For ships with the service notation **pontoon - crane**, it is to be possible to lower the crane boom or the derrick structure and to secure them to the pontoon during the voyage.

## **4 Hull girder strength**

### **4.1 Yielding check**

#### **4.1.1 Non-propelled units lifted by crane**

For non-propelled units intended to be lifted on board ship by crane, the hull girder strength is to be checked, in the condition of fully-loaded barge lifted by crane, through criteria to be agreed with the Society on a case-by-case basis.

In general, the equivalent Von Mises stress  $\sigma_{eq}$  in the hull girder when lifted by crane are to comply with the criteria defined in Pt B, Ch 6, Sec 1, [3.5] for harbour/sheltered operations.

#### **4.1.2 Ships with service notation pontoon carrying special cargoes**

For ships with the service notation **pontoon** intended for the carriage of special cargoes, such as parts of offshore units, the hull girder strength is to be checked through criteria to be agreed with the Society on a case-by-case basis.

Moreover, where these ships are fitted with arrangements for launching the above special cargoes, additional calculations are to be carried out in order to evaluate the stresses during the various stages of launching. The Society may accept stresses higher than those in [4.1.1], to be considered on a case-by-case basis, taking into account favourable sea and weather conditions during launching.

#### **4.1.3 Ships with service notation pontoon - crane**

For ships with the service notation **pontoon - crane** having length greater than 65 m, the hull girder strength is to be checked when the lifting appliance is operated, in accordance with the requirements of Pt E, Ch 8, Sec 4.

## **5 Hull scantlings**

### **5.1 General**

#### **5.1.1 Net thickness of strength deck plating**

Within the cargo area, the thickness of strength deck plating is to be increased by 1,5 mm with respect to that calculated according to Pt B, Ch 7, Sec 4.

#### **5.2 Hull scantlings of non-propelled units with the service notation pontoon fitted with arrangements and systems for launching operations**

##### **5.2.1 Additional information**

In addition to the documentation specified in Pt B, Ch 1, Sec 4, the following information is to be submitted to the Society:

- maximum draught of the ship during the different stages of the launching operations
- operating loads and their distribution
- launching cradle location.

##### **5.2.2 Scantlings draught**

$T_{SC}$  is to be taken not less than the maximum draught resulting from the different stages of launching.

##### **5.2.3 Deck scantlings**

The scantlings of decks are to be in accordance with Part B, Chapter 7, considering the maximum loads acting on the launching cradle.

The thickness of deck plating in way of launch ground ways is to be suitably increased if the cradle may be placed in different positions.

The scantlings of decks in way of pivoting and end areas of the cradle are to be obtained through direct calculations, to be carried out according to the criteria in Pt B, Ch 8, Sec 1.

##### **5.2.4 Launching cradles**

The launching cradles are to be adequately connected to deck structures and arranged, as far as possible, in way of longitudinal bulkheads or at least of girders.

#### **5.3 Hull scantlings of non-propelled units with service notation pontoon - crane**

##### **5.3.1 Loads transmitted by the lifting appliances**

The forces and moments transmitted by the lifting appliances to the ship's structures, during both lifting service and navigation, are to be submitted to the Society in the initial stage of the design.

##### **5.3.2 Ship's structures**

The ship's structures, subjected to the forces transmitted by the lifting appliances, are to be reinforced to the Society's satisfaction.

##### **5.3.3 Lifting appliances**

The check of the behaviour of the lifting appliances at sea is outside the scope of the classification and is under the responsibility of the Designer. However, where the requirements in [3.2.1] may not be complied with (i.e. sailing with boom or derrick up) or where, exceptionally, trips with suspended load are envisaged, the Designer is to submit the check of the lifting appliances during navigation to the Society for information.

## **6 Hull outfitting**

### **6.1 Equipment**

#### **6.1.1 Manned non-propelled units**

The equipment of anchors, chain cables and ropes to be fitted on board manned non-propelled units is to comply with Pt B, Ch 12, Sec 4.

Chain cables for anchors may be replaced by steel ropes having the same breaking load. The ropes are to be connected to the anchors by approximately 10 m of chain cable complying with Pt B, Ch 12, Sec 4.

Non-propelled units continuously assisted by a tug may have only one anchor complying with Pt B, Ch 12, Sec 4 and a chain rope having length neither less than 75% of the length obtained according to Pt B, Ch 12, Sec 4 nor less than 220 m.

#### **6.1.2 Unmanned non-propelled units**

For unmanned non-propelled units, the equipment is not required for classification purposes. The scantlings of anchors, chain cables and ropes to be fitted on board are the responsibility of the Designer.

#### **6.1.3 Towing arrangements**

Non-propelled units are to be fitted with suitable arrangements for towing, with scantlings under the responsibility of the Designer.

The Society may, at the specific request of the interested parties, check the above arrangements and the associated hull strengthening; to this end, the maximum pull for which the arrangements are to be checked is to be specified on the plans.

# Section 3 Machinery and Systems

## 1 General

### 1.1 Application

1.1.1 This Section provides requirements for bilge systems of non propelled units.

### 1.2 Documents to be submitted

1.2.1 The documents listed in Tab 1 are to be submitted for approval.

**Table 1 : Documents to be submitted**

No.	Description of the document (1)	Status of the review
1	Diagram of the bilge system	A
2	Diagram of the central priming system intended for the bilge pumps, where provided	A
3	Capacity, prime mover and location of the bilge pumps	A

(1) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.

## 2 Bilge system

### 2.1 Bilge system in ships having no source of electrical power

#### 2.1.1 General

Where there is no source of electrical power on board, hand pumps are to be provided, in sufficient number and so positioned as to permit an adequate drainage of all the compartments of the ship.

#### 2.1.2 Arrangement of the bilge system

The bilge system is to comply with one of the following arrangements:

- at least one pump is to be provided for each compartment
- at least two pumps connected to a bilge main are to be provided. The main is to have branch pipes allowing the draining of each compartment through at least one suction.

#### 2.1.3 Hand pumps

- Hand pumps are to be capable of being operated from positions above the load waterline and are to be readily accessible at any time.
- Hand pumps are to have a maximum suction height not exceeding 7,30 m.

#### 2.1.4 Size of bilge pipes

- The internal diameter, in mm, of suction pipes is not to be less than the diameter given by the following formula:

$$d_1 = \frac{T}{100} + 50$$

where:

T : Underdeck tonnage, in t.

- When the ship is subdivided into small watertight compartments, the diameter of these suctions need not exceed 50 mm.

### 2.2 Bilge system in ships having a source of electrical power

#### 2.2.1 General

On board ships having no propelling machinery but having a source of electrical power, mechanical pumps are to be provided for draining the various compartments of the ship.

#### 2.2.2 Arrangement of the bilge system

The bilge system is to comply with the provisions of Pt C, Ch 1, Sec 10, [6.3] to Pt C, Ch 1, Sec 10, [6.6] applicable to the spaces concerned, except that direct suctions need not be provided.

### **2.2.3 Bilge pumps**

The number and capacity of the bilge pumps are to comply with the relevant requirements of Pt C, Ch 1, Sec 10, [6.7].

### **2.2.4 Size of bilge pipes**

The size of bilge pipes is to comply with the relevant requirements of Pt C, Ch 1, Sec 10, [6.8].

# Section 2 Ship Arrangement

## 1 General

### 1.1 Definitions

#### 1.1.1 Working deck

The working deck is generally the lowest complete exposed deck above the deepest operating waterline from which fishing is undertaken.

The Society may accept a lower complete deck as a working deck provided that such a deck is situated above the deepest operating waterline.

## 2 General arrangement design

### 2.1 Subdivision arrangement

#### 2.1.1 Disposition of collision bulkhead

The collision bulkhead is to be located at a distance from the forward perpendicular  $FP_{LL}$  of not less than 5% and no more than 8% of the length  $L_{LL}$  of the ship.

Where any part of the ship below the waterline extends forward perpendicular, e.g. a bulbous bow, the above distance, in m, are to be measured from a point either:

- at mid-length of such extension, or
- at a distance 1,5% of the length  $L_{LL}$  of the ship forward of the forward perpendicular, where this distance is lesser.

#### 2.1.2 Height of transverse watertight bulkheads

Transverse watertight bulkheads are to be watertight up to the working deck.

Where a long forward superstructure is fitted, the collision bulkhead is to be extended weathertight to the next deck above the working deck. The extension need not be fitted directly above the bulkhead below provided it is located within the limits prescribed in [2.1.1] and the part of the deck which forms the step is made effectively watertight.

#### 2.1.3 Openings in collision bulkhead

Openings in the collision bulkhead below the working deck are not allowed.

Where penetration of the collision bulkhead is necessary for piping, arrangements are to be fitted to maintain the watertight integrity and strength, with suitable valves operable from above the freeboard deck, whose valve chest is to be secured at the bulkhead inside the fore peak.

Where the collision bulkhead extends above the working deck, openings above the working deck are allowed provided that they are supplied with weathertight means of closure.

#### 2.1.4 Openings in watertight bulkheads

The number of openings in watertight bulkheads is to be kept to a minimum compatible with the design and proper working of the ship.

Where penetration of watertight bulkheads and internal decks is necessary for access, piping, ventilation, electrical cables, etc., arrangements are to be fitted to maintain the watertight integrity and strength.

# Section 3 Hull and Stability

## 1 General

### 1.1 Documents to be submitted

1.1.1 In addition to the documentation requested in Part B, the following documents and information are to be submitted:

- minimum design temperature of refrigerated spaces,
- structural reinforcements in way of load carrying structures, such as masts, gantries, trawl gallows and winches, including the maximum brake load of the winches.

## 2 Stability

### 2.1 Intact stability

#### 2.1.1 Application

The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.14], with the assumptions in [2.1.2], is to be in compliance with the requirements in [2.1.3].

#### 2.1.2 Assumptions for calculating loading conditions

The assumptions for calculating the loading conditions in Pt B, Ch 3, App 2, [1.2.14] are as follows:

- allowance is to be made for the weight of the wet fishing nets and tackle, etc., on deck
- in all cases the cargo is to be assumed to be homogeneous unless this is inconsistent with practice
- deck cargo is to be included if such a practice is anticipated
- water ballast is normally to be included only if carried in tanks which are specially provided for this purpose.

#### 2.1.3 Intact stability criteria

- The general intact stability criteria in Pt B, Ch 3, Sec 2, [2] are to be applied to fishing vessels equal to or greater than 24 m in length, except for the requirements below.
- The initial metacentric height  $GM_0$  is to be not less than 0,35 m for single deck vessels.
- The metacentric height  $GM_0$  may be reduced to the satisfaction of the Society but in no case is  $GM_0$  to be less than 0,15 m for vessels with complete superstructure or vessels equal to or greater than 70 m in length.

Where arrangements other than bilge keels are provided to limit the angle of roll, the above stability criteria are to be maintained in all operating conditions.

#### 2.1.4 Severe wind and rolling criterion (weather criterion)

The requirements in Pt B, Ch 3, Sec 2, [3] are to be complied with by:

- fishing vessels equal to or greater than 45 m in length
- fishing vessels in the length range between 24 m and 45 m, with the values of wind pressure defined in Tab 1, depending on the vertical distance  $h$ , in m, measured from the centre of the projected vertical area of the ship above the waterline to the waterline.

#### 2.1.5 Icing

For vessels operating in areas where ice accretion is expected, the requirements in Pt B, Ch 3, Sec 2, [6] are to be complied with.

**Table 1 : Values of wind pressure**

Vertical distance $h$ , in m	Wind pressure, in kN/m <sup>2</sup>
1	0,316
2	0,386
3	0,429
4	0,460
5	0,485
6 and over	0,504

### **3 Design loads**

#### **3.1 Fish holds**

**3.1.1** The internal liquid pressures in fish holds are to be determined according to Pt B, Ch 5, Sec 6, [1] with  $p_c$  as defined by the Designer. As a guidance,  $p_c$  may be taken as follows:

- 0,7 for holds intended to carry dry fish or fish stored in ice,
- 1,025 for holds intended to carry live fish or frozen fish into sea water,
- 1,2 for holds intended to freeze or store fish into brine.

Note 1: If applicable, a design vapour pressure  $P_{pv}$  is to be considered for live fish stored in sea water to take into account the injection of oxygen.

Note 2: In case of salt stored onboard for brine production, weight of salt and associated distribution along the ship are to be provided.

#### **3.2 Working deck**

**3.2.1** The static pressure  $P_{dl-s}$  to be considered on working decks is to be taken as defined by the Designer, without being less than 8,5 kN/m<sup>2</sup>.

### **4 Hull scantlings**

#### **4.1 Fish holds**

**4.1.1** Fish holds scantlings are to be checked according to the applicable requirements of Part B, Chapter 7 for the design load sets LC-1, LC-3 and LC-4 as defined in Pt B, Ch 7, Sec 2, [2].

**4.1.2** The thickness of fish holds plating is to be increased by 1 mm with respect to that calculated according to Pt B, Ch 7, Sec 4. This thickness increase is to be combined with the one defined in [4.2.1] if applicable.

#### **4.2 Bottom, side and decks plating**

**4.2.1** The thickness of bottom, side and exposed decks other than superstructures plating is to be increased by 0,5 mm with respect to that calculated according to Pt B, Ch 7, Sec 4. This thickness increase is to be combined with the one defined in [4.1.2] if applicable.

#### **4.3 Aft ramp**

##### **4.3.1 Plating of the aft ramp and of the lower part of the aft ramp side**

The plating thickness of the aft ramp and of the lower part of the aft ramp sides is to be increased by 1,5 mm with respect to that calculated according to Pt B, Ch 11, Sec 3, [5] for side plating with the same plate panel dimensions.

The net plating thickness of the aft ramp and of the lower part of the aft ramp side is to be not less than 10,5 mm.

##### **4.3.2 Plating of the upper part of the aft ramp sides**

The plating thickness of the upper part of the aft ramp sides is to be not less than the value calculated according to Pt B, Ch 11, Sec 3, [5] for side plating with the same plate panel dimensions.

### **5 Arrangement for hull and superstructure openings**

#### **5.1 General**

##### **5.1.1 Door sills**

The height of the sill of the doors is to be not less than:

- 600 mm above the working deck
- 300 mm above the deck of the lowest tier of superstructures.

For doors protected from the direct impact of waves, except for those giving direct access to machinery spaces, the height of the sill may be taken not less than:

- 380 mm above the working deck
- 150 mm above the deck of the lowest tier of superstructures

### **6 Lifting appliances and fishing devices**

#### **6.1 General**

**6.1.1** The limits of application to lifting appliances are defined in Pt B, Ch 1, Sec 1, [1.2].

**6.1.2** The requirements in [6] apply to the reinforcements under decks supporting fishing devices, and to the strength check of fishing devices and masts if welded to the deck.

## **6.2 Design loads**

**6.2.1** The design loads and load angles to be considered for the strength check of masts, fishing devices and reinforcements under decks are to be submitted by the Designer based on the following assumptions:

- the weights of booms and net hauling fittings
- the cargo loads, to be taken equal to the maximum traction loads of the different lifting appliances, considering the rolling-up diameters defined in [6.2.2].

**6.2.2** The rolling-up diameters to be taken for the maximum traction loads of the lifting appliances are:

- for the fishing winches: the mid rolling-up diameter
- for the net winches: the maximum rolling-up diameter
- for the winding-tackles: the minimum rolling-up diameter.

## **6.3 Strength check**

### **6.3.1 Calculation of stresses in the structural elements**

The stresses in the structural elements of masts, fishing devices and reinforcements under decks are to be obtained by means of direct calculations, using the design loads specified in [6.2].

### **6.3.2 Yielding check**

The Von Mises equivalent stresses in the structural elements of masts, fishing devices and reinforcements under decks are to comply with the following formula:

- for beam grillage analysis:  
 $\sigma_{eq} \leq 0,5 R_{eH}$
- for standard mesh FE analysis (s x s):  
 $\sigma_{eq} \leq 0,6 R_y$
- for fine mesh FE analysis (50 x 50 mm):
  - for elements not adjacent to welding:  
 $\sigma_{eq} \leq R_y$
  - for elements adjacent to welding:  
 $\sigma_{eq} \leq 0,9 R_y$

where:

$\sigma_{eq}$  : Von Mises equivalent stress, in N/mm<sup>2</sup>, to be obtained as a result of direct calculations

### **6.3.3 Buckling check**

The buckling strength of the structural elements of masts and fishing devices is to be checked in compliance with Part B, Chapter 9.

## **7 Hull outfitting**

### **7.1 Rudder stock scantlings**

**7.1.1** The rudder stock diameter is to be increased by 5% with respect to that obtained from the formula in Pt B, Ch 12, Sec 1, [4].

### **7.2 Equipment**

#### **7.2.1 General**

Anchors referred to in this section are bower anchors.

Fishing vessels are to be provided with equipment in anchors, chain cables and ropes to be obtained from Tab 2, based on their Equipment Number EN, to be calculated according to Pt B, Ch 12, Sec 4, [1].

The equipment in anchors, chain cables and ropes of fishing vessels with the navigation notation **coastal area** may be obtained from Tab 2 based on the Equipment Number EN corresponding to the row above that relevant to the Equipment Number calculated for the ship considered.

In general, stockless anchors are to be adopted.

For ships with EN greater than 720, the determination of the equipment is to be considered by the Society on a case-by-case basis. The mooring lines are given as a guidance, but are not required as a condition of classification.

Table 2 : Equipment

Equipment number EN A < EN ≤ B		Stockless bower anchors		Stud link chain cables for bower anchors			Mooring lines (1)		
A	B	N	Mass per anchor, in kg	Total length, in m	Diameter, in mm		N	Length of each line, in m	Ship design minimum breaking load, in kN
					mild steel	high strength steel

660	720	2	2100	440	46	40	4	160	127

(1) The mooring lines are given as a guidance, but are not required as a condition of classification.

### 7.2.2 Anchors

The required mass for each anchor is to be obtained from Tab 2.

The individual mass of a main anchor may differ by  $\pm 7\%$  from the mass required for each anchor, provided that the total mass of anchors is not less than the total mass required in Tab 2.

The mass of the head of an ordinary stockless anchor, including pins and accessories, is to be not less than 60% of the total mass of the anchor.

Where a stock anchor is provided, the mass of the anchor, excluding the stock, is to be not less than 80% of the mass required in Tab 2 for a stockless anchor. The mass of the stock is to be not less than 25% of the mass of the anchor without the stock but including the connecting shackle.

### 7.2.3 Scantlings of stud link chain cables

The mass and geometry of stud link chain cables, including the links, are to be in compliance with the requirements in NR 216 Materials, Ch 4, Sec 1, [2].

The diameter of stud link chain cables is to be not less than the value in Tab 2.

#### **7.2.4 Chain cable arrangement**

Chain cables are to be made by lengths of 27,5 m each, joined together by Dee or lugless shackles.

The total length of chain cables, as required in Tab 2, is to be divided into approximately equal parts between the two anchors ready for use.

Where different arrangements are provided, they are to be considered by the Society on a case-by-case basis.

When chain cables are replaced by trawl warps, the anchor is to be positioned on the forecastle deck so that it may be readily cast after it has been shackled to the trawl warp. Chocks or rollers are to be fitted at suitable locations, along the path of the trawl warps, between the winch and the mooring chocks.

## **8 Protection of hull metallic structures**

### **8.1 Protection of cargo sides by battens**

**8.1.1** In cargo spaces, where thermal insulation is fitted, battens formed by spaced planks are generally to be fitted longitudinally.

### **8.2 Deck composition**

**8.2.1** The deck composition is to be of such a material as to prevent corrosion as far as possible and is to be effectively secured to the steel structures underneath by means of suitable connections.

# Section 4 Machinery

## 1 General

### 1.1 Application

**1.1.1** Machinery systems fitted on board ships having the notation **fishing vessel** are to comply with the relevant sections of Part C, Chapter 1, with the exception of tests and the following systems:

- bilge system
- scuppers and sanitary discharges
- air pipes and sounding devices
- ventilation
- oil fuel systems
- cooling systems
- lubricating oil systems
- compressed air systems
- hydraulic systems
- exhaust gas system
- refrigerating installations
- propelling and auxiliary machinery
- steering gear,

for which substitutive requirements are provided in this Section.

**1.1.2** This Section does not cover the design and performances of the fishing equipment. However, the piping systems and pressure vessels serving the fishing equipment are required to comply with the relevant Sections of Part C.

### 1.2 Documents to be submitted

**1.2.1** In addition to the documents listed in Tab 1 and Tab 2, the diagram of the piping systems (hydraulic system, etc.) serving the fishing equipment is to be submitted for approval.

**Table 1 : Documents to be submitted**

No.	Document (1)
1	Drawing showing the arrangement of the sea chests and ship side valves
2	Diagram of the bilge and ballast systems (in and outside machinery spaces)
3	Specification of the central priming system intended for bilge pumps, when provided
4	Diagram of the scuppers and sanitary discharge systems
5	Diagram of the air, sounding and overflow systems
6	Diagram of cooling systems (sea and fresh waters)
7	Diagram of fuel oil system
8	Drawings of the fuel oil tanks not forming part of the ship's structure
9	Diagram of the lubricating oil system
10	Diagram of the thermal oil system
11	Diagram of the hydraulic systems intended for essential services or located in machinery spaces
12	Diagram of the compressed air system
13	Diagram of the hydraulic and pneumatic remote control systems
14	Diagram of the exhaust gas system
15	Diagram of drip trays and gutterway draining system
16	Arrangement of the ventilation system
(1) To be submitted for approval. Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.	

**Table 2 : Information to be submitted**

No.	I/A (1)	Document
1	I	Nature, service temperature and pressure of the fluids
2	A	Material, external diameter and wall thickness of the pipes
3	A	Type of the connections between pipe lengths, including details of the weldings, where provided
4	A	Material, type and size of the accessories
5	A	For plastic pipes: <ul style="list-style-type: none"> <li>• the chemical composition</li> <li>• the physical and mechanical characteristics in function of temperature</li> <li>• the characteristics of inflammability and fire resistance</li> <li>• the resistance to the products intended to be conveyed</li> </ul>
(1) A = to be submitted for approval ; I = to be submitted for information		

### 1.3 Tests - Trials in ships $L \geq 24$ m

1.3.1 See Part C, Chapter 1.

### 1.4 Tests - Trials in ships $L < 24$ m

#### 1.4.1 General

The building and fitting of fluid systems, pumps, pipes and their accessories, as well as other installations referred to in this Chapter are to be attended by a Society's Surveyor, at the Builder's request.

Pneumatic tests are to be avoided whenever possible. When such testing is essential in lieu of hydraulic pressure test, procedure for testing is to be submitted to the Society for acceptance prior to testing.

#### 1.4.2 Testing on board

After assembly onboard, all fittings and accessories being fitted, a hydraulic pressure test is to be carried out for compressed air and oil fuel pipes.

As a rule, the test pressure is not to be less than 1,5 times the service pressure.

#### 1.4.3 Hydraulic tests of oil fuel bunkers, tanks and accessories

The oil fuel bunkers and tanks not forming part of the ship's structure are to be submitted to a hydraulic test under a pressure corresponding to the maximum liquid level in these spaces or in the air or overflow pipes, subject to a minimum of 2,40 m above the top. This minimum height is to be 3,60 m for tanks intended to contain oil fuel having a flash point below 60°C.

Non metallic or metallic flexible pipes and expansion joints are to be tested in accordance with the requirements stated in [1.10.4] item e) and [1.11.7] item a), as appropriate.

### 1.5 General requirements applicable to all piping systems in ships $L \geq 24$ m

1.5.1 See relevant requirements of Pt C, Ch 1, Sec 10, [1] and Pt C, Ch 1, Sec 10, [5].

### 1.6 General requirements applicable to all piping systems in ships $L < 24$ m

#### 1.6.1 Materials

The manufacturer's test certificate for materials for valves and fittings can be accepted in lieu of the Society's materials certificate where the maximum conditions are not beyond those shown in Tab 3.

**Table 3 : Maximum conditions for acceptance of manufacturer's test certificate**

Material	Maximum conditions
Spheroidal or nodular cast iron	DN < 50 and PxDN < 2500
Carbon and low alloy steel	-10°C < t < 300°C and DN < 50, or -10°C < t < 300°C and PxDN < 2500
Cupreous alloy (1)	t < 200°C and DN < 50, or t < 200°C and PxDN < 1500
(1) See Pt C, Ch 1, Sec 10, [2.1]. <b>Note 1:</b> DN = nominal diameter, P = working pressure, t = working temperature.	

### **1.6.2 Fixing and arrangement of the pipes**

- a) Except where otherwise permitted, piping and pumping systems covered by this Chapter are to be permanently fixed onboard ship.
- b) Unless otherwise specified, the fluid lines referred to in this Chapter are to consist of pipes connected to the ship's structure by means of collars or similar devices.
- c) As far as possible, pipes are not to pass near switchboards or other electrical apparatuses. If this requirement is impossible to satisfy, gutterways or masks are to be provided wherever deemed necessary to prevent projections of liquid on live parts.
- d) These provisions also apply to the exhaust pipes of internal combustion engines.

### **1.6.3 Protection of pipes**

Pipes are to be efficiently protected against corrosion particularly in their most exposed parts, either by selection of their constituent materials, or by an appropriate coating or treatment.

### **1.6.4 Accessories**

Locks, valves and other accessories are generally to be so placed that they are easily visible and accessible for manoeuvring, control and maintenance.

## **1.7 Sea inlets and overboard discharges in ships $L \geq 24$ m**

**1.7.1** See Pt C, Ch 1, Sec 10, [2.8].

## **1.8 Sea inlets and ship side valves in ships $L < 24$ m**

### **1.8.1 Valves**

All sea inlet and outlet pipes are to be provided with valves fixed:

- directly on the plating, or
- on steel chests built on the plating, or
- on strong distance pieces as short as possible which may be welded to the plating.

### **1.8.2 Strainers**

Sea inlets are to be fitted with strainers. The flow section through each strainer is not to be less than twice the total section of the suction pipes connected to the said inlet.

### **1.8.3 Materials**

The valves on sea inlets and overboard discharges are to be of steel or appropriate non-brittle material.

Similar provisions apply to distance pieces connecting the valves to the shell plating.

### **1.8.4 Protection against corrosion**

Efficient arrangements such as the fitting of zinc anodes are to be made in order to protect the steel parts of sea inlets and discharges against corrosion.

## **1.9 Non-metallic rigid pipes in ships $L \geq 24$ m**

**1.9.1** See Pt C, Ch 1, App 3.

## **1.10 Non-metallic rigid pipes in ships $L < 24$ m**

### **1.10.1 General**

- a) The Society may permit the use of rigid pipes made of plastics in lieu of metallic pipes in the conditions specified in [1.10.2], [1.10.3] and [1.10.4].
- b) These requirements apply to thermoplastic materials but, where appropriate, may also be applied to pipes manufactured in fibre reinforced thermosetting resins.
- c) For every application, characteristics of the proposed plastics are to be given to the Society, namely:
  - the chemical composition
  - the physical and mechanical characteristics in function of the temperature
  - the fire properties
  - eventually, the resistance to the various products likely to come into contact with those plastics.

### **1.10.2 Use of plastic pipes**

- a) Pipes made of plastics are permitted, as a general rule, for:
  - scupper and sanitary discharge pipes
  - ballast pipes except for the parts passing through engine rooms, dangerous spaces and oil fuel bunkers or located between pumps and their suctions and discharges
  - individual bilge pipes for small compartments such as chain lockers.
- b) For other pipes such as air and sounding pipes of compartments not intended to contain oil fuel, the Society may accept the use of plastics subject to an examination of the relevant drawings.
- c) Pipes made of plastics may be used for fluid systems not covered by the classification provided the requirements given in [1.10.3] are complied with.
- d) Pipes made of plastics are not to be used where they are subject to temperatures above 60°C or below 0°C.  
The use at a higher temperature for particular applications is subject to special examination.
- e) Any proposed service for plastic pipes not mentioned above is to be submitted to the Society for special consideration.

### **1.10.3 Intactness of watertight subdivision and fire divisions**

- a) As a rule, pipes made of plastics cannot pass through watertight bulkheads.
- b) If, however, such a passage cannot be avoided, arrangements are to be made in order to ensure the integrity of the subdivision in case of pipe breakage. Such arrangements are to be submitted to the Society.
- c) The use of pipes made of plastics is generally to be avoided wherever the destruction of these pipes in case of fire would compromise the intactness of subdivision or the safety of the ship.
- d) Where pipes made of plastics are to pass through fire divisions, the arrangements taken to ensure the fire integrity of these divisions are to be submitted to the Society.

### **1.10.4 Design and construction**

- a) Pipes and fittings are to be of a robust construction and are to comply with the requirements of such national standards as may be consistent with their intended use.  
Particulars of scantlings and joints are to be submitted for examination.
- b) All pipes are to be adequately but freely supported. Suitable provision for expansion and contraction is to be made in each range of pipes to allow for important clearance between pipes made of plastics and steel structures, in consideration of the difference between their individual coefficients of thermal expansion.
- c) All fittings and branches are to be suitable for the intended service and are to have joints of cemented, flanged or other approved types.
- d) The bursting pressure of pipes, fittings and joints made of plastics, at their service temperature, is not to be less than 4 times their maximum service pressure, with a minimum of 5 bar.
- e) After completion, pipes and fittings are to be subjected to a hydraulic pressure test, to be applied during at least 5 minutes under a pressure not less than 1,5 times the service pressure.

## **1.11 Flexible hoses and expansion joints**

### **1.11.1 General**

- a) The Society may permit the use of flexible hoses and expansion joints, both in metallic and non-metallic materials, provided they are approved for the intended service.
- b) Flexible hoses and expansion joints are to be of a type approved by the Society, designed in accordance with [1.11.3] and tested in accordance with [1.11.6].
- c) Flexible hoses and expansion joints are to be installed in accordance with the requirements stated in [1.11.5].
- d) Flexible hoses and expansion joints intended for piping systems with a design temperature below the ambient temperature will be given special consideration by the Society.

### **1.11.2 Documentation**

The information, drawings and documentation listed in [1.2.1], Tab 1 and Tab 2 are to be submitted to the Society for each type of flexible hose or expansion joint intended to be used.

### **1.11.3 Design of flexible hoses and expansion joints**

- a) Flexible pipes and expansion joints are to be made of materials resistant to the marine environment and to the fluid they are to convey. Metallic materials are to comply with Pt C, Ch 1, Sec 10, [2.1.2].

- b) Flexible pipes and expansion joints are to be designed so as to withstand:
  - external contact with hydrocarbons
  - internal pressure
  - vibrations
  - pressure impulses.
- c) Flexible pipes intended to convey fuel oil or lubricating oil and end attachments are to be of fire-resisting materials of adequate strength and are to be constructed to the satisfaction of the Society.
- d) Where a protective lining is provided for this purpose, it is to be impervious to hydrocarbons and to hydrocarbon vapours.
- e) Flexible pipes intended to convey:
  - gaseous fluid at a pressure higher than 1 MPa
  - fuel oil or lubricating oil,are to be fitted with a metallic braid.
- f) As a general rule, flexible hoses are to be fitted with crimped connections or equivalent. For water pipes subject to a pressure not exceeding 0,5 MPa, as well as for scavenge air and supercharge air lines of internal combustion engines, clips made of galvanised steel or corrosion-resistant material with thickness not less than 0,4 mm may be used.
- g) Flexible pipes and expansion joints are to be so designed that their bursting pressure at the service temperature is not less than 4 times their maximum service pressure, with a minimum of 2 MPa. Exemptions from this requirement may be granted for expansion joints of large diameter used on sea water lines.
- h) The junctions of flexible hoses and expansion joints to their couplings are to withstand a pressure at least equal to the bursting pressure defined in item f).

#### **1.11.4 Conditions of use of flexible hoses and expansion joints**

- a) The use of flexible hoses and expansion joints is to be limited as far as practicable.
- b) The position of flexible hoses and expansion joints is to be clearly shown on the piping drawings submitted to the Society.
- c) The use of non-metallic expansion joints on pipes connected to sea inlets and overboard discharges is to be given special consideration by the Society. As a rule, the fitting of such joints between the ship side and the valves mentioned in Pt C, Ch 1, Sec 10, [2.8.3] or [1.8.1], as applicable, is not permitted. Furthermore, unless the above-mentioned valves are fitted with remote controls operable from places located above the freeboard deck, efficient means are to be provided, wherever necessary, to limit the flooding of the ship in the event of rupture of the expansion joints.
- d) Expansion joints may be fitted in sea water lines, provided they are arranged with guards which effectively enclose, but do not interfere with, the action of the expansion joints and reduce to the minimum practicable any flow of water into the machinery spaces in the event of failure of the flexible elements.
- e) Use of expansion joints in water lines for other services, including ballast lines in machinery spaces, in duct keels and inside double bottom water ballast tanks, and bilge lines inside double bottom tanks and deep tanks, is to be given special consideration by the Society.

#### **1.11.5 Arrangement of flexible hoses and expansion joints**

- a) Flexible hoses and expansion joints are to be so arranged as to be accessible at all times.
- b) Flexible hoses and expansion joints are to be as short as possible.
- c) The radius of curvature of flexible hoses is not to be less than the minimum recommended by the manufacturer.
- d) The adjoining pipes are to be suitably aligned, supported, guided and anchored.
- e) Isolating valves are to be provided permitting the isolation of flexible hoses intended to convey flammable oil or compressed air.
- f) Expansion joints are to be protected against over extension or over compression.
- g) Where they are likely to suffer external damage, flexible hoses and expansion joints of the bellows type are to be provided with adequate protection.

#### **1.11.6 Type tests of flexible hoses and expansion joints**

- a) Type approval tests are to be carried out on a flexible hose or an expansion joint of each type and each size, in accordance with Tab 4.
- b) The flexible pipes or expansion joints subjected to the tests are to be fitted with their connections.
- c) The fire-resistance test is to be carried out in the conditions hereafter; other test methods may be applied after special examination.

The flexible pipe is to be subjected to fire for 30 minutes at a temperature of 800°C, while water at the maximum service pressure is circulated inside the pipe; the temperature of the water at the outlets is not to be less than 80°C. No leak is to be recorded during and after the test.
- d) Flexible pipes or expansion joints granted with a type approval certificate issued by the Society for the intended conditions of use are exempted from type-tests.

**1.11.7 Hydraulic tests**

- a) Each flexible pipe or expansion joint, together with its connections, is to undergo a hydraulic test under a pressure at least equal to twice the maximum service pressure, subject to a minimum of 10 bar.
- b) During the test, the pipe or expansion joint is to be repeatedly deformed from its geometrical axis.

**1.11.8 Marking**

Each flexible pipe or expansion joint is to be stencilled or otherwise marked with its specified maximum service pressure and, when used in other than ambient temperature, its maximum or minimum service temperature or both.

**Table 4 : Type tests to be performed for flexible hoses and expansion joints**

Type test	Required
Bursting	Yes
Fire-resistance	Yes (1)
Vibration	Yes (2)
Pressure impulse	Yes
Flexibility	Yes (3)
Cyclic expansion	Yes (4)
Resistance	Yes (5)
(1) Only for flexible hoses and expansion joints used in flammable oil and sea water systems. (2) Only for flexible hoses and expansion joints fitted to engines, pumps, compressors or other sources of high vibrations. (3) Only for flexible hoses conveying low temperature fluids. (4) Only for piping systems subjected to expansion cycles. (5) Internal to the conveyed fluid and external to UV.	

**1.11.9 Periodical replacement - Spare parts**

- a) Flexible pipes or expansion joints are to be periodically replaced according to the periodicity depending on their types.
- b) A spare is recommended for each type of flexible pipe or expansion joint the failure of which could impair the operation of main engines, that of auxiliary engines for essential services or the safety of the ship.

**1.12 Metallic flexible pipes and joints**

**1.12.1** Metallic flexible pipes and joints are to comply with the requirements stated in [1.11], as far as applicable. Fire-resistance tests need not be carried out.

**2 Bilge system in ships L ≥ 24 m**

**2.1 General**

**2.1.1 Application**

The following provisions supersede those given in Pt C, Ch 1, Sec 10, [6].

**2.1.2 Principle**

- a) Fishing vessels are to be provided with an efficient bilge pumping system capable of pumping from and draining, under all practical conditions, any watertight compartment other than spaces exclusively intended for the carriage of fresh water, water ballast or fuel oil, for which other efficient means of pumping are to be provided.
- b) In fishing vessels where fishing handling or processing may cause quantities of water to accumulate in enclosed spaces, adequate drainage is to be provided.
- c) The bilge pumping system is to consist of pumps connected to a bilge main line so arranged as to allow the draining of all spaces mentioned in item a).
- d) Bilge pumping arrangement may be dispensed with in particular compartments where no equipment nor openings are likely to leak.
- e) Where expressly permitted, some small compartments may be drained by means of hand pumps.
- f) Bilge and ballast systems are to be so designed as to prevent the possibility of water passing from the sea and from water ballast spaces into the cargo and machinery spaces, or from one compartment to another. Provisions are to be made to prevent any space having bilge and ballast connections being inadvertently flooded from the sea when containing cargo, or being discharged through the bilge system when containing water ballast.
- g) Where there are common valves between bilge and fire fighting lines, they are to have a locked device on his handwheels in order to avoid the discharge of bilge water into the fighting circuit.

## **2.2 Design of the bilge system**

### **2.2.1 General**

- a) All suction pipes up to the connection with the bilge pumps are to be independent from any other piping system of the ship.
- b) Non-return valves are to be fitted on:
  - direct and emergency suction in machinery spaces
  - the pipe connections to bilge distribution boxes
  - the suction of pumps having also connections from the sea or from compartments normally intended to contain liquid
  - the direct suction connected to independent bilge pumps, where required.
- c) All compartments are to be provided with at least one suction on each side. However, in the case of short and narrow compartments, a single suction ensuring an efficient draining may be accepted.

### **2.2.2 Draining of machinery spaces**

- a) Machinery spaces of ships with double bottom, or where the rise of floor is less than 5°, are to be provided on each side with one bilge suction connected to the bilge main.
- b) Machinery spaces of ships without double bottom, or where the rise of floor exceeds 5°, may be provided with only one bilge suction located in the centreline and connected to the bilge main.
- c) In addition to the bilge suction required in items a) and b), machinery spaces are to be provided with a direct suction, which is to be led direct to an independent power bilge pump and so arranged that it can be used independently of the bilge main.

### **2.2.3 Emergency bilge suction**

- a) The emergency bilge suction is to be led directly from the drainage level of the machinery space to the greater capacity sea water pump. Its capacity is to be at least equal to the required capacity of each bilge pump as determined in [2.3.4].
- b) The emergency bilge suction is to be located at the lowest possible level in the machinery spaces.
- c) The diameter of emergency bilge suction pipes is to be at least the diameter of the suction connected to of the sea water pump in normal operation.
- d) The high of the hand-wheels of the non-return valves controlling emergency bilge suction are to rise at least 450 mm above the manoeuvring floor.
- e) If the requirement mentioned in d) can not be verified, the height of the hand-wheels of the non-return valves is to be the minimum height to permit the easy operation of the valve.

### **2.2.4 Draining of holds**

- a) Holds of ships with double bottom, or where the rise of floor is less than 5°, are to be provided on each side with one bilge suction connected to the bilge main.
- b) Holds of ships without double bottom, or where the rise of floor exceeds 5°, may be provided with only one bilge suction located in the centreline and connected to the bilge main.
- c) Holds greater than 30 m in length, bilge suction are to be provided in the fore and aft ends and connected to the bilge main.

### **2.2.5 Draining of refrigerated spaces**

Refrigerated spaces are to be provided with drainage arrangement allowing the continuous drainage of condensates.

### **2.2.6 Draining of fore and aft peaks**

- a) Fore and aft peaks, where not used as tanks, are to be fitted with a bilge suction connected to the bilge main. Passage through the collision bulkhead is to comply with [2.5.2].
- b) Peaks of small dimensions may be drained by means of a hand pump provided that the suction lift is well within the capacity of the pump and in no case exceeds 7,30 m.

### **2.2.7 Draining of double bottom compartments**

Double bottom compartments, where not used as tanks, are to be provided with bilge suction. Their number and location are to comply with the provisions of [2.2.4]. However, if deemed acceptable by the Society, the cofferdams fitted between two different compartments of the double bottom may be provided with one bilge suction only.

### **2.2.8 Draining of other compartments**

- a) Provision is to be made for the drainage of chain lockers and other fore spaces by means of hand or power pump suction or hydraulic ejectors.
- b) Provision is to be made for the drainage of the steering gear compartment and other spaces located above the aft peak by means of suction connected to the bilge main or by means of hand pumps or hydraulic ejectors.
- c) These spaces may, however, be drained by means of scuppers discharging to the shaft tunnel, provided that the discharge pipes are fitted with self-closing valves situated in easily visible and accessible positions.

- d) Fish processing spaces are to be fitted with drainage means, the capacity of which is four times the normal feedwater flow in the space.

**2.3 Bilge pumps**

**2.3.1 Number and arrangement of pumps**

- a) Fishing vessels are to be provided with at least two power bilge pumps of the self-priming type connected to the bilge main and having the capacity required in [2.3.4]. One of these pumps may be driven by the propulsion machinery.
- b) Each bilge pump may be replaced by two or more pumps, provided that they are connected to the bilge main and that their total capacity is not less than that required in [2.3.4].
- c) One of the bilge pumps required in item a) may be replaced by a hydraulic ejector having the capacity required in [2.3.4] and connected to a high pressure water pump.
- d) Where permitted, hand pumps are to be operable from an easily accessible position above the load waterline.

**2.3.2 Location of bilge pumps**

Bilge pumps are to be located on the aft side of the collision bulkhead. This may not apply to those pumps only used for the draining of the spaces located on the fore side of the collision bulkhead.

**2.3.3 Use of pumps intended for other duties**

- a) Pumps used for sanitary service, general service or ballast may be considered as independent bilge pumps provided that:
  - they have the capacity required in [2.3.4]
  - they are of the self-priming type
  - they are connected to the bilge system.
- b) Non-return valves are to be provided in accordance with [2.2.1], item b).

**2.3.4 Bilge pump capacity**

- a) The water speed V in the bilge main and the capacity Q of each bilge pump are to be not less than the values given in Tab 5.
- b) If the capacity of one of the pumps is less than the rule capacity, the deficiency may be compensated by an excess capacity of the other pumps. Such deficiency is, however, not to exceed 30% of the rule capacity.

**Table 5 : Water speed and pump capacity**

Ship's length	L < 35	L ≥ 35
Water speed	V = 1,22	V = 2,00
Pump capacity	Q = 0,00345 d <sup>2</sup>	Q = 0,00565 d <sup>2</sup>
L : Length of the ship, in m V : Minimum water speed in the bilge main, in m/s Q : Minimum capacity of each pump, in m <sup>3</sup> /h d : Internal diameter of the bilge main, in mm, as defined in [2.4.1].		

**2.4 Size of bilge pipes**

**2.4.1 Bilge main line**

- a) The diameter of the bilge main is to be calculated according to the following formula:

$$d = 25 + 1,68\sqrt{L(B + D)}$$

without being less than 50 mm,

where:

- d : Internal diameter of the bilge main, in mm
- L : Length of the ship between perpendiculars, in m
- B : Breadth of the ship, in m
- D : Depth of the ship, measured up to the bulkhead deck, in m.

- b) The actual internal diameter may be rounded off. The nearest standard size is in no case to be more than 5 mm smaller than that obtained from the formula given in item a).

**2.4.2 Branch bilge suction pipes**

- a) The diameter of the pipes situated between the distribution boxes and the suction in the various spaces (holds, machinery space, etc) is to be calculated according to the following formulae:

$$d_1 = 25 + 2,16\sqrt{L_1(B + D)}$$

without being less than 50 mm,

where:

$d_1$  : Internal diameter of the suction pipe, in mm

$L_1$  : Length of the space considered, in m

$L, B, D$  : Length, breadth and depth of the ship as defined in [2.4.1].

- b) The actual internal diameter may be rounded off. The nearest standard size is in no case to be more than 5 mm smaller than that obtained from the formula given in item a).

## **2.5 Bilge piping arrangement**

### **2.5.1 Passage through double bottom compartments and tanks**

Bilge pipes are not to pass through double bottom compartments or tanks unless they are enclosed in appropriate pipe tunnels. Where this is not practicable, pipes are to be of reinforced thickness as per Pt C, Ch 1, Sec 10, Tab 6 and made of either one piece or several pieces assembled by welding or by reinforced flanges.

### **2.5.2 Passage through the collision bulkhead**

- a) A maximum of two pipes may pass through the collision bulkhead below the freeboard deck, unless otherwise justified. Such pipes are to be fitted with suitable valves operable from above the freeboard deck and the valve chest is to be secured at the bulkhead inside the fore peak. Such valves may be fitted on the after side of the collision bulkhead provided that they are readily accessible under all service conditions and the space in which they are located is not a cargo space. All valves are to be of steel, bronze or other approved ductile material. Valves of ordinary cast iron or similar material are not acceptable.
- b) The remote operation device of the valve referred to in a) is to include an indicator to show whether the valve is open or shut.

### **2.5.3 Bilge suction in machinery spaces and shaft tunnels**

In machinery spaces and shaft tunnels, the termination pipes of the bilge suction are to be straight and vertical and are to be led to mud boxes so arranged as to be easily inspected and cleaned. The lower end of the termination pipe is not to be fitted with a strum box.

### **2.5.4 Bilge suction in other compartments**

In compartments other than machinery spaces and shaft tunnels, the open ends of bilge suction pipes are to be fitted with strum boxes or strainers having holes not more than 10 mm in diameter. The total area of such holes is not to be less than twice the required cross-section of the suction pipe.

### **2.5.5 Bilge alarms**

Propulsion machinery spaces are to be fitted with a bilge level sensor capable of indicating water ingress in those spaces at the bridge by means of a visual and audible alarm.

## **2.6 Materials**

**2.6.1** All bilge pipes used in fuel storage tanks or in boiler or machinery spaces, including spaces in which oil-setting tanks or fuel oil pumping units are situated, are to be of steel or other suitable material non-sensitive to heat.

## **3 Bilge system in ships $L < 24$ m**

### **3.1 General**

#### **3.1.1 Principle**

All ships are to be provided with efficient means for pumping and draining any watertight space with at least one suction pipe when the ship is on an even keel and either is upright or has a list of up to 5°.

#### **3.1.2 Independence of the lines**

As a general rule, bilge lines are to be distinct from the other lines of the ship.

However, this requirement need not be applied to pipes located between collecting boxes and pump suction or between pumps and overboard discharges.

#### **3.1.3 Intactness of watertight subdivision**

The lines and accessories are to be so arranged as to prevent intercommunication of compartments which are to remain segregated from each other or the accidental connection of these compartments directly to the sea.

#### **3.1.4 Bilge main**

A bilge main is to be provided for draining the different compartments for ships the length of which is greater than, or equal to, 12 m.

### 3.1.5 Number and distribution of suction

At least two bilge suction are to be provided for draining the propulsion engine room. At least one of these suction is to be connected directly to a bilge pump.

The suction are to be located at the lowest points of the compartment.

Additional suction may be required if the flow of water towards the suction is disturbed by irregularities of the bottom.

At least one bilge suction is to be provided in each compartment located between two watertight bulkheads.

## 3.2 Pumps and ejectors

### 3.2.1 Pumps

- a) At least two power bilge pumps are to be provided; one of these pumps may be driven by a main propulsive engine.
- b) The Society may permit, after special consideration, that one of the pumps be replaced by an ejector.
- c) For ships the length of which is greater than, or equal to, 12 m, the bilge pumps are to be connected to the bilge main mentioned in [3.1.4].
- d) For ships having the navigation notation **coastal area**, the Society may permit, after special consideration, that one of bilge pumps be a fixed hand pump.
- e) Small compartments may be drained by means of portable or fixed hand pumps.

### 3.2.2 Ejectors

Where an ejector is used in lieu of a driven pump, its suction capacity is not to be less than the required capacity of the pump it replaces.

### 3.2.3 Capacity of the pumps

The capacity of the bilge pumps is to be such that a speed of water not less than 1,22 m/s may be obtained in the bilge main, the diameter of which is given in [3.3.1]. The capacity of each pump is therefore not to be less than:

$$Q = 0,00345 d_1^2$$

where:

- Q : Minimum capacity of each pump, in m<sup>3</sup>/h  
d<sub>1</sub> : Internal diameter, in mm, of the bilge main as defined in [3.3.1].

## 3.3 Size of bilge pipes

### 3.3.1 Bilge main

The internal diameter, in mm, of the bilge main, is to be of the commercial size nearest to the diameter given in the following formula:

$$d_1 = 25 + 1,68 \sqrt{L(B+C)}$$

without being less than 35 mm,

where:

- L, B : Rule length and breadth, respectively, of the ship, in m, defined in Pt B, Ch 1, Sec 3  
C : Moulded depth of the ship, in m, at the freeboard deck.

### 3.3.2 Suction in holds and machinery spaces

The internal diameter, in mm, of bilge pipes situated between collecting boxes and suction in holds and machinery spaces, is to be of the commercial size nearest to the diameter given by the following formula:

$$d_2 = 25 + 2,16 \sqrt{L_1(B+C)}$$

without being less than 35 mm,

where:

- B, C : Dimensions having the same meaning as in [3.3.1]  
L<sub>1</sub> : Length of the compartment, in m.

## 3.4 Arrangement of bilge lines and their accessories

### 3.4.1 Passage of pipes through certain compartments

If not contained in pipe tunnels, the part of bilge pipes passing through compartments intended to contain oil fuel are to have reinforced thickness and are to consist of a single piece. These pipes are to be provided with non-return valves at their ends in the holds.

### **3.4.2 Passage through watertight bulkheads**

No bilge cock or similar device is to be fitted on the collision bulkhead.

The fitting of bilge cocks or similar devices on other watertight bulkheads is to be avoided as far as possible. However, where such accessories are provided, they are to be accessible at any time and capable of being closed from positions above the deck. An indication is to be provided to show whether these valves are open or close.

### **3.4.3 Non-return valves**

Accessories are to be provided to prevent intercommunication of compartments or lines which are to remain segregated from each other. For this purpose, non-return valves or similar devices are to be fitted, namely on the pipe connections to bilge distribution boxes or to the alternative cocks, if any.

### **3.4.4 Strainers and mud boxes**

Strainers and mud boxes are to be fitted on bilge lines wherever they are necessary.

## **4 Scuppers and sanitary discharges**

### **4.1 Principle**

**4.1.1** Scuppers, sufficient in number and suitable in size, are to be provided to permit the drainage of water likely to accumulate in the spaces which are not located in the ship's bottom.

**4.1.2** The number of scuppers and sanitary discharge openings in the shell plating is to be reduced to a minimum, either by making each discharge serve as many as possible of the sanitary and other pipes, or in any other satisfactory manner.

### **4.2 General**

**4.2.1** Discharges led through the shell either from spaces below the working deck or from within enclosed superstructures or deckhouses on the working deck fitted with weathertight doors are to be fitted with accessible means for preventing water from passing inboard.

**4.2.2** Each separate discharge is to have an automatic non-return valve with a positive means of closing it from an accessible position, except when:

- satisfactory analysis is submitted to the Society, demonstrating that the entry of water into the vessel through the opening is not likely to lead to dangerous flooding, and
- the piping is of reinforced thickness as per Pt C, Ch 1, Sec 10, Tab 6.

**4.2.3** The means for operating the positive action valve is to be provided with an indicator showing whether the valve is open or closed.

### **4.3 Discharges through manned machinery spaces**

**4.3.1** In manned machinery spaces, main and auxiliary discharges essential for the operation of machinery may be controlled locally. The controls are to be accessible and are to be provided with indicators showing whether the valves are open or closed.

### **4.4 Materials**

**4.4.1** Fittings attached to the shell and the valves required in [4.2.2] are to be of steel, bronze or other ductile material.

**4.4.2** All pipes between the shell and the valves are to be of steel. However, in spaces other than machinery spaces of vessels constructed of material other than steel, the use of other materials may be permitted, subject to special consideration by the Society.

## **5 Air pipes and sounding devices in ships $L \geq 24$ m**

### **5.1 Air pipes**

#### **5.1.1 General**

Air pipes are to be fitted to all spaces which are not fitted with alternative ventilation arrangements.

Air pipes are to be so arranged and the upper part of compartments so designed that air or gas likely to accumulate in the said compartments can freely evacuate.

When only one air pipe is provided, it is not to be used as filling pipe.

### **5.1.2 Exposed parts of air pipes**

Where air pipes to tanks and void spaces below deck extend above the working or the superstructure decks, the exposed parts of the pipes are to be of strength equivalent to the adjacent structures and fitted with the appropriate protection.

### **5.1.3 Means of closing**

Openings of air pipes are to be provided with means of closing, permanently attached to the pipe or adjacent structure.

### **5.1.4 Height of air pipes**

The height of air pipes above deck to the point where water may have access below is to be at least:

- 760 mm on the working deck, and
- 450 mm on the superstructure deck.

The Society may accept reduction of the height of an air pipe to avoid interference with the fishing operations.

### **5.1.5 Special arrangements for air pipes of flammable oil tanks**

- a) Air pipes from fuel oil and thermal oil tanks are to discharge to a safe position on the open deck where no danger will be incurred from issuing oil or gases.

Where fitted, wire gauze diaphragms are to be of corrosion resistant material and readily removable for cleaning and replacement. The clear area of such diaphragms is not to be less than the cross-sectional area of the pipe.

- b) Air pipes of lubricating or hydraulic oil storage tanks not subject to flooding in the event of hull damage may be led to machinery spaces, provided that in the case of overflowing the oil cannot come into contact with electrical equipment, hot surfaces or other sources of ignition.
- c) The location and arrangement of vent pipes for fuel oil service, settling and lubrication oil tanks are to be such that, in the event of a broken vent pipe, there is no risk of ingress of seawater or rainwater.
- d) Where seawater or rainwater may enter fuel oil service, settling and lubrication oil tanks through broken air pipes, arrangements such as water traps with:
- automatic draining, or
  - alarm for water accumulation,
- are to be provided.

### **5.1.6 Construction of air pipes**

- a) Where air pipes to ballast and other tanks extend above the freeboard deck or superstructure deck, the exposed parts of the pipes are to be of substantial construction, with a minimum wall thickness of at least:

- 6,0 mm for pipes of 80 mm or smaller external diameter,
- 8,5 mm for pipes of 165 mm or greater external diameter.

Intermediate minimum thicknesses may be determined by linear interpolation.

- b) Air pipes with height exceeding 900 mm are to be additionally supported.
- c) In each compartment likely to be pumped up, and where no overflow pipe is provided, the total cross-sectional area of air pipes is not to be less than 1,25 times the cross-sectional area of the corresponding filling pipes.
- d) The internal diameter of air pipes is not to be less than 50 mm, except for tanks of less than 2 m<sup>3</sup>.

## **5.2 Sounding and level gauging devices**

### **5.2.1 General**

Sounding devices are to be fitted:

- to the bilges of those compartments which are not readily accessible at all times during voyages, and
- to all tanks and cofferdams.

### **5.2.2 Termination of sounding pipes**

Where sounding pipes are fitted, their upper ends are to extend to a readily accessible position and, where practicable, above the working deck.

### **5.2.3 Means of closing**

The openings of the sounding pipes are to be provided with permanently attached means of closing. Sounding pipes which are not extended above the working deck are to be fitted with automatic self-closing devices.

### **5.2.4 Special arrangements for sounding pipes of flammable oil tanks**

Where tanks containing fuel oil or hydraulic oil are fitted with sounding pipes, their upper ends are to terminate in safe positions and are to be fitted with suitable means of closure.

Gauges made of heat-resistant glass of substantial thickness and protected with a metal case may be used, provided that automatic closing valves are fitted. The level gauge is to be of an approved type. Other means of ascertaining the amount of oil contained in the tank may be permitted provided their failure or overfilling will not permit release of fuel.

### **5.2.5 Construction of sounding pipes**

- a) Sounding pipes are normally to be straight. If it is necessary to provide bends in such pipes, the curvature is to be as small as possible to permit the ready passage of the sounding apparatus.
- b) Bent portions of sounding pipes are to have reinforced thickness and be suitably supported.
- c) The internal diameter of sounding pipes is not to be less than 32 mm. Where sounding pipes pass through refrigerated spaces, or through the insulation of refrigerated spaces in which the temperature may be below 0°C, their internal diameter is to be at least 60 mm.
- d) Doubling plates are to be placed under the lower ends of sounding pipes in order to prevent damage to the hull. When sounding pipes with closed lower ends are used, the closing plate is to have reinforced scantlings.

## **6 Air pipes and sounding devices in ships L < 24 m**

### **6.1 Air pipes**

#### **6.1.1 General**

Air pipes are to be fitted to all compartments intended to contain liquid or which are not fitted with alternative ventilation arrangements.

These air pipes are to be so arranged as to be self-draining when the ship is on an even keel.

#### **6.1.2 Number and position of air pipes**

Air pipes are to be so arranged and the upper part of compartments so designed that air or gas likely to accumulate in the said compartments can freely evacuate.

When only one air pipe is provided, it is not to be used as filling pipe.

#### **6.1.3 Tank air pipes**

Air pipes of compartments likely to contain liquid hydrocarbons, cofferdams or any capacity likely to be pumped up are to be led out, at a sufficient height above the deck.

Air pipes of all compartments which can be run up from the sea are to be led to above the deck.

Moreover, air pipes of compartments containing liquid hydrocarbons are not to be led to a place where danger could be the consequence of the evacuation of hydrocarbons or hydrocarbon vapours through these openings.

Air pipes of lubricating oil tanks and bunkers may be led to the machinery spaces, provided that in case of overflow the oil cannot come into contact with electrical apparatus or with surfaces likely to be at a high temperature.

#### **6.1.4 Open ends of air pipes**

Efficient, permanently attached devices are to be provided permitting, should the necessity arise, to close the upper openings of air pipes in order to prevent any accidental entry of water into the spaces concerned.

Where the tank venting system is not of an automatic type approved by the Society, provision is to be made for relieving vacuum when the tanks are being pumped out, and for this purpose a hole of about 10 mm in diameter in the bend of the air pipe, or at a suitable position in the closing device, is acceptable.

#### **6.1.5 Construction**

In each compartment likely to be pumped up, and where no overflow pipe is provided, the total cross-sectional area of air pipes is not to be less than the cross-sectional area of the corresponding filling pipes.

## **6.2 Sounding and level gauging devices**

### **6.2.1 General**

Arrangements are to be made for sounding the tanks intended to contain liquid as well as all the compartments which are not readily accessible at all times.

### **6.2.2 Upper ends of sounding pipes**

As a general rule, the sounding pipes are to end above the deck in easily accessible places and are to be fitted with efficient closing appliances.

However, in machinery spaces, when this requirement cannot be met, short sounding pipes may be used which are to lead to readily accessible positions above the floor and fitted with efficient closing appliances. When such sounding pipes are used for oil fuel or lubricating oil tanks, they are not to end close to electric motors or switchboards and are to be fitted with automatic closing devices.

### **6.2.3 Construction**

- a) Internal diameter of sounding pipes is not to be less than 30 mm.
- b) Doubling plates are to be placed under the lower ends of sounding pipes in order to prevent damage to the hull.

### **6.2.4 Level-indicator systems**

- a) Level-indicator systems are to be of robust construction and suitably protected.
- b) When used on fuel tanks or bunkers, level-indicator systems are to meet the requirements stated in [12.1.4].

## **7 Ventilation in ships $\geq 24$ m**

### **7.1**

**7.1.1** See Pt C, Ch 1, Sec 1, [3.1.1] and Pt C, Ch 1, Sec 1, [3.6.1].

See also Pt C, Ch 4, Sec 2, [2.1] and Pt C, Ch 4, Sec 6, [4].

## **8 Ventilation in ships $< 24$ m**

### **8.1**

**8.1.1** Adequate ventilation is to be provided for spaces containing engines, boilers or other heat generating apparatuses, as well as for spaces where flammable vapours are likely to accumulate.

**8.1.2** Ventilators serving the machinery spaces are to be capable of being closed in case of fire, from outside the said spaces. Skylights and other openings serving these spaces are to meet the following requirements:

- The skylights containing wire-reinforced glass panels are to be fitted with external shutters of steel or other equivalent material permanently attached
- Insulating materials in accommodation spaces, service spaces, control stations and machinery spaces except in refrigerated compartments are to be non-combustible. The surface of insulation fitted on the internal boundaries of machinery spaces is to be impervious to oil or oil vapours.

**8.1.3** Ventilation of spaces containing propulsive plant and its auxiliaries is to be mechanical.

**8.1.4** Mechanical ventilating fans are to be capable of being stopped from outside the space supplied by these ventilating fans.

## **9 Engine cooling systems in ships $L \geq 24$ m**

### **9.1**

**9.1.1** See Pt C, Ch 1, Sec 10, [10].

## **10 Engine cooling systems in ships $L < 24$ m**

### **10.1 Principle**

#### **10.1.1**

- a) Provision is to be made so that the cooling of main engines and of lubricating oil or fresh water coolers for these engines can be suitably ensured in all normal operating conditions.
- b) Generally, cooling water to propulsion engines and to lubricating oil or fresh water coolers is to be capable of being supplied by two separate means.
- c) Engine cooling systems in ships having several propulsion engines are to be given special consideration by the Society.

### **10.2 Motorships**

#### **10.2.1**

- a) The second means stated in [10.1.1] item b) for engine cooling may consist of a satisfactory connection to a general service pump of sufficient capacity.
- b) Where the power per engine does not exceed 370 kW or when the ratio of the power per engine expressed in kW to the rotating speed in revolutions per minute does not exceed 0,75, the Society may permit that the second means be a spare pump ready to be connected to the cooling system. Provision is to be made for the corresponding disassembling and reassembling operations to be carried out on board in a time as short as possible.

### **10.3 Fresh water cooling system**

**10.3.1** Where the engines are cooled by fresh water, the second means stated in [10.1.1] item b) may be omitted if a connection is fitted from the fresh water system to a suitable salt water system.

### **10.4 Cooling pumps**

**10.4.1** The pumps which may be connected to cooling systems may be either independent or driven by the machine they serve. Relief valves are to be fitted on the discharge of cooling pumps driven by main engines, except for centrifugal type pumps.

### **10.5 Sea inlets**

#### **10.5.1**

- a) Not less than two sea inlets are to be provided for the engine cooling system. These sea inlets are to be distinct for the two means of cooling given in [10.1.1] item b), but they may be cross connected by a cross pipe.
- b) These sea inlets are to be low inlets and one of them may be that of the ballast pump or of the general service pump. A sea-inlet is considered as low provided it remains submerged under all normal navigating conditions.

### **10.6 Filters**

**10.6.1** Where propulsive engines are directly cooled by sea water, either in normal service or in emergency, filters are to be fitted on the suction of cooling pumps.

### **10.7 Operating control**

**10.7.1** Means are to be provided for controlling the temperature and the water circulation of each engine.

### **10.8 Materials**

**10.8.1** The materials used for cooling systems are to be such as to limit the effects of galvanic corrosion and erosion, considering the circulation speeds adopted.

## **11 Oil fuel systems in ships $L \geq 24m$**

### **11.1**

**11.1.1** See Pt C, Ch 1, Sec 10, [11].

## **12 Oil fuel systems in ships $L < 24m$**

### **12.1 General**

#### **12.1.1 Scope**

The requirements stated in [12.1] and [12.2] are applicable to oil fuel systems for the service of propulsion engines and auxiliary machines. The flash point of the oil fuel used, determined by means of closed cup test, is not to be lower than 60°C.

The use for propulsion engines and auxiliary machine of oil fuel having a flash point lower than 60°C is subject to a special examination by the Society.

#### **12.1.2 Pump controls**

The power supply to oil fuel transfer pumps and to other pumps of the oil fuel system as well as to oil fuel separators is to be capable of being stopped from an always accessible place in the event of fire within the compartment where this equipment is located.

#### **12.1.3 Drip-trays and gutterways**

Drip-trays or gutterways with appropriate discharge devices are to be fitted:

- under pumps, valves and filters
- under oil fuel tanks and bunkers which are not part of the ship's structure, as well as
- under all the accessories subject to oil fuel leakage.

#### **12.1.4 Level indicators**

- a) Gauge cocks for checking the level in the tanks are not to be used.

The glasses of any level indicator fitted on such tanks are to be made of heat-resistant material and are to be efficiently protected against shock. Such level indicators are to be fitted with self-closing cocks at their lower end as well as at their upper end if the latter is below the maximum liquid level.

- b) Where the fuel transfer system does not include power pumps but only hand pumps, the valves to be provided at the lower end of level-indicators for fuel tanks, with the exception of daily service tanks, need not to be of the self-closing type. These valves are however to be readily accessible and instruction plates are to be fitted near these valves specifying that they are to be maintained closed except during transfer operations.

### **12.2 Oil fuel tanks and bunkers**

#### **12.2.1 Location of oil fuel tanks and bunkers**

- a) Location of oil fuel tanks and bunkers is to be chosen in a way to avoid any abnormal rise in temperature in these capacities.
- b) The use of free standing oil fuel tanks is not permitted in high fire risk areas.

#### **12.2.2 Suctions and discharges to oil fuel tanks and bunkers**

- a) All suction pipes to oil fuel tanks and bunkers, including those in double bottom, are to be provided with valves.

In the case of bunkers and oil fuel storage, settling or daily service tanks other than those in the double bottom, the valves are to be fitted directly on the plating of these bunkers and tanks and are to be so arranged that they can always be remotely closed in the event of fire taking place in the compartment where they are located.

- b) Where the oil fuel transfer installation does not include power pumps but only hand pumps, the suction valves to oil fuel tanks and bunkers, with the exception of daily service tanks, need not to be provided with remote controls. These valves are however to be readily accessible and instruction plates are to be fitted in their vicinity specifying that they are to be maintained closed except during transfer operations.
- c) Where the discharge pipes to oil fuel bunkers and tanks are not led to the upper part of the said bunkers and tanks, they are to be provided with non-return valves at their ends.

#### **12.2.3 Drains**

Daily service tanks are to be provided with drains permitting the evacuation of water and impurities likely to accumulate in the lower part of these tanks. These drains are to be fitted with self-closing valves or cocks.

#### **12.2.4 Materials - Tests**

- a) The use of materials other than steel for fuel bunkers and tanks which are not part of the ship's structure is specially examined.
- b) Oil fuel tanks and bunkers are to be tested under the conditions specified in [1.4.3].

### **12.3 Transfer pipes**

#### **12.3.1 Arrangement of the transfer system**

The transfer system together with its accessories are to be so arranged that oil fuel cannot enter compartments the structure of which does not allow them to be filled with oil fuel or compartments intended to contain drinking water.

#### **12.3.2 Transfer pumps**

Where oil fuel is transferred by means of a power pump, arrangements are to be made so that oil fuel may be pumped, in the event of damage to this pump, by means of a stand-by pump, which can be a hand pump.

#### **12.3.3 Passage through particular compartments**

No fuel pipes are to pass through fresh water tanks and no fresh water pipes are to pass through fuel oil tanks.

### **12.4 Oil fuel supply to engines**

**12.4.1** The suctions of engine fuel pumps are to be so arranged as to prevent the suction of gathered water and sludge likely to accumulate after decanting at the lower part of service tanks.

**12.4.2** Two filters, or similar devices, are to be provided and so arranged that one of the filters can be overhauled while the other is in use.

### **12.5 Materials - Construction**

**12.5.1** Low-pressure oil fuel pipes are generally to be made of steel. Where the internal diameter of these pipes does not exceed 25 mm, they may be of seamless copper or copper-alloy unless they pass through oil fuel tanks.

**12.5.2** Transfer oil fuel pipes may be of non metallic hoses in the conditions stated in [1.10].

**12.5.3** The pipes are to be connected by means of close-fitting flanges or other devices deemed equivalent for the application considered. The materials of the joints are to be impervious to liquid hydrocarbons.

## **13 Lubricating oil systems in ships $L \geq 24$ m**

### **13.1**

**13.1.1** See Pt C, Ch 1, Sec 10, [12].

## **14 Lubricating oil systems in ships $L < 24$ m**

### **14.1 General**

**14.1.1** The lubricating oil systems are to be so arranged as to operate satisfactorily when the ship is inclined from the normal position to angles of up to  $15^\circ$  transversely or  $5^\circ$  longitudinally, or when rolling to angles of up to  $22^\circ 30'$  or pitching up to  $7^\circ 30'$ . Lubricating oil pipes are to be independent of any other fluid system.

### **14.2 Lubricating pumps**

#### **14.2.1**

- a) Main engines are normally to be provided with at least two power lubricating pumps. Where the installation includes at least two propulsive units, the Society may permit that only one pump be provided for each propulsive unit.
- b) Where the power per engine does not exceed 370 kW or when the ratio of the power per engine expressed in kW to the rotating speed in revolutions per minute does not exceed 0,75, the Society may permit that one of the pumps mentioned in item a) be a spare pump ready to be connected to the lubricating oil system. Provision is to be made for the corresponding disassembling and reassembling operations to be carried out on board in a time as short as possible.

### **14.3 Filters**

**14.3.1** In forced lubrication systems, a device is to be fitted which efficiently filters the lubricating oil in the circuit. The filters provided for this purpose are to be so arranged that they can be easily cleaned without stopping the lubrication of the machines.

### **14.4 Safety devices**

**14.4.1** Lubricating oil systems for propulsive engines are to be provided with an alarm device giving audible warning in the event of an appreciable reduction of the oil pressure.

## **15 Hydraulic systems in ships $L \geq 24$ m**

### **15.1**

**15.1.1** See Pt C, Ch 1, Sec 10, [14].

## **16 Hydraulic systems in ships $L < 24$ m**

### **16.1 General**

**16.1.1** Installations using flammable oils are to be given special consideration by the Society.

### **16.2 Safety and monitoring devices**

**16.2.1** Whenever practicable, the hydraulic power units are to be located outside the main engine or boiler rooms. Shields or similar devices are to be provided around the hydraulic power units in order to avoid accidental oil spray or oil mist on heated surfaces which may ignite oil.

## **17 Compressed air systems in ships $L \geq 24$ m**

### **17.1**

**17.1.1** See Pt C, Ch 1, Sec 10, [17].

## **18 Compressed air systems in ships L < 24 m**

### **18.1**

#### **18.1.1 Starting compressed air systems**

- a) The compressed air system for starting main engines is to be so arranged that it is possible to ensure the initial charge of the air receiver(s). A hand compressor may be used for this purpose. Alternatively a compressor with a hand started prime mover may be used.
- b) The prescription a) can be considered as fulfilled when the starting of the main engines is conducted, normally or under emergency, by starting devices such as fuses, inertia starters or other means deemed equivalent.
- c) When only one air compressor is used for filling the air receivers, there are to be at least two air receivers.
- d) The main engine air receivers are to have a total capacity sufficient to provide, without replenishment:
  - 12 consecutive starts of the reversible type engines
  - 6 consecutive starts of the non-reversible type engines.

#### **18.2 Accessories for compressed air systems**

**18.2.1** The receivers, compressors, pipes and other accessories of the compressed air systems are to be fitted with adequate devices to avoid any appreciable overpressure in any point of the system.

#### **18.3 Arrangement of compressed air systems**

##### **18.3.1**

- a) Efficient oil and water separators are to be provided on the discharge of compressors.
- b) Non-return valves or other safety devices are to be provided on the starting air mains of each engine.

#### **18.4 Construction - Material**

##### **18.4.1**

- a) The construction and scantlings of compressed air pipes and of their accessories are to comply with the requirements of Pt C, Ch 1, Sec 10.
- b) Air receivers are to be constructed in accordance with the relevant requirements of Pt C, Ch 1, Sec 3.

## **19 Exhaust gas systems in ships L ≥ 24 m**

### **19.1**

**19.1.1** See Pt C, Ch 1, Sec 10, [17].

## **20 Exhaust gas systems in ships L < 24 m**

### **20.1 Hull outlet**

**20.1.1** Where exhaust gas pipes are led overboard close to the load waterline, arrangements are to be made to prevent any entry of water in the ship or in the engines while in normal operation.

### **20.2 Cooling and lagging**

**20.2.1** The exhaust gas pipes and silencers which pass through spaces of the ship where a temperature rise might be dangerous are to be efficiently cooled or lagged.

### **20.3 Water-cooled exhaust gas pipes**

**20.3.1** When water-cooled exhaust gas pipes are used, a high temperature alarm must be fitted after the water injection device. Alternatively, a low sea water flow rate may be fitted.

## **21 Refrigeration systems for the preservation of the catch**

### **21.1 General**

**21.1.1** Refrigeration systems are to be so designed, constructed, tested and installed as to take account of the safety of the system and also the emission of chlorofluorocarbons (CFCs) or any other ozone-depleting substances from the refrigerant held in quantities or concentrations which are hazardous to human health or to the environment.

**21.1.2** Methylchloride or CFCs whose ozone-depleting potential is higher than 5% of CFC-11 are not to be used as refrigerants.

**21.1.3** Adequate guidance for the safe operation of the refrigeration system and emergency procedures are to be provided by means of suitable notices displayed on board the vessel.

## **21.2 Design of refrigeration systems**

**21.2.1** Refrigeration systems are to be adequately protected against vibration, shock, expansion, shrinkage, etc. and are to be provided with an automatic safety control device to prevent a dangerous rise in temperature and pressure.

**21.2.2** Refrigeration systems in which toxic or flammable refrigerants are used are to be provided with drainage devices leading to a place where the refrigerant presents no danger to the vessel or to persons on board.

## **21.3 Arrangement of the refrigerating machinery spaces and refrigerating rooms**

### **21.3.1 Separation of spaces**

- a) Any space containing refrigerating machinery, including condensers and gas tanks utilising toxic refrigerants, is to be separated from any adjacent space by gas-tight bulkheads. Any space containing refrigerating machinery, including condensers and gas tanks utilizing toxic refrigerants, is to be fitted with a leak detection system having an indicator outside the space adjacent to the entrance and is to be provided with an independent ventilation system and a water-spraying system.
- b) For fishing vessels under 55 m in length, ammonia plants are allowed to be located in the machinery space provided that they comply with the provisions of Pt C, Ch 1, Sec 16, [2.3.2].

### **21.3.2 Exits from spaces**

In refrigerating machinery spaces and refrigerating rooms, alarms are to be connected to the wheelhouse or control stations or escape exits to prevent persons being trapped. At least one exit from each such space is to be capable of being opened from the inside. Where practicable, exits from spaces containing refrigerating machinery using toxic or flammable gas are not to lead directly into accommodation spaces.

## **21.4 Breathing apparatus**

**21.4.1** Where any refrigerant harmful to persons is used in a refrigeration system, at least two sets of breathing apparatus are to be provided, one of which is to be placed in a position not likely to become inaccessible in the event of leakage of refrigerant. Breathing apparatus provided as part of the vessel's fire-fighting equipment may be considered as meeting all or part of this provision provided its location meets both purposes. Where self-contained breathing apparatus is used, spare cylinders are to be provided. Alternative arrangement authorized by the administration concerned may be accepted.

## **22 Propelling and auxiliary machinery in ships $L \geq 24$ m**

### **22.1**

**22.1.1** See Pt C, Ch 1, Sec 7.

## **23 Propelling and auxiliary machinery in ships $L < 24$ m**

### **23.1 Shafting**

#### **23.1.1 Propeller shaft diameter**

The diameter of the shaft going through the stern tube is not to be less than the diameter  $d$ , in mm, given by the following formula:

$$d = 126 \cdot \left( \frac{P}{N} \cdot \frac{560}{R_m + 160} \right)^{1/3}$$

where:

- P : Maximum continuous power of the propulsion machinery, in kW  
N : Shaft revolutions per minute

$R_m$  : Minimum tensile strength of the shaft material, in N/mm<sup>2</sup>. In the above formula,  $R_m$  is not to be taken greater than:

- 600 N/mm<sup>2</sup> for intermediate shaft in carbon and carbon manganese steels
- 800 N/mm<sup>2</sup> for intermediate shaft in alloy steels
- 600 N/mm<sup>2</sup> for propeller shaft in carbon, carbon manganese and alloy steels.

In case of stainless steels and in other particular cases, at the discretion of the Society, the value of  $R_m$  to be introduced in the above formula is to be specially considered.

Furthermore, the shaft diameter is not to be less than 25 mm for carbon steel or carbon manganese steel, and 20 mm for the other materials.

### 23.1.2 Intermediate shaft diameter

The diameter, in mm, of the intermediate shafts is not to be less than:

$$d' = 0,87 d$$

## 23.2 Shaft accessories

### 23.2.1 Coupling bolts

The diameter of coupling bolts at the joining faces of the couplings is to be not less than the diameter  $D_b$ , given, in mm, by the following formula, for intermediate, propeller and thrust shafts:

$$D_b = 0,65 \cdot \left( \frac{d^3 \cdot (R_m + 160)}{n \cdot D_C \cdot R_b} \right)^{1/2}$$

where:

- $d'$  : Intermediate shaft diameter defined in [23.1.2]  
 $n$  : Number of bolts in the coupling  
 $D_C$  : Pitch circle diameter of the coupling bolts, in mm  
 $R_b$  : Ultimate tensile strength of the bolt metal, in N/mm<sup>2</sup>.

### 23.2.2 Shaft liners

The thickness of bronze shaft liners in way of the bushes and stern gland is to be not less than the thickness  $e$ , in mm, given by the following formula:

$$e = \frac{d + 230}{32}$$

where:

- $d$  : Actual diameter of the propeller shaft, in mm.

### 23.2.3 Stern bearing

#### a) Water lubrication

The length of the after bearing of the propeller shaft is not to be less than 4 times the rule diameter of the propeller shaft; furthermore the bearing is to be made of a type approved synthetic material.

For a bearing design substantiated by experimental data to the satisfaction of the Society, consideration may be given to a bearing length less than 4 times, but in no case less than 2 times, the rule diameter of the shaft in way of the bearing.

#### b) Oil lubrication

The length of the after bearing of the propeller shaft is not to be less than 2 times the rule diameter of the propeller shaft; furthermore:

- the bearing material is to be of the antifrictional type
- the oil gland is to be type approved.

#### c) Other arrangements

The other arrangements beside those defined in items a) and b) are to be given special consideration. The length of the after bearing of the propeller shaft is not to be less than 3,5 times the rule diameter of the propeller shaft.

### 23.2.4 Sealing gland

#### a) The sealing glands must be readily accessible, for inspection or replacement

#### b) The sealing glands are to be periodically inspected.

The temporary actions to be taken in case of accidental failure of a main component, as well as the inspection periodicity and the replacement schedule of parts subject to wear or deterioration, are to be specified.

The wear strength of non-metallic parts is to be established, either by satisfactory operations, or by relevant tests.

An easy to fit emergency device may be accepted.

## **24 Steering gear**

### **24.1 Application**

**24.1.1** The provisions of this Article apply in addition to those of Pt C, Ch 1, Sec 14. with the exception of Sub-Articles Pt C, Ch 1, Sec 14, [2.1] to Pt C, Ch 1, Sec 14, [2.4].

### **24.2 General**

**24.2.1** Unless expressly provided otherwise, every ship is to be provided with main steering gear and auxiliary steering gear to the satisfaction of the Society.

### **24.3 Strength, performance and power operation of the steering gear**

#### **24.3.1 Main steering gear**

The main steering gear and rudder stock are to be:

- a) of adequate strength and capable of steering the ship at maximum ahead service speed, which is to be demonstrated
- b) capable of putting the rudder over from 35° on one side to 35° on the other side with the ship at its deepest seagoing draught and running ahead at maximum ahead service speed and, under the same conditions, from 35° on either side to 30° on the other side in not more than 28 s
- c) operated by power where necessary to fulfil the requirements of b), and
- d) so designed that they will not be damaged at maximum astern speed; however, this design requirement need not be proved by trials at maximum astern speed and maximum rudder angle.

#### **24.3.2 Auxiliary steering gear**

The auxiliary steering gear is to be:

- a) of adequate strength and sufficient to steer the ship at navigable speed and capable of being brought speedily into action in an emergency,
- b) capable of putting the rudder over from 15° on one side to 15° on the other side in not more than 60s with the ship at its deepest seagoing draught and running ahead at one half of the maximum ahead service speed or 7 knots, whichever is the greater, and
- c) operated by power where necessary to meet the requirements of b).

#### **24.3.3 Hand operation**

Hand operation of steering gear is permitted when it requires an effort less than 160 N.

### **24.4 Control of the steering gear**

#### **24.4.1 Control of the main steering gear**

- a) Control of the main steering gear is to be provided on the navigation bridge.
- b) Where the main steering gear is arranged in accordance with [24.5.2], two independent control systems are to be provided, both operable from the navigation bridge. This does not require duplication of the steering wheel or steering lever.

#### **24.4.2 Control of the auxiliary steering gear**

- a) Control of the auxiliary steering gear is to be provided on the navigation bridge, in the steering gear compartment or in another suitable position.
- b) If the auxiliary steering gear is power operated, its control system is also to be independent of that of the main steering gear.

### **24.5 Availability**

#### **24.5.1 Arrangement of main and auxiliary means for actuating the rudder**

The main steering gear and the auxiliary means for actuating the rudder are to be arranged so that a single failure in one will not render the other inoperative.

#### **24.5.2 Omission of the auxiliary steering gear**

Where the main steering gear comprises two or more identical power units, auxiliary steering gear need not be fitted, provided that the main steering gear is capable of operating the rudder:

- a) as required in [24.3.1], item b), while operating with all power units
- b) as required in [24.3.2], item b), while any one of the power units is out of operation.

**24.5.3 Hydraulic power supply**

Hydraulic power installations supplying steering gear may also supply other equipment at the same time provided that the operation of the steering gear is not affected:

- a) by the operation of this equipment, or
- b) by any failure of this equipment or of its hydraulic supply piping.

# Section 5 Electrical Installations

## 1 General

### 1.1 Application

**1.1.1** The requirements contained in Part C, Chapter 2 apply to fishing vessels, except for those contained in Pt C, Ch 2, Sec 1, [2]; Pt C, Ch 2, Sec 15, [2]; Pt C, Ch 2, Sec 3, [2]; Pt C, Ch 2, Sec 3, [3]; Pt C, Ch 2, Sec 11, [1]; Pt C, Ch 2, Sec 11, [2]; Pt C, Ch 2, Sec 11, [3]; Pt C, Ch 2, Sec 11, [4], and Pt C, Ch 2, Sec 11, [5], which are replaced by all those contained in this Section.

## 2 Documentation to be submitted

### 2.1

**2.1.1** The documents listed in Tab 1 are to be submitted.

Where the length is less than 24 m, the Society may give exemptions to the documents to be submitted.

**Table 1 : Documents to be submitted**

No.	I/A (1)	Documents to be submitted
1	A	Single line diagram of main and emergency power and lighting systems
2	I	Electrical power balance (main and emergency supply)
3	A	Calculation of short-circuit currents for each installation in which the sum of rated power of the energy sources which may be connected contemporaneously to the network is greater than 500 kW
4	A	List of circuits including, for each supply and distribution circuit, data concerning the nominal current, the cable type, length and cross-section, the nominal and setting values of the protective and control devices
5	A	Single line diagram and detailed diagram of the main switchboard
6	A	Single line diagram and detailed diagram of the emergency switchboard
7	A	Diagram of the most important section boards and motor control centres (above 100 kW)
8	A	Detailed diagram of the navigation-light switchboard
(1) A: to be submitted for approval; I: to be submitted for information.		

## 3 Type approved components

### 3.1

**3.1.1** The following components are to be type approved case-by-case based on submission of adequate documentation and execution of tests:

- electrical cables
- switching devices (circuit-breakers, contactors, disconnectors, etc.) and overcurrent protective devices
- electronic components used for tasks essential to safety.

## 4 General requirements for system design, location and installation

### 4.1 Design and construction

**4.1.1** The design and construction of electrical installations are to be such as to provide:

- a) the services necessary to maintain the vessel in normal operational and habitable conditions without having recourse to an emergency source of power,
- b) the services listed in [4.4.2] when failure of the main source of electrical power occurs, and
- c) protection of the crew and vessel from electrical hazards.

## **4.2 Distribution**

### **4.2.1 Supply systems**

Distribution systems given in Pt C, Ch 2, Sec 3, [1] may be used on board of fishing vessels. Where length is less than 24 m, on d.c. installations, two-wire systems with one pole earthed may be used.

**4.2.2** General requirements given in Pt C, Ch 2, Sec 3, [1.1.3] and Pt C, Ch 2, Sec 3, [1.1.4] are applicable to fishing vessels. In addition, where length is less than 24 m, every conductor carrying the current from a circuit to the hull is to have the same cross section as the corresponding insulated conductor. In d.c. installations, one pole of generator and of supplied appliances is to be earthed in readily accessible places.

**4.2.3** The hull return system of distribution is not to be used for power, heating or lighting in vessels of 75 m of length and over.

**4.2.4** The requirement in [4.2.3] does not preclude, under conditions approved by the Society, the use of:

- a) impressed current cathodic protective systems
- b) limited and locally earthed systems, or
- c) insulation level monitoring devices provided the circulation current does not exceed 30 mA under the most unfavourable conditions.

**4.2.5** Where the hull return system is used, all final subcircuits (all circuits fitted after the last protective device) are to be two-wire and special precautions are to be taken to the satisfaction of the Society.

### **4.3 Main source of electrical power**

**4.3.1** Where the electrical power constitutes the only means of maintaining auxiliary services essential for the propulsion and safety of the vessel, a main source of electrical power is to be provided which is to include at least two generating sets, one of which may be driven by the main engine. The Society may accept other arrangements having equivalent electrical capability.

**4.3.2** The power of these sets is to be such as to ensure the functioning of the services referred to in [4.1.1] a), excluding the power required in fishing activities, processing and preservation of the catch, in the event of any one of the generating sets being stopped. However, in vessels of less than 45 m, in the event of any one of the generating sets being stopped, it is only necessary to ensure the functioning of the services essential for the propulsion and safety of the vessel.

**4.3.3** The arrangement of the vessel's main source of electrical power is to be such that the services referred to in [4.1.1] a) can be maintained regardless of the number of revolutions and direction of the main propelling engines or shafting.

**4.3.4** Where transformers constitute an essential part of the supply system required by this item, the system is to be so arranged as to ensure continuity of the supply.

**4.3.5** The arrangement of the main electric lighting system is to be such that a fire or other casualty in spaces containing the main source of electrical power, including transformers, if any, will not render the emergency lighting system inoperative.

**4.3.6** The arrangement of the emergency electric lighting system is to be such that a fire or other casualty in spaces containing the emergency source of electrical power, including transformers, if any, will not render the main lighting system inoperative.

**4.3.7** Navigation lights, if solely electrical, are to be supplied through their own separate switchboard and adequate means for the monitoring of such lights are to be provided.

**4.3.8** For fishing vessels propelled by electrical power and having two or more constant voltage propulsion generating sets which constitute the source of electrical energy for the ship's auxiliary services, see Pt C, Ch 2, Sec 14.

**4.3.9** Load shedding or other equivalent arrangements should be provided to protect the generators required in the present Article against sustained overload.

The load shedding should be automatic.

The non-essential services, services for habitability and, if necessary, the secondary essential services may be shed in order to make sure that the connected generator set(s) is/are not overloaded.

**4.3.10** Where paralleling operation of the generators is needed, necessary instruments for this operation are to be provided.

**4.3.11** Where the length is greater than 24 m, the measurement devices are to be in accordance with the general requirements given in Pt C, Ch 2, Sec 8, [1.6.1] to Pt C, Ch 2, Sec 8, [1.6.8].

Where the length is less than 24 m.

- a) The following instruments are to be normally provided:
- for each generator:
    - one ammeter with mark indicating the normal full load value (for installations where the rated voltage is below 24 V and fitted with a load limit, only a charge control lamp can be provided)
    - one voltmeter
    - one lamp indicator to indicate the generator voltage
    - one battery charging control lamp
  - for each battery:
    - one ammeter with two-sided deviation
  - for busbars:
    - one voltmeter
  - for three-phase system, it is to be provided, in addition:
    - one ammeter per phase or one ammeter with commutator permitting to measure the current in each phase
    - one frequency meter
    - one synchronising device if alternators are arranged to run in parallel
    - one wattmeter for alternators over 50 kVA.

b) Protection:

Measuring instruments connected to the network and indicator lamps are to be protected by a fuse. Where a measuring instrument and an indicator lamp correspond to the same indication, each one is to be provided with a fuse.

Requirements given in Pt C, Ch 2, Sec 8, [1.6.13], Pt C, Ch 2, Sec 8, [1.6.14] and Pt C, Ch 2, Sec 8, [1.6.15], are applicable to all fishing vessels.

**4.3.12** The main switchboards are to be placed far away from flammable gas, vapour accumulation, acid gas or other liquid. Their location is to be such that there is no pipe carrying liquids above, beside or near them. When this cannot be avoided, pipes are to be built joint less or provided with protections.

#### **4.4 Emergency source of electrical power**

**4.4.1** A self-contained emergency source of electrical power located, to the satisfaction of the Society, outside machinery spaces is to be provided and so arranged as to ensure its functioning in the event of fire or other causes of failure of the main electrical installations.

**4.4.2** The emergency source of electrical power is to be capable, having regard to starting currents and the transitory nature of certain loads, of serving simultaneously for a period of at least three hours:

- a) the VHF radio installation and, if applicable:
- 1) the MF radio installation
  - 2) the ship earth station and
  - 3) the MF/HF radio installation
- b) internal communication equipment, fire detection systems and signals which may be required in an emergency
- c) the navigation lights if solely electrical and the emergency lights:
- 1) of launching stations and overside of the vessel
  - 2) in all alleyways, stairways and exits
  - 3) in spaces containing machinery or the emergency source of power
  - 4) in control stations, and
  - 5) in fishing handling and fish processing spaces, and
- d) the operation of the emergency fire pump, if any.

**4.4.3** The emergency source of electrical power may be either a generator or an accumulator battery.

**4.4.4** Where the emergency source of electrical power is a generator, it is to be provided both with an independent fuel supply and with efficient starting arrangements to the satisfaction of the Society. Unless a second independent means of starting the emergency generator is provided, the single source of stored energy is to be protected to preclude its complete depletion by the automatic starting system.

**4.4.5** Where the emergency source of electrical power is an accumulator battery, it is to be capable of carrying the emergency load without recharging whilst maintaining the voltage of the battery throughout the discharge period within plus or minus 12% of its nominal voltage. In the event of failure of the main power supply, this accumulator battery is to be automatically connected

to the emergency switchboard and is to immediately supply at least those services specified in [4.4.2], items b) and c). The emergency switchboard is to be provided with an auxiliary switch allowing the battery to be connected manually, in case of failure of the automatic connection system.

**4.4.6** When the length is less than 24 m, the start of the main engine of the ship is carried out by electrical starter and where the emergency source of power is a storage battery, the emergency source of power can be considered as the second required starting power source for the main engine. Then:

- The starting system cables are to be designed to permit the necessary commutation with a change over switch and fixed connections.
- The available power of the emergency battery is to be adequate to supply the emergency services during the time specified in above paragraphs, and, in principle, have the capacity of six consecutive starts of the main engine.

**4.4.7** The emergency switchboard is to be installed as near as is practicable to the emergency source of power and is to be located in accordance with [4.4.1]. Where the emergency source of power is a generator, the emergency switchboard is to be located in the same place unless the operation of the emergency switchboard would thereby be impaired.

**4.4.8** An accumulator battery, other than batteries fitted for the radio transmitter and receiver in vessels of less than 45 m in length, is to be installed in a well ventilated space which is not to be the space containing the emergency switchboard. An indicator is to be mounted in a suitable place on the main switchboard or in the machinery control room to indicate when the battery constituting the emergency source of power is being discharged.

**4.4.9** The emergency switchboard is to be supplied in normal operation from the main switchboard by an interconnector feeder which is to be protected at the main switchboard against overload and short-circuit and which is to be disconnected automatically at the emergency switchboard upon failure of the main source of electrical power.

Where the system is arranged for feedback operation, the interconnector feeder is also to be protected at the emergency switchboard at least against short-circuit.

For ships whose length is equal to or greater than 45 m, the arrangement at the emergency switchboard is to be such that in the event of failure of the main power supply an automatic connection of the emergency supply will be provided.

**4.4.10** The emergency generator and its prime mover and any emergency accumulator battery are to be so arranged as to ensure that they will function at full rated power when the vessel is upright and when rolling up to an angle of 22,5° either way and simultaneously pitching 10° by bow or stern, or in any combination of angles within those limits.

**4.4.11** The emergency source of electrical power and automation starting equipment is to be so constructed and arranged as to enable adequate testing to be carried out by the crew while the vessel is in operating condition.

**4.4.12** When the length is less than 24 m, the Society may exempt Owners from the installation of the emergency source of electrical power.

**4.4.13** Where emergency generator is used in port, the requirements stated in Pt C, Ch 2, Sec 3, [2.4] are applicable.

## **4.5 Precaution against shock, fire and other hazards of electrical origin**

**4.5.1** Exposed permanently fixed metal parts of electrical machines or equipment which are not intended to be live but which are liable under fault conditions to become live are to be earthed (grounded) unless:

- a) they are supplied at a voltage not exceeding 50 V direct current or 50 V, root mean square between conductors; auto-transformers are not to be used for the purpose of achieving this alternative current voltage, or
- b) they are supplied at a voltage not exceeding 250 V by safety isolating transformers supplying one consuming device only, or
- c) they are constructed in accordance with the principle of double insulation.

**4.5.2** Electrical apparatus is to be so constructed and installed that it will not cause injury when handled or touched in the normal manner.

**4.5.3** Main and emergency switchboards are to be so arranged as to afford easy access as may be needed to apparatus and equipment, without danger to attendants. The sides, backs and, where necessary, the fronts of switchboards are to be suitably guarded. Exposed live parts having voltages to earth exceeding a voltage to be specified by the Society are not to be installed on the front of the switchboards. There are to be non-conducting mats or gratings at the front and rear, where necessary.

**4.5.4** When a distribution system, whether primary or secondary, for power, heating or lighting, with no connection to earth is used, a device capable of monitoring the insulation level to earth is to be provided.

**4.5.5** When a distribution system is in accordance with [4.5.4] and a voltage exceeding 50 V direct current or 50 V, root mean square, between conductors, is used, a device capable of continuously monitoring the insulation level to earth and of giving an audible or visual indication of abnormally low insulation values is to be provided.

**4.5.6** Distribution systems which are supplied at a voltage not exceeding 250 V direct current or 250 V, root mean square, between conductors, and which are limited in extent, may comply with [4.5.4], subject to the satisfaction of the Society.

**4.5.7** Except as permitted by the Society in exceptional circumstances, all metal sheaths and armour of cables are to be electrically continuous and to be earthed.

**4.5.8** All electrical cables are to be at least of a flame-retardant type and are to be so installed as not to impair their original flame-retarding properties. The Society may permit the use of special types of cables where necessary for specific applications, such as radio frequency cables, which do not comply with the foregoing.

**4.5.9** Cables and wiring serving essential or emergency power, lighting, internal communications or signals are as far as practicable to be routed clear of galleys, machinery spaces of category A and other high fire risk areas and laundries, fish handling and fish processing spaces and other spaces where there is a high moisture content. Cables connecting fire pumps to the emergency switchboard are to be of a fire-resistant type where they pass through high fire risk areas. Where practicable, all such cables are to be run in such a manner as to preclude their being rendered unserviceable by heating of the bulkheads which may be caused by a fire in an adjacent space.

**4.5.10** Where cables which are installed in spaces where the risk of fire or explosion exists in the event of an electrical fault, special precautions against such risk are to be taken to the satisfaction of the Society. When fitted in places where flammable gases or vapours may accumulate, or in rooms intended to mainly contain accumulators, paint or similar material, the equipment is to be of a safety type approved by the Society.

**4.5.11** Wiring is to be supported in such a manner as to avoid chafing or other damage.

**4.5.12** Terminations and joints in all conductors are to be made such that they retain the original electrical, mechanical, flame-retarding and, where necessary, fire-resisting properties of the cable.

**4.5.13** Cables installed in refrigerated compartments are to be suitable for low temperatures and high humidity.

**4.5.14** Circuits are to be protected against short-circuit. Circuits are also to be protected against overload, unless otherwise specified in these Rules or where the Society may exceptionally otherwise permit.

**4.5.15** The rating or appropriate setting of the overload protective device for each circuit is to be permanently indicated at the location of the protective device.

**4.5.16** Lighting fittings are to be so arranged as to prevent temperature rises which could damage the wiring and to prevent surrounding material from becoming excessively hot.

**4.5.17** Lighting or power circuits terminating in a space where the risk of fire or explosion exists are to be provided with isolating switches outside the space.

**4.5.18** The housing of accumulator batteries is to be constructed and ventilated to the satisfaction of the Society.

**4.5.19** Electrical or other equipment which may constitute a source of ignition of flammable vapours is not permitted in these compartments except as provided for in [4.5.21].

**4.5.20** An accumulator battery is not to be located in accommodation spaces unless installed in a hermetically sealed container.

**4.5.21** In spaces where flammable mixtures are liable to collect and in any compartments assigned principally to the containment of an accumulator battery, no electrical equipment is to be installed unless the Society is satisfied that it is:

- a) essential for operational purposes
- b) of a type which will not ignite the mixture concerned
- c) appropriate for the space concerned, and
- d) appropriately certified for safe usage in the dusts, vapours or gases likely to be encountered.

**4.5.22** Where shore supply is provided, requirements stated in Pt C, Ch 2, Sec 3, [3.7] are applicable. The socket-outlets used for the supply of the ship from the shore network and when the voltage exceeds 50 V, are to be provided with a built-in earth connection provided to be connected to the earth.

**4.5.23** On board of ship with non-metallic hull, bonding is to be provided between the frame of generators, the bed plate of the pumps, the bed plate of the motors and the earth plate, if fitted. All the elements of the fuel installation are to be electrically bonded and connected to the above bonding.

**4.5.24** If the protection of cables against overload current is made by fuses, their rating is to be selected according to the maximum permissible current in the cable.

**4.5.25** Particular attention is to be paid to the fixing of equipment made of cast brass or other copper alloys on aluminium decks or bulkheads.

#### **4.5.26 Heaters**

Electric heaters are to be permanently installed.

They are to be constructed and installed in such a way that clothing or other combustible objects cannot be left there or be hung above these heaters.

#### **4.6 Engineers' alarm**

**4.6.1** In vessels of 75 m in length and over, an engineers' alarm is to be provided to be operated from the engine control room or at the manoeuvring platform as appropriate, and is to be clearly audible in the engineers' accommodation.

#### **4.7 Steering gear**

**4.7.1** For the steering gear, general requirements included in Ch 15, Sec 4, [24] are applicable. Where length of the fishing vessel is less than 24 m, the Society may give exemptions to these requirements.

#### **4.8 Fire detection and fire alarm**

**4.8.1** The fire detection and fire alarm system are to be supplied from the main source and an emergency source.

#### **4.9 Alarm - Communication**

**4.9.1** For the crew muster, an alarm system operated from the bridge is to be provided. This system may be part of the general alarm system.

**4.9.2** Ships of 12 m or more in length are to be equipped with a system enabling the general broadcast of alarm and messages in case of damage or ship escape.

**4.9.3** The bridge operating compartment is to be fitted with the internal communication and control means as quoted hereunder:

- An engine room telegraph with repeater, or equivalent system, is to be provided and duplicated by another independent system, enabling the communication with the engine control position. If the size and arrangement of the ship make useless the equipment mentioned above, only a dual calling system such as telephone, megaphone or bell may be fitted.
- If the propelling machinery is remote-controlled from the bridge-operating compartment, at least one order telegraph, reversible or with repeater, is to be fitted at the local direct engine control position.
- Furthermore, unless the size and arrangement of the ship make useless this equipment, the bridge operating compartment is to be connected by means of a reversible voice communication system to the local control of steering gear, propelling machinery and the service accommodation.

#### **4.10 Final sub-circuits**

**4.10.1** Every final sub-circuit connected to a distribution panel is to be protected, unless otherwise specified, by a fuse or a maximum current circuit breaker on each insulated pole. These circuits can be controlled by single pole switches in dry spaces of the accommodation.

A separate final sub-circuit is to be provided for every apparatus assuming an essential service and for each motor rated 1 kW or more.

#### **4.11 Electric cables**

**4.11.1** General requirements given in Pt C, Ch 2, Sec 3, [9] are applicable for all fishing vessels.

##### **4.11.2 Choice of runs**

- a) Cable runs are to be as straight and accessible as possible.
- b) Cable runs are to be fitted away from source of water. Cables exposed to the risk of mechanical damage, if not armoured or enclosed in steel conduits, are to be protected by a casing.
- c) The cable runs are to be so designed that the internal radius of bend does not exceed at any point the permissible value for the cable concerned. In the absence of values specified by the manufacturer, the following values are to be adopted as minima for the internal radius of bend:
  - 4 d for rubber-like insulated cables without metallic covering (6 d if  $d > 25$  mm)
  - 6 d for rubber-like insulated cables with metallic covering or for silicone asbestos cables.

##### **4.11.3 Cable fixing**

- a) Cables are to be bunched as regularly as possible.
- b) Cables are to be so arranged as to avoid any friction; if needed, fastening parts are to be used. The distance between fastening parts is to be defined according to the cable nature and the special installation provisions. The distance between two fastening parts is generally not to exceed 0,50 m.

## **4.12 Switchboard**

### **4.12.1 Installation**

When the voltage exceeds 50 volts, AC or DC, an insulated mat, grating or impregnated wood surface is to be provided in front of switchboards and also at the rear if access to the rear is provided. The insulated mat, grating or surface is to be oil-resistant and non-slippery.

### **4.12.2 Design - Construction**

Generally, switchboards or enclosures containing switchboards are to be constructed of durable, flame retardant and non-hygroscopic materials. In addition, mechanical features of the materials are to be suitable for the service conditions.

Live parts normally submitted to a voltage exceeding 50 volts are not to be installed without protection on the front of switchboards.

The switchboard frame or enclosures containing switchboards are to be earthed.

Air clearances between live parts are to be suitable for the rated voltage or protected by means of insulating and fireproof shields.

Every switchboard part, including the connections, is to be easily accessible.

## **4.13 Rotating electrical machines**

### **4.13.1 Location - Installation**

Machines and their gears are to be located in spaces suitably ventilated where flammable dusts, vapours or gases cannot accumulate. Where this condition, in the case of motors, cannot be fulfilled, the Society is to be advised accordingly and a special consideration will be given, after examination, of the proposed arrangements.

### **4.13.2 Earthing**

Bed plates and framework of machines or generating sets are to be efficiently earthed; no insulating material is to be placed between the prime movers and the alternators and generally between the prime movers and the driven machines, unless there is one efficient earthing of each part.

### **4.13.3 Generators speed control**

Prime movers for driving generators are to be fitted with a speed regulator in such a way that at all loads between no load and rated power the permanent speed variations cannot exceed 5% of the rated speed. For Diesel generating sets, when the rated power is suddenly thrown off, the transient speed variations are not to exceed 10%.

The generators driven by the propulsion engine, by a geared shaft or by an auxiliary set intended for another purpose, are to be designed with consideration that the variation of speed may occur in service.

### **4.13.4 Particular provisions for the motor control device - Starters**

- a) DC and AC motors of more than 0,5 kW are to be fitted with a under-voltage protection and a protection against overload. Under-voltage protection may not be provided for steering gear motor or any other motor the continuous running of, which is essential.
- b) When the starter, the selector switch or all other equipment used to cut off completely the supply of the motor is at a distance from it, it is recommended that one of the following measures be applied:
  - locking of the disconnecting switch of the circuit in open position, or removable fuses
  - installation near to the motor of a second disconnecting switch.

## **4.14 Batteries**

**4.14.1** As general, Pt C, Ch 2, Sec 11, [6] is applicable.

**4.14.2** Where the length is less than 24 m, the following is also applicable:

- Batteries which can be charged by a power exceeding 2 kW (calculated from the maximum charging current of the charging apparatus and from the nominal voltage of the battery) are to be installed in a ventilated suitable space or in a locker protected from dangerous gas accumulation.

**4.14.3** For all fishing vessels:

- a) All spaces especially reserved for batteries, including lockers or chests, boxes, shelves are to be protected against the deleterious effects of the electrolyte. The batteries are to be so manufactured and installed that no electrolyte discharge may occur under 22°5 inclination.
- b) Deck boxes are to be provided with exhaust ducts on top and air inlets at lower part. The assembly is to be suitably weatherproof. For battery of low capacity, only openings on the top of the battery box are required.

## **5 Lightning protection**

### **5.1 Application**

**5.1.1** A lightning protection system is to be fitted for:

- a) ships with wooden hull or of composite construction with wooden masts
- b) ships with wooden hull or of composite construction with steel masts
- c) ships with steel hull with wooden masts.

**5.1.2** Lightning conductors are to be fitted to all wooden masts or topmasts. In vessels constructed of non-conductive materials, the lightning conductors are to be connected to a copper plate fixed to the vessel's hull well below the waterline.

**5.1.3** Lightning fittings exposed to risks of mechanical damage are to be suitably protected or strongly built.

# Section 6 Fire Protection

## 1 General

### 1.1 Application

**1.1.1** This Section provides requirements for the fire safety of ships having the service notation **fishing vessel** and a length of 65 m or less.

Type approval of materials and products listed in a) to h) of [1.3.1] and Articles [5], [6], [7], [8], [9] and [10] of this Section apply only to ships assigned with the additional service feature **F**.

The fire safety of fishing vessels having a length of more than 65 m is to comply with the provisions of Part C, Chapter 4.

### 1.2 National regulations

**1.2.1** When the Administration of the State whose flag the ship is entitled to fly has issued specific regulations covering fire protection, the Society may accept such regulations for classification purpose in lieu of those given in this Chapter.

In such cases, a memorandum indicating those specific regulations applied is issued.

### 1.3 Type approved products

**1.3.1** The following materials, equipment, systems or products in general used for fire protection are to be type approved by the Society, except for special cases for which the acceptance may be given for individual ships on the basis of suitable documentation and/or tests:

- a) fire-resisting and fire-retarding divisions (bulkheads or decks) and associated doors
- b) automatic closing devices of fire doors
- c) materials for pipes penetrating A or B class divisions (where they are not of steel or other equivalent material)
- d) materials for oil or fuel oil pipes (where they are not of steel or copper and its alloys)
- e) bulkhead or deck penetrations for electrical cables passing through A or B class divisions
- f) materials with low flame spread characteristics including paints, varnishes and similar, when they are required to have such characteristics
- g) non-combustible materials
- h) non-readily igniting materials for primary deck coverings
- i) fixed foam fire-extinguishing systems and portable foam fire-extinguishing units
- j) sensing heads for automatic fire alarm and fire detection systems
- k) portable fire extinguishers
- l) extinguishing media substitute for the foam in fire extinguishers
- m) fire hoses
- n) fire hydrants and nozzles, including dual-purpose nozzles, for fire hoses.

As regards the type approval, the requirements of Part A apply.

### 1.4 Definitions

#### 1.4.1 Foreword

For the purpose of this Section, unless otherwise stated, the definitions given in [1.4.2] to [1.4.13] below apply.

#### 1.4.2 Non-combustible material

Non-combustible material is a material which neither burns nor gives off flammable vapours in sufficient quantity for self-ignition when heated to approximately 750°C. Such property is to be demonstrated by means of a test performed in accordance with a procedure accepted by the Society.

Any other material is to be considered as a combustible material.

#### 1.4.3 Standard fire test - A class divisions - B class divisions

Refer to the definitions given in Pt C, Ch 4, Sec 1, [2.1.1] and Pt C, Ch 4, Sec 1, [2.4.1].

The Society may require a test of a prototype bulkhead of A or B class to ensure that it meets the requirements for integrity or temperature rise.

#### **1.4.4 Steel or other equivalent material**

Where the words “steel or other equivalent material” occur, “equivalent material” means any non-combustible material which, by itself or due to insulation provided, has structural and integrity properties equivalent to steel at the end of the applicable exposure to the standard fire test (e.g. aluminium alloy with appropriate insulation).

#### **1.4.5 Low flame spread**

“Low flame spread” means that the surface thus described offers an adequate resistance to the spread of flame. Such a property is to be demonstrated by a test procedure deemed acceptable by the Society.

#### **1.4.6 Accommodation spaces**

“Accommodation spaces” are those spaces normally used by the crew such as corridors, lavatories, cabins, offices, lounges, dining rooms and other similar spaces.

#### **1.4.7 Service spaces**

“Service spaces” are those spaces used for galleys, pantries containing cooking appliances, lockers, storerooms, workshops other than those forming part of machinery spaces, and similar spaces and trunks to such spaces. They also include the spaces used for the storage of the fishing nets.

#### **1.4.8 Cargo spaces**

“Cargo spaces” are all spaces used for the storage of the fish and the trunks to such spaces.

#### **1.4.9 Machinery spaces of category A**

“Machinery spaces of category A” are those spaces which contain internal combustion type machinery, used for:

- either main propulsion, or
- other purposes where such machinery has in the aggregate a total power output of not less than 750 kW,

or which contain any oil-fired boiler or fuel unit.

#### **1.4.10 Machinery spaces**

“Machinery spaces” are those machinery spaces of category A and all other spaces containing the propulsion machinery, boilers, fuel oil units, steam and internal combustion engines, generators and major electric motors, steering gear, oil filling stations, ventilation and air conditioning machinery, refrigerating machinery, stabilisers and similar spaces or trunks to such spaces.

#### **1.4.11 Control stations**

“Control stations” are those spaces containing the main navigating equipment, the ship’s radio, the emergency source of power, or where the fire recording and fire control equipment is centralised.

#### **1.4.12 Continuous B-class ceilings or linings**

“Continuous B-class ceilings or linings” are those B-class ceilings or linings which terminate only at a “A” or “B” class division.

#### **1.4.13 Materials which do not readily ignite**

“Materials which do not readily ignite” are materials having approved characteristics of ignitability. These characteristics are to be obtained from a test procedure deemed acceptable by the Society.

## **2 Water fire-fighting system**

### **2.1 General**

#### **2.1.1**

- a) Every ship is to be provided with a water fire-fighting system consisting of fire pumps, fire main, hydrants and hoses complying as applicable with the provisions of this Article, depending on the length of the ship.
- b) The water fire-fighting system is to be independent of any other system of the ship. A connection with the washing system is permitted, however.

### **2.2 Number and type of fire pumps**

#### **2.2.1 Ships with $L \geq 45$ m**

All ships having a length of 45 m or more are to be provided with:

- at least two main fire pumps; one is to be independently driven and power operated and the other may be driven by the propulsion engine
- one emergency fire pump complying with [2.3.2], if a fire in any compartment could put all the fire pumps out of action.

Note 1: In the case of ships having a restricted navigation notation, the emergency fire pump may be omitted.

**2.2.2 Ships with 24 m ≤ L < 45 m**

Ships having a length of 24 m and above but less than 45 m are to be provided with:

- at least one main fire pump, independently driven and power-operated
- one emergency fire pump, except when the main fire pump, its source of power and its sea connection are located outside the spaces containing the propulsion machinery or oil fired boilers.

Note 1: In the case of ships having a restricted navigation notation, the emergency fire pump may be omitted.

**2.2.3 Ships with 15 m ≤ L < 24 m**

Ships having a length of 15 m and above but less than 24 m are to be provided with:

- at least one pump for the fire fighting service, power-operated
- one hand pump complying with [2.3.3], except when the power-operated pump is independently driven.

**2.2.4 Ships with L < 15 m**

Ships having a length less than 15 m are to be provided with at least one hand pump complying with [2.3.3].

**2.3 Characteristics and arrangement of fire pumps**

**2.3.1 Main fire pumps**

a) When delivering together for fire-fighting purposes at the pressure specified in [2.4.1], item b), the required fire pumps, other than hand pumps and the emergency fire pump, are to have a total capacity Q, in m<sup>3</sup>/h, not less than that determined from the following formula:

$$Q = (0,15\sqrt{L(B+D)} + 2,25)^2$$

where:

- L : Length of the ship between perpendiculars, in m
- B : Breadth of the ship, in m
- D : Depth of the ship, measured up to the bulkhead deck, in m.

However, the total capacity of the main fire pumps need not exceed 180 m<sup>3</sup>/h.

- b) When several power-operated fire pumps other than the fire emergency pump are required, each pump is to have a capacity not less than 80% of the total required capacity divided by the minimum number of required fire pumps. Each such pump is, in any event, to be capable of delivering at least the two jets of water required in [2.4.1], item b). These fire pumps are to be capable of supplying the fire main system under the required conditions. Where more than the minimum number of required pumps are installed, the capacity of such additional pumps may be less than that required above, provided it is deemed satisfactory by the Society.
- c) Sanitary, ballast, bilge or general service pumps may be accepted as fire pumps, provided they are not normally used for pumping oil and that, if they are subject to occasional duty for the transfer or pumping of fuel oil, suitable change-over arrangements are fitted.

**2.3.2 Emergency fire pumps**

The emergency fire pump and its location are to comply with the following requirements:

- a) The capacity of the pump is not to be less than 40% of the total capacity of the main fire pumps and in any case not less than:
- 25 m<sup>3</sup>/h for ships having a length of 45 m or more
  - 15 m<sup>3</sup>/h for ships having a length less than 45 m.
- b) When the pump is delivering the quantity of water required by clause a) above, the pressure at any hydrant is not to be less than the minimum pressures required in [2.4.1], item b).
- c) Any diesel driven power source for the emergency fire pump is to be capable of being readily started in all the temperature conditions likely to be encountered, taking into account the navigation assigned to the ship.
- d) Any service fuel tank is to contain a sufficient quantity of fuel to enable the emergency fire pump to run on full load for at least 3 h and sufficient reserves of fuel are to be available outside machinery spaces to enable the pump to run on full load for an additional 15 h.
- e) The emergency fire pump is to be of the self-priming type and capable of operating under all conditions of immersion, list, trim, roll and pitch likely to be encountered in service. The sea suction valve is to be capable of being operated from a position close to the pump.
- f) The emergency fire pump and its source of power are to be installed in a safe and readily accessible position located in a separate compartment as far as possible from the compartment containing the main fire pumps and their source of power.

When this is not practicable, the emergency fire pump may be located in a compartment adjacent to the one containing the main fire pumps, provided that the bulkheads and decks forming the boundaries of both compartments are insulated to A-60 standard.

Note 1: For ships having a length less than 45 m and a restricted navigation notation, the emergency fire pump may also be portable and located in a space other than the one containing the main fire pump.

### **2.3.3 Hand pumps**

Hand pumps are to have a capacity of at least two thirds of that required for the bilge pump and a total suction head to project a sufficient jet of water to the satisfaction of the Society.

## **2.4 Fire main, hydrants and hoses**

### **2.4.1 Diameter of, and pressure in, the fire main**

- a) The diameter of the fire main and water service pipes is to be sufficient for the effective distribution of the maximum required discharge from all the main fire pumps operating simultaneously. However, this diameter need only be sufficient for the discharge of 140 m<sup>3</sup>/h.
- b) When main power fire pumps are delivering the quantity of water required in [2.3.1] item a) through the fire main, fire hoses and nozzles, the pressure maintained at any hydrant is not to be less than 0,25 N/mm<sup>2</sup>.

### **2.4.2 Pipes and hydrants**

- a) Materials readily rendered ineffective by heat are not to be used for the fire main and hydrants unless adequately protected. The pipes and hydrants are to be so placed that the fire hoses may be easily coupled to them. The arrangement of pipes and hydrants is to be such as to avoid the possibility of freezing.
- b) A valve is to be fitted to serve each fire hose so that any hose may be removed while the fire pumps are at work.
- c) Isolating valves to separate the section of the fire main within the machinery space containing the main fire pump or pumps from the rest of the fire main are to be fitted in easily accessible and safe positions outside the machinery space. The fire main is to be so arranged that, when the isolating valves are shut, all the hydrants of the ship except those in the machinery space referred to above may be supplied with water by a fire pump not located in this machinery space through pipes which do not enter this space. Exceptionally, the Society may permit short lengths of the emergency fire pump suction and discharge piping to penetrate the machinery space if it is impracticable to route it externally provided that the integrity of the fire main is maintained by the enclosure of the piping in a substantial steel casing.

### **2.4.3 Number and position of hydrants**

- a) Fire hydrants are to be positioned so as to allow easy and quick connection of fire hoses and so that at least one jet can be directed into any part of the ship which is normally accessible during navigation.
- b) The jet required in item a) is to be from a single length of fire hose.
- c) In addition to the requirements of item a), machinery spaces of category A are to be provided with at least one fire hydrant complete with fire hose and dual-purpose nozzle. This fire hydrant is to be located outside the space and near the entrance.
- d) For every required fire hydrant there is to be one fire hose. At least one spare fire hose is to be provided in addition to this requirement.
- e) Single lengths of fire hose are not to exceed 20 m.
- f) Fire hoses are to be of an approved material. Each fire hose is to be provided with couplings and a dual-purpose nozzle.
- g) Except where fire hoses are permanently attached to the fire main, the couplings of fire hoses and nozzles are to be completely interchangeable.
- h) The nozzles as required by item f) are to be appropriate to the delivery capacity of the fire pumps fitted, but in any case are to have a diameter of not less than 12 mm.

## **3 Fire-extinguishing appliances in machinery spaces**

### **3.1 Fixed fire-extinguishing systems**

**3.1.1** Spaces containing oil-fired boilers, fuel oil units or internal combustion machinery having a total power output of not less than 750 kW are to be provided with one of the following fixed fire-extinguishing systems, to the satisfaction of the Society:

- a pressure water-spraying installation
- a fire-smothering gas installation
- a fire-extinguishing installation using vapours from low toxicity vapourizing liquids, or
- a fire-extinguishing installation using high expansion foam.

**3.1.2** Fire-extinguishing systems using halogenated hydrocarbon are prohibited.

**3.1.3** Where the engine and boiler rooms are not entirely separated from each other or if fuel oil can drain from the boiler room into the engine room, the combined engine and boiler rooms are to be considered as one compartment.

**3.1.4** Installations listed in [3.1.1] are to be controlled from readily accessible positions outside the protected spaces not likely to be cut off by a fire in the protected space. Arrangements are to be made to ensure the supply of power and water necessary for the operation of the system in the event of fire in the protected space.

## **3.2 Additional fire-extinguishing arrangements**

**3.2.1** In all machinery spaces of category A at least two portable extinguishers are to be provided, of a type suitable for extinguishing fires involving fuel oil. Where such spaces contain machinery, which has a total power output of not less than 250 kW, at least three such extinguishers are to be provided. One of the extinguishers is to be stowed near the entrance to the space.

**3.2.2** Ships having machinery spaces not protected by a fixed fire-extinguishing system are to be provided with at least a 45 l foam extinguisher or its equivalent, suitable for fighting oil fires. Where the size of the machinery spaces makes this provision impracticable, the Society may accept an additional number of portable fire extinguishers.

## **4 Fire extinguishers**

### **4.1 Design and installation of fire extinguishers**

#### **4.1.1 General**

All fire extinguishers are to be of a type and characteristics approved by the Society.

#### **4.1.2 Equivalences**

- a) The Society reserves the right to establish equivalences between the various types of extinguishers.
- b) Foam extinguishers may be replaced by equivalent extinguishers deemed appropriate by the Society.

#### **4.1.3 Spare charges**

A sufficient number of spare charges is to be provided. In general, spare charges are to be provided for 10% of the portable water or foam extinguishers on the ship, with a minimum of 5 spare charges of each type. However, the number of spare charges need not exceed the number of water or foam extinguishers on board.

#### **4.1.4 Capacity of portable fire extinguishers**

The capacity of required portable fluid extinguishers is not to be more than 13,5 l and not less than 9 l. Other extinguishers are to be at least as portable as the 13,5 l fluid extinguishers and are to have a fire-extinguishing capability at least equivalent to a 9 l fluid extinguisher.

#### **4.1.5 Extinguishing medium**

Fire extinguishers containing an extinguishing medium which, in the opinion of the Society, either by itself or under expected conditions of use gives off toxic gases in such quantities as to endanger persons are not permitted.

#### **4.1.6 Installation**

One of the portable fire extinguishers intended for use in any space is to be stowed near the entrance to that space.

### **4.2 Arrangement of fire extinguishers in accommodation and service spaces**

#### **4.2.1 General**

All ships are to be provided with a sufficient number of portable fire extinguishers such that, in any accommodation or service spaces, a fire extinguisher is readily available in case of need. The type of the extinguisher is to be suitable for the type of fire which is likely to break out in the space concerned.

#### **4.2.2 Number and type of extinguishers in the various spaces**

- a) Accommodation spaces are to be provided with at least:
  - 5 water or foam extinguishers, with a minimum of one such extinguisher for each 'tweendeck, for ships having a length of 45 m or more
  - 3 water or foam extinguishers, with a minimum of one such extinguisher for each 'tweendeck, for ships having a length of 24 m or more but less than 45 m
  - 1 water or foam extinguisher for each 'tweendeck, for ships having a length less than 24 m.
- b) In the vicinity of switchboards or section boards having a power of 20 kW or more, at least one carbon dioxide or powder extinguisher is to be provided.
- c) Spaces containing a galley are to be provided with at least one foam or powder extinguisher.

- d) Stores containing paint or other easily flammable products used on board are to be provided with at least one foam or carbon dioxide or powder extinguisher.
- e) The navigation bridge is to be provided with at least one foam or carbon dioxide extinguisher.
- f) The spaces containing the ship's radio equipment are to be provided with at least two carbon dioxide extinguishers.

Note 1: In small ships where the sole electric switchboard and/or the sole radio station is/are located on the navigation bridge or in the same position as the wheelhouse, only two extinguishers need be provided, one of the water type, the other of the carbon dioxide type or equivalent.

## **5 Structural fire protection**

### **5.1**

**5.1.1** Hull, superstructures, structural bulkheads, decks and deckhouses are to be of steel. However, in special cases, the Society may accept the use of other equivalent materials (such as aluminium alloys) when the fire risk has been taken into account and provided that such material is so insulated that, in the event of fire, the structure cannot collapse.

### **5.2 Ships of 45 m in length and over**

**5.2.1** The decks and bulkheads separating machinery spaces of category A from accommodation spaces, service spaces or control stations are to be constructed to "A-60" Class standard where the machinery space of category A is not provided with a fixed fire-extinguishing system and to "A-30" Class standard where such a system is fitted. Decks and bulkheads separating other machinery spaces from accommodation, service spaces and control stations are to be constructed to "A-0" Class standard. Decks and bulkheads separating control stations from accommodation and service spaces are to be constructed to "A" Class standard, insulated to the satisfaction of the Society, except that the Society may permit the fitting of "B-15" Class divisions for separating such spaces as skipper's cabin from the wheelhouse.

#### **5.2.2**

- a) The bulkheads of corridors serving accommodation spaces, service spaces and control stations are to be of "B-15" Class divisions.
- b) Any bulkhead required by item a) is to extend from deck to deck unless a continuous ceiling of the same Class as the bulkhead is fitted on both sides of the bulkhead, in which case the bulkhead can terminate at the continuous ceiling.

**5.2.3** Interior stairways serving accommodation spaces, service spaces or control stations are to be of steel or other equivalent material. Such stairways are to be within enclosures constructed of "B-15" Class divisions, provided that where a stairway penetrates only one deck, it need be enclosed at one level only.

**5.2.4** Doors and other closures of openings in bulkheads and decks referred to in [5.2.1] and [5.2.2], doors fitted to stairway enclosures referred to in [5.2.3] and doors fitted in engine and boiler casings, are to be as far as practicable equivalent in resisting fire to the divisions in which they are fitted. Doors to machinery spaces of category A are to be self-closing.

**5.2.5** Lift trunks, which pass through the accommodation and service spaces, are to be constructed of steel or equivalent material and are to be provided with means of closing which will permit control of draught and smoke.

#### **5.2.6**

- a) The boundary bulkheads and decks of spaces containing any emergency source of power and bulkheads and decks between galleys, paint rooms, lamp rooms or any store-rooms which contain appreciable quantities of highly flammable materials, and accommodation spaces, service spaces or control stations are to be of "A" Class divisions insulated to the satisfaction of the Society, having in mind the risk of fire, except that the Society may accept "B-15" Class divisions between galley and accommodation spaces, service spaces and control stations when the galley contains electrically heated furnaces, electrically heated hot water appliances or other electrically heated appliances only.
- b) Highly flammable products are to be carried in suitably sealed containers.

**5.2.7** Where bulkheads or decks, required by [5.2.1], [5.2.2], [5.2.4] or [5.2.6] to be of "A" Class or "B" Class divisions, are penetrated for the passage of electrical cables, pipes, trunks, ducts, etc., arrangements are to be made to ensure that the fire integrity of the division is not impaired.

**5.2.8** Air spaces enclosed behind ceilings, panellings or linings in accommodation spaces, service spaces and control stations are to be divided by close-fitting draught stops spaced not more than 7 m apart.

**5.2.9** Windows and skylights to machinery spaces are to be as follows:

- a) Where skylights can be opened they are to be capable of being closed from outside the space. Skylights containing glass panels are to be fitted with external shutters of steel or other equivalent material permanently attached.
- b) Glass or similar materials are not to be fitted in machinery space boundaries. This does not preclude the use of wire-reinforced glass for skylights and glass in control rooms within the machinery spaces; and
- c) In skylights referred to in item a) wire-reinforced glass is to be used.

**5.2.10** Insulating materials in accommodation spaces, service spaces except domestic refrigerating compartments, control stations and machinery space are to be non-combustible. The surface of insulation fitted on the internal boundaries of machinery spaces of category A is to be impervious to oil or oil vapours.

**5.2.11** Within compartments used for stowage of fish, combustible insulation is to be protected by close-fitting cladding.

**5.2.12** Notwithstanding the requirements of this sub-article, the Society may accept "A-0" class divisions in lieu of "B-15" class divisions, having regard to the amount of combustible materials used in adjacent spaces.

### **5.3 Ships of 24 m in length and over but less than 45 m**

**5.3.1** The decks and bulkheads separating machinery spaces of category A from accommodation spaces, service spaces or control stations are to be constructed to "A-60" Class standard where the machinery space of category A is not provided with a fixed fire-extinguishing system and to "A-0" Class standard where such a system is fitted. Decks and bulkheads separating other machinery spaces from accommodation, service spaces and control stations are to be constructed to "A-0" Class standard. Decks and bulkheads separating control stations from accommodation and service spaces are to be constructed to "B" Class standard, insulated to the satisfaction of the Society.

#### **5.3.2**

- a) The bulkheads of corridors serving accommodation spaces, service spaces or control stations are to be of "B-0" Class divisions.
- b) Any bulkhead of corridors serving accommodation spaces, services and central stations is to extend from deck to deck unless a continuous ceiling of the same Class as the bulkhead is fitted on both sides of the bulkhead, in which case the bulkhead can terminate at the continuous ceiling.

**5.3.3** Interior stairways serving accommodation spaces, service spaces or control stations are to be of steel or other equivalent material. Such stairways connecting more than two decks are to be within enclosures constructed of "B-15" Class divisions.

**5.3.4** Doors and other closures of openings in bulkheads and decks referred to in [5.3.1] and [5.3.2], doors fitted to stairway enclosures referred to in [5.3.3] and doors fitted in engine and boiler casings, are to be as far as practicable equivalent in resisting fire to the divisions in which they are fitted. Doors to machinery spaces of category A are to be self-closing.

**5.3.5** Lift trunks, which pass through the accommodation and service spaces, are to be constructed of steel or equivalent material and are to be provided with means of closing which will permit control of draught and smoke.

#### **5.3.6**

- a) The boundary bulkheads and decks of spaces containing any emergency source of power and bulkheads and decks between galleys, paint rooms, lamp rooms or any store-rooms which contain appreciable quantities of highly flammable materials, and accommodation spaces, service spaces or control stations are to be of "A" Class divisions insulated to the satisfaction of the Society, having in mind the risk of fire, except that the Society may accept "B-15" Class divisions between galley and accommodation spaces, service spaces and control stations when the galley contains electrically heated furnaces, electrically heated hot water appliances or other electrically heated appliances only.
- b) Highly flammable products are to be carried in suitably sealed containers.

**5.3.7** Where bulkheads or decks, required by [5.3.1], [5.3.2], [5.3.4] or [5.3.6] to be of "A" Class or "B" Class divisions, are penetrated for the passage of electrical cables, pipes, trunks, ducts, etc., arrangements are to be made to ensure that the fire integrity of the division is not impaired.

**5.3.8** Air spaces enclosed behind ceilings, panellings or linings in accommodation spaces, service spaces and control stations are to be divided by close-fitting draught stops spaced not more than 7 m apart.

**5.3.9** Windows and skylights to machinery spaces are to be as follows:

- a) Where skylights can be opened they are to be capable of being closed from outside the space. Skylights containing glass panels are to be fitted with external shutters of steel or other equivalent material permanently attached.
- b) Glass or similar materials are not to be fitted in machinery space boundaries. This does not preclude the use of wire-reinforced glass for skylights and glass in control rooms within the machinery spaces; and
- c) In skylights referred to in item a) wire-reinforced glass is to be used.

**5.3.10** Insulating materials in accommodation spaces, service spaces except domestic refrigerating compartments, control stations and machinery space are to be non-combustible. The surface of insulation fitted on the internal boundaries of machinery spaces of category A is to be impervious to oil or oil vapours.

**5.3.11** Within compartments used for stowage of fish, combustible insulation is to be protected by close-fitting cladding.

**5.3.12** Notwithstanding the requirements of this sub-article, the Society may accept "A-0" class divisions in lieu of "B-15" class divisions, having regard to the amount of combustible materials used in adjacent spaces.

## **5.4 Ships of less than 24 m in length**

**5.4.1** If steel decks or steel bulkheads in accommodation form the top or side of a fuel oil tank, they are to be coated with a non-combustible material of thickness and density to the satisfaction of the Society. Manholes or other openings to fuel oil tanks are not to be positioned in the accommodation.

**5.4.2** External bulkheads and ship's sides, which delimit the accommodation spaces, are to be insulated with an appropriate insulating material. Bulkheads between accommodation spaces and machinery spaces or cargo spaces are to be insulated with a non-combustible material of thickness and density to the satisfaction of the Society. The surface of insulation fitted on the internal boundaries of the machinery spaces of category A and in spaces into which oil products may penetrate is to be impervious to oil or oil vapours.

**5.4.3** All insulation in accommodation spaces and the wheelhouse is to be made of non-combustible materials. Combustible insulation fitted in spaces used for the storage or processing of fish is to be protected by a tight non-combustible covering.

**5.4.4** Where there is a door between the accommodation space and the machinery space, this door is to be a self-closing door of steel or equivalent. Doors between galley rooms and dining rooms might be permitted, provided they are made of fire-retardant material; the same applies to a serving hatch. Where only electric cooking appliances are used in the galley, the galley and the mess room could be seen as one common room, divided into two appropriate compartments.

## **6 Ventilation systems**

### **6.1**

**6.1.1** Means are to be provided to stop fans and close main openings to ventilation systems from outside the spaces served.

**6.1.2** Means are to be provided for closing, from a safe position, the annular spaces around funnels.

**6.1.3** Ventilation openings may be permitted in and under the doors in corridor bulkheads except that such openings are not permitted in and under stairway enclosure doors. The openings are to be provided only in the lower half of a door. Where such opening is in or under a door, the total net area of any such opening or openings is not to exceed 0,05 m<sup>2</sup>. When such opening is cut in a door, it is to be fitted with a grill made of non-combustible material.

**6.1.4** Ventilation ducts for machinery spaces of category A or galleys are not in general to pass through accommodation spaces, service spaces or control stations. Where the Society permits this arrangement, the ducts are to be constructed of steel or equivalent material and arranged to preserve the integrity of the divisions.

**6.1.5** Ventilation ducts of accommodation spaces, service spaces or control stations are not in general to pass through machinery spaces of category A or through galleys. Where the Society permits this arrangement, the ducts are to be constructed of steel or equivalent material and arranged to preserve the integrity of the divisions.

**6.1.6** Storerooms containing appreciable quantities of highly flammable products are to be provided with ventilation arrangements, which are separate from other ventilation systems. Ventilation is to be arranged at high and low levels and the inlets and outlets of ventilators are to be positioned in safe areas. Suitable wire mesh guards to arrest sparks are to be fitted over inlet and outlet ventilation openings.

**6.1.7** Ventilation systems serving machinery spaces are to be independent of systems serving other spaces.

**6.1.8** Where ducts serve spaces on both sides of "A" Class bulkheads or decks, dampers are to be fitted so as to prevent the spread of smoke between compartments. Manual dampers are to be operable from both sides of the bulkhead or the deck. Where the ducts with a free cross-sectional area exceeding 0,02 m<sup>2</sup> pass through "A" Class bulkheads or decks, automatic self-closing dampers are to be fitted.

**6.1.9** Where the ventilation ducts with a free cross-sectional area exceeding 0,02 m<sup>2</sup> pass through "A" Class bulkheads or decks, the opening is to be lined with a steel sheet sleeve, unless the ducts passing through the bulkheads or decks are of steel in the vicinity of passage through the deck or bulkhead and comply, in that portion of the duct, with the following:

- a) For ducts with a free cross-sectional area exceeding 0,02 m<sup>2</sup>, the sleeves are to have a thickness of at least 3 mm and a length of at least 900 mm. When passing through bulkheads, this length is preferably to be divided evenly on each side of the bulkhead. Ducts with free cross-sectional area exceeding 0,02 m<sup>2</sup> are to be provided with fire insulation. The insulation is to

have at least the same fire integrity as the bulkhead or deck through which the duct passes. Equivalent penetration protection is to be provided to the satisfaction of the Society; and

- b) Ducts with a free cross-sectional area exceeding 0,075 m<sup>2</sup> are to be fitted with fire dampers in addition to the recommendations of item a). The fire damper is to operate automatically but is also to be capable of being closed manually from both sides of the bulkhead or deck. The damper is to be provided with an indicator which shows whether the damper is open or closed. Fire dampers are not required, however, where ducts pass through spaces surrounded by "A" Class divisions without serving those spaces, provided those ducts have the same fire integrity as the bulkheads which they penetrate.

**6.1.10** Where they pass through accommodation spaces or spaces containing combustible materials, the exhaust ducts from galley ranges are to be constructed of "A" Class divisions. Each exhaust duct is to be fitted with:

- a grease trap readily removable for cleaning
- a fire damper located at the lower end of the duct
- arrangements, operable from within the galley, for shutting off the exhaust fans
- fixed means for extinguishing a fire within the duct.

The outlet ducts are to be easily accessible for cleaning.

## **7 Prevention of fire**

### **7.1**

**7.1.1** The insulation of accommodation spaces, service spaces, control stations and machinery spaces is to consist of non-combustible material.

The insulation of refrigerated spaces and fish holds may consist of self-extinguishing materials, at the satisfaction of the Society.

**7.1.2** Impervious linings and adhesives used for the insulation of refrigeration plants, as well as for the insulation of the related piping, may be of combustible materials, but their quantity is to be as limited as possible and their exposed surfaces are to have a resistance to the flame spread deemed satisfactory by the Society.

**7.1.3** In spaces where penetration of oil products is possible, the surface of insulation is to be impervious to oil or oil vapours.

**7.1.4** All exposed surfaces in accommodation spaces, service spaces, control stations, corridors, stairways trunks and associated hidden and inaccessible spaces behind bulkheads, ceilings, panels and linings are to have low flame spread characteristics.

**7.1.5** Paints, varnishes and other finishes used on exposed interior surfaces are not to be capable of producing excessive quantities of smoke or toxic gases or vapours. The Society is to be satisfied that they are not of a nature to offer undue fire hazard.

**7.1.6** Primary deck coverings within accommodation and service spaces and control stations are to be of approved material which will not readily ignite or give rise to toxic or explosive hazards at elevated temperatures.

#### **7.1.7**

- a) In accommodation and service spaces and control stations, pipes penetrating "A" or "B" Class divisions are to be of approved materials having regard to the temperature that such divisions are required to withstand. Where the Society permits the conveying of oil and combustible liquids through accommodation and service spaces, the pipes conveying oil or combustible liquids are to be of an approved material having regard to the fire risk.
- b) Materials readily rendered ineffective by heat are not to be used for overboard scuppers, sanitary discharges, and other outlets which are close to the waterline and where the failure of the material in the event of fire would give rise to danger of flooding.

**7.1.8** All waste receptacles other than those used in fish processing are to be constructed of non-combustible materials with no openings in the sides and bottom.

**7.1.9** Machinery driving fuel oil transfer pumps, oil fuel unit pumps and other similar fuel pumps are to be fitted with remote controls situated outside the space concerned so that they can be stopped in the event of a fire arising in the space in which they are located.

**7.1.10** Drip trays are to be fitted where necessary to prevent oil leaking into bilges.

**7.1.11** Electric heating appliances are to be so designed and installed as to reduce fire risks to a minimum. The decks and bulkheads on which they are installed are to be adequately protected with non-combustible material.

Heating appliances having exposed electrical parts or naked flame and stoves burning solid fuels are not permitted.

## 8 Means of escape

### 8.1

**8.1.1** Stairways and ladders leading to and from all accommodation spaces and in spaces, in which the crew is normally employed, other than machinery spaces, are to be so arranged as to provide ready means of escape to the open deck and thence to the survival craft. In particular in relation to these spaces:

- a) at all levels of accommodation, at least two widely separated means of escape are to be provided which may include the normal means of access from each restricted space or group of spaces
- b)
  - below the weather deck, the means of escape is to be a stairway and the second escape may be a trunk or a stairway; and
  - above the weather deck, the means of escape are to be stairways or doors to an open deck or a combination thereof. Where it is not practicable to fit stairways or doors, one of these means of escape may be by means of adequately sized portholes or hatches protected where necessary against ice accretion
- c) exceptionally the Society may permit only one means of escape, due regard being paid to the nature and location of spaces and to the number of persons who normally might be accommodated or employed there
- d) a corridor or part of a corridor from which there is only one route of escape is preferably not to exceed 2,5 m in length and in no case to be greater than 5,0 m in length, and
- e) the width and continuity of the means of escape are to be to the satisfaction of the Society.

**8.1.2** Two means of escape are to be provided from every machinery space of category A, which are to be as widely separated as possible. Vertical escapes are to be by means of steel ladders. Where the size of the machinery spaces makes it impracticable, one of these means of escape may be omitted. In such cases special consideration is to be given to the remaining exit.

**8.1.3** Lifts are not to be considered as forming one of the required means of escape.

## 9 Fire detection

### 9.1

**9.1.1** Where appreciable amounts of combustible materials are used on the construction of accommodation spaces, service spaces and control stations, special consideration is to be given to the installation of an automatic fire alarm and fire detection system in those spaces, having due regard to the size of those spaces, their arrangement and location relative to control stations as well as, where applicable, the flame-spread characteristics of the installed furniture.

## 10 Storage of gas cylinders and dangerous materials

### 10.1

**10.1.1** Cylinders for compressed, liquefied or dissolved gases are to be clearly marked by means of prescribed identifying colours, are to have a clearly legible identification of the name and chemical formula of their contents and are to be properly secured.

**10.1.2** Cylinders containing flammable or other dangerous gases and expended cylinders are to be stored, properly secured, on open decks and all valves, pressure regulators and pipes leading from such cylinders are to be protected against damage. Cylinders are to be protected against excessive variations in temperature, direct rays of the sun, and accumulation of snow. However, the Society may permit such cylinders to be stored in compartments complying with the requirements of [10.1.3] to [10.1.5].

**10.1.3** Spaces containing highly flammable liquids, such as volatile paints, paraffin, benzole, etc., and, where permitted, liquefied gas are to have direct access from open decks only. Pressure-adjusting devices and relief valves are to exhaust within the compartment. Where boundary bulkheads of such compartments adjoin other enclosed spaces, they are to be gastight.

**10.1.4** Except as necessary for service within the space, electrical wiring and fittings are not permitted within compartments used for the storage of highly flammable liquids or liquefied gases. Where such electrical fittings are installed, they are to be to the satisfaction of the Society for use in a flammable atmosphere. Sources of heat are to be kept clear of such spaces and "No Smoking" and "No Naked Light" notices are to be displayed in a prominent position.

**10.1.5** Separate storage is to be provided for each type of compressed gas. Compartments used for the storage of such gases are not to be used for storage of other combustible products nor for tools or objects not part of the gas distribution system. However, the Society may relax these requirements considering the characteristics, volume and intended use of such compressed gases.

# Part D

## Service Notations

---

### CHAPTER 16

## OFFSHORE PATROL VESSELS

---

Section 1	General
Section 2	Stability
Section 3	Machinery
Section 4	Electricity and Automation
Section 5	Fire safety

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **OPV**, as defined in Pt A, Ch 1, Sec 2, [4.7.1].

**1.1.2** Requirements apply as a function of number of persons on board as defined in [1.2] and in any case the number of passengers as defined in [1.2.3] is limited to 12.

**1.1.3** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**1.1.4** References given in Tab 1 are specified for the use of technical criteria and do not mean the full adoption of referenced documents.

**1.1.5** Attention is to be drawn on the possible additional requirements of the flag administration, if any.

### 1.2 Number of persons on board

**1.2.1** The number of persons on board, N, is defined as the sum of:

- number of members of the crew
- number of special personnel, as defined in [1.2.2]
- number of passengers, as defined in [1.2.3], limited to 12.

**(1)** Applicable requirements with respect to discharges and scuppers. see Pt C, Ch 1, Sec 10, [8].

**(2)** Application of these requirements are to be applied except that specific rules for passenger ships are not to be taken into account.

**(3)** In addition, requirements of NR396, Chapter 3 apply if  $V \geq 7,16\Delta^{1/6}$  where V is the ship speed, in knots, and  $\Delta$  is the displacement of the ship, in tons.

**(4)** The number of persons N is defined in [1.2].

**Note 1:**

NR396: Rules for the Classification of High Speed Craft.

NR566: Hull Arrangement, Stability and Systems for Ships less than 500 GT.

NR600: Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m.

**1.2.2** Special personnel means all persons who are not passengers or members of the crew or children of under one year of age and who are carried on board in connection with the special purpose of that ship because of special work being carried out aboard that ship.

**1.2.3** Passengers means every persons other than:

- The captain and the members of the crew or other persons employed or engaged in any capacity on board a ship on business of that ship and
- A child under one year of age.

**Table 2 : Applicable requirements for fire safety**

(1) Offshore patrol vessels with more than 200 persons will be subject to special consideration by the Society.  
(2) The present Chapter does not include this case (NA = not applicable).

# Section 2 Stability

## 1 General

### 1.1 Application

**1.1.1** Offshore patrol vessels may be assigned the service notation **OPV** only after it has been demonstrated that their stability is adequate.

Adequate stability means compliance with standards laid down by the relevant Administration or with the requirements specified in this Section.

In any case, the level of stability is not to be less than that provided by the Rules.

#### 1.1.2 Intact stability

Ships granted with service notation **OPV** are to comply with:

- the provision of NR566, Ch 1, Sec 3, [2] regarding intact stability
- additional requirements of this Section, as applicable.

#### 1.1.3 Damage stability

Damage stability should comply with provisions of NR566, Ch 1, Sec 3, [3] and additional requirements of this Section, as applicable, when at least one of the following conditions is met:

- the additional class notation **SDS** is granted
- the offshore patrol vessel is carrying more than 60 persons on board.

When damage stability is required, the additional class notation **SDS** is to be granted to the offshore patrol vessel.

In case a double bottom is not in accordance with the applicable rules then it is to be demonstrated that the ship is capable of withstanding bottom damages as per [3.2].

## 2 Intact Stability

### 2.1 Maximum turning angle

**2.1.1** The angle of heel on account of turning may not exceed 10° when calculated using the following formula:

$$M_R = 0,02 V_0^2 \Delta \frac{(KG - T_1/2)}{L_{WL}}$$

where:

- $M_R$  : heeling moment, in t.m
- $V_0$  : Maximum service speed, in m/s
- $T_1$  : Mean draught above the keel, in m
- $KG$  : Height of centre of gravity above keel, in m
- $L_{WL}$  : Length measured at waterline corresponding to mean draught  $T_1$ .

### 2.2 Crowding angle for offshore patrol vessels carrying more than 60 persons

**2.2.1** The angle of heel on account of crowding of persons to one side as defined below may not exceed 10°:

- A minimum weight of 75 kg is to be assumed for each person except that this value may be increased subject to the approval of the Society
- The height of the centre of gravity for person is to be assumed equal to 1m above deck level for person standing upright
- Persons are to be considered as distributed to produce the most unfavourable combination of person heeling moment and/or initial metacentric height, which may be obtained in practice. In this connection, a value higher than four persons per square meter is not necessary.

## 3 Damage stability

### 3.1 Offshore patrol vessels carrying more than 60 persons

**3.1.1** Application of requirements in NR566, Ch1, Sec3, [3] where the ship is considered as a passenger ship. However the requirement regarding the margin line is not to be considered.

### **3.2 Bottom damages**

**3.2.1** Bottom damage stability should comply with provision of NR566, Ch 1, Sec 3, [3] assuming bottom damages at any position along the ship's bottom and with an extent specified in Tab 1.

## **4 Damage control documentation for ships greater than or equal to 500 GT**

### **4.1**

**4.1.1** The damage control documentation is to be submitted.

**Table 1 : Assumed extent of damage**

	For 0,3 L from the forward perpendicular of the ship	Any other part of the ship
Longitudinal extent	$1/3 L^{2/3}$ or 14,5 m, whichever is less	$1/3 L^{2/3}$ or 14,5 m, whichever is less
Transverse extent	B/6 or 10 m, whichever is less	B/6 or 5 m, whichever is less
Vertical extent, measured from the keel line	B/20 or 2 m, whichever is less	B/20 or 2 m, whichever is less

# Section 3 Machinery

## 1 General

### 1.1 Application

1.1.1 This Section concerns specific requirements regarding:

- Capacity of service tanks for offshore patrol vessels with  $GT \geq 500$
- Bilge pumping arrangement and prevention for progressive flooding for ship where damage stability is required in accordance with Ch 16, Sec 2, [1.1.3].

### 1.2 Capacity of service tanks for offshore patrol vessels with $GT \geq 500$

1.2.1 Notwithstanding Pt C, Ch 1, Sec 10, [11.9.2], items b), c) and d), the capacity of service tanks should comply with NR566, Ch 2, Sec 6, [4.2.2], Note 2 excluded.

### 1.3 Progressive flooding

#### 1.3.1 Application

Requirements [1.3.2] and [1.3.3] apply for offshore vessels for which damage stability is required.

#### 1.3.2 Offshore patrol vessels with $GT \geq 500$

Pt C, Ch 1, Sec 10, [5.5] is to be replaced by NR566, Ch 2, Sec 4, [5.9].

#### 1.3.3 Offshore patrol vessels with $GT < 500$

Requirements as stated in NR566, Ch 2, Sec 4, [5.9] should apply.

### 1.4 Bilge pumping after flooding

#### 1.4.1 Application

Requirements [1.4.2] and [1.4.3] apply for offshore vessels carrying more than 60 persons, for which damage stability is required.

#### 1.4.2 Offshore patrol vessels with $GT \geq 500$

In addition to the requirements as stated in Pt C, Ch 1, Sec 10, [6], provision of NR566, Ch 2, Sec 5, [1.6] should apply.

#### 1.4.3 Offshore patrol vessels with $GT < 500$

Requirements as stated in NR566, Ch 2, Sec 5, [1.6] should apply.

## Section 4 Electricity and Automation

### 1 General

#### 1.1 Application

1.1.1 The requirements in this Section apply to offshore patrol vessels carrying more than 60 persons.

#### 1.2 General alarm for ships with $GT < 500$

1.2.1 In addition to the requirements required in NR566, Ch 3, Sec 2, [3.11.1], the following requirements in NR566, Ch 3, Sec 2, [3.11.2], item b), should apply.

#### 1.3 Emergency source of electrical power for ships with $GT \geq 500$

1.3.1 Notwithstanding Pt C, Ch 2, Sec 3, [2.3.13], items b) and c), where the emergency source of electrical power is a generator, it shall be started automatically upon failure of the electrical power supply to the emergency switchboard and shall be automatically connected to the services referred in Pt C, Ch 2, Sec 3, [3.6.7]. The automatic starting system and the characteristics of the prime mover shall be such as to permit the emergency generator to carry its full rated load as quickly as is safe and practicable, subject to a maximum of 45 s.

In addition, a transitional source of emergency electrical power as specified in Pt C, Ch 2, Sec 3, [2.3.16] is to be provided in all cases when the emergency source of power is a generator.

#### 1.4 Public address system for ships with $GT \geq 500$

1.4.1 Where the public address system is used to supplement the general emergency alarm system as per Pt C, Ch 2, Sec 3, [3.14.2], it is to be arranged to operate on the main source of electrical power, the emergency source of electrical power and the transitional source of electrical power as required in [1.3] and Pt C, Ch 2, Sec 3, [3.6].

## Section 5 Fire safety

### 1 General

#### 1.1 Application

1.1.1 The applicable requirements are defined in Ch 16, Sec 1, Tab 2.

Part C, Chapter 4 and Rule Note NR566 are to be applied except that specific rules for passenger ships are not to be taken into account.

1.1.2 Fire safety of offshore patrol vessels carrying more than 200 persons will be subject to special consideration by the Society.

### 2 Materials

#### 2.1 Steel or equivalent

2.1.1 In case the application of Part C, Chapter 4 is required, all indications “steel” (without the extension “or equivalent”) in these rules, can be replaced by “steel or equivalent”.

2.1.2 In case the application of Part C, Chapter 4 is required, aluminium bulkheads are generally to be insulated on both sides. However, if one of the two spaces have little or no fire risk such as voids, sanitary spaces, carbon dioxide rooms and similar spaces, insulation need only to be applied on the side that is exposed to the greatest fire risk.

### 3 Specific requirements

#### 3.1 Offshore patrol vessels carrying more than 60 persons

3.1.1 For offshore patrol vessels carrying more than 60 persons and when the application of NR566 is authorised, the following additional rules apply:

- exposed surfaces of bulkheads, walls, linings and ceilings in accommodation and service spaces and control stations are to be low flame spread
- remote starting of one fire pump is to be provided from wheel house.

#### 3.2 Ammunition storage compartments

3.2.1 The protection of ammunition storage compartments will be subject to special consideration by the Society. Applicable rules will be based on a common agreement with the shipowner and the shipyard, including aspects of fire detection, structural fire integrity, ventilation, fire fighting and electrical equipment protection.

### TUGS

---

Section 1	General
Section 2	Stability
Section 3	Hull Structure
Section 4	Integrated Tug / Barge Combination
Section 5	Testing
Appendix 1	Bollard Pull Trials

# Section 1 General

## 1 General

### 1.1 Application

1.1.1 Ships complying with the requirements of this Chapter are eligible for the assignment of one of the following service notations:

- tug
- salvage tug
- escort tug

as defined in Pt A, Ch 1, Sec 2, [4.10].

These service notations are always completed by the additional service feature **standardized design bollard pull** =  $[T_{BP} / 9,81]$  t, where the design Bollard Pull  $T_{BP}$  is defined in [2.1].

The service notation **escort tug** is always completed by the following additional service features:

- **design maximum braking force** =  $[T_{X,MAX} / 9,81]$  t
- **design maximum escort speed** =  $[V_{MAX}]$  kn
- **design maximum steering force** =  $[T_{Y,MAX} / 9,81]$  t

where the design maximum values are defined in [2.7].

Ships which are likely to operate at sea within specific limits may, under certain conditions, be granted an operating area notation. For the definition of operating area notation, reference is made to Pt A, Ch 1, Sec 2, [5.3].

1.1.2 Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1 and specific requirements for testing as detailed in Ch 1, Sec 5
- Ch 1, Sec 4 for tugs assigned with the additional service feature **barge combined**.

## 2 Definitions

### 2.1 Design bollard pull

**2.1.1** The design bollard pull  $T_{BP}$ , in kN, is the maximum sustained towline force the tug is capable of generating at zero forward speed, to be initially specified by the Designer and to be verified by a full scale test, generally referred to as bollard pull test (see Ch 1, Sec 5, [2.1.1]).

**2.1.2** Where the value of the design bollard pull is not provided, the following default values may be used for preliminary design review:

- $T_{BP} = 0,204 N P_S$   
for conventional tugs with propellers fitted with nozzles, as described in Ch 1, Sec 3, [2.1.2]
- $T_{BP} = 0,176 N P_S$   
for tractor tugs and ASD tugs with steerable propellers fitted with nozzles, as described in Ch 1, Sec 3, [2.1.3] and Ch 1, Sec 3, [2.1.4] respectively.

where:

- N : Number of propellers  
 $P_S$  : Maximum continuous power per propeller shaft, in kW.

### 2.2 Reference towline force

**2.2.1** The reference (quasi-static) towline force  $T$ , in kN, is considered to represent:

- the design bollard pull  $T_{BP}$  for service notations **tug** and **salvage tug**, see [2.1]
- the design maximum steady towline force  $T_{ESC,MAX}$  for service notation **escort tug**, see [2.7].

### 2.3 Design load

**2.3.1** The design load  $DL$ , in kN, is the force taken into consideration for the strength assessment and testing of the towing equipment and the associated supporting structures, and is to be taken as not less than:

$$DL = DAF T_{BP}$$

where:

DAF : Dynamic amplification factor taking into consideration dynamic effects.

Reference values for the DAF are given in:

- for service notations **tug** and **salvage tug**:  
Ch 1, Sec 3, [2.7.2]
- for service notation **escort tug**:  
Ch 1, Sec 3, [3.2.2].

### 2.4 Winch brake holding load

**2.4.1** The winch brake holding load  $BHL$ , in kN, is the maximum towline force the towing winch can withstand without slipping of the (activated) brake, considering the towline at the first inner layer.

**2.4.2** The  $BHL$  is a reference for the strength assessment and testing of towing winches and associated towing fittings (e.g. fairlead, staple, gob-eye) as well as their supporting structures.

### 2.5 Towline breaking strength

**2.5.1** The towline breaking strength, in kN, is the tension required to cause failure of the towline (parting of the towline).

### 2.6 Escort tugs indirect towing modes

#### 2.6.1 General

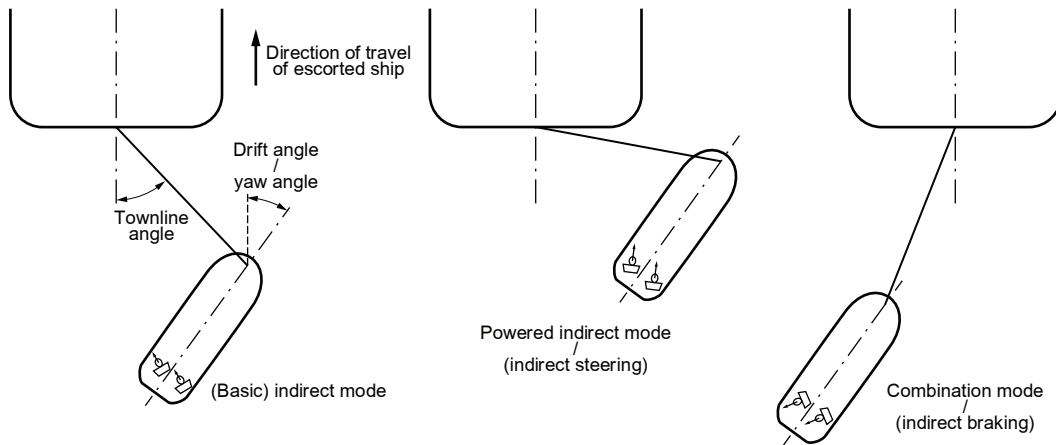

Escorting is considered to include active (emergency) steering, braking and otherwise controlling of the escorted ship by the tug operating in indirect towing mode, whereby the ahead speed of the escorted ship is within a typical speed range of 6 to 10 knots.

Escort tugs may work in different indirect towing modes, depending on the required action towards the escorted ship (e.g. steering, braking). The main indirect towing modes relevant for escort tugs are schematically shown in Fig 1.

Where reference is made to “indirect steering” the objective is to maximise the steering force in indirect towing mode.

Where reference is made to “indirect braking” the objective is to maximise the braking force in indirect towing mode.

Figure 1 : Schematic overview of indirect towing modes (escort tug)

### 2.6.2 Indirect towing principle

In indirect towing mode, the towline force is resulting from the (quasi-static) equilibrium condition reached between the forces and moments arising from the hydrodynamic lift and drag forces acting on the hull and appendices of the tug advancing through the water at a drift angle relative to the water flow, the thrust vector and the towline force.

Note 1: In direct towing mode the thrust is directly applied to generate the towline force, whereby hydrodynamic lift and drag forces play no significant role.

### 2.6.3 Various indirect towing modes

- In (basic) indirect mode the towline force is generated primarily by the hydrodynamic forces acting on the hull and skeg, with the thrust used solely to maintain the desired drift angle (also referred to as yaw angle)
- In powered indirect mode (indirect steering) the transverse component of thrust is used to maintain the desired drift angle, while a significant longitudinal component of thrust is applied in forward direction of the tug.

Compared to the (basic) indirect mode, the tug is operating more sideways of the escorted ship with a relatively large towline angle, generating a higher steering force

- In combination mode (indirect braking) the same principle as for the indirect steering mode is applied, except that the longitudinal component of thrust is applied in aftward rather than forward direction.

Compared to the (basic) indirect mode, the tug is operating more behind the escorted ship with a relatively small towline angle, generating a higher braking force.

### 2.6.4 Specific considerations

- For indirect towing modes it is recommended to design the tug to generate high (indirect) towline forces with minimal propulsion thrust, while respecting the limits imposed by stability and strength considerations (towing equipment, general hull structure).
- The propulsion engines are to ensure sufficient thrust for manoeuvring the tug quickly for any drift angle (refer to angle  $\beta$  as defined in [2.7.2]).
- In the case of loss of propulsion, the heeling moment due to the remaining forces is to lead to a safe equilibrium position of the tug with reduced heeling angle.

## 2.7 Escort forces and speed

**2.7.1** The steady towline force during escorting,  $T_{ESC}$ , in kN, is the towline force associated with the considered (quasi-static) equilibrium in indirect towing mode, excluding short time-duration dynamic effects, for a given loading condition and escort speed  $V$ , see Fig 2. The steady towline force is applied by the tug on the stern of the escorted ship.

**2.7.2** The following angles are defined in relation to escort operations (see Fig 2):

- The towline angle  $\alpha$ , in deg, is the angle between the towline and the centreline of the escorted ship, and
- The drift angle  $\beta$ , in deg, is the angle between the centreline of the tug and the centreline of the escorted ship (also referred to as yaw angle).

**2.7.3** The steady towline force  $T_{ESC}$  can be decomposed into a steering force  $T_Y$  and a braking force  $T_X$  (see Fig 2):

- The steering force  $T_Y$ , in kN, is the transverse component of the steady towline force  $T_{ESC}$  with respect to the escorted ship
- The braking force  $T_X$ , in kN, is the longitudinal component of the steady towline force  $T_{ESC}$  with respect to the escorted ship.

Figure 2 : Typical escort configuration

**2.7.4** The design maximum escort speed  $V_{MAX}$  in kn, is the highest escort speed  $V$  for which the escort tug is designed to perform escort operations, to be specified by the Designer and not to be taken higher than 10 knots.

Note 1: For high powered escort tugs with a free running speed of more than 15 knots the Society may, on a case-by-case basis, accept a design maximum escort speed of 12 knots.

**2.7.5** The following rated values of the above defined escort forces are to be specified by the designer:

- The rated steady towline force  $T_{ESC,R}$  in kN, is the highest anticipated steady towline force  $T_{ESC}$  as obtained from the evaluation of the escort forces for a particular loading condition and escort speed, taking into account the applicable stability and strength criteria
- The rated steering force  $T_{Y,R}$  in kN, is the highest anticipated steering force  $T_Y$ , as obtained from the evaluation of the escort forces for a particular loading condition and escort speed, taking into account the applicable stability and strength criteria
- The rated maximum braking force  $T_{X,R}$  in kN, is the highest anticipated braking force  $T_X$ , as obtained from the evaluation of the escort forces for a particular loading condition and escort speed, taking into account the applicable stability and strength criteria.

**2.7.6** The following maximum values of the above defined rated escort forces are to be specified by the designer:

- The design maximum steady towline force  $T_{ESC,MAX}$  in kN, is the highest rated steady towline force  $T_{ESC,R}$  over the applicable range of loading conditions and escort speeds
- The design maximum steering force  $T_{Y,MAX}$  in kN, is the highest rated steering force  $T_{Y,R}$  over the applicable range of loading conditions and escort speeds
- The design maximum braking force  $T_{X,MAX}$  in kN, is the highest rated braking force  $T_{X,R}$  over the applicable range of loading conditions and escort speeds.

**2.7.7** The matrix of rated steady towline forces  $T_{ESC,R}$ , steering forces  $T_{Y,R}$  and braking forces  $T_{X,R}$  is to be initially specified by the Designer and to be verified by the Society on the basis of the results of:

- full scale trials, or
- model testing, or
- a computer simulation program accepted by the Society.

**2.7.8** Full scale trials, where applicable, should be performed in accordance with a procedure agreed with the Society prior to commencement of the trials and comply with the requirements of Ch 1, Sec 5, [3.2].

**2.7.9** Model testing, where applicable, should be performed in accordance with a procedure agreed with the Society prior to commencement of the tests and comply with the requirements of Ch 1, Sec 5, [3.2]. Special attention is to be paid to scale effects when processing the measurement result to create predictions at full scale.

**2.7.10** Computer simulation programs for predicting escort performance are to comply with the requirements of Ch 1, Sec 5, [3.1].

## 2.8 Towing winch emergency release systems

**2.8.1** Emergency release system refers to the mechanism and associated control arrangements that are used to release the load on the towline in a controlled manner under both normal and blackout conditions.

**2.8.2** Maximum design load is the maximum load that can be held by the winch as defined by the manufacturer (the manufacturer’s rating).

**2.8.3** Fleet angle is the angle between the applied load (towline force) and the towline as it is wound onto the winch drum (see Fig 3).

**Figure 3 : Towline fleet angle**

### **3 Fire safety**

#### **3.1 Suppression of fire**

##### **3.1.1 Fire pumps**

For tugs assigned with the operating area notation **operating within 5 miles from shore**, the portable fire pump required in NR566, Ch 4, Sec 5, [2.2.3] may be omitted.

##### **3.1.2 Fixed fire-extinguishing system**

Tugs assigned with the operating area notation **operating within 5 miles from shore** may be considered as ships of less than 12 m operating in **coastal area** or **sheltered area** according to NR566, Ch 4, Sec 5, [4.2].

# Section 2 Stability

## 1 Application

### 1.1

1.1.1 The requirements of this Section apply as follows depending on the ship service notation:

- **tug**, mainly intended for towing services, are to comply with the requirements in Article [2]
- **salvage tug**, having specific equipment for salvage services, are to comply with the requirements in Article [2]
- **escort tug**, mainly intended for escort services such as for steering, braking and otherwise controlling escorted ships, are to comply with the requirements in Articles [2] and [3].

In addition, ships with the additional service feature **large combined** are to comply with the applicable requirements in Ch 1, Sec 4.

## 2 General requirements

### 2.1 Openings

#### 2.1.1 Openings which cannot be closed weathertight

Openings in the hull, superstructures or deckhouses which cannot be closed weathertight are to be considered as unprotected openings and, consequently, as down-flooding points for the purpose of stability calculations (the lower edge of such openings is to be taken into account).

#### 2.1.2 Ventilation openings of machinery space and emergency generator room

It is recognised that for tugs, due to their size and arrangement, compliance with the requirements of ICLL Reg. 17(3) for ventilators necessary to continuously supply the machinery space and the emergency generator room may not be practicable. Lesser heights of the coamings of these particular openings may be accepted if the openings:

- are positioned as close to the centreline and as high above the deck as practicable in order to maximise the down-flooding angle and to minimise exposure to green water
- are provided with weathertight closing appliances in combination with suitable arrangements, such as separators fitted with drains
- are equipped with efficient protective louvers and mist eliminators
- have a coaming height of not less than 900 mm above the deck
- are considered as unprotected openings and, consequently, as down-flooding points for the purpose of stability calculations.

### 2.2 Stability booklet

2.2.1 *The stability booklet for ships engaged in harbour, coastal or ocean going towing operations and/or escort operations is to contain additional information on:*

- *maximum bollard pull*
- *details on the towing arrangement, including location and type of the towing point(s) such as towing hook, staple, fairlead or any other point serving that purpose*
- *recommendations on the use of roll reduction systems*
- *If any wire, etc. is included as part of the lightship weight, clear guidance on the quantity and size is to be given*
- *maximum and minimum draught for towing and escort operations*
- *instructions on the use of the quick-release device*

### 2.3 Intact stability

2.3.1 The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.11] is to be in compliance with the requirements in Pt B, Ch 3, Sec 2.

#### 2.3.2 Additional intact stability criteria

All the loading conditions reported in the trim and stability booklet which are intended for towing operations are also to be checked in order to investigate the ship's capability to withstand the effect of the transverse heeling moments induced by:

- the combined action of the towline force and the thrust vector (self-tripping, see [2.3.3]),
- the hydrodynamic resistance of the hull (tow-tripping, see [2.3.4]).

Figure 1 : Heeling and righting arms curves

### 2.3.3 Self-tripping

A tug may be considered as having sufficient stability to withstand the self-tripping heeling moment if the following condition is complied with (see Fig 1):

$$A \geq B$$

where:

- A : Area, in m.rad, contained between the righting arm and the heeling arm curves, measured from the heeling angle  $\theta_C$  to the heeling angle  $\theta_D$
- B : Area, in m.rad, contained between the heeling arm and the righting arm curves, measured from zero heel ( $\theta = 0$ ) to the heeling angle  $\theta_C$
- $\theta_C$  : Heeling angle of equilibrium, corresponding to the first intersection between heeling and righting arms curves
- $\theta_D$  : Heeling angle, to be taken as the lesser of:
  - heeling angle corresponding to the second intersection between heeling and righting arm curves
  - the angle of downflooding.

The self-tripping heeling arm curve is to be calculated as follows:

$$b_H = \sum b_{Hi}$$

where:

- $b_{Hi}$  : Heeling arm induced by one thruster or group of thrusters  $i$ , in m, calculated as follows:

$$b_{Hi} = \frac{T_{BPI} c_i (h_i \cos \theta - r \sin \theta)}{9,81 \Delta}$$

- $T_{BPI}$  : Amount of thrust, in kN, generated by one thruster or group of thrusters  $i$ . The sum of all the individual thrusts is to be equal to the design Bollard Pull, as defined in Ch 1, Sec 1, [2.1].
- $h_i$  : Vertical distance, in m, between the towing point (fairlead, staple, towing hook or equivalent fitting) and the horizontal centreline of the propulsion unit or group of units  $i$ , as relevant for the considered towing situation
- $r$  : Transverse offset, in m, between the towing point and the ship's centerline.  
The towing point is the location where the towline force is applied to the ship (fairlead, staple, towing hook or equivalent fitting).

When the towing point is not at the center line, the most unfavourable tow line position is to be considered.

- $c_i$  : Coefficient to be taken equal to:
  - $c = 0,90 / (1 + d_i / L_{LL})$  for a group of 2 azimuthing thrusters, but is in no case to be taken less than:
    - 0,70 for ASD tugs towing over the stern and tractor tugs towing over the bow
    - 0,50 for ASD tugs towing over the bow and tractor tugs towing over the stern, respectively
  - $c = 1 / (1 + d_i / L_{LL})$  for a single azimuthing thruster
  - $c = 0,50$  for non-azimuth propulsion unit or group of units

$\Delta$  : Loading condition displacement, in tons

$\theta$  : Angle of heel, in degrees

$d_i$  : Longitudinal distance, in m, between the towing point (fairlead, staple, towing hook or equivalent fitting) and the vertical centreline of the propulsion unit or group of units  $i$ , as relevant for the considered towing situation

$L_{LL}$  : Load line length, in m, defined in Pt B, Ch 1, Sec 3, [2.1.2].

### 2.3.4 Tow-tripping

A tug may be considered as having sufficient stability to withstand the tow-tripping heeling moment if the first intersection between the righting arm curve and the tow-tripping heeling arm curve for tow-tripping occurs at an angle of heel less than the angle of downflooding.

The tow-tripping heeling arm curve is to be calculated as follows:

$$b_H = \frac{C_1 C_2 \gamma V^2 A_p (h \cos \theta - r \sin \theta + C_3 T)}{19,62 \Delta}$$

where:

$C_1$  : Lateral traction coefficient, taken equal to:

$$C_1 = 2,8 \left( \frac{L_s}{L_{LL}} - 0,1 \right)$$

without being taken lower than 0,1 and greater than 1

$L_s$  : Longitudinal distance, in m, from the aft end of  $L_{LL}$  to the towing point

$C_2$  : Angle of heel correction for  $C_1$ , taken equal to:

$$C_2 = \left( \frac{\theta}{3\theta_d} + 0,5 \right)$$

without being taken lower than 1

$\theta_d$  : Angle to deck edge, in deg, taken equal to:

$$\theta_d = \text{atan} \left( \frac{2f}{B} \right)$$

$f$  : Freeboard amidships, in m

$\gamma$  : Specific water density, in t/m<sup>3</sup>, to be taken equal to 1,025

$V$  : Lateral velocity, in m/s, to be taken equal to 2,57 (5 knots)

$A_p$  : Lateral projected area, in m<sup>2</sup>, of the underwater hull

$C_3$  : Distance from the center of  $A_p$  to the waterline as a fraction of the draught related to the heeling angle, taken equal to:

$$C_3 = \left( \frac{\theta}{\theta_d} \right) 0,26 + 0,3$$

without being taken lower than 0,5 and greater than 0,83

$T$  : Loading condition draught, in m

$h$  : Vertical distance, in m, from the waterline to the towing point.

### 3 Additional requirements for escort tugs

#### 3.1 Intact stability

**3.1.1** All the loading conditions reported in the trim and stability booklet which are intended for escorting operations are also to be checked in order to investigate the tug's capability to withstand the effect of the transverse heeling moment induced by the combined action of the following forces:

- hydrodynamic forces acting on the hull and appendices
- thrust forces
- steady towline force.

**3.1.2** Allowance is to be made for the anticipated type of wire or rope on storage reels and wire on the winches when calculating loading conditions.

**3.1.3** The stability calculations are to be performed on the basis of the highest anticipated heeling moment for the considered loading condition, which is to be obtained from the results of full scale tests, model tests, or, alternatively, the results of a computer simulation program accepted by the Society (refer to Ch 1, Sec 5, [3.1]).

**3.1.4** For each relevant loading condition the evaluation of the highest anticipated heeling moment is to be performed for the applicable range of speeds and towline angles, as defined in the escort towing arrangement plan. As a minimum, the conditions corresponding to the design maximum steering force  $T_{Y,MAX}$ , and design maximum braking force  $T_{X,MAX}$ , as defined in Ch 1, Sec 1, [2.7], are to be included in the evaluation.

**3.1.5** The highest anticipated heeling moment is to be assumed constant for the purpose of the stability calculations.

**3.1.6** The value of the highest anticipated heeling moment is to be specified by the Designer in the stability calculations. In addition, an arrangement drawing with the location of the towing points and propulsion units is to be included in the stability booklet. In this drawing the longitudinal and vertical distance, in m, from the towing point to the relevant centrelines of the propulsion units and the baseline, respectively, are to be specified.

**3.1.7** Preliminary stability calculations on the basis of estimated highest heeling moment and associated heeling arm values may be submitted for (preliminary) examination. If after verification of the heeling arm values on the basis of the results of escort performance trials, model tests or a computer simulation program accepted by the Society (refer to Ch 1, Sec 5, [3.1]) the final values exceed the estimated values, the stability calculations have to be updated for the final heeling moment and heeling arm values. It is recommended to include a reasonable margin in the estimated values (on the basis of design experience).

**3.1.8 Criteria**

An escort tug may be considered as having sufficient stability to withstand the heeling moment arising from the towline, if the three following conditions are complied with:

$A \geq 1,25 B$

$C \geq 1,40 D$

$\theta_C \leq 15^\circ$

where:

- A : Righting arm curve area, in m-rad, measured from the heeling angle  $\theta_C$  to a heeling angle of  $20^\circ$  (see Fig 2)
- B : Heeling arm curve area, in m-rad, measured from the heeling angle  $\theta_C$  to a heeling angle of  $20^\circ$  (see Fig 2)
- C : Righting arm curve area, in m-rad, measured from zero heel ( $\theta = 0$ ) to the heeling angle  $\theta_D$  (see Fig 3)
- D : Heeling arm curve area, in m-rad, measured from zero heel ( $\theta = 0$ ) to the heeling angle  $\theta_D$  (see Fig 3)

**Figure 2 : Definition of the areas A and B**

**Figure 3 : Definition of the areas C and D**

- $\theta_C$  : Heeling angle of equilibrium, corresponding to the first intersection between heeling arm and righting arm curves, to be obtained when the highest anticipated heeling moment resulting from the steady towline force  $T_{ESC}$  as defined in Ch 1, Sec 1, Fig 2, is applied to the escort tug
- $\theta_D$  : Heeling angle, to be taken as the lesser of:
- the angle of downflooding
  - 40°
  - the heeling angle corresponding to the second intersection between heeling and righting arms heeling and righting arm curves.

### 3.2 Stability booklet

**3.2.1** Additional operating information is to be provided in the stability booklet in relation to the design limitations related to the assignment of the service notation **escort tug**.

As a minimum, the following information is to be included:

- Design operating area and environmental conditions for performing escort operations (refer to Pt A, Ch 1, Sec 2, [4.10])
- The maximum escort speed  $V_{MAX}$  (refer to Ch 1, Sec 1, [2.7])
- A table with permissible values of heeling angle and steady towline force as function of loading condition and escort speed (based on the rated steering and braking forces as obtained from Ch 1, Sec 5, [3.1] or Ch 1, Sec 5, [3.2], as applicable)
- Instructions to the master regarding the handling of the escort tug and the associated towing equipment, demonstrating the implementation of effective means to limit the steady towline force and heeling angle within the permissible limits and the use of the emergency release system.

Note 1: Adjustable audible or visible alarms, providing a warning to the master when the heeling angle and/or steady towline force exceeds the permissible value(s) applicable to the relevant loading condition and escort speed, in combination with appropriate handling instructions are as effective means.

The table with permissible values of heeling angle and steady towline force as function of loading condition and escort speed is to be displayed in the wheelhouse next to the control desk or another appropriate location.

### 3.3 Inclinerometer

**3.3.1** Escort tugs are to be equipped with a calibrated heeling angle measurement system (inclinerometer).

The measured heeling angle is to be displayed in the wheelhouse next to the control desk or another appropriate location.

# Section 3 Hull Structure

## 1 General

### 1.1 Application

1.1.1 The requirements of this Section apply as follows depending on the ship service notation:

- **tug**, mainly intended for towing services, are to comply with the requirements in Article [2]
- **salvage tug**, having specific equipment for salvage services, are to comply with the requirements in Articles [2] and [4]
- **escort tug**, mainly intended for escort services such as for steering, braking and otherwise controlling escorted ships, are to comply with the requirements in Articles [2] and [3].

In addition, ships with the additional service feature **barge combined** are to comply with the applicable requirements in Ch 1, Sec 4.

### 1.2 Documents to be submitted

1.2.1 In addition to the documentation requested in Part B, the following documents are to be submitted for approval:

- description of the connection between the towing system (winch and hook) and the hull structure with indication of the design loads.

## 2 General requirements

### 2.1 Typical design arrangements

#### 2.1.1 General

In general, tugs are completely decked ships provided with an ample drift surface and, where intended for service outside sheltered areas, with a forecastle or half forecastle, or at least with a large sheer forward.

#### 2.1.2 Conventional tugs

Conventional tugs have fixed single or multiple shaft arrangement. The propeller(s) can be of fixed pitch or controllable pitch type, normally fitted with Kort nozzle(s). Steering is done by means of rudder(s) or steerable nozzle(s). The towing point is normally located slightly aft of the centre of lateral resistance for towing over the stern with a towing hook and/or towing winch. Conventional tugs may also be equipped to perform pushing operations.

#### 2.1.3 Tractor tugs

Tractor tugs are fitted with omnidirectional thrusters (typically two steerable propellers or Voith-Schneider type cycloidal propulsion units), which are located forward of the towing point (usually not more than 30% of the length from the forward end). A skeg or vertical fin is fitted aft. Towing is performed over the stern with a towing winch and/or towing hook.

Tractor tugs may also be equipped to perform pushing operations.

#### 2.1.4 Azimuth stern drive tugs (ASD tugs)

Azimuth stern drive (ASD) tugs are fitted with multiple steerable propellers located near the aft end. Typically, ASD tugs can perform towing operations over the bow with the forward towing winch (towing operation similar to a tractor tug) and over the stern with a towing hook and/or second towing winch (towing operation similar to a conventional tug). In both cases the towing point is located forward of the thrusters. ASD tugs may be fitted with a skeg, the size and location depending on the intended function.

ASD tugs may also be equipped to perform pushing operations.

#### 2.1.5 Other design arrangements

Other tug design arrangements, having towing and propulsion configurations different from the design arrangements described in [2.1.1] to [2.1.4], have been developed and built, and are to be considered by the Society on a case-by-case basis.

For tugs with combined aft and fore thrusters, every thruster having the same longitudinal location is to be considered as belonging to the same group of thrusters.

### 2.2 Structure design principles

#### 2.2.1 Bollards

For tugs equipped for side towing, the relevant bollards are to be effectively fixed on the deck in way of side transverses and deck beams or bulkheads.

### **2.2.2 Fenders**

A strong fender for the protection of the tug's sides is to be fitted at deck level.

Alternatively, loose side fenders may be fitted, provided that they are supported by vertical ordinary stiffeners extending from the lightship waterline to the fenders themselves.

### **2.2.3 Floors**

Floors are to be arranged with a welded face plate in the machinery space; elsewhere, floor flanging may be accepted as an alternative to the fitting of welded face plates.

### **2.2.4 Shaft tunnels**

For tugs having small depth, the shaft tunnel may be omitted. In this case, access to the shaft line is to be given through the floor of the space above.

## **2.3 Hull scantlings**

### **2.3.1 General**

The net scantlings of plating, ordinary stiffeners and primary supporting members are to be in accordance with the applicable requirements defined in Ch 1, Sec 1, considering a scantling draught T not less than 0,85 D for the calculation of hull girder loads and local loads.

## **2.4 Other structures**

### **2.4.1 Machinery casings**

Exposed machinery casings are to be not less than 900 mm in height, measured from the upper surface of the deck, and provided with weathertight means of closure.

In general, the longitudinal sides of the machinery casings are to be extended downwards by a deck girder to which the deck beams are to be connected.

Side ordinary stiffeners are to be connected to the deck. Their spacing is to be not greater than 0,75 m.

### **2.4.2 Emergency exits from machinery space**

Emergency exits from the machinery space to the upper deck are to be located as high as possible above the waterline and in way of the ship's centreline, so that they may be used even at extreme angles of heel.

Escape hatch coaming heights are to be not less than 600 mm above the upper surface of the deck.

Escape hatch covers are to have hinges fitted such that the predominant direction of green sea will cause the cover to close and are to be capable of being opened and closed weathertight from either side.

### **2.4.3 Height of hatchway coamings**

The height of the hatchway coamings is to be not less than 300 mm. Hatch covers are to be fitted with efficient securing devices.

## **2.5 Rudder and bulwarks**

### **2.5.1 Rudder**

For tugs, the rudder stock diameter is to be increased by 5% with respect to that calculated according to the applicable requirement.

### **2.5.2 Bulwarks**

The bulwarks are to be sloped inboard to avoid distortions likely to occur during contact. Their height may be reduced where required by operational necessities.

## **2.6 Anchoring and mooring equipment**

**2.6.1** In the formula in Pt B, Ch 12, Sec 4, [1.2.2] for the determination of the Equipment Number, the term "2,0 h B" may be replaced by the term:

$$2,0 \left( aB + \sum h_n b_n \right)$$

to give:

$$EN = \Delta^{2/3} + 2 \left[ \left( aB + \sum h_n b_n \right) + S_{fun} \right] + 0,1 A$$

where:

$b_n$  : breadth, in m, of the widest superstructure or deckhouse of each tier having a breadth greater than B/4

$\Delta$ , a, B,  $h_n$ ,  $S_{fun}$  and A as defined in Pt B, Ch 12, Sec 4, [1.2.2].

**2.6.2 Wire ropes**

Wire ropes may be used as an alternative to chain cables as follows:

- a) Where  $L \leq 40$  m, chain cables may be replaced by wire ropes of equal minimum breaking strength, which are to have:
  - a length 1,5 times the required chain cable length, and
  - a short length of chain cable between the wire rope and the anchor, having a length equal to 12,5 m or the distance from the anchor in the stowed position to the winch, whichever is the lesser.
- b) Where  $40 \text{ m} < L \leq 90$  m, both chain cables may be replaced by wire rope of equal minimum breaking strength which are to have:
  - a length 1,5 times the required chain cable length, and
  - a minimum mass per unit length of 30% of the required Grade 2 chain cable, and
  - a short length of chain cable between the wire rope and the anchor, having a length equal to 12,5 m or the distance from the anchor in the stowed position to the winch, whichever is the lesser.

**2.6.3 Number of anchors**

The number of anchors depends on the service notation and optional operating area notation, the propulsion arrangement and the application of a fixed fire-fighting installation. In general, the recommended number of anchors and chain cables is shown in Tab 1.

A reduction of the number of anchors and chain cables may be accepted as depicted in Tab 1 if the following conditions, based on redundancy principles, are complied with:

- the tug is equipped with at least twin propulsion, of which each main engine can maintain sufficient propulsion power to safely return to berth. For this purpose, the main engines should be able to run self-supporting, i.e. independent of generator sets intended for auxiliary power, unless these are able to run parallel and, in case of black-out, have automatic starting and connecting to switchboard within 45 seconds
- a single failure, except fire, is not to cause total propulsion failure
- a fixed fire fighting installation is provided.

It may be considered by the tug builder and operator to apply a spare anchor as an alternative to a second bower anchor. In such case special provisions, such as a crane and suitable storage space for the spare anchor, are to be present on board and the weight and dimensions of the anchor are to be such that it can be handled swiftly. For tugs with the operating area notation **operating  $\leq 4$  h from a place of refuge**, effectively operating in a fixed and limited area, the spare anchor may be stored ashore.

**Table 1 : Number of anchors and chain cables**

Service notation	Operating area notation	Number of anchor and chain cables	
		General	Reduced based on redundancy principles (1)
<b>tug</b>	<b>operating within 5 miles from shore</b>	1	0
<b>tug</b>	<b>operating <math>\leq 4</math> h from a place of refuge</b>	2	1
<b>tug</b>	–	2	2
<b>salvage tug</b>	–	2	2
<b>escort tug</b>	<b>operating <math>\leq 4</math> h from a place of refuge</b>	2	1
<b>escort tug</b>	–	2	2
(1) As detailed in [2.6.3].			

**2.7 Towing equipment**

**2.7.1 General**

Towing winches, towing hooks and towline guiding fittings (fairleads, staples, gob-eyes, towing pins, etc.) are normally to be arranged in way of the tug's centerline, in such a position as to minimise heeling moment exerted by the towline force. Effective means are to be provided to lead and restrain the towline within the designed limits of its sweep.

Materials used in towing equipment are to comply with the applicable class requirements for materials. Class certificates are required for the materials used for winch drums, drum shafts, winch brake components, winch supporting frames, towing hooks and towline guiding fittings.

**2.7.2 Design load**

The design load DL to be considered for the strength assessment of the towing equipment and the associated supporting structures is given in Tab 2.

**Table 2 : Design loads for equipments used for towing operations and supporting structures**

Service notation	Operating area notation	$T_{BP}$ , in kN	DL, in kN
<b>tug</b>	<b>operating within 5 miles from shore</b>	$T_{BP} \leq 200$	$2 T_{BP}$
		$200 < T_{BP} < 800$	$[(2600 - T_{BP}) / 1200] T_{BP}$
		$T_{BP} \geq 800$	$1,5 T_{BP}$
<b>tug salvage tug escort tug</b>	-	$T_{BP} \leq 400$	$2,5 T_{BP}$
		$400 < T_{BP} < 1000$	$[(3400 - T_{BP}) / 1200] T_{BP}$
		$T_{BP} \geq 1000$	$2 T_{BP}$

**Note 1:** The DL takes into consideration dynamic effects through the application of the dynamic amplification factor (DAF) (see also Ch 1, Sec 1, [2.3]).

**2.7.3 Towing winches**

- a) The winch brake shall normally act directly on the drum and shall be operable in case of failure of the primary power supply system (either manually or otherwise arranged).
- b) The in-board end of the towline is to be attached to the winch drum with a weak link or similar arrangement that is designed to release the towline at low load.
- c) Towing winches are to be provided with an emergency release system as described in [2.7.4].
- d) Means are to be provided to prevent the fleet angle as shown on Ch 1, Sec 1, Fig 3 from becoming great enough to inhibit operation of the emergency release system.
- e) The dimensioning of the winch drum is to take into account the rope bending specifications provided by the towline manufacturer.
- f) Due consideration is to be given to the proper spooling of the towline on the winch drum, as well as preventing the towline to slip over the flanges of the drum.
- g) Towing winches (in particular the components which are exposed to the tension in the towline, such as the winch drums, drum shafts, brakes, support frame and connection to the hull structure) shall be able to:
  - sustain the DL, as specified in [2.7.2] without permanent deformation, and
  - sustain the BHL, as defined Ch 1, Sec 1, [2.4], without exceeding an equivalent stress level (based on Von Mises criterion) of  $0,80 R_{eH}$ .
  - sustain the loads for the rated pull condition, as foreseen by the Designer, without exceeding an equivalent stress level (based on Von Mises criterion) of  $0,40 R_{eH}$ .

where:

$R_{eH}$  : Minimum specified yield stress of material, in N/mm<sup>2</sup>

rated pull: Winch maximum hauling in load at the first inner layer.

- h) Where deemed necessary by the Society, buckling and/or fatigue analysis, performed in accordance with a standard or code of practice recognised by the Society, may be required to be submitted for information.
- i) Towing winches may be equipped with an active pay-out and haul-in system for automatic adjustment of towline. In that case the relevant requirements of [3.2.3] and Ch 1, Sec 5, [3.3] are to be complied with.
- j) It is recommended that the towing winch is fitted with equipment to continuously measure the tension in the towline. In case a towline measurement system is installed on board, the measured data are to be displayed in the wheelhouse next to the control desk or another appropriate location.

**2.7.4 Emergency release system**

- a) Performance:
  - 1) The emergency release system is to operate across the full range of towline load, fleet angle and ship heel angle under all normal and reasonably foreseeable abnormal conditions (these may include, but are not limited to, the following: vessel electrical failure, variable towline load (for example due to heavy weather), etc.).
  - 2) The emergency release system is to be capable of operating with towline loads up to at least 100 per cent of the maximum design load.
  - 3) The emergency release system is to function as quickly as is reasonably practicable and within a maximum of three seconds after activation.
  - 4) The emergency release system is to allow the winch drum to rotate and the towline to pay out in a controlled manner such that, when the emergency release system is activated, there is sufficient resistance to rotation to avoid uncontrolled unwinding of the towline from the drum. Spinning (free, uncontrolled rotation) of the winch drum is to be avoided, as this could cause the towline to get stuck and disable the release function of the winch.

- 5) Once the emergency release is activated, the towline load required to rotate the winch drum is to be no greater than:
    - the lesser of five tonnes or five per cent of the maximum design load when two layers of towline are on the drum, or
    - 15 per cent of the maximum design load where it is demonstrated that this resistance to rotation does not exceed 25 per cent of the force that will result in listing sufficient for the immersion of the lowest unprotected opening.
  - 6) Emergency release of the towline is to be possible in the event of a blackout. For this purpose, where additional sources of energy are required, such sources are to comply with item 7) below.
  - 7) The sources of energy required by item 6) are to be sufficient to achieve the most onerous of the following conditions (as applicable):
    - sufficient for at least three attempts to release the towline (i.e. three activations of the emergency release system). Where the system provides energy for more than one winch it is to be sufficient for three activations of the most demanding winch connected to it.
    - Where the winch design is such that the drum release mechanism requires continuous application of power (e.g. where the brake is applied by spring tension and released using hydraulic or pneumatic power) sufficient power is to be provided to operate the emergency release system (e.g. hold the brake open and allow release of the towline) in the event of a blackout for a minimum of five minutes. This may be reduced to the time required for the full length of the towline to feed off the winch drum at the load specified in item 5) if this is less than five minutes.
- b) Monitoring and control:
- 1) Emergency release operation is to be possible from the bridge and from the winch control station on deck. The winch control station on deck is to be in a safe location.

A position in close proximity to the winch is not regarded as “safe location”, unless it is documented that the position is at least protected against towline break or winch failure.
  - 2) The emergency release control is to be located close to an emergency stop button for winch operation, if provided, and both are to be clearly identifiable, clearly visible, easily accessible and positioned to allow safe operability.
  - 3) The emergency release function is to take priority over any emergency stop function. Activation of the winch emergency stop from any location is not to inhibit operation of the emergency release system from any location.
  - 4) Emergency release system control buttons are to require positive action to cancel, the positive action may be made at a different control position from the one where the emergency release was activated. It is always to be possible to cancel the emergency release from the bridge regardless of the activation location and without manual intervention on the working deck.
  - 5) Controls for emergency use are to be protected against accidental use.
  - 6) Indications are to be provided on the bridge for all power supply and/or pressure levels related to the normal operation of the emergency release system. Alarms are to activate automatically if any level falls outside of the limits within which the emergency release system is fully operational.

The following emergency release system alarms and indications are to be provided on the bridge:

    - Low fluid pressure in the control system
    - Low accumulator/ air pressure
    - Low battery voltage (separate alarm and indication not required where electrical power is supplied from the tug's emergency batteries).
  - 7) Wherever practicable, control of the emergency release system is to be provided by a hard-wired system, fully independent of programmable electronic systems.
  - 8) Computer based systems that operate or may affect the control of emergency release systems are to meet the requirements for Category III systems (see Pt C, Ch 3, Sec 3, [2.3]).
  - 9) Components critical for the safe operation of the emergency release system are to be identified by the manufacturer.
- c) General test requirements
- 1) For each emergency release system or type thereof, the performance requirements of paragraph a) are to be verified either at the manufacturer's works or as part of the commissioning of the towing winch when it is installed on board. In any case, this test is to be witnessed by a Surveyor. Where verification solely through testing is impracticable (e.g. due to health and safety), testing may be combined with inspection, analysis or demonstration in agreement with the Society.
  - 2) The performance capabilities, as well as instructions for operation, of the emergency release system are to be documented by the manufacturer and made available on board the ship on which the winch has been installed.
  - 3) Instructions for surveys of the emergency release system are to be documented by the manufacturer, agreed by the Society and made available on board the ship on which the winch has been installed.
  - 4) Where necessary for conducting the annual and special surveys of the winch, adequately sized strong points are to be provided on deck.

d) Installation trials

- 1) The full functionality of the emergency release system is to be tested as part of the shipboard commissioning trials to the satisfaction of the surveyor. Testing may be conducted either during a bollard pull test or by applying the towline load against a strong point on the deck of the tug that is certified to the appropriate load.
- 2) Where the performance of the winch in accordance with paragraph a) has previously been verified, the load applied for the installation trials is to be at least the lesser of 30% of the maximum design load or 80% of vessel bollard pull.

**2.7.5 Towing hooks**

- a) Towing hooks and their load carrying attachments (connecting the towing hook to the hull structure) shall be able to sustain the DL, as specified in [2.7.2], without exceeding an equivalent stress level (based on Von Mises criterion) of  $0,80 R_{eH}$ .
- b) Towing hooks shall be provided with an emergency release system operable from a position on the bridge with full view and control of the towing operation, as well as at a location near the hook where the device can be safely operated. Identical means of control for the emergency release systems shall be provided at each control station and are to be protected against unintentional use.

The force necessary to open the hook under load is to be not greater than 150 N.

The applicable procedures for the emergency quick-release device shall be communicated to the crew and vital information shall be displayed next to the control desk or another appropriate location.

**2.7.6 Towlines**

- a) The breaking strength of towlines is not to be less than the DL, as specified in [2.7.2].  
In addition, the breaking strength of towlines used on a towing winch is not to be less than the BHL of the associated winch (see Ch 1, Sec 1, [2.4]).
- b) The towline shall be protected from being damaged by chafing and abrasion. To this end cargo rails, bulwarks, and other elements supporting the towline should be sufficiently rounded with consideration to the bend radius limit of the towline in order to ensure that the towline breaking strength is maintained.
- c) It is recommended that the total length of the towline applied on a towing winch is such that under normal operation, at least half a layer remains on the drum. In no case less than three turns shall remain on the drum in under normal operation.

**2.7.7 Towline guiding fittings**

- a) Towline guiding fittings, such as fairleads, staples, gob-eyes, towing pins, stern rollers and equivalent components which guide the towline, shall be able to sustain the force exerted by the towline loaded under a tension equal to the DL, as specified in [2.7.2], in the most unfavourable anticipated position of the towline without exceeding the following stress level criteria:

- Normal stress:  
 $\sigma \leq 0,75 R_{ref}$
- Shear stress:  
 $\tau \leq 0,47 R_{ref}$
- Equivalent stress:  
 $\sigma_{VM} \leq 0,85 R_{ref}$

where:

$R_{ref}$  : Reference stress of the material, in N/mm<sup>2</sup>, normally to be taken as 235/k, but may be taken as  $R_{eH}$  for fittings not made of welded construction.

- b) Towline guiding fittings used for guiding the towline when towing on a towing winch shall be able to sustain the force exerted by the towline loaded under a tension equal to the BHL of the associated winch, as specified in Ch 1, Sec 1, [2.4], in the most unfavourable anticipated position of the towline without exceeding the stress level criteria mentioned in a).
- c) Where a towline guiding fitting (e.g. fairlead or guide pin) has been designed for a specific Safe Working Load SWL, defined as the maximum static working load, the fitting shall be able to sustain a force equal to 2 times the SWL without exceeding the stress level criteria mentioned in a).
- d) In case the yielding check of the towline guiding fittings is carried out by means of a three dimensional finite element model, the permissible stress levels given above may be increased by 10 per cent (compared to a beam model).

**2.7.8 Supporting structures**

- a) The supporting structures of towing equipment shall be able to sustain the load exerted on the supporting structure under the action of the towline loaded under a tension equal to the DL, as specified in [2.7.2], in the most unfavourable anticipated position of the towline, without exceeding the stress level criteria specified in [2.7.7].
- b) Supporting structures of towing equipment engaged when towing on a towing winch shall be able to sustain the load exerted on the supporting structure under the action of the towline loaded under a tension equal to the BHL of the associated winch, as specified in Ch 1, Sec 1, [2.4], in the most unfavourable anticipated position of the towline without exceeding the stress level criteria specified in [2.7.7].

- c) Where a towline guiding fitting has been designed for a specific Safe Working Load SWL, defined as the maximum static working load, the associated supporting structure shall be able to sustain a force equal to 2 times the SWL without exceeding the stress level criteria specified in [2.7.7].
- d) In case the yielding check of the towing equipment supporting structures is carried out by means of a three dimensional finite element model, the permissible stress levels given above may be increased by 10 per cent (compared to a beam model).

**2.7.9 Fendering**

- a) A robust and efficient fendering system is to be fitted in areas intended for pushing. The fendering system purpose is to distribute the pushing force and limit its dynamic component on the hull structure of both the tug and the assisted ship.
- b) For the purpose of this requirement, it is considered that during pushing operations, the contact between the tug and the assisted ship is maintained and that no bouncing (e.g. under wave action) is taking place. Forces resulting from bouncing loads are not taken into consideration, as it is understood that pushing operations (in waves) are normally halted when bouncing starts taking place (due to operational difficulties to keep position within the pushing area of the assisted ship as well as to control the associated impact type loads).
- c) The design load DL to be considered for the strength assessment of the fender supporting structure may be taken as follows:

$$DL = 1,5 T_{BP}$$

where:

$T_{BP}$  : Design bollard pull, as defined in Ch 1, Sec 1, [2.1].

The DL takes into consideration anticipated dynamic effects through the application of the dynamic amplification factor (see also Ch 1, Sec 1, [2.3]), but not bouncing effects (see above).

The fender supporting structure shall be able to sustain the DL, as specified above, without exceeding the stress level criteria specified in [2.7.7].

**3 Additional requirements for escort tugs**

**3.1 Structural design principles**

**3.1.1 Hull shape**

The hull shape is to be such as to provide adequate hydrodynamic lift and drag forces and to avoid excessive trim angles for large heeling angles.

**3.1.2 Bulwark**

A bulwark is to be fitted all around the weather deck.

**3.2 Equipment for escort operations**

**3.2.1 General**

Towing winches and towline guiding fittings (fairleads, staples, etc.) used for escort services are normally to be arranged in way of the tug's centreline, in such a position as to minimise heeling moment.

Materials used in towing equipment are to comply with the applicable class requirements for materials. Class certificates are required for the materials used for winch drums, drum shafts, winch brake components, winch supporting frames and towline guiding fittings.

**3.2.2 Design load**

The design load DL to be considered for the strength assessment of the towing equipment used for escort services and the associated supporting structures is given in Tab 3.

**Table 3 : Design Loads for equipment used for escort operations and supporting structures**

$T_{ESC,MAX}$ in kN	DL, in kN	
	General case	Escort tugs assigned with the operating area notation <b>escort service limited to non-exposed waters</b>
$\leq 500$	$3 T_{ESC,MAX}$	$2,4 T_{ESC,MAX}$
$500 < T_{ESC,MAX} \leq 1000$	$[(2000 - T_{ESC,MAX}) / 500] T_{ESC,MAX}$	$[(2000 - T_{ESC,MAX}) / 625] T_{ESC,MAX}$
$> 1000$	$2 T_{ESC,MAX}$	$1,6 T_{ESC,MAX}$

**Note 1:** The DL takes into consideration dynamic effects through the application of the Dynamic Amplification Factor (DAF) (see also Ch 1, Sec 1, [2.3]).

**3.2.3 Escort winches**

- a) The winch brake shall normally act directly on the drum and shall be operable in case of failure of the primary power supply system (either manually or otherwise arranged).

- b) Escort winches intended to be used in conditions where dynamic oscillations of the towline are likely to occur, such as in open sea areas or other areas exposed to waves, are to be equipped with an active pay-out and haul-in system.

This system is to automatically and reliably pay-out the towline in a controlled manner when the towline force exceeds a pre-set (adjustable) level equal to 110 per cent of the rated towline force  $T_{ESC,R}$  and, as the towline force is reduced, actively haul-in the towline to prevent slack-line events and maintain a pre-set or adjustable towline force consistent with the rated towline force.

Pay-out and haul-in speeds and pull capability shall be chosen taking into account the anticipated escort services and the dynamic characteristics of the escort tug.

- c) Escort operations in conditions where dynamic oscillations of the towline are likely to occur may not be based on the use of the brakes of the winch drum.
- d) Escort operations performed by escort tugs with the operating area notation **escort service limited to non-exposed waters** and any escort operation in calm water conditions, such as in ports and sheltered (confined) waters, may be based on the use of the brakes of the winch drum. As a minimum, the winch brake holding load BHL is to be equal to or greater than two times the maximum steady towline force  $T_{ESC,MAX}$ .
- e) Escort winches are to be fitted with equipment to continuously measure the tension in the towline.

The measured data are to be displayed in the wheelhouse next to the control desk or another appropriate location.

- f) The escort towing system is to be designed so as to enable the proper spooling of the towline on the winch drum when hauling in. Generally this can be achieved by a suitable design of the fairlead or staple guiding the towline between the escort winch and the assisted ship.

Where a spooling device is fitted, this device should be designed for the same Design Load and stress criteria as the towline guiding fittings, see [3.2.5].

- g) Winches are to be provided with an emergency release system as defined in [2.7.4].

- h) The dimensioning of the winch drum is to take into account the rope bending specifications provided by the towline manufacturer.

Due consideration is to be given to preventing the towline to slip over the flanges of the drum.

- i) Escort winches (in particular the components which are exposed to the tension in the towline, such as the winch drums, drum shafts, brakes, support frame and connection to the hull structure) shall be able to:

- sustain the DL, as specified in [3.2.2] without permanent deformation, and
- sustain the BHL, as defined in Ch 1, Sec 1, [2.4], without exceeding an equivalent stress level (based on Von Mises criterion) of  $0,80 R_{eH}$
- sustain the loads for the rated pull condition, as foreseen by the Designer, without exceeding an equivalent stress level (based on Von Mises criterion) of  $0,40 R_{eH}$ .

where:

$R_{eH}$  : Minimum specified yield stress of material, in  $N/mm^2$

rated pull: Winch maximum hauling in load at the first inner layer.

- j) Where deemed necessary by the Society, buckling and/or fatigue analysis, performed in accordance with a standard or code of practice recognized by the Society, may be required to be submitted for information.

### 3.2.4 Towlines

- a) The breaking strength of towlines used for escort services is not to be less than the DL, as specified in [3.2.2].

In addition, the breaking strength for towlines used for escort services on an escort winch is not to be less than the BHL of the associated escort winch (see Ch 1, Sec 1, [2.4]).

- b) The towline shall be protected from being damaged by chafing and abrasion. To this end cargo rails, bulwarks, and other elements supporting the towline should be adequately rounded.
- c) It is recommended that the total length of the towline applied on a towing winch is such that under normal operation, at least half a layer remains on the drum. In no case less than three turns shall remain on the drum in under normal operation.

**3.2.5 Towline guiding fittings**

- a) Towline guiding fittings used for escort services, such as fairleads, staples and equivalent components which guide the towline, shall be able to sustain the force exerted by the towline loaded under a tension equal to the DL, as specified in [3.2.2], in the most unfavourable anticipated position of the towline without exceeding the stress level criteria specified in [2.7.7].
- b) In addition, towline guiding fittings shall be able to sustain the force exerted by the towline loaded under a tension equal to the BHL of the associated winch, as specified in Ch 1, Sec 1, [2.4], in the most unfavourable anticipated position of the towline without exceeding the stress level criteria specified in [2.7.7].
- c) Where a towline guiding fitting has been designed for a specific safe working load SWL, defined as the maximum static working load, the fitting shall be able to sustain a force equal to 2 times the SWL without exceeding the stress level criteria specified in [2.7.7].
- d) In case the yielding check of the towline guiding fittings is carried out by means of a three dimensional finite element model, the permissible stress levels given above may be increased by 10 per cent (compared to a beam model).

**3.2.6 Supporting structures**

- a) The supporting structures of towing equipment used for escort services shall be able to sustain the load exerted on the supporting structure under the action of the towline loaded under a tension equal to the DL, as specified in [3.2.2], in the most unfavourable anticipated position of the towline, without exceeding the stress level criteria specified in [2.7.7].
- b) In addition, supporting structures of towing equipment used for escort services shall be able to sustain the load exerted on the supporting structure under the action of the towline loaded under a tension equal to the BHL of the associated winch, as specified in Ch 1, Sec 1, [2.4], in the most unfavourable anticipated position of the towline without exceeding the stress level criteria specified in [2.7.7].
- c) Where a towline guiding fitting has been designed for a specific safe working load SWL, defined as the maximum static working load, the associated supporting structure shall be able to sustain a force equal to 2 times the SWL without exceeding the stress level criteria specified in [2.7.7].
- d) In case the yielding check of the towing equipment supporting structures is carried out by means of a three dimensional finite element model, the permissible stress levels given above may be increased by 10 per cent (compared to a beam model).

**4 Additional requirements for salvage tugs**

**4.1 Equipment**

**4.1.1** Ships with the navigation notation **salvage tug** are to be fitted with the additional equipment specified in Tab 4.

**Table 4 : Additional equipment for salvage tugs**

Arrangement or equipment	Number of items
Fixed or movable drainage pumps having approximately the same capacity <b>(1) (2) (3)</b>	2 or more pumps of total capacity $\geq 400 \text{ m}^3/\text{h}$
Fire pumps each capable of throwing two simultaneous jets of water having a horizontal reach not less than 30 m <b>(4)</b>	2 pumps, each having a capacity $\geq 60 \text{ m}^3/\text{h}$
Breathing apparatuses for divers	2
Gas masks with filter	2
Cargo boom	1, with service load $\geq 1 \text{ t}$
Power operated winch capable of producing an adequate pull	1
Water stops to stop leaks of approximately 1 x 2 m	4
Complete set of equipment for flame cutting with at least 25 metres of flexible piping	1
Drain hoses	at least 20 m per pump
Fire hoses	10
Connections for fire main	at least 3
Power operated diver's compressor, with associated equipment <b>(5)</b>	1
<b>(1)</b> For each pump fitted on board, a suction strainer and, in the case of non self-priming pumps, a foot valve, are also to be provided. <b>(2)</b> Where portable pumps are used, they are to be capable of effectively operating even with transverse and longitudinal inclinations up to 20°. <b>(3)</b> These pumps are additional to the drain pumps intended for the drainage service of the ship. <b>(4)</b> These pumps may be the same required for drainage purposes provided they have an adequate head. <b>(5)</b> As an alternative, a compressor for recharging the oxygen tanks of divers may be provided together with two complete sets of equipment for divers. <b>(6)</b> Winding drums fitted on board are to be capable of housing wire ropes of suitable size and length not normally less than 350 m.	

Arrangement or equipment	Number of items
Additional towline equipment	1
Lamps for underwater operation	2
Floodlight of power $\geq 500$ W	1
Working lamps	2
Winding drums with wire ropes	see <b>(6)</b>
Electrical cables, each not less than 100 metres long and capable of supplying at least 50 kW	3
Tackles with lifting capacity of 1 t	2
Tackles with lifting capacity of 3 t	2
Radar with a range not less than 24 nautical miles	1
Echo-sounding device with a range of 100 m	1
Hydraulic jackets with lifting capacity of 10 t	2
Hydraulic jackets with lifting capacity of 20 t	2
Portable electrical drill with a set of twist bits having diameters up to 20 mm	1
<p><b>(1)</b> For each pump fitted on board, a suction strainer and, in the case of non self-priming pumps, a foot valve, are also to be provided.</p> <p><b>(2)</b> Where portable pumps are used, they are to be capable of effectively operating even with transverse and longitudinal inclinations up to 20°.</p> <p><b>(3)</b> These pumps are additional to the drain pumps intended for the drainage service of the ship.</p> <p><b>(4)</b> These pumps may be the same required for drainage purposes provided they have an adequate head.</p> <p><b>(5)</b> As an alternative, a compressor for recharging the oxygen tanks of divers may be provided together with two complete sets of equipment for divers.</p> <p><b>(6)</b> Winding drums fitted on board are to be capable of housing wire ropes of suitable size and length not normally less than 350 m.</p>	

## Section 4 Integrated Tug / Barge Combination

### Symbols

$R_y$  : Minimum yield stress, in N/mm<sup>2</sup>, of the material, to be taken equal to 235/k N/mm<sup>2</sup>, unless otherwise specified.

### 1 General

#### 1.1 Application

##### 1.1.1 General

The requirements of this Section apply to the integrated tug/barge combinations constituted by:

- a tug, to which the additional service feature **barge combined** is assigned
- a barge, to which the additional service feature **tug combined** is assigned

and specify the criteria these combinations are to satisfy in addition to those in:

- Ch 1, Sec 3, [2] Ch 1, Sec 2, [2], and Ch 1, Sec 5, [2] for the tug
- Pt D, Ch 14, Sec 2 for the barge.

**1.1.2** When a series of barges may be operated in combination with a specific tug, the identification numbers of such barges are to be indicated in the tug class certificate.

**1.1.3** When a series of tugs may be operated in combination with a specific barge, the identification numbers of such tugs are to be indicated in the barge Certificate of Classification.

#### 1.2 Permanent connections

**1.2.1** An integrated tug/barge combination is connected with permanent connection if the tug and the barge cannot be disconnected in open sea. The connection is such that no relative motion between the tug and the barge is permitted.

#### 1.3 Removable connections

##### 1.3.1 General

An integrated tug/barge combination is connected with removable connection if the tug and the barge can be disconnected in open sea. The disconnecting procedure is to be performed safely by one man and is to take less than 5 min. After disconnection in open sea, the tug is to be arranged to tow the barge by hawser.

The procedure for disconnecting and reconnecting at sea the integrated tug/barge combination is to be made available for guidance to the Master.

##### 1.3.2 Types of removable connections

The removable connection is classed in the two following types:

- rigid connection, if no relative motion between the tug and the barge is permitted
- flexible connection, if relative motion between the tug and the barge is permitted (e.g. the tug is free to pitch with respect to the barge).

##### 1.3.3 Tug

The tug is to have the capability of separating from the barge and shifting to tow it by hawser.

#### 1.4 Documents to be submitted

**1.4.1** In addition to the documentation requested in Pt B, Ch 1, Sec 4, the following documents are to be submitted:

- Structural arrangement of the fore part of the tug, showing details of reinforcements in way of the connecting point,
- Structural arrangement of the aft part of the barge, showing details of reinforcements in way of the connecting point,
- Details of the connection system.

## 2 General arrangement design

### 2.1 Bulkhead arrangement

#### 2.1.1 Number and disposition of barge transverse watertight bulkheads

In applying the criteria in Pt B, Ch 2, Sec 1, the barge is to be fitted at least with an aftermost transverse watertight bulkhead located forward of the connection area and extended from side to side.

The cargo spaces are to be separated from the other spaces not used for cargo by watertight bulkheads.

#### 2.1.2 Barge collision bulkhead

The collision bulkhead of the barge is to be located at a distance, in m, from the fore end of L of not less than  $0,05 L_{LLC}$  or 10 m, whichever is the lesser, and not more than  $0,08 L_{LLB}$ , where:

- $L_{LLC}$  : Ship's length, in m, measured between the aft and fore ends of L of the integrated tug/barge combination, taken at the fore and aft ends of the load line length
- $L_{LLB}$  : Ship's length, in m, measured between the aft and fore ends of L of the barge considered as an individual ship, taken at the fore and aft ends of the load line length.

## 3 Integrated tug/barge combinations with permanent connection: stability, freeboard, design loads, hull scantlings and equipment

### 3.1 Stability calculations

**3.1.1** The integrated tug/barge combination is to comply with the applicable intact and, where additional notation SDS is requested, damage stability requirements in Part B, Chapter 3 considering the integrated tug/barge combination as a ship of the size of the combination.

### 3.2 Freeboard calculation

**3.2.1** The freeboard is to be taken as the greatest of:

- the freeboard of the tug, considered as an individual ship
- the freeboard of the barge, considered as an individual ship
- the freeboard of the integrated tug/barge combination, considered as a ship of the size of the combination. For the freeboard calculation the barge is to be considered as being manned.

### 3.3 Still water hull girder loads

**3.3.1** The still water hull girder loads and the forces transmitted through the connection are to be calculated for each loading condition considering the integrated tug/barge combination as a ship of the size of the combination.

### 3.4 Wave hull girder loads

**3.4.1** The wave hull girder loads and the forces transmitted through the connection are to be calculated according to Pt B, Ch 5, Sec 4 considering the integrated tug/barge combination as a ship of the size of the combination.

#### 3.4.2 Direct calculation

When deemed necessary by the Society, the wave hull girder loads and the forces transmitted through the connection are to be obtained from a complete analysis of the integrated tug/barge combination motion and acceleration in irregular waves, unless such data are available from similar ships.

These loads are to be obtained as the most probable the integrated tug/barge combination, considered as a ship of the size of the combination, may experience during its operating life for a return period of 25 years. For this calculation, the wave statistics relevant to the area of navigation and/or worst weather condition expressed by the navigation notation assigned to the integrated tug/barge combination are to be taken into account. For unrestricted navigation, the wave statistics relevant to the North Atlantic are to be taken into account.

When the difference between the tug and the barge depths is not considered negligible by the Society, its effects are to be considered in evaluating the buoyancy force distributions and the corresponding hull girder loads on the tug structures immediately aft of the connection section, for the different wave encountering conditions.

### 3.5 Still water local loads

**3.5.1** The still water local loads are to be calculated according to Pt B, Ch 5, Sec 5 and Pt B, Ch 5, Sec 6 for each loading condition and draught of the integrated tug/barge combination. The draught of the integrated tug/barge combination is to be taken not less than  $0,85 D$ , where  $D$  is the greater of the tug and the barge depths and not greater than the draught of the barge.

### **3.6 Wave local loads**

**3.6.1** The wave local loads are to be calculated according to Pt B, Ch 5, Sec 5 and Pt B, Ch 5, Sec 6 considering the integrated tug/barge combination as a ship of the size of the combination. The draught of the integrated tug/barge combination is to be taken not less than  $0,85 D$ , where  $D$  is the greater of the tug and the barge depths and not greater than the draught of the barge.

### **3.7 Hull girder strength**

#### **3.7.1 Strength check**

The longitudinal strength is to comply with Part B, Chapter 6, where the hull girder loads are those defined in [3.3] and [3.4].

#### **3.7.2 Loading manual**

The loading manual is to include the (cargo and ballast) loading conditions of the integrated tug/barge combination at sea and in port conditions on the basis of which the approval of its hull structural scantlings is based.

The manual is to indicate the still water bending moment and shear force along the length of the integrated tug/barge combination as well as the permissible values at each hull section.

Information on loading and unloading sequences is to be provided for guidance to the Master.

### **3.8 Scantlings of plating, ordinary stiffeners and primary supporting members**

**3.8.1** The scantlings of plating, ordinary stiffeners and primary supporting members are to be in accordance with Part B, Chapter 7 or NR600, as applicable, where the hull girder and local loads are those defined in [3.3] to [3.6].

In any case, the scantlings of plating, ordinary stiffeners and primary supporting members of the tug and the barge are to be not less than those obtained according to Ch 1, Sec 3 and Pt D, Ch 14, Sec 2 for the tug alone and the barge alone, respectively.

### **3.9 Equipment**

**3.9.1** The equipment is to be in accordance with the requirements in both

- Ch 1, Sec 3, [2.6] for the tug, and
- Pt D, Ch 14, Sec 2, for the barge, considering the barge as a ship of the size of the integrated tug/barge combination.

## **4 Integrated tug/barge combination with removable connection: stability, freeboard, design loads, hull scantlings and equipment**

### **4.1 Stability calculations**

**4.1.1** The integrated tug/barge combination is to comply with the applicable intact stability requirement in Part B, Chapter 3, considering the integrated tug/barge combination as a ship of the size of the combination.

### **4.2 Freeboard calculation**

**4.2.1** The freeboard is to be calculated for the tug and the barge considered as individual ships.

### **4.3 Still water hull girder loads**

#### **4.3.1 General**

The still water hull girder loads and the forces transmitted through the connection are to be calculated for each loading condition considering the integrated tug/barge combination as a ship of the size of the combination.

#### **4.3.2 Integrated tug/barge combination with removable flexible connection**

For integrated tug/barge combinations with removable flexible connection, the effect of the degrees of freedom of the connection on the still water hull girder loads in the combination may be taken into account (e.g. free pitch of the tug with respect to the barge implies vertical bending moment equal to zero in the connection).

### **4.4 Wave hull girder loads**

**4.4.1** The wave hull girder loads and the forces transmitted through the connection are to be calculated according to [3.4].

#### **4.4.2 Integrated tug/barge combination with removable flexible connection**

For integrated tug/barge combinations with removable flexible connection, the effect of the degrees of freedom of the connection on the wave hull girder loads in the combination may be taken into account (e.g. free pitch of the tug with respect to the barge implies vertical bending moment equal to zero in the connection).

## **4.5 Still water local loads**

**4.5.1** The still water local loads are to be calculated according to Pt B, Ch 5, Sec 5 and Pt B, Ch 5, Sec 6 or NR600, as applicable, for each loading condition and draught of the integrated tug/barge combination. The draught of the integrated tug/barge combination is to be taken not less than  $0,85 D$ , where  $D$  is the greater of the tug and the barge depths and not greater than the draught of the barge.

## **4.6 Dynamic local loads**

**4.6.1** The dynamic local loads are to be calculated according to Pt B, Ch 5, Sec 5 and Pt B, Ch 5, Sec 6 considering the integrated tug/barge combination as a ship of the size of the combination. The draught of the integrated tug/barge combination is to be taken not less than  $0,85 D$ , where  $D$  is the greater of the tug and the barge depths and not greater than the draught of the barge.

## **4.7 Hull girder strength**

**4.7.1** The longitudinal strength is to comply with Part B, Chapter 6, where the hull girder loads are those defined in [4.3] and [4.4].

### **4.7.2 Loading manual**

The loading manual is to include the items specified in [3.7.2].

## **4.8 Scantlings of plating, ordinary stiffeners and primary supporting members**

### **4.8.1 Integrated tug/barge combinations with removable rigid connection**

For integrated tug/barge combinations with removable rigid connection, the scantlings of plating, ordinary stiffeners and primary supporting members are to be in accordance with Part B, Chapter 7 or NR600, as applicable, where the hull girder and local loads are those defined in [4.3] to [4.6].

In any case, the scantlings of plating, ordinary stiffeners and primary supporting members of the tug and the barge are to be not less than those obtained according to Ch 1, Sec 3, for the tug alone, and Pt D, Ch 14, Sec 2 for the barge alone.

### **4.8.2 Integrated tug/barge combinations with removable flexible connection**

For integrated tug/barge combinations with removable flexible connection, the scantlings of plating, ordinary stiffeners and primary supporting members of the tug and the barge are to be not less than those obtained according to Ch 1, Sec 3 and Pt D, Ch 14, Sec 2 for the tug alone and the barge alone, respectively.

## **4.9 Equipment**

**4.9.1** The equipment is to be in accordance with [3.9.1].

## **5 Connection**

### **5.1 General**

**5.1.1** The components of the connecting/disconnecting system are to be fitted on the tug.

Where the connecting system is located on a tug superstructure, this is to be checked according to Pt B, Ch 11, Sec 5 or NR600, as applicable. The efficiency of the structural connection between this superstructure and the underlying hull structures is to be ensured.

**5.1.2** The connecting system is to comply with the following requirements:

- it is to be permanently locked in position, at sea, with remote indication and control on the bridge
- it is to remain locked in the event of damage to the control system. A local control is to be provided for enabling the disconnection from the coupler machinery room.

### **5.2 Scantlings**

#### **5.2.1 General**

The bow of the tug and the stern of the barge are to be reinforced in order to withstand the connection forces.

The structure reinforcements are to be continued in aft and fore directions of the integrated tug/barge combination in order to transmit the connection forces to the hull structure of the tug and the barge.

#### **5.2.2 Calculation of stresses in the connection**

The stresses in the connection are to be obtained by means of direct calculations, where the connection forces are to be obtained according to [3.3] and [3.4] or [4.3] and [4.4], as applicable.

When calculating the stresses in the connection, pre-loading from locking devices, if any, is to be taken into account.

For notch type connections, the analysis of the barge wing walls is to take into account the effects of bending moment, shear force and torque.

### **5.2.3 Shear check of the structural elements of the connection**

The shear stresses in the structural elements of the connection are to comply with the following formula:

$$\tau \leq 0,5 R_y$$

where:

$\tau$  : Shear stress, in N/mm<sup>2</sup>, to be obtained as a result of direct calculations.

### **5.2.4 Yielding check of the structural elements of the connection**

The Von Mises equivalent stresses in the structural elements of the connection are to comply with the following formula:

$$\sigma_E \leq 0,78 R_y$$

where:

$\sigma_E$  : Von Mises equivalent stress, in N/mm<sup>2</sup>, to be obtained as a result of direct calculations.

### **5.2.5 Deflections**

Deflections of the structural elements in the connection are to be obtained from direct calculations, to be carried out in accordance with [5.2.2] and submitted to the Society for review.

Deflection and pre-loading of the connection, if any, are to be considered in order to avoid hammering in the connection area.

## **6 Other structures**

### **6.1 Tug fore part**

#### **6.1.1 General**

For integrated tug/barge combinations with permanent connection or removable rigid connection, the tug fore structure is to be aligned with the barge aft structure in way of the notch or the dock bottom.

#### **6.1.2 Scantlings**

The scantlings of the fore part of the tug are to be in accordance with Part B, Chapter 7 or NR600, as applicable, considering the hull girder loads, the local loads and the connection forces defined in [3.3] to [3.6] for integrated tug/barge combinations with permanent connection or [4.3] to [4.6] for integrated tug/barge combinations with removable connection.

### **6.2 Tug aft part**

#### **6.2.1 Scantlings for integrated tug/barge combinations with permanent or removable rigid connections**

The scantlings of the aft part of the tug are to be in accordance with Pt B, Ch 11, Sec 3 or NR600, as applicable, considering this part as belonging to a ship of the size of the integrated tug/barge combination.

#### **6.2.2 Scantlings for integrated tug/barge combinations with removable flexible connections**

The scantlings of the aft part of the tug are to be in accordance with Pt B, Ch 11, Sec 3 or NR600, as applicable, considering the tug as an individual ship.

### **6.3 Barge fore part**

#### **6.3.1 Scantlings for integrated tug/barge combinations with permanent or removable rigid connections**

The scantlings of the fore part of the barge are to be in accordance with Pt B, Ch 11, Sec 1 or NR600, as applicable, considering this part as belonging to a ship of the size of the integrated tug/barge combination.

#### **6.3.2 Scantlings for integrated tug/barge combinations with removable flexible connections**

The scantlings of the fore part of the barge are to be in accordance with Pt B, Ch 11, Sec 1 or NR600, as applicable, considering the barge as an individual ship.

### **6.4 Barge aft part**

**6.4.1** For integrated tug/barge combinations with permanent connection or removable rigid connection, the barge aft structure is to be aligned with the tug fore structure in way of the notch or the dock bottom.

#### **6.4.2 Scantlings**

The scantlings of the aft part of the barge are to be in accordance with Part B, Chapter 7 or NR600, as applicable, considering the hull girder loads, the local loads and the connection forces defined in [3.3] to [3.6] for integrated tug/barge combinations with permanent connection or [4.3] to [4.6] for integrated tug/barge combinations with removable connection.

## **7 Hull outfitting**

### **7.1 Rudder and steering gear**

**7.1.1** The tug rudder and steering gear are to be in accordance with Pt B, Ch 12, Sec 1 and Pt C, Ch 1, Sec 14, respectively, considering the maximum service speed (in ahead and astern condition) of the tug as an individual ship and the maximum service speed (in ahead and astern condition) of the integrated tug/barge combination.

The characteristics and performance of the rudder and the steering gear are to ensure the manoeuvrability of the integrated tug/barge combination.

## **8 Construction and testing**

### **8.1 Test of the disconnection procedure of removable connection**

**8.1.1** Tests are to be carried out in order to demonstrate the capability of the tug to be safely disconnected from the barge within 5 min by one man.

These tests may be performed in harbour. However, additional information is to be submitted to the Society in order to demonstrate the capability of the tug and the barge of being safely disconnected and reconnected at sea. The operating procedure, indicating the maximum or pre-fixed sea states, is to be made available for guidance to the Master, as indicated in [1.3.1].

# Section 5 Testing

## 1 General

### 1.1 Application

1.1.1 The requirements of this Section apply as follows depending on the ship service notation:

- **tug**, mainly intended for towing services, are to comply with the requirements in Article [2]
- **salvage tug**, having specific equipment for salvage services, are to comply with the requirements in Article [2]
- **escort tug**, mainly intended for escort services such as for steering, braking and otherwise controlling escorted ships, are to comply with the requirements in Articles [2] and [3]

In addition, ships with the additional service feature **barge combined** are to comply with the applicable requirements in Ch 1, Sec 4.

## 2 General requirements

### 2.1 Bollard Pull test

2.1.1 The design bollard pull is to be verified by means of a bollard pull test performed in accordance with Ch 1, App 1.

2.1.2 For tugs capable of towing over the stern (ahead towing) as well as over the bow (astern towing), the bollard pull test is to be performed for both.

2.1.3 The measured Bollard Pull is to be not less than 3% lower and not more than 1% higher than the design bollard pull specified in Pt A, Ch 1, Sec 2, [4.10], otherwise the design bollard pull is to be amended accordingly.

In case the measured bollard pull is more than 1% higher than the design bollard pull, it is to be demonstrated by the Designer that the applicable hull structure and stability requirements of this Chapter are complied with.

2.1.4 The bollard pull test is to be carried out in the presence of a Surveyor of the Society. The test procedure location and conditions (see Ch 1, App 1, [3]) are to be agreed with the Society.

### 2.2 Towing winches

2.2.1 Towing winches, including the associated emergency release systems are to be load tested at the DL, as defined in Ch 1, Sec 3, [2.7.2], or at the BHL, as defined in Ch 1, Sec 1, [2.4], whichever is the greatest, unless a complete calculation verifying that all the load bearing parts of the winch comply with the requirements in Ch 1, Sec 3, [2.7.3] is submitted to the Society for information and is deemed acceptable.

Generally, load testing is to be conducted at a special facility equipped to generate the required line tension (e.g. maker's premises) and to be witnessed by the Society.

In case a towing winch is of conventional, proven design, for which load testing has been previously performed and deemed acceptable by the Society, it is sufficient to perform on board function testing in accordance with [2.2.2].

Note 1: The Society may request the winch manufacturer to supply records of the load tests performed.

2.2.2 Towing winches are to be function tested on board.

The correct functioning of the winch brake, the load carrying winch components and the associated supporting structure is to be demonstrated at a towline force equal to the design bollard pull, as defined in Ch 1, Sec 1, [2.1].

Winch operating modes to be function tested include hauling in and paying out of the towline, as well as braking.

Hydraulic and electrical systems shall be function tested on board in accordance with the Society's requirements for machinery and electrical systems.

### 2.3 Towing hooks

2.3.1 Towing hooks, including the associated emergency release systems, are normally to be load tested at the DL, as defined in Ch 1, Sec 3, [2.7.2], unless complete calculation verifying that the hook complies with the requirements in Ch 1, Sec 3, [2.7.5] is submitted to the Society for information and is deemed acceptable.

Generally, load testing is to be conducted at a special facility equipped to generate the required line tension (e.g. maker's premises) and to be witnessed by the Society.

In case a towing hook is of conventional, proven design, for which load testing has been previously performed and deemed acceptable by the Society, it is sufficient to perform on board function testing in accordance with [2.3.2].

Note 1: The Society may request the winch manufacturer to supply records of the load tests performed.

**2.3.2** Towing hooks are to be function tested on board. The correct functioning of the hook and the associated supporting structure is to be demonstrated at a towline force equal to the design Bollard Pull, as defined Ch 1, Sec 1, [2.1].

## **2.4 Emergency release system**

**2.4.1** For each emergency release system or type thereof, the performance requirements of Ch 1, Sec 3, [2.7.4] are to be verified either at the manufacturer's works or as part of the commissioning of the towing winch when it is installed on board. Where verification solely through testing is impracticable (e.g. due to health and safety), testing may be combined with inspection, analysis or demonstration on a case-by-case basis.

**2.4.2** The performance capabilities of the emergency release system are to be documented and made available on board the ship on which the winch has been installed.

**2.4.3** The full functionality of the emergency release system is to be tested as part of the shipboard commissioning trials to the satisfaction of the surveyor. Testing may be conducted either during a Bollard Pull test or by applying the towline load against a strong point on the deck of the tug that is certified to the appropriate load.

**2.4.4** Where the performance of the winch in accordance with Ch 1, Sec 3, [2.7.4] has previously been verified, the load applied for the installation trials is not to be lower than 30% of the BHL of the associated winch, as specified in Ch 1, Sec 1, [2.4].

**2.4.5** For novel or particular designs the emergency release systems are also to be load tested with the towline at an upward angle of 45 degrees with the horizontal plane at a towline force of not less than 50 per cent of the design bollard pull, as defined Ch 1, Sec 1, [2.1].

## **3 Additional requirements for escort tugs**

### **3.1 Escort performance simulations**

**3.1.1** Where the highest anticipated heeling moment is obtained from the results of a computer simulation program, the basic assumptions and theoretical models underlying the software are to be presented in detail to the Society. Items to be addressed include:

- hydrodynamic lift and drag computation (hull and appendices)
- modelling of thrust forces
- interaction effects between hull, skeg and (steerable) propulsion units
- flow separation effects
- water pile-up effects
- effects of waves and/or swell
- dynamic effects before a steady state is reached (e.g. during initiation and turning manoeuvres) and scaling effects (if any).

**3.1.2** A validation report, containing comparisons between simulation results and full scale and/or model test results, is to be presented to the Society.

**3.1.3** A clear description of the input and output data is to be provided, along with explanations on how the output data are obtained/calculated by the software.

**3.1.4** As a minimum, for each relevant loading condition (see Ch 1, Sec 2, [3.1.1]) the following set of results is to be provided in tabular form as function of the escort speed for the rated values of the steering force  $T_{Y,R}$  and the braking force  $T_{X,R}$ :

- Rated steering force  $T_{Y,R}$  or steering force  $T_Y$  corresponding to rated braking force  $T_{X,R}$ , as applicable
- Rated braking force  $T_{X,R}$  or braking force  $T_X$  corresponding to rated steering force  $T_{Y,R}$ , as applicable
- Corresponding towline force  $T_{ESC}$
- All corresponding forces acting in transverse direction (hydrodynamic, thrust and towline)
- Corresponding heeling angle
- Corresponding heeling moment
- Corresponding towline angle relative to the escorted ship (refer to  $\alpha$  in Ch 1, Sec 1, [2.7.2])
- Corresponding drift angle of the escort tug (refer to  $\beta$  in Ch 1, Sec 1, [2.7.2]).

Note 1: The highest anticipated values of the steering force, braking force, towline force and heeling moment do not normally all occur in the same condition (defined by the position of escort tug relative to the escorted ship and the drift angle), although more than one parameter may have its highest value in a particular condition. Hence it is necessary to consider at least two conditions: one for the highest anticipated steering force and one for the highest anticipated braking force. In case the highest anticipated heeling moment and/or towline force do not occur in either one of these two conditions, the relevant conditions are to be added.

**3.1.5** It is recommended that the results of the escort performance simulations are presented in the form of diagrams showing the envelope of the (steady state) combinations of steering and braking forces obtained from the simulations. Such diagrams should cover the applicable escort speed range, with a recommended step of 2 knots.

## **3.2 Escort performance trials**

**3.2.1** Escort performance trials at full scale or model scale may be carried out in order to obtain the characteristics of escort tugs defined in Ch 1, Sec 1, [2.7].

**3.2.2** The trials are to cover the applicable range of loading conditions and escort speeds.

**3.2.3** The following documents are to be submitted for information prior to testing:

- Relevant loading conditions, defined by draught (or displacement) and trim, for which the tug is designed to perform escort services
- Applicable range of test speeds of the escorted ship: the speed is defined as the relative speed with respect to the sea, taking into account current effects
- Main propulsion characteristics, in particular power and maximum orientation angle of the rudder(s) (propellers);
- Preliminary calculation of the rated steering force  $T_{Y,R}$ , rated braking force  $T_{X,R}$  and rated steady towline force  $T_{ESC,R}$  as defined in Ch 1, Sec 1, [2.7], as well as the corresponding heeling moments and heeling angles, for the range of test speeds
- Calculation of the route deviation of the escorted ship (for testing purposes the escorted ship is to be selected so that the route deviation induced by the tug is kept reasonably small)
- Preliminary stability calculations for the above mentioned conditions
- Escort towing arrangement plan, including the load cell and specification of the components
- Documentation relevant to the Bollard Pull test, see [2.1.1].

**3.2.4** Prior to commencing the escort performance trials the following data are to be recorded:

- Wind speed and direction
- Sea state, including significant wave height and peak period
- Current speed and direction
- Water depth
- Loading condition of the escort tug: draught (or displacement) and trim
- Loading condition of the escorted ship.

**3.2.5** Testing is to be performed over the applicable range of towline angles as defined in the escort towing arrangement plan. The length of the towline and the angle of the towline with the horizontal plane are to represent a typical operating condition.

**3.2.6** As a minimum, the following data is to be collected during testing for post-processing and analysis:

- Towline force (tension)  $T_{ESC}$
- Towline angle  $\alpha$ , as defined in Ch 1, Sec 1, [2.7.2]
- Drift angle  $\beta$ , as defined Ch 1, Sec 1, [2.7.2]
- Heeling angle of the escort tug
- Towline length and angle of towline with the horizontal plane.

**3.2.7** It is also recommended to measure the following data:

- Power setting and orientation angle of rudder(s) (propellers) of the escort tug
- Time needed to make the tug swing from the equilibrium position to its mirror position (see Ch 1, Sec 1, Fig 2).

**3.2.8** For each combination of loading condition and test speed:

- The rated steering force  $T_{Y,R}$  and rated braking force  $T_{X,R}$  are to be calculated on the basis of the corresponding measured steady towline force  $T_{ESC}$  and the associated measured towline angle, drift angle and the angle between the towline and the horizontal plane.
- The maximum heeling arm is to be calculated on the basis of the corresponding measured steady towline force  $T_{ESC}$ , as defined in Ch 1, Sec 1, [2.7], the associated measured heeling angle and the GZ curve applicable to the loading condition considered.

Note 1: The GZ curve is to be based on the escort tug in upright position before commencing the escort operation.

**3.2.9** As a minimum, for each tested loading condition the following set of results is to be provided in tabular form as function of the escort speed for the rated values of the steering force  $T_{Y,R}$  and the braking force  $T_{X,R}$ :

- Rated steering force  $T_{Y,R}$  or steering force  $T_Y$  corresponding to rated braking force  $T_{X,R}$ , as applicable
- Rated braking force  $T_{X,R}$  or braking force  $T_X$  corresponding to rated steering force  $T_{Y,R}$ , as applicable
- Corresponding towline force  $T_{ESC,R}$

- Corresponding heeling angle
- Corresponding heeling moment
- Corresponding towline angle relative to the escorted ship (refer to  $\alpha$  in Ch 1, Sec 1, [2.7.2])
- Corresponding drift angle of the escort tug (refer to  $\beta$  in Ch 1, Sec 1, [2.7.2]).

Note 1: The highest anticipated values of the steering force, braking force, towline force and heeling moment do not normally all occur in the same condition (defined by the position of escort tug relative to the escorted ship and the drift angle), although more than one parameter may have its highest value in a particular condition. Hence it is necessary to consider at least two conditions: one for the highest anticipated steering force and one for the highest anticipated braking force. In case the highest anticipated heeling moment and/or towline force do not occur in either one of these two conditions, the relevant conditions are to be added.

**3.2.10** For model testing, due consideration is to be paid to scale effects for establishing the escort tug characteristics at full scale from the model test results.

### **3.3 Escort equipment testing**

#### **3.3.1 Load testing**

Escort winches, including the associated emergency release system are normally to be load tested at the DL, as defined in Ch 1, Sec 3, [3.2.2], or the BHL, as defined in Ch 1, Sec 1, [2.4], whichever is the greatest, unless a complete calculation verifying that all the load bearing parts of the winch comply with the requirements in Ch 1, Sec 3, [3.2.3] is submitted to the Society for information and is deemed acceptable.

Generally, load testing is to be conducted at a special facility equipped to generate the required line tension (e.g. maker's premises) and to be witnessed by the Society.

In case an escort winch is of conventional, proven design, for which load testing has been previously performed and deemed acceptable by the Society, it is sufficient to perform on board function testing in accordance with [3.3.2].

Note 1: The Society may request the winch manufacturer to supply records of the load tests performed.

#### **3.3.2 Function testing**

In general, the proper functioning of the towing equipment used for escort services is to be verified by on board testing and to be witnessed by the Society. Function testing is to be performed both for normal operating conditions and in accordance with the escort towing arrangement plan as well as in emergency conditions (emergency release, failure of main power supply). The safe operation of the escort winch from all control stations is to be demonstrated.

Escort winches are to be function tested on board.

The correct functioning of the winch brake, the load carrying winch components and the associated supporting structure is to be demonstrated at a towline force equal to the design Bollard Pull, as defined in Ch 1, Sec 1, [2.1].

The emergency release systems are to be function tested according to [2.4].

Winch operating modes to be function tested include hauling in and paying out of the towline, braking and the active pay-out and haul-in system when fitted (see Ch 1, Sec 3, [3.2.3]).

Hydraulic and electrical systems shall be function tested onboard in accordance with the Society's requirements for machinery and electrical systems.

# Appendix 1      Bollard Pull Trials

## 1 General

### 1.1 Purpose

1.1.1 The purpose of this Appendix is to:

- ensure that the reported bollard pull figure represents the realistic performance of the vessel that can be met in service conditions at an acceptable level of accuracy, irrespective of the specific conditions met during the execution of the bollard pull trial that are known to affect the vessel's performance
- facilitate a repeatable performance figure in accordance with clear definitions.

### 1.2 Application

1.2.1 This Appendix applies to ships with multiple propulsors, with or without nozzles.

1.2.2 This Appendix does not apply to the following ships:

- ships whereby propulsors are mounted under a large flat bottom (e.g. specialised ships with multiple thrusters for dynamic positioning operation)
- single propulsor towing vessels.

## 2 General requirements

### 2.1 Bollard pull trial

2.1.1 A bollard pull trial is a full scale test with a vessel to determine the horizontal towline force which the main propulsion systems can generate at a vessel speed equal to zero knots.

The bollard pull trial is to be executed in unrestricted and calm water, without external influences such as wind and current. One end of the towline is to be attached to a dedicated towing point on the vessel (e.g. towing winch or hook) and the other end is to be attached to an external strongpoint (fixed bollard ashore, seabed secured anchor or otherwise). The towline force is to be measured by a calibrated load cell which is normally fitted between the towline and the external strongpoint. The engine power at which the bollard pull trial is executed is to be measured and reported in conjunction with the steady state line pull.

### 2.2 Bollard pull trial conditions

2.2.1 The vessel's bollard pull is the towing force provided by the specified propulsors, recorded as being maintained in a steady state condition for a duration of not less than 5 minutes and performed at rated power as defined in [2.3.1] at a speed through water of zero knots.

2.2.2 The operating profile for the bollard pull trial condition is to represent normal service conditions, such that sufficient auxiliary power is available for normal and safe operation of the vessel.

2.2.3 Engine speed and brake power are to be measured simultaneously with towline force during the bollard pull trial and are to be reported on the test report (see [8]).

2.2.4 Bollard pull trials conducted in hybrid mode, whereby batteries or other supplementary power devices are used to provide additional power for a limited period of time, are to be separately listed as "Hybrid Bollard Pull (HBP)", and have an associated time of validity for each operational mode of such HBP.

### 2.3 Engine rating

2.3.1 The bollard pull trial is to be performed up to the maximum power of the engines which is available in service. Maximum power means:

- a) For marine diesel and/or gas engines: The maximum brake power that the engine can deliver in service, and that corresponds to the power recorded during 100% load testing at the Factory Acceptance Tests of the engine.
- b) For electric propulsion machines: Design power for normal service conditions defined for the electric motor, specified on the motor name plate.
- c) For Hybrid propulsion systems (diesel or gas mechanical propulsion with electrical power take-in):  
The sum of the power defined in item a) and item b) above for all propulsion machines.

d) In case the design power of the propeller is less than the maximum power of the engine(s), the maximum power is to be taken as the design power of the propeller.

**2.3.2** The engine speed is to be within the Original Equipment Manufacturer (OEM) specified speed range, which is to be consistent with the type approval of the engine and the certification of the propulsion train (e.g. Torsional Vibration Calculations).

**2.3.3** The available output power has to match the conditions stated in [2.2.2].

**2.3.4** The propulsion and engine configuration used during the bollard pull trial is to be stated on the certificate. This includes a specification of the power generation systems (output of engines / fuel cells / battery banks etc.), propulsion motors (mechanical, electrical, hybrid) and propulsion systems (number of propellers, use of (retractable) thrusters etc.) used during the bollard pull trial.

## 2.4 Steady state phase

**2.4.1** The steady state phase of the bollard pull trial is the time interval during which a steady towline force is measured. The steady state phase represents the highest consecutive 5 minute period, logged as per [4.4] during a 15 minute trial under effectively constant trial conditions stated in this trial test procedure. The definition of the highest consecutive 5 minutes period is to be in accordance with [7.2].

**2.4.2** The 15 minute trial window starts after the initial build up and subsidence in line tension of associated dynamic effects, as shown in Fig 1. During this period only small changes in steering angles associated with maintenance of vessel position are permitted. Strong sway motions are to be avoided.

**2.4.3** In Hybrid mode (Diesel/Diesel-Electric power plus that available from the batteries) the available battery power for propulsion might decrease during the execution of the bollard pull trial. In this case the reported bollard pull is to be defined by calculating the mean power and towline force over a period of 5 minutes as minimum, and noted down as a separate entry in the bollard pull certificate as 'Hybrid Bollard Pull (HBP)' with an associated maximum time for which that HBP rating is valid in service. The designed power availability duration is to be provided by the designer of the propulsion system.

**Figure 1 : Schematic representation of towline force as a function of time during bollard pull trial**

## 3 Requirements for the trial site

### 3.1 Water depth and radius

**3.1.1** The minimum total water depth, which is to be maintained at least in a radius of 2 times the ship's length around the towing vessel, is 4 times the propeller immersion depth ( $h_{imm}$ ).

**3.1.2** The propeller immersion depth is the distance between the water surface and the centre of the propulsion unit, as indicated in Fig 2. For propulsion systems with vertical axis, the centre line of the jet-stream is used, i.e. the middle of the blades as indicated in Fig 3.

**3.1.3** The water depth during the trial is to be recorded on the bollard pull trial report.

### 3.2 Ship to shore distance

**3.2.1** The minimum distance between quay and centre of the propeller closest to shore is 50 times the propeller diameter to avoid water circulation affecting the bollard pull.

Figure 2 : Definition of propeller immersion depth and ship to shore distance

Figure 3 : Definition of immersion depth and ship to shore distance for a propulsion system with vertical axis

### 3.3 Current

3.3.1 The current speed is to be less than 0,5 knots from the bow or sides. If the current is approaching the vessel from the stern, the current is to be less than 0,3 knots. When the bollard pull trial is performed with side current, the towing vessel is to be allowed to shift position by letting it move with the current and not to steer against it, while maintaining heading relative to the towline. It is not allowed to fix the position of the towing vessel by cables, other vessels or other means. Bow thrusters may be used to hold position if this does not negatively affect the power available for main propulsion, see also [6.1.1].

### 3.4 Water density

3.4.1 Water density is to be recorded on the bollard pull trial report. No corrections for water density are to be applied.

### 3.5 Waves

3.5.1 The bollard pull trial is to be conducted in calm water conditions as far as possible. In any case, the maximum significant wave height encountered during the bollard pull trial is not to exceed 0,5 m. No corrections for waves are to be applied.

### 3.6 Wind

3.6.1 Transverse wind may cause sway movements that have to be compensated by applying rudder. This may degrade vessel bollard pull performance. Wind speed during the bollard pull trial is to be as low as possible but not more than 10m/s (5 Beaufort scale).

### 3.7 Outside temperature

3.7.1 It is recommended to perform trials in non-tropic conditions (air temperature  $< 45^{\circ}\text{C}$ , water temperature  $< 32^{\circ}\text{C}$ ) to avoid engine performance degradation. No corrections for environmental conditions are to be applied.

Note 1: It is recommended to log relevant engine parameters during the trials.

### 3.8 Towline

3.8.1 A torsion-free towline (e.g. synthetic) is recommended to ensure that the load cell measures, as intended, in direct tension.

### 3.9 Vessel orientation relative to the quay

3.9.1 The heading relative to the quay side (assuming solid quay sides) is to be chosen such that propeller wash can freely move without being re-directed in the direction of the vessel. Towing is not to be done in enclosed harbours, as recirculation is more likely to occur, resulting in unsteady performance. Minimum line length, water depth and associated radius are to be observed. Fig 4 presents examples of acceptable and unacceptable vessel orientations relative to the quay.

## 4 Instrumentation

### 4.1 Load cell

4.1.1 The load cell is to be installed between the strongpoint and towline, either on board or on shore. The load cell is to have a digital output and be capable of sampling at a rate of 1 Hz or faster.

4.1.2 To maximise accuracy the following conditions are to be met:

- a) The load cell calibration and certificate is not to be older than 12 months and is to be provided with the bollard pull certificate. The calibration procedure of the load cell is to be in accordance with the requirements stated in [4.1.3].
- b) The load cell is to have an uncertainty in accordance with an ISO 7500-1 Class 1 machine, which is to be stated on the load cell calibration certificate.
- c) When a steel stranded wire is used during the bollard pull trial, the load cell is to be proven to be torsion insensitive in accordance to the requirements in [4.1.4].
- d) Spacer rings are to be installed between load cell and shackle ears as indicated in Fig 5 to avoid misalignments during testing. Spacer rings are plastic rings specially made to fill the gaps between shackle ears and load cell, and thus centrally align the load cell.
- e) Shackle pins are to be free from surface imperfections such as dents or bend.
- f) The towline is to be connected first to a shackle, which is consecutively connected to a second shackle that holds the load cell (see Fig 5).
- g) When a load pin shackle is used, a centralising bobbin as indicated in Fig 6 is to be used in order to ensure correct alignment, in addition to additional shackles. The towline is not to be connected directly to the load shackle.
- h) The load cell / load shackle and connected shackles are not to touch the quayside edge or ground (see Fig 7) to avoid misalignment, bending and corresponding offsets in measurements. The shackles denoted by 'Additional Shackles' in Fig 5 are allowed to touch the ground if not possible otherwise.
- i) The test is to be conducted at the same temperature as during the calibration of the load cell, within a tolerance of  $\pm 10^{\circ}\text{C}$ . If this condition cannot be fulfilled, the load cell is to be certified to be suitable for the temperature during the trial.
- j) The load cell is to be set to zero prior to the trial, when the towline is not yet connected and free from any load. After the trial, when the load cell is free from any load, the reading is to be checked again.

**Figure 5 : Recommended load cell arrangement with spacer rings and additional shackles**

Figure 6 : Recommended load shackle arrangement with centralising bobbin and shackles

Figure 7 : Load cell touching ground, causing bending moments and misalignment of the load cell

Figure 8 : Schematic of calibration procedure according to ISO 7500-1

#### 4.1.3 Load cell calibration requirements

Load cells are to be calibrated according to ISO 7500-1 (“standard calibration”). The load cell is to be calibrated with the same shackle pin diameter as it is used during bollard pull testing. If calibration is done on a horizontal calibration machine, spacer rings are to be used to improve alignment.

Fig 8 presents a schematic of the calibration procedure, which consists of the following steps in chronological order:

- pre-load to the maximum of the load cell's scale
- pre-load to the maximum of the load cell's scale
- pre-load to the maximum of the load cell's scale
- stepwise load increase comprising at least five discrete force levels at equal intervals between 20% and 100% of the maximum range of the scale
- rotation of the load cell by 180 degrees, around the X, Y or Z axis and a rotation of the shackle pins connected with the load cell by 30 degrees
- repetition of steps c- e for two more times.

For each discrete force, the arithmetic mean of the values obtained for each series of measurements is to be calculated. From these mean values, the relative accuracy error and the relative repeatability error are to be calculated. The preload runs are to be omitted.

#### 4.1.4 Torsional insensitivity

When a steel stranded wire is used during the bollard pull trial, the load cell is to be proven to be torsional insensitive to a torsion value  $T$ , in kN.m, of at least:

$$T = C_1 \cdot BP_{design} \cdot D_{line}$$

Where:

$BP_{design}$  : Vessel's design bollard pull at 100% engine load, in kN

$C_1$  : Towline wire torsion factor ( $c_1 = 0,07$  for 6/36 steel stranded wires, unless documented otherwise)

$D_{line}$  : Diameter of the towline, in m.

The insensitivity of the load cell is to be proven by the load cell manufacturer by means of systematic tests. When a rotation resistant rope is used (e.g. some synthetic ropes), this requirement is not applicable.

## 4.2 Engine speed measurement

4.2.1 The engine speed is to be continuously measured using a pickup sensor or via the engine control system of the engine's manufacturer and recorded digitally during the trial.

## 4.3 Power measurement

4.3.1 Engine brake power is to be measured using a dedicated shaft torque / engine speed measurement system for first and second ships of a series. Torque measurement systems based on strain gauges are most common, but other techniques, e.g. using optical deflection measurement, are also allowed. Engine speed can be measured using an optical or magnetic pickup sensor.

4.3.2 The power measurement is to represent engine brake power as tested during shop tests. For third and further of series the engine control system can be used provided its accuracy has been verified based on the first two vessels of a series. The dedicated shaft torsion/engine speed sensor reading is leading for the engine power.

4.3.3 The uncertainty of the engine power measurement should be according to ITTC standard 7.5-04-01-01.1 (total bias uncertainty +/-2%).

4.3.4 Shaft material properties, i.e. the G-Modulus, are to be fully described and documented by the Shipbuilder. If no certificate based on an actual shaft torsional test is available, a G-Modulus of 82400 N/mm<sup>2</sup> is to be used for regular shaft steel.

4.3.5 If power cannot be measured directly on the engine's output shaft, it may be calculated by measuring power on the propeller shaft and correcting for power losses between engine flywheel and measurement point. These losses are to be confirmed by their respective manufacturer and stated in the trial report. Suggested measurement locations for various propulsion configurations are included in Note 1.

Note 1: The objective of the power measurement is to measure engine brake power. For ships with a diesel direct propulsion layout (see Fig 9), the shaft power measurement system can be installed directly on the output shaft of the engine, as close to the engine as possible to avoid shaft losses.

For ships with multiple engines coupled to a gearbox (see Fig 10), where there is insufficient space between main engine and gearbox to install a shaft power meter shaft power is to be measured on the propeller shaft. If a PTO is installed, it is to be declutched or unloaded. Auxiliaries connected to the gearbox or PTO that are necessary for the normal operation of the engine such as cooling or oil circulation pumps are to remain operational during the test. The main engine brake power is to be calculated by calculating the gearbox losses and adding them to the measured shaft power.

For ships with a hybrid propulsion system (see Fig 11), where both an electric motor and combustion engine provide power to a single shaft, the combined power is to be measured. Both the combustion engine and PTI are not to run at a rating higher than 100% load.

For diesel electric ships (see Fig 12) the design power of the electric motor is the limiting factor for power output. The brake power of the electric motor is to be determined using a power measurement system on the output shaft. If this is not possible, the power to the electric motor is to be determined with a power spectrum analyser or other means.

4.3.6 In case carbon shafts are used and no steel section is available for the installation of a power measurement system, the engine rating during the bollard pull trial is to be determined on a case by case basis with the parties involved. Without a direct measurement of the shaft brake power, no power is to be reported on the trial certificate.

4.3.7 The power meter zero setting is to be done according to its maker's instructions prior to the trials.

Figure 9 : Power measurement on a diesel direct propulsion arrangement

Figure 10 : Power measurement on a geared diesel direct propulsion arrangement with PTO (declutched)

Figure 11 : Power measurement on a Hybrid propulsion arrangement

Figure 12 : Power measurement on a Diesel-Electric propulsion arrangement

#### 4.4 Data logging

**4.4.1** The readings of the towline force, engine speed and shaft torque are to be recorded continuously and automatically on a digital system with a sample frequency of at least 1 Hz in order to capture the natural fluctuations in the forces. A higher sampling rate is recommended to identify measurement errors and dynamic effects more clearly. Each load cell reading is to be tagged with a time stamp and synchronised with the power measurements on the vessel.

**4.4.2** Measurement is to commence prior to the bollard pull trial, so that the steady state phase and no-load reading can be identified during post processing of the data.

**4.4.3** The following data are to be recorded at the beginning of the trial: Draft and trim, wind, waves, current, water depth, water density, distance to quay, fuel quality, towline diameter, length, and material. If conditions vary during the test, the variances at completion of the trial are also to be recorded.

## **5 Trial preparation**

### **5.1 Draught and trim**

**5.1.1** The draught and trim of the towing vessel are to be representative for typical service conditions and are to be stated on the certificate.

### **5.2 Propellers**

**5.2.1** The propellers used during the trial are to be the same as used for service conditions. It is strongly recommended to clean/polish the propellers immediately before trials, as blade roughness and fouling negatively affects thrust and power efficiency.

### **5.3 Fuel**

**5.3.1** The fuel used during the trial is to be representative for the normal service operation of the vessel. The fuel type and calorific value are to be stated on the certificate.

## **6 Trial execution**

### **6.1 General**

**6.1.1** During the trial a visual observation of the load cell reading on the bridge is recommended, so that the commencement of the steady state phase can be judged. Minimal sway motion is recommended to avoid performance drops. The use of a bow thruster is allowed to maintain position during the trial, when this does not affect the power available to the main propulsion system. Stern side thrusters are not to be used unless it is demonstrated that they do not affect the inflow velocity.

**6.1.2** At least four power settings are to be tested between 25% and 100% load: maximum power in accordance with [2.3.1], 85%, 60% and 40% of the rated power are recommended.

### **6.2 Steps to be performed**

**6.2.1** The following steps are to be performed for the bollard pull trial:

- a) Make sure the load cell, wireless indicator, test location and environmental conditions are according to the requirements stated in this Appendix.
- b) Tare the load cell (set to zero) prior to the test when the load cell and shackles are not yet connected.
- c) Connect load cell and towline. Slowly put tension on the towline. Ensure correct alignment of the load cell and shackles. Re-align when necessary.
- d) Increase tension on the towline until the maximum power, as defined in [2.3.1] is reached. Check power rating using the engine shaft power meter.
- e) When the vessel has a stable position and heading and line fluctuations are constant, start a 15 minute run recording the towline force, power and engine speed.
- f) Reduce power to other engine ratings (85%, 60% and 40% recommended). When the vessel is stable and line fluctuations are constant, start measurement. The minimum measurement period is hereby 5 minutes. A longer period (15 min) is recommended to capture a more stable performance.
- g) Repeat steps b) to f) for the other direction of towing (stern / bow) if applicable.

**6.2.2** During the test a log sheet is to be filled in. Minimum reporting requirements are listed in Article [8].

## **7 Data analysis**

### **7.1 Validation of recorded data**

**7.1.1** The logged towline force is to be plotted on a time scale and evaluated for measurement errors, outliers and to identify the steady state period. The towline force is to have a smooth, sinusoidal character as a function of the mass-spring system behaviour of the towline and vessel. If the data quality is poor, indicated by stepwise data, missing data and large non-periodic fluctuations, the bollard pull trial is to be repeated.

### **7.2 Identification of steady state performance**

**7.2.1** The determination of the highest consecutive 5 minute period of stationary performance is to be performed after the trial using the logged data. The calculation of the average bollard pull over the 5 minute period is performed using a normal arithmetic average over the selected period (using at least 300 consecutive data points). Clear outliers due to sensor errors are to be removed prior to calculation of the average. The average of the propulsion power and engine speed is to be determined over the same 5 minute data period.

## 8 Reporting

### 8.1 Trial report requirements

**8.1.1** The bollard pull test certificate is to be accompanied with a trial report. The report is to contain at least the following information:

- characteristics of the vessel, propulsion system and main engines/propulsion motors, including Original Equipment manufacturer (OEM)-defined consecutive periods of available maximum power
- the propulsion and engine configuration used during the bollard pull trial. This includes a specification of the power generation systems (output of engines / fuel cells / battery banks etc.), propulsion motors (mechanical, electrical, hybrid) and propulsion systems (number of propellers, use of retractable thrusters etc.) used during the bollard pull trial
- used method of power measurement and used mechanical/electrical efficiency if applicable
- fuel characteristics
- location, water depth and line length during the trial
- environmental characteristics: ambient temperature, wave height, water density, wind and current speed and direction relative to the vessel
- towline and load cell-shackle arrangement
- calibration certificate of load cell
- log sheet with results of each 5 minute trial, including power, engine speed and line pull for all tested load cases
- name and contact information for persons performing and witnessing the trial on behalf of shipyard, owner and main component manufacturers
- for re-evaluation trials at part-load operation: the original bollard pull - shaft power curve including the measured points at part load, and the calculation method to derive to the resulting extrapolated bollard pull at maximum power.

## 9 Part load bollard pull re-evaluation trials

### 9.1 Application

**9.1.1** A new bollard pull trial is required:

- for class renewal; or
- in case of overhaul or alteration of the engines and/or propulsion system.

In those cases where a suitable bollard is unavailable, e.g. because the available bollard has an insufficient safe working load, bollard pull trials may be performed at reduced load. These trials are no substitute for full bollard pull trials, but can be used to evaluate the validity of previous test results performed at 100% load. This Article lists the prerequisites for such trials, the test and analysis procedure.

### 9.2 Trial overview

**9.2.1** A full-range bollard pull trial as described in Article [6] provides a bollard pull versus shaft power performance curve over the complete power range. This curve is to be evaluated in the performance re-evaluation trials at part load. The performance re-evaluation is to be done in three steps:

- Step 1: The capabilities of the engines after overhaul are evaluated, by testing each individual prime mover separately at the highest power the engine can deliver (in compliance with [2.3]). The engine power is hereby logged.
- Step 2: A bollard pull trial is performed at the maximum safe working load of the bollard with all prime movers in operation, but at part load.
- Step 3: The measured bollard pull is compared with the original performance curve of the vessel. If the measurement results are within  $\pm 3\%$  the original curve, the original curve is still valid and can be intersected at the combined maximum power measured in step 1. If the deviations are larger the curve is to be shifted accordingly.

### 9.3 Prerequisites

**9.3.1** Bollard Pull Performance Re-evaluation Trials are only valid when the following conditions are met:

- a) Bollard pull trials have been performed in the past where a minimum of 4 power settings have been tested between 25% and 100% rated power according to this Appendix, whereby delivered power is measured using a dedicated power measurement system on the drive shafts.
- b) The maximum rated power of each prime mover can be tested separately. For ships with combinator mode and father/son arrangement, a temporary change in engine speed-pitch may be necessary to avoid overloading the engine when testing one engine per shaft.
- c) The same propeller and nozzles as during the initial full load bollard pull trial are in place.
- d) The propellers are re-conditioned (polished) to the same condition as for the initial full load bollard pull trial according to the relevant ISO propeller class or similar.

- e) The propeller nozzles have no surface damage and are in the same condition as for the initial full load bollard pull trial.
- f) A bollard is available with a safe working load that exceeds the power rating of each individual prime mover, so that the maximum power of each prime mover can be safely tested. For example, for tugs with a father/son engine arrangement, with two engines providing 60% / 40% of the total available power, the bollard is to be strong enough to hold the bollard pull obtained at 60% of the total available power.

**9.3.2** If the above conditions cannot be met, normal bollard pull trials according to Article [6] are to be performed.

**9.4 Step 1: Evaluation of engine power**

**9.4.1** The engine capability of each prime mover is determined by loading the engine up to 100% load in a bollard pull setup (zero ship speed). The following procedure is to be followed:

- a) Tare the shaft power measurement system according to manufacturer recommendations
- b) Make sure the test location and environmental conditions are according to the requirements stated in this Appendix
- c) Slowly put tension on the towline
  - for vessels with multiple prime movers per propeller: engage one prime mover per shaft. Operate both shafts for symmetric operation (see Fig 13, left arrangement)
  - for vessels with 2 propellers and two engines: disengage one propulsion unit so only one propeller is in operation. The other propeller may weather vane or stand still (see Fig 13, right arrangement)
  - for vessels with multiple propellers: engage one prime mover
- d) Increase power up to the power as stated in [2.3]
- e) Stabilise vessel and start a 5 minute power measurement. Bollard pull is not measured. For ships with one propeller in operation strong rudder usage may be necessary to stabilize vessel
- f) Repeat step c) and d) to test the other prime movers
- g) Calculate the total power capacity,  $P_{Total}$ , of the main engines using:

$$P_{Total} = \frac{\sum_{i=1}^n P_{ME^{(i)}}}{\eta_{gear}}$$

Where:

- $P_{Total}$  : Total available power for all prime movers combined
- $P_{ME}$  : Engine power for each 'i' prime mover as obtained in step (d) and (e)
- $\eta_{gear}$  : Gearbox efficiency ( $\eta_{gear} = 1$  when there is no gearbox between measurement system and engine output shaft). The same gearbox efficiency as used during the new-build bollard pull trials is to be used.

**Figure 13 : Propulsion configurations for individual engine performance testing**

## **9.5 Step 2: Re-evaluation of propulsion efficiency**

**9.5.1** The propulsion efficiency curve (towline force versus shaft power) is to be evaluated at the maximum safe working load of the bollard. The following procedure is to be followed:

- a) Make sure the load cell, wireless indicator, test location and environmental conditions are according to the requirements stated in this Appendix.
- b) Tare the load cell prior to the test when the load cell and shackles are not yet connected.
- c) Ensure correct alignment of the load cell and shackles. Re-align when necessary.
- d) Engage all engines and propellers and increase power until towline tension has reached maximum safe working load of bollard.
- e) When the vessel is stable and line fluctuations are constant, start a 15 minute run recording the bollard pull, power and engine speed in accordance with the procedure documented in [6].
- f) Reduce power to 40% of the total available power. When the vessel is stable and line fluctuations are constant, start a new 15 minute run recording the bollard pull, power and engine speed.
- g) Repeat above steps for astern operation if applicable.
- h) Plot measurement results in the original propulsion efficiency curve.

Steps a) to f) are to be performed in accordance with the normal procedures and environmental restrictions as documented in this Appendix.

## **9.6 Step 3: Re-evaluation of bollard pull capability at available power**

**9.6.1** The offset between the measured data points and the original performance is to be assessed through the towline pull ratio,  $\alpha_{BP}$ :

$$\alpha_{BP} = \frac{BP_{Evaluate}}{BP_{Original}}$$

Where

$BP_{Evaluate}$  : Bollard pull-power performance curve obtained during re-evaluation trials, (see [9.5])

$BP_{Original}$  : Original Bollard pull-Power performance curve from full power trials.

To obtain the bollard pull at  $P_{Total}$  either the original performance curve is used, or the curve is first shifted:

- a) if  $0,97 < \alpha_{BP} < 1,03$

the original BP-Power curve is used to intersect the new bollard pull capability at  $P_{Total}$ , as shown in Fig 14

- b) if  $\alpha_{BP} > 1,03$

the curve is shifted vertically by multiplying the curve with  $\alpha_{BP}$  to match the data points, as depicted in Fig 15. It is to be demonstrated that the applicable hull structure and stability requirements are complied with.

- c) if  $\alpha_{BP} < 0,97$

the curve is shifted vertically by multiplying the curve with  $\alpha_{BP}$  to match the data points, as depicted in Fig 15.

If  $P_{Total}$  is more than the highest power rating from the original BP-trial, the bollard pull is determined from the highest rating from the original BP-trial. No extrapolation beyond the original curve is allowed.

For tests in ahead direction the curve for ahead trials is to be used; for astern trials the curve for astern direction.

## **9.7 Presentation of results**

**9.7.1** The original Shaft power - Bollard pull curve including its measurement points, and the method to derive to the resulting extrapolated bollard pull at rated power, is to be clearly documented.

Figure 14 : Procedure for estimating bollard pull at  $P_{Total}$  from part load trials

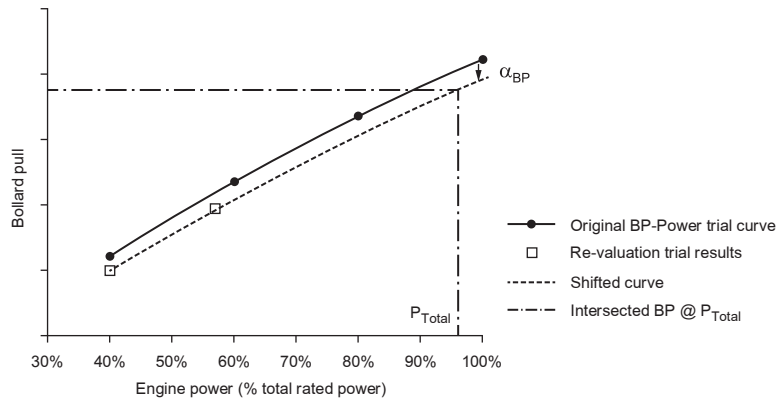

Figure 15 : Procedure for estimating bollard pull at  $P_{Total}$  when  $\alpha_{BP} < 0,97$  or  $\alpha_{BP} > 1,03$

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **anchor handling** as defined in Pt A, Ch 1, Sec 2, [4.11.2].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1 and specific requirements for testing as defined in Ch 2, Sec 5.

**Table 1 : Applicable requirements**

### 1.2 Definitions

#### 1.2.1 Anchor handling winch

Winch dedicated to anchor handling operations.

#### 1.2.2 Wire

A dedicated line (wire rope, synthetic rope or chain cable) used for the handling of anchors by means of the anchor handling winch.

#### 1.2.3 Stern roller

A roller or similar equipment arranged at the aft boundary of the ship to launch and recover the anchors.

The stern roller is designed to adequately support the working line during the launching/recovering of anchors.

#### 1.2.4 Wire stopper (i.e. shark jaw, karm fork)

Deck equipment designed to temporary secure the inboard end of the working line.

#### 1.2.5 Guide pin

Deck equipment guiding the working lines to the intended sectors

#### 1.2.6 Design bollard pull (BP)

The design bollard pull  $T_{BP}$ , in kN, is the maximum sustained towline force the vessel is capable of generating at zero forward speed, as defined in Ch 1, Sec 1, [2.1.1].

### 1.2.7 Safe working load (SWL)

Load to be specified by the applicant of each shipboard fitting. Individual SWLs are to be marked on each concerned fitting.

### 1.2.8 Loads on anchor handling winch

- Rated line pull (RP): Maximum rope tension, in kN, that the winch can haul at the relevant layer, in normal service condition, when the drum rotates at its maximum service speed. The rated line pull is defined for a specific reeled layer which is to be specified by the party applying for classification. The reeled layer may be the first layer (in contact with the drum) or the outer layer.
- Brake holding load (BHL): Maximum rope tension, in kN, with holding brake activated
- Rendering load (RL): Maximum rope tension, in kN, at the drum exit when the drum just starts rotating in the opposite direction of the applied driving torque with a first layer of rope wound on the drum.

## Section 2                      General Arrangement

### 1 General

#### 1.1 Access to machinery space and spaces below the exposed cargo deck

**1.1.1** *Access to the machinery space excluding emergency access and removal hatches, should, if possible, be arranged within the forecastle. Any access to the machinery space from the exposed cargo deck should be provided with two weathertight closures.*

*Access to spaces below the exposed cargo deck should be from a position within or above the superstructure deck.*

Other arrangement may be considered by the Society on a case by case basis

## Section 3 Stability

### 1 General

#### 1.1 Assumptions

**1.1.1** During anchor handling, the wire comes from the anchor handling winch and is controlled by the guide pins and connected, over the stern roller, to the lifted item (see Fig 1).

**Figure 1 : Schematic definition of equipment**

**1.1.2** For vessels used for anchor handling while their towing capacity and/or the traction power of their winches is/are already in action, calculations are to be made showing the maximum acceptable tension to which the vessel is able to be exposed.

**1.1.3** The compliance with the relevant stability criteria are to be made for each set of towing pins and its associated permissible line tensions, including any physical element or arrangement that can restrict the line movement

Moreover, the loading conditions defined in Pt B, Ch 3, App 2, [1.2.12] are to be checked regarding the stability criteria defined in [1.6] when applying the design tension  $T_w$  for the tow pin set nearest to centreline, as a minimum for the lowest  $\alpha$  equal to 5 degrees.

Allowance is to be made for the anticipated weight of cargo on and below deck, chain in lockers, anticipated type of wire or rope on storage reels and wire on the winches when calculating loading conditions.

#### 1.2 Definitions

**1.2.1** The tension  $T_w$  in the wire, its vertical component  $T_{Wz}$  and its horizontal component  $T_{Wy}$ , as well as the angles  $\alpha$  and  $\beta$  defining the wire position are shown in Fig 2, where:

- $T_w$  : Permissible tension in the wire, in t, which can be applied to the ship as loaded while working through a specified tow pin set, at each  $\alpha$ , for which all stability criteria can be met.  $T_w$  should in no circumstance be taken as greater than  $T_D$ .
- $T_D$  : Design maximum wire tension, to be taken as the maximum winch wire pull or maximum static winch brake holding force, whichever is greater.
- $T_{Wz}$  : Vertical component of the wire tension causing the ship to trim:  $T_{Wz} = T_w \sin \beta$
- $T_{Wy}$  : Horizontal component of the wire tension causing the ship to heel:  $T_{Wy} = T_w \sin \alpha \cos \beta$
- $\alpha$  : Horizontal angle between the centreline and the vector at which the wire tension is applied to the ship in the upright position, positive outboard.
- $\beta$  : Vertical angle between the waterplane and the vector at which the wire tension is applied to the ship, positive downwards.  $\beta$  is to be taken at the maximum heeling moment angle as  $\tan^{-1}(y / (h \cdot \sin \alpha))$ , but not less than  $\cos^{-1}(1,5 T_{BP} / T_w \cdot \cos \alpha)$ , using consistent units.
- $T_{BP}$  : Design bollard pull as defined in Ch 2, Sec 1, [1.2.6]
- $y$  : Torque arm, in m, of the vertical component  $T_{Wz}$  (see Fig 3 and Fig 4).  
 $y$  is equal to the transverse distance from the vessel centreline to the outboard point at which the wire tension is applied to the ship and is obtained by the formula:  
 $y = y_0 + x \tan \alpha$   
 $y$  is not to be taken greater than  $B/2$  and may be limited to a physical restriction of the transverse wire movement. Cargo rails, cranes, A-frames may be considered as physical restrictions.
- $y_0$  : Transverse distance, in m, between the vessel centreline and the inner part of the guide pin or any physical restriction of the transverse wire movement
- $x$  : Longitudinal distance, in m, between the stern and the guide pin or any physical restriction of the transverse wire movement

Figure 2 : Tension and position of wire

Figure 3 : Vessel with single pair of guide pins

Figure 4 : Vessel with double pair of guide pins

### 1.3 Heeling moment

1.3.1 The most unfavourable conditions for transverse tension are to be considered for the calculations.

Calculations are to be made for the maximum acceptable wire tension  $T_W$  allowing the vessel to fulfil the requirements of [1.6] during anchor handling operations.

The heeling arm  $b_h$  is to be calculated, in m, as the total effect of the horizontal and vertical transverse components  $T_{Wy}$  and  $T_{Wz}$  of wire tension  $T_W$ , as follows:

$$b_h = T_W(h \sin \alpha \cos \beta + y \sin \beta) \frac{\cos \theta}{D} = (T_{Wy} \cdot h + T_{Wz} \cdot y) \frac{\cos \theta}{D}$$

where:

- h : Torque arm, in m, of the horizontal component  $T_{Wy}$   
h is equal to the vertical distance from the centre of the main propulsion propeller or of the stern side propellers, whichever is deeper (see Fig 5), to either:
  - the uppermost part of the guide pins
  - a point on a line defined between the highest point of the winch pay-out and the top of the stern or any physical restriction of the transverse wire movement.
 In case of azimuth thrusters, h is to be measured from the centre of the deepest drive (see Fig 6)
- D : Displacement of the considered loading condition, in t, including the vertical component  $T_{Wz}$  of the towing force
- $\theta$  : Angle of heel, in deg.

Figure 5 : Vessel with stern side propellers and a fixed propulsion propeller

Figure 6 : Vessel with azimuth thrusters and a moveable propulsion propeller

## 1.4 Permissible tension

1.4.1 The permissible tension  $T_w$  as function of  $\alpha$  can be calculated by direct stability calculations, provided that the following are met:

- the heeling lever is to be taken as defined in [1.3] for each  $\alpha$
- the stability criteria defined in [1.6] is to be met
- $\alpha$  is not to be taken less than 5 degrees, except as permitted by [1.4.2]
- Intervals of  $\alpha$  are not to be more than 5 degrees, except that larger intervals may be accepted, provided that the permissible tension is limited to the higher  $\alpha$  by forming working sectors.

1.4.2 For the case of a planned operation to retrieve a stuck anchor in which the ship is on station above the anchor and the ship has low or no speed,  $\alpha$  may be taken as less than 5 degrees.

## 1.5 Calculation of stability curves

1.5.1 Curves (or tables) of the permissible tension as a function of permissible KG (or GM) are to be provided for the draught (or displacement) and trim values covering the intended anchor handling operations. The curves (or tables) are to be developed under the following assumptions:

- the maximum allowable KG from the approved stability booklet
- information of permissible tension curve or table for each set of towing pins, including any physical element or arrangement that can restrict the line movement as function of the stability limiting curve are to be included
- where desirable, a permissible tension curve or table is to be provided for any specific loading condition
- the draught (or displacement), trim and KG (or GM) to be taken into consideration are those before application of the tension
- where tables are provided that divide the operational, cautionary and stop work zones (see [1.7.2]), the limiting angles associated with physical features of the stern, including the roller, may be used to define the boundaries between the operational and cautionary zones.

## 1.6 Intact stability

1.6.1 The stability of the vessel, for the loading conditions included in Pt B, Ch 3, App 2, [1.2.11], is to be in compliance with the requirements of Pt B, Ch 3, Sec 2.

For all loading condition intended for anchor handling operations, the vessel is to comply with the following criteria, under the assumptions set out in [1.1]:

- a) The residual area between the righting lever curve and the heeling arm curve calculated in accordance with [1.3.1] should not be less than 0,070 metre-radians. The area is determined from the first intersection of the two curves to the second intersection or the angle of down-flooding,  $\theta_f$ , whichever is less.
- b) The maximum residual righting lever GZ between the righting lever curve and the heeling arm curve calculated in accordance with [1.3.1] should be at least 0,2 m.
- c) The maximum heeling angle is to be limited to one of the following angles, whichever occurs first (see Fig 7):
  - heeling angle equivalent to GZ value equal to 50% of  $GZ_{max}$
  - angle of deck immersion
  - 15°.

**Figure 7 : Heeling and righting arm curves**

- d) A minimum freeboard at stern, on centreline, of at least 0,005L should be maintained in all operating conditions, with a displacement D, as defined in [1.3.1]. In the case of anchor retrieval operation, a lower minimum freeboard may be accepted provided that due consideration has been given to this in the operation plan.
- e) Loading conditions other than the most unfavourable ones and associated with anchor handling operations need to be calculated in the same way as described in item a), taking into account the prevailing practice with regards to loads on deck and winch reels.

Generally, when calculating the trim and the righting arm curve, the vertical component of the towing force is added as a weight in the loading condition located at the centreline and at the stern of the vessel (normally the stern roller).

## 1.7 Information to be displayed

**1.7.1** Information stating the maximum allowed tension in the wire, as well as the corresponding angle  $\alpha$ , in accordance with the calculations performed for each loading condition, are to be communicated to the vessel's crew and displayed next to the control desk or at any location where the navigator on duty can easily see the information from his command post.

The displayed information is to be under the form of diagrams, prepared so that the master can easily determine the maximum tension that can be applied to the vessel, as a function of the angle  $\alpha$ , for a given value of trim and displacement (or draught), so as to satisfy the stability criteria (see Fig 9).

**1.7.2** The results are to be given in tables (see Tab 2 completed by Fig 8) and diagrams (see Fig 9) showing the maximum tension (corresponding to the maximum acceptable heeling moment) as a function of angle  $\alpha$ , provided for the draught (or displacement) and trim values covering the intended anchor handling operations (values before application of the tension), as well as the operational zones defined as follows:

- an “operational zone” in which normal operations up to the permissible tension are to occur
- a “cautionary zone” where operations may be reduced or halted to assess the ship’s options to return to the operational zone: the cautionary zone is to be not less than an angle of 10 degrees unless information in Tab 1 provides otherwise.
- a “stop work zone” in which the operation is to be stopped, for which, in normal operations, the “cautionary zone”/“stop work zone” boundary is not to exceed 45 degrees or the point at which the wire rises above the deck. Notwithstanding this, due consideration may be given to different operations from typical anchor handling operations where the planned operation ensures the safety of the ship

**1.7.3** Definitions of permissible tensions and zones based on the availability of tension monitoring and onboard stability instrument are provided in Tab 1.

## 1.8 Stability booklet

**1.8.1** The following information is to be included in the stability booklet in addition to the information required in Pt B, Ch 3, App 2:

- maximum bollard pull, winch pull capacity and brake holding force

- details on the anchor handling arrangement such as location of the fastening point of the wire, type and arrangement of towing pins, stern roller, all points or elements where the tension is applied to the ship
- identification of critical downflooding openings
- guidance on the permissible tensions for each mode of operation and for each set of towing pins, including any physical element or arrangement that can restrict the wire movement, as function of all relevant stability criteria
- recommendations on the use of roll reduction systems
- additional information defined in [1.7].

**1.9 Stability instrument**

**1.9.1** A stability instrument may be used for determining the permissible tension and checking compliance with relevant stability criteria.

Two types of stability instrument may be used on board.

- either a software checking the intended or actual tension on the basis of the permissible tension curves, or
- a software performing direct stability calculations to check compliance with the relevant criteria, for a given loading condition (before application of the tension force), a given tension and a given wire position (defined by angles  $\alpha$  and  $\beta$ )

The procedure to be followed, as well as the list of technical details to be sent in order to obtain loading instrument approval, are given in Pt B, Ch 1, Sec 5, [3].

**Figure 8 : Example of the operational, cautionary and stop work zones illustration**

**Figure 9 : Example of permissible tension sector diagram**

**Table 1 : Definition of permissible tensions and zones**

	Availability of tension monitoring and onboard stability instrument		
	Tension monitoring is not available	Tension monitoring is available but no stability instrument is available	Both tension monitoring and stability instrument are available
Permissible tension $T_W$	Design maximum line tension, $T_W$ , in the operational zone	$T_W$ as described in stability booklet, operational planning guidelines, or specific operational plan	$T_W$ as calculated by the stability instrument for the actual loading condition
Permissible table	<ul style="list-style-type: none"> <li>• First <math>\alpha</math> is to be <math>5^\circ</math></li> <li>• The only permissible tension is the design maximum wire tension, <math>T_D</math></li> <li>• Figures in the table will be <math>T_D</math> for <math>\alpha</math> which <math>T_W \geq T_D</math></li> <li>• The cautionary zone would include positions where <math>T_D &gt; T_W \geq</math> maximum winch wire pull</li> <li>• The stop work zone is every other position where <math>T_W &lt;</math> maximum winch wire pull. If criteria is not fulfilled at <math>\alpha = 5^\circ</math>, anchor handling is not to be performed without winch information</li> </ul>	<ul style="list-style-type: none"> <li>• Tables may be prepared for different values of draft, trim, KG or GM, or specific predefined loading conditions</li> <li>• Values in the tables are to range from <math>\alpha = 0^\circ</math> to <math>\alpha = 90^\circ</math></li> <li>• A table is to identify <math>T_W</math> at critical points and is to be provided for each set of towing pins</li> </ul>	Tables or curves provided in the stability booklet may be used where $T_W$ , throughout the non specific operational zone, exceeds the maximum anticipated wire tension; otherwise, tables or curves calculated for the actual loading condition must be developed
Zones	<ul style="list-style-type: none"> <li>• The operational zone is to be defined as the sector between the two outboard <math>\alpha</math> values for which <math>T_W \geq T_D</math></li> <li>• The cautionary zone is to be defined as the sector between the <math>\alpha</math> at which <math>T_W = T_D</math> and the <math>\alpha</math> at which <math>T_W =</math> maximum winch wire pull</li> <li>• The stop work zone is to cover every other positions. The definition of the sectors is to be documented in the stability booklet, the operational planning guidelines, or the specific operational plan</li> <li>• The sector diagram may be prepared for multiple loading conditions</li> <li>• If the limiting <math>\alpha</math> is less than <math>5^\circ</math> anchor handling operations should not be performed without winch modifications</li> </ul>	<ul style="list-style-type: none"> <li>• The zones may be developed based on normal operational practices contained in the operational planning guidelines, e.g. the operational zone on the stern roller, cautionary zone for not more than <math>15^\circ</math> past the stern roller and the stop work zone otherwise or developed for a specific operation where the outboard <math>\alpha</math> values at which <math>T_W =</math> maximum anticipated wire tension minus <math>10^\circ</math> defines the operational zone, if <math>\alpha</math> is greater than <math>20^\circ</math></li> <li>• If this <math>\alpha</math> is less than <math>20^\circ</math>, the operational zone is defined as the sector between half the outboard <math>\alpha</math> values at which <math>T_W =</math> maximum anticipated wire tension</li> <li>• In each case, the cautionary zone is defined between the limit of the operational zone and the <math>\alpha</math> value at which <math>T_W =</math> maximum anticipated wire tension</li> <li>• In each case, the operational zone must be identified for the anticipated wire tension</li> </ul>	

**Table 2 : Example of permissible wire tension table**

	NA		Operational zone		Operational zone		Cautionary zone		Cautionary zone		Stop zone		Stop zone		Stop zone		Stop zone				

**Note 1:**

- Trim is negative by the bow. Interpolate between drafts only. For intermediate trim values, use lower permissible tension.
- Table is for planning and monitoring anchor handling operation. Specific loading conditions may be required for each anchor move.
- Trim should be minimized or by bow for anchor moves where high wire tensions are expected.
- Wire horizontal angle is relative to vessel's centerline. For intermediate angle values, use the higher table value.

**Note 2:**

- NA indicates where the angle of tow wire is not geometrically possible (i.e. at centerline in the case of wire going through outer guide pins). Permissible tensions are provided for reference only.
- If wire angle falls into the "Cautionary zone" and the wire tension exceeds the permissible value, corrective actions are required.
- If wire angle falls into the "Stop zone" and the wire tension exceeds the permissible value, operations are to be stopped and tension in the line is to be reduced.
- If planned wire tension exceeds the permissible values of the "Operational zone", additional calculations are required. Operations should not be planned for high angles.

**Note 3:** Vessel loading must be in accordance with the approved stability booklet and include assumed margins.

# Section 4 Hull Structure

## 1 Documentation

### 1.1 Documents to be submitted

**1.1.1** In addition to the documentation requested in Part B, the plans and documents listed in Tab 1 are to be submitted as applicable.

The listed plans are to be construction plans complete with all the dimensions and are to contain full indication on the type of materials employed.

Plans of equipment which are type-approved by the Society need not be submitted, provided the types and model numbers are made available.

**Table 1 : Documents to be submitted**

No.	A / I (1)	Document
1	I	General arrangement showing: <ul style="list-style-type: none"> <li>- detail arrangement of anchor handling deck equipment (wire stopper, guide pins, etc.)</li> <li>- typical arrangement of cargo on deck (anchors, wires, chain cables, etc.)</li> <li>- chain lockers used for mooring deployment</li> <li>- anchor handling/towing winch</li> <li>- tugger winches</li> <li>- stern roller, including lateral limits on both ends</li> <li>- lifting appliances, if any</li> <li>- typical paths of lines between winches and stern roller, showing the limit line sectors</li> </ul>
2	I	Design information of deck winches, including: <ul style="list-style-type: none"> <li>- detailed drawing of winches</li> <li>- maximum rated line pull (RP), and the reeled layer for which the rated line pull is defined</li> <li>- brake holding load (BHL), and the reeled layer for which the rated line pull is defined</li> <li>- rendering load (RL)</li> <li>- specification of emergency quick release system including response time and intended remaining holding force after release</li> <li>- strength calculation of the drum with flanges, shafts with coupling, framework and brakes</li> <li>- minimum guaranteed breaking strength of the wire</li> </ul>

(1)	A = to be submitted for approval; I = to be submitted for information	

## 2 General requirements

### 2.1 Deck equipment

**2.1.1** It is the Designer's responsibility to check the consistency of strength capacity of the deck equipment (stern roller, wire stopper, guide pins) in relation to the performance of the winch.

### 2.2 Loading manual

**2.2.1** For ships greater than 90 m in length, the loading manual is to include a loading condition corresponding to the chain lockers being fully loaded and winches fully loaded with the heaviest anticipated line type.

### 2.3 Design loads

**2.3.1** The design loads DL defined below are to be taken not less than the maximum value of the tension in the wire (or chain cable) during anchor handling resulting from the stability analysis.

Local strength of deck structure is to be based on the following design loads:

- in way of anchor handling winch:  
DL = max (1,5 T<sub>BP</sub>; 1,5 RP; BHL)
- in way of guide pins:  
DL = max (2 SWL; 1,5 RP; BHL)
- in way of wire stopper:  
DL = max (2 SWL; 1,5 RP; BHL)
- in way of stern roller:  
DL = max (2 SWL; 1,5 RP; BHL)

Strength of anchor handling winch is to be based on the two following design loads DL:

- case 1:  
DL = max (1,5 T<sub>BP</sub>; 1,5 RP)
- case 2:  
DL = BHL as defined in Ch 2, Sec 1, [1.2].

Strength of deck equipment (guide pins, wire stopper, stern roller) is to be based on the same design loads as those considered for the deck foundations.

### 2.4 Deck structure

**2.4.1** Local reinforcements are to be provided in way of deck areas subjected to concentrated loads.

The strength checking required in [2.5], [2.6] and [2.7] are to be based on the following criteria:

- Stress level in the deck structure is not to exceed the following permissible stresses:
  - normal stress:  
 $\sigma \leq 0,75 R_y$
  - shear stress:  
 $\tau \leq 0,47 R_y$
  - equivalent stress:  
 $\sigma_{VM} \leq 0,85 R_y$

where:

$R_y$  : Minimum yield stress, in N/mm<sup>2</sup>, of the material, to be taken equal to 235/k unless otherwise specified.

- In case the yielding check of the structure is carried out by means of a three-dimensional finite element model, these permissible stress levels may be increased by 10 per cent.
- Where necessary, buckling strength is to be checked.

Strength of the deck structure is to be checked considering:

- in way of anchor handling winch, including welds:  
design load DL as defined in [2.3], with the following assumptions:
  - wire considered at the most unfavourable layer of the drum, in general
  - direction of wire cable taken in the most unfavourable direction allowed by the anchor handling equipment.
- in way of anchor handling deck equipment other than winches (i.e. guide pins, wire stopper), including welds:  
design load DL as defined in [2.3], exerted in the most unfavourable directions, with the most severe vertical location.

- in way of stern roller, including welds:  
design load DL as defined in [2.3], considering an anchor hanging underwater below the stern roller at a negative angle of 30° with respect to a vertical axis (see Fig 1).
- in way of handling and/or lifting appliances, if any, including welds:  
the maximum dynamic reactions exerted by lifting appliance pedestal, according to the lifting appliance certification.

**Figure 1 : Angle of hanged anchor with respect to vertical axis**

## 2.5 Anchor handling winch

**2.5.1** The combined stress is not to exceed the following permissible stress depending on the design load, for both cases defined in [2.3]:

- for case 1:  
 $\sigma_{VM} \leq R_e$
- for case 2:  
 $\sigma_{VM} \leq 0,9 R_e$

where:

$R_e$  : Minimum specified yield stress of material, in N/mm<sup>2</sup>

The emergency quick-release system is to be designed to:

- allow drum release in all operational modes, including emergency mode, in the shortest possible delay
- be activated locally at the winch and from a position at the bridge with full view and control of the operation
- operate even in dead ship condition
- be protected against unintentional operation.

A winch intended for functions of anchor handling and towing is to meet both the requirements of Ch 1, Sec 3, [2.7] and the requirements above.

Strength is to be checked on the basis of the calculations submitted, in particular the components which are exposed to the tension in the towline, such as the winch drums, drum shafts, brakes and support frame.

## 2.6 Anchor handling deck equipment other than winches

**2.6.1** Strength of the deck equipment used for anchor handling, including guide pins and wire stopper, is to be checked under the maximum load on the wire equal to design load DL as defined in [2.3], exerted in the most unfavourable directions, with the most severe vertical location.

Stress levels in the anchor handling deck equipment are not to exceed the following permissible stresses:

- normal stress:  
 $\sigma \leq 0,75 R_e$
- shear stress:  
 $\tau \leq 0,47 R_e$
- equivalent stress:  
 $\sigma_{VM} \leq 0,85 R_e$

In case the yielding check of the structures is carried out by means of a three-dimensional finite element model, these permissible stress levels may be increased by 10 per cent.

Where necessary, buckling strength is to be checked.

## **2.7 Stern roller**

**2.7.1** The structure of the stern roller is to be checked under design load DL as defined in [2.3], considering an anchor hanging underwater below the stern roller at a negative angle of 30° with respect to a vertical axis (see Fig 1).

For strength purposes, design load DL as defined in [2.3] is to be considered in any transverse position on the stern roller, as allowed by the actual locations of the guide pins and the anchor handling deck equipment.

The bending, shearing and combined stresses are not to exceed the following permissible stresses:

- normal stress:  
 $\sigma \leq 0,75 R_e$
- shear stress:  
 $\tau \leq 0,47 R_e$
- equivalent stress:  
 $\sigma_{VM} \leq 0,85 R_e$

Where necessary, buckling strength is to be checked.

## **2.8 Wire**

**2.8.1** The minimum breaking strength of the wire is not to be less than the design load DL defined in [2.3] for the anchor handling winch.

The towline is to be protected from being damaged by chafing and abrasion. To this end, cargo rails, bulwarks, and all the elements supporting the towline are to be adequately rounded.

Strength of the wire attachment on the winch is to allow breaking in case the line is to be run out. Under normal operation, at least 3 turns of wire on the drum are considered.

## **2.9 Anchor handling arrangements**

**2.9.1** Stop pins or other design features meant to impede the movement of the wire further outboard are to be installed

**2.9.2** The working deck is to be marked with contrasting colours or other identifiers such as guide pins, stop pins or similar easily identifiable points that identify operational zones for the line to aid operator observation.

# Section 5                      Testing

## 1 General

### 1.1 Load test

1.1.1 Load test is to be performed at the manufacturer workshop, for hoisting operation, and witnessed by the Society.

1.1.2 Winches are to be tested at design load DL, as defined in Ch 2, Sec 4, [2.3]. However, in case the winch is not of novel or particular design, it is sufficient to perform load test at the design bollard pull  $T_{BP}$ . In this case, it may be performed on board during commissioning trials and is to be witnessed by the Society.

### 1.2 Functional test

1.2.1 The tests are performed to check the proper:

- operation of the equipment within the specified limitations
- arrangement of the towline sectors and the towline paths, as shown on the arrangement drawing
- functioning under the normal operation modes
- functioning under the emergency operation modes, including the emergency release and the dead ship operations.

In particular, the emergency quick-release systems are to be function tested at the design bollard pull  $T_{BP}$ .

### 1.3 Operational tests

1.3.1 Prior to anchor handling operation, operational tests are to be performed by the crew in order to ensure the satisfactory operation of the winches and deck equipment, in particular the emergency quick-release system, as requested by the operational manual.

1.3.2 Records of the operational tests are to be kept on board and made available to the Society upon request.

# Part E

## Service Notations for Offshore Service Vessels and Tugs

---

### CHAPTER 3 SUPPLY VESSELS

---

Section 1	General
Section 2	General Arrangement
Section 3	Stability
Section 4	Hull Structure
Section 5	Machinery and Cargo Systems
Section 6	Electrical Installations, Instrumentation and Automation
Section 7	Fire Prevention, Protection and Extinction

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** The present Chapter applies to ships defined as per [1.5.30] and [1.5.41], hereafter referred to as OSV(s).

OSV(s) means:

- well-stimulation vessels, and/or
- ships which are primarily engaged in the transport of stores, materials and equipment, including:
  - oil products with a flashpoint greater than 60°C, and/or
  - hazardous and noxious liquid substances,
 to, from and between offshore installations.

Attention is drawn to the Owner that compliance of this Chapter for a ship intended to carry oil product with a flashpoint equal to or less than 60°C is submitted to prior agreement by the Administration considering this ship as an OSV and not as an oil tanker, in particular regarding the statutory regulations dealing with the ship general arrangement.

### 1.1.2 Carriage of oil products

The requirements of the present Chapter regarding the carriage of oil products are to be in compliance with MARPOL Annex I, Regulation 2.2.

Note 1: When intended to carry less than 200 m<sup>3</sup> of non-flammable oil products only, supply vessels need not to comply with the specific requirements for the carriage of oil products.

### 1.1.3 Carriage of heated cargoes

For OSVs intended to carry cargoes heated at a temperature of 90°C or more, the design of the cargo tanks is subject to special consideration.

### 1.1.4 Carriage of hazardous and noxious goods in packaged form

The provisions in this Chapter do not regulate the transport of hazardous and noxious goods in packaged form.

### 1.1.5 Equivalents to the OSV Chemical Code

The IMO OSV Chemical Code chapter 1 paragraph 1.3 may allow equivalents to the provision of the Code. In the scope of the assignment of the additional service feature **HNLS** and/or **WELLSTIM** defined in [1.3], these equivalent provisions are to be transmitted to the Society for review.

## 1.2 IMO regulations

**1.2.1** The requirements of the present Chapter are generally consistent with the following International Maritime Organisation (IMO) regulations:

- OSV Code – Code of safe practice for the carriage of cargoes and persons by offshore supply vessels adopted by IMO Resolution A.863(20), as amended by Resolution MSC 237(82).
- Offshore Supply Vessel Guidelines – Guidelines for the design and construction of offshore supply vessels adopted by IMO Resolution A.469(XII), as amended by Resolutions MSC 235(82) and MSC 335(90).
- IBC Code – IMO International Code for the Construction and Equipment of Ships carrying Dangerous Chemicals in Bulk, as amended.
- OSV Chemical Code – IMO OSV Chemical Code for the transport and handling of hazardous and noxious liquid substances in bulk on Offshore Support Vessels adopted by IMO Resolution A.1122(30).

**1.2.2** The present Chapter does not cover Chapter 13 and Chapter 15 of the OSV Chemical Code (with the exception of sections 15.5.4 and 15.5.5) which are outside the scope of classification.

## 1.3 Classification notations

### 1.3.1 Service notation supply

Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **supply**, as defined in Pt A, Ch 1, Sec 2, [4.12.10].

Where applicable, the service notation **supply** is to be completed by the additional service feature **HNLS** (as defined in [1.3.2]) and/or **WELLSTIM** (as defined in [1.3.3])

**1.3.2 Additional service feature HNLS**

Ships granted with the service notation **supply** and intended to carry the following products:

- products which are listed in chapters 17 or 18 of the IBC Code and the latest edition of the MEPC.2/Circular (Provisional categorization of liquid substances in accordance with MARPOL Annex II and the IBC Code) and their related references to chapters 15 and 19; and/or
- oil-based/water-based mud containing mixtures of products listed in chapters 17 and 18 of the IBC Code and the MEPC.2/Circular; and/or
- liquid carbon dioxide (high purity and reclaimed quality) and liquid nitrogen; and/or
- contaminated backloads (see [1.5.4]),

are to be assigned with the additional service feature **HNLS** completed, where applicable, by:

one or several of the following notations subject to the products listed hereabove are considered:

- FP**≤60°C when the ship may carry products with a flash point equal to or less than 60°C.
- toxic** when the ship may carry toxic products (see [1.5.39])
- acids** when the ship may carry acids (see [1.5.1])
- LG** when the ship may carry liquid carbon dioxide and/or liquid nitrogen

**1.3.3 Additional service feature WELLSTIM**

The additional service feature **WELLSTIM** may be assigned to ships granted with the service notation **supply** when intended to carry products used in a blending (see [1.5.5]) or production process dedicated to the search and exploitation of seabed mineral resources, this process being installed on-board to facilitate such operations.

Where applicable, the additional service feature **WELLSTIM** is to be completed by one or several of the following notations: - **FP**≤60°C, -**toxic**, -**acids** and -**LG** as defined in [1.3.2].

**1.4 Applicable rules**

**1.4.1** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT
Ship arrangement	L ≥ 65 or 90 m (1)	<ul style="list-style-type: none"> <li>• Part B</li> <li>• Ch 3, Sec 2</li> </ul>	<ul style="list-style-type: none"> <li>• NR566 (2)</li> <li>• Ch 3, Sec 2</li> </ul>
	L < 65 or 90 m (1)	<ul style="list-style-type: none"> <li>• NR600</li> <li>• Ch 3, Sec 2</li> </ul>	<ul style="list-style-type: none"> <li>• NR566 (2)</li> <li>• Ch 3, Sec 2</li> </ul>
Hull	L ≥ 65 or 90 m (1)	<ul style="list-style-type: none"> <li>• Part B</li> <li>• Ch 3, Sec 4</li> </ul>	<ul style="list-style-type: none"> <li>• Part B</li> <li>• Ch 3, Sec 4</li> </ul>
	L < 65 or 90 m (1)	<ul style="list-style-type: none"> <li>• NR600</li> <li>• Ch 3, Sec 4</li> </ul>	<ul style="list-style-type: none"> <li>• NR600</li> <li>• Ch 3, Sec 4</li> </ul>
Stability		<ul style="list-style-type: none"> <li>• Part B</li> <li>• Ch 3, Sec 3</li> </ul>	<ul style="list-style-type: none"> <li>• Part B</li> <li>• Ch 3, Sec 3</li> </ul>
Machinery and cargo systems		<ul style="list-style-type: none"> <li>• Part C</li> <li>• Ch 3, Sec 5</li> </ul>	<ul style="list-style-type: none"> <li>• NR566 (2)</li> <li>• Ch 3, Sec 5</li> </ul>
Electrical installations and automation		<ul style="list-style-type: none"> <li>• Part C</li> <li>• Ch 3, Sec 6</li> </ul>	<ul style="list-style-type: none"> <li>• NR566 (2)</li> <li>• Ch 3, Sec 6</li> </ul>
Fire protection, detection and extinction		<ul style="list-style-type: none"> <li>• Part C</li> <li>• Ch 3, Sec 7</li> </ul>	<ul style="list-style-type: none"> <li>• NR566 (2)</li> <li>• Ch 3, Sec 7</li> </ul>

(1) Refer to the scope of application of NR600.

(2) For ships granted with **HNLS** and/or **WELLSTIM** service features, the limit of 500 GT does not apply for the specific requirements associated to these service features

**Note 1:**

NR566: Hull Arrangement, Stability and Systems for Ships less than 500 GT.

NR600: Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m.

**Note 2:** For ships granted with **HNLS** and/or **WELLSTIM** service features, in case of conflict, requirements mentioned in this Chapter shall prevail

## 1.5 Definitions

### 1.5.1 Acids

Products are deemed to be acids when in Chapter 17 of IBC Code, or the latest edition of the MEPC.2/Circ., paragraph 15.11 is assigned in column o.

### 1.5.2 Accommodation spaces

Accommodation spaces are those spaces used for public spaces, corridors, lavatories, cabins, offices, hospitals, cinemas, games and hobbies rooms, barber shops, pantries containing no cooking appliances and similar spaces.

### 1.5.3 Administration

Administration means the Government of the State whose flag the vessel is entitled to fly.

### 1.5.4 Backload

Backload means contaminated bulk liquids, taken on board a vessel offshore, for transport either back to shore or to alternate offshore site.

### 1.5.5 Blending additives

Blending additives means small amounts of liquid substances used during blending of products or production processes of cargoes for use in the search and exploitation of seabed mineral resources on board vessels used to facilitate such operations.

### 1.5.6 Cargo area

Cargo area is that part of the offshore support vessel where:

- a) a pollution hazard only substance having a flashpoint exceeding 60°C and not defined as toxic, is likely to be present and includes cargo tanks, portable tanks used as deck cargo tanks, slop tanks, cargo pump-rooms, pump-rooms adjacent to cargo tanks and enclosed spaces in which pipes containing cargoes are located. Areas on open deck are not considered part of the cargo area.
- b) a safety hazard substance having a flashpoint exceeding 60°C and not defined as a toxic, is likely to be present and includes cargo tanks, portable tanks used as deck cargo tanks, slop tanks, cargo pump-rooms, pump-rooms adjacent to cargo tanks, hold spaces in which independent tanks are located, cofferdams surrounding integral tanks, enclosed spaces in which pipes containing cargoes are located and the following deck areas:
  - 1) within 3 m of cargo tank installed on deck or portable tanks used as deck cargo tanks;
  - 2) areas on open deck, or semi-enclosed spaces on deck, within 3 m of any cargo tank access outlet;
  - 3) areas on open deck over an integral tank without an overlaying cofferdam plus the open deck area extending transversely and longitudinally for a distance of 3 m beyond each side of the tank;
  - 4) areas on open deck, or semi-enclosed spaces on deck, within 3 m of cargo manifold valve, cargo valve, cargo pipe flange, except spaces within the 3 m zone that are separated by an enclosed bulkhead to the minimum height as given in item 6);
  - 5) areas on open deck, or semi-enclosed spaces on open deck above and in the vicinity of any cargo tank vent outlet intended for the passage of large volumes of vapour mixture during cargo loading, within a vertical cylinder of unlimited height and 3 m radius upon the centre of the outlet, and within a hemisphere of 3 m radius below the outlet;
  - 6) areas on the open deck within spillage coamings surrounding cargo manifold valves and 3 m beyond these, up to a height of 2.4 m above the deck; and
  - 7) compartments for cargo hoses.
- c) a substance having a flashpoint not exceeding 60°C, or defined as toxic or vapours of such cargo, is likely to be present and includes cargo tanks, portable tanks used as deck cargo tanks, slop tanks, cargo pump-rooms, pump-rooms adjacent to cargo tanks, hold spaces in which independent tanks are located, cofferdams surrounding integral tanks, enclosed spaces in which pipes containing cargoes are located and the following deck areas:
  - 1) within 3 m of cargo tank installed on deck or portable tanks used as deck cargo tanks;
  - 2) areas on open deck, or semi-enclosed spaces on deck, within 4.5 m of gas or vapour outlet, cargo manifold valve, cargo valve, cargo pipe flange, cargo pump-room ventilation outlets and cargo tank openings for pressure release provided to permit the flow of small volumes of gas or vapour mixtures caused by thermal variation;
  - 3) areas on open deck, or semi-enclosed spaces on open deck above and in the vicinity of any cargo gas outlet intended for the passage of large volumes of gas or vapour mixture during cargo loading, within a vertical cylinder of unlimited height and 10 m radius centred upon the centre of the outlet, and within a hemisphere of 10 m radius below the outlet;
  - 4) areas on open deck, or semi-enclosed spaces on deck, within 3m of cargo pump-room entrances, cargo pump-room ventilation inlet, openings into cofferdams;
  - 5) areas on the open deck within spillage coamings surrounding cargo manifold valves and 3 m beyond these, up to a height of 2.4m above the deck;
  - 6) compartments for cargo hoses; and
  - 7) within the hose landing area.

**1.5.7 Cargo control station**

*Cargo control station means a location that is manned during cargo transfer operations for the purpose of directing or controlling the loading or unloading of cargo.*

**1.5.8 Cargo pump-room**

*Cargo pump-room is a space containing pumps and their accessories for the handling of the products.*

**1.5.9 Cargo tank**

*Cargo tank is the envelope designed to contain the cargo.*

**1.5.10 Cofferdam**

*Cofferdam is the isolating space between two adjacent steel bulkheads or decks. This space may be a void space or a ballast space.*

**1.5.11 Control stations**

*Control stations are those spaces in which vessels' radio or main navigating equipment or the emergency source of power is located or where the fire-recording or fire-control equipment is centralized. This does not include special fire-control equipment which can be most practically located in the cargo area.*

**1.5.12 Dangerous goods**

*Dangerous goods mean the substances, materials and articles covered by the IMDG Code.*

*IMDG Code means the International Maritime Dangerous Goods Code (resolution MSC.122(75), as amended)*

**1.5.13 Deck spread**

*Deck spread means portable tanks, piping, equipment, processing equipment and control stations secured to the vessel by permanent means and used in the operation of the vessel.*

**1.5.14 Density**

*Density is the ratio of the mass to the volume of a product, expressed in terms of kilograms per cubic metre. This applies to liquids, gases and vapours.*

**1.5.15 Flammable liquid**

*A flammable liquid is any liquid having a flashpoint (closed cup test) not exceeding 60°C determined by an approved flashpoint apparatus.*

Note 1: A liquid heated within 15°C of its flashpoint is also considered as a flammable liquid.

**1.5.16 Flashpoint**

*Flashpoint is the temperature in degrees Celsius at which a product will give off enough flammable vapour to be ignited. Values given in the Chapter are those for a "closed cup test" determined by an approved flashpoint apparatus.*

**1.5.17 Fuel oil**

*Fuel oil means any oil used as fuel in connection with the propulsion and auxiliary machinery of the ship on which such oil is carried.*

**1.5.18 Gravity tank**

*Gravity tank means a tank having a design pressure not greater than 0,07 MPa gauge at the top of the tank. A gravity tank may be independent or integral. A gravity tank should be constructed and tested according to recognized standards, taking account of the temperature of carriage and relative density of the cargo.*

**1.5.19 Gas-safe area**

*Gas-safe area is an area which is not defined as hazardous.*

**1.5.20 Hazardous area**

*Hazardous area is an area in which an explosive atmosphere is or may be expected to be present in quantities such as to require special precautions for the construction, installation and use of electrical apparatus.*

**1.5.21 Hold space**

*Hold space is the space enclosed by the vessels' structure in which an independent cargo tank is situated.*

**1.5.22 Hose landing area**

*Hose landing area means an area on the main deck, except those in compartments for cargo hoses, where cargo hoses of substances having a flashpoint not exceeding 60°C and/or defined as toxic are located during cargo transfer.*

**1.5.23 Independent**

*Independent means that a piping or venting system, for example, is in no way connected to another system and that there are no provisions available for the potential connection to other systems.*

**1.5.24 Independent tank**

*Independent tank means a cargo containment envelope which is not contiguous with, or part of, the hull structure.*

*An independent tank is built and installed so as to eliminate whenever possible (or in any event to minimize) its stressing as a result of stressing or motion of the adjacent hull structure. An independent tank is not essential to the structural completeness of the ship's hull.*

**1.5.25 Integral tank**

*Integral tank means a cargo containment envelope which forms part of the ship's hull and which may be stressed in the same manner and by the same loads which stress the contiguous hull structure and which is normally essential to the structural completeness of the ship's hull.*

**1.5.26 IGC Code**

*International Gas Carrier Code (IGC Code) means the International Code for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk (resolution MSC.5(48), as amended).*

**1.5.27 MARPOL**

*MARPOL means the International Convention for the Prevention of Pollution from Ships, 1973, as modified by the Protocol of 1978 relating thereto, as amended.*

**1.5.28 Noxious liquid substance**

*Noxious liquid substance means any substance indicated in the Pollution Category column of chapter 17 or 18 of the International Bulk Chemical Code, or the current MEPC.2/Circular or provisionally assessed under the requirements of regulation 6.3 of MARPOL Annex II as falling into categories X, Y or Z.*

**1.5.29 Offshore portable tank**

*Offshore portable tank means a portable tank specially designed for repeated use for transport of dangerous goods to, from and between offshore facilities. An offshore portable tank is designed and constructed in accordance with the Guidelines for the approval of containers handled in open seas (MSC/Circ.860)*

**1.5.30 Offshore support vessels**

*Offshore support vessels (OSVs) are:*

- a) *multi-mission vessels which are primarily engaged in the transport of stores, materials and equipment to and from mobile offshore drilling units, fixed and floating platforms and other similar offshore installations; or*
- b) *multi-mission vessels, including well-stimulation vessels, but excluding mobile offshore drilling units, derrick barges, pipe-laying barges and floating accommodation units, which are otherwise primarily engaged in supporting the work of offshore installations.*

**1.5.31 Oil product**

*Oil product means petroleum in any form including crude oil, sludge, oil refuse and refined products (other than the petrochemicals which are subject to the provisions of Annex II of MARPOL 73/78, as amended) and excludes fuel oil as defined in [1.5.17].*

**1.5.32 Open deck**

*Open deck is defined as an open or semi-enclosed space on cargo deck or inside of the cargo rail. Semi-enclosed spaces are those spaces that either:*

- a) *are open at two ends; or*
- b) *have an opening at one end, and are provided with adequate natural ventilation effective over their entire length through permanent openings distributed in the side plating or deckhead or from above, the openings having a total area of at least 10% of the total area of the space sides.*

**1.5.33 Pollution hazard only substance**

*Pollution hazard only substance means a substance having an entry only of "P" in column d in chapter 17 of the IBC Code.*

**1.5.34 Portable tank**

*Portable tank means a multimodal tank used for the transport of dangerous goods.*

**1.5.35 Pump-room**

*Pump-room is a space, located in the cargo area, containing pumps and their accessories for the handling of ballast and oil fuel.*

**1.5.36 Safety hazard substance**

*Safety hazard substance means a substance having an entry of "S" or "S/P" in column d in chapter 17 of the International Bulk Chemical Code.*

**1.5.37 Separate**

*Separate means that a cargo piping system or cargo vent system, for example, is not connected to another cargo piping or cargo vent system.*

The separation may be achieved by the use of design or operational methods. Operational methods are not to be used within a cargo tank and are to consist of one of the following types:

- removing of spool pieces or valves and blanking of pipe ends
- arrangement of two spectacle flanges in series, with provisions of detecting leakage into the pipe between the two spectacle flanges.

**1.5.38 SOLAS**

*SOLAS means the International Convention for the Safety of Life at Sea, 1974, as amended.*

**1.5.39 Toxic products**

Products are deemed to be toxic when in Chapter 17 of IBC Code, or the latest edition of the MEPC.2/Circ., paragraph 15.12 is assigned in column o.

**1.5.40 Void space**

*Void space is an enclosed space in the cargo area external to a cargo tank, other than a hold space, ballast space, oil fuel tank, cargo pump-room, pump-room, or any space in normal use by personnel.*

**1.5.41 Well-stimulation vessel**

*Well-stimulation vessel means an offshore support vessel with specialized equipment and industrial personnel that deliver products and services directly into a well-head.*

**2 Documents to be submitted**

**2.1 General**

**2.1.1** The documents listed in Tab 2 are to be provided in addition to the documents listed in the applicable rules specified in [1.4].

**Table 2 : Documents to be submitted**

No.	Documents to be submitted	I/A (1)
Hull		
1.1	General arrangement	I
1.2	Access arrangement	A
1.3	Arrangement of entrances, air inlets and openings to accommodation service, machinery spaces and control stations	A
1.4	Capacity plan with clear indications of: <ul style="list-style-type: none"> <li>• cargo tanks with nature and density of cargoes and indicating whether the product is flammable</li> <li>• fuel oil tanks</li> <li>• cofferdams adjacent to cargo tanks</li> </ul>	I

## Section 2 General Arrangement

### 1 Compartment arrangement

#### 1.1 General

##### 1.1.1 Watertight integrity

The machinery spaces and other working and living spaces in the hull are to be separated from the other compartments by watertight bulkheads.

##### 1.1.2 Afterpeak bulkhead

An afterpeak bulkhead is to be fitted and made watertight up to the freeboard deck. The afterpeak bulkhead may, however, be stepped below the freeboard deck, provided the degree of safety of the supply vessel as regards subdivision is not thereby diminished.

##### 1.1.3 Location of cargo tanks

All cargo tanks are to be located aft of the collision bulkhead and forward of the aft peak.

#### 1.2 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features

**1.2.1** With reference to OSV Chemical Code Chapter 2, section 2.1.5, the following requirements are, in particular, to be complied with:

- a) Double bottoms:  
Requirements mentioned in Pt B, Ch 2, Sec 2, [3] are to be referred to.
- b) Collision bulkhead:  
Requirements mentioned in Pt B, Ch 2, Sec 1, [3] are to be referred to.
- c) After peak, machinery space and stern tubes:  
Requirements mentioned in Pt B, Ch 2, Sec 1, [4] are to be referred to.
- d) Height of transverse watertight bulkheads other than collision bulkhead and after peak bulkhead:  
Requirements mentioned in Pt B, Ch 2, Sec 1, [5] are to be referred to.
- e) Openings in watertight bulkheads and internal decks:  
Requirements mentioned in Pt B, Ch 2, Sec 1, [6.2] and Pt B, Ch 2, Sec 1, [6.3] are to be referred to.
- f) Openings in the shell plating below the bulkhead deck:  
Requirements mentioned in:
  - Pt B, Ch 11, Sec 12, [2], Pt B, Ch 11, Sec 12, [3] and Pt B, Ch 11, Sec 12, [4], and
  - Pt C, Ch 1, Sec 10, [8]
 are to be referred to, taking into account Ch 3, Sec 5, [1.5.1].

##### 1.2.2 Location of cargo tanks

Requirements mentioned in OSV Chemical Code Chapter 2, section 2.9.1 are to be referred to.

##### 1.2.3 Cargo segregation

Requirements mentioned in OSV Chemical Code Chapter 3, section 3.1.1, 3.1.2.1, 3.1.2.2, 3.1.6 and 3.1.7 are to be referred to.

##### 1.2.4 Accommodation, service space and control stations

Requirements mentioned in OSV Chemical Code Chapter 3, section 3.2 are to be referred to.

#### 1.3 Compartment arrangement in way of oil product cargo tanks

##### 1.3.1 Ships carrying oil products with a flashpoint more than 60°C

A cargo tank carrying exclusively oil products having a flashpoint exceeding 60°C (closed cup test) are to be segregated from accommodation spaces, drinking water and stores for human consumption by means of a cofferdam, void space, cargo pump-room, fuel oil tank, or other similar space. On-deck stowage of independent tanks or installation of independent tanks in otherwise empty hold spaces is to be considered as satisfactory.

##### 1.3.2 Length of cargo tanks

*The length of each cargo tank shall not exceed 10 metres or one of the values of Tab 1, as applicable, whichever is the greater.*

Note 1: When the aggregate capacity of oil tanks is less than 200 m<sup>3</sup>, this requirements might not be applied.

**1.3.3 Slop tanks**

Requirements mentioned in Pt D, Ch 7, Sec 2, [3.5.1] and Pt D, Ch 7, Sec 2, [3.6] are to be applied.

Note 1: When aggregate capacity of oil tanks does not exceed 1000 m<sup>3</sup>, these requirements might not be applied.

**Table 1 : Length of cargo tanks**

Longitudinal bulkhead	Type of cargo tank	$b_i/B$ (1)	Centreline bulkhead	Length (m)
No bulkhead	–	–	–	$(0,5 b_i/B + 0,1) L$ (2)
Centreline bulkhead	–	–	–	$(0,25 b_i/B + 0,15) L$
Two or more bulkheads	Wing cargo tank	–	–	0,2 L
	Centre cargo tank	if $b_i/B > 1/5$	–	0,2 L
		if $b_i/B < 1/5$	No	$(0,5 b_i/B + 0,1) L$
			Yes	$(0,25 b_i/B + 0,15) L$

(1) Where  $b_i$  is the minimum distance from the side of the supply vessel to the outer longitudinal bulkhead of the tank in question measured inboard at right angles to the centreline at the level corresponding to the assigned summer freeboard.  
 (2) Not to exceed 0,2 L.

**2 Access arrangement and access to spaces**

**2.1 Access arrangement in way of cargo tanks for oil products**

**2.1.1 Direct access from open deck**

Supply vessels are to be provided with the following:

- a) Access to cargo tanks is to be direct from the open deck and such as to ensure their complete inspection except for access to cargo tanks in double-bottoms that may be through a cargo pump-room, pump-room, deep cofferdam, pipe tunnel or similar dry compartments, provided that the ventilation of these spaces complies with Ch 3, Sec 5, [6.1.1].
- b) Access to cargo pumps does not need to be from the open deck provided that the access is independent of watertight doors.

**2.1.2 Dimension of access openings**

The following requirements are applicable for all the spaces referred to in [2.1.1]:

- a) For access through horizontal openings, hatches or manholes, the dimensions are to be sufficient to allow a person wearing a self-contained air-breathing apparatus and protective equipment to ascend or descend any ladder without obstruction and also to provide a clear opening to facilitate the hoisting of an injured person from the bottom of the space. The minimum clear opening is not to be less than 600 mm by 600 mm.
- b) For access through vertical openings, or manholes providing passage through the length and breadth of the space, the minimum clear opening is not to be less than 600 mm by 800 mm at a height of not more than 600 mm from the bottom shell plating unless gratings or other footholds are provided.
- c) Smaller dimensions may be approved by the Society in special circumstances, if the ability to traverse such openings or to remove an injured person can be proved to the satisfaction of the Society.

**2.2 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features**

**2.2.1 Access to spaces in the cargo area**

Requirements mentioned in OSV Chemical Code Chapter 3, section 3.3 are to be referred to.

**2.2.2 Additional requirements for ships granted with notations -FP≤60°C or -acids or -toxic**

In addition to the requirements mentioned in [2.2.1], the following apply:

- a) For cargo tanks segregation, requirements mentioned in OSV Chemical Code Chapter 4, sections 4.1.2 and 4.1.3, are to be referred to.
- b) For the location of openings into accommodation, passageways, service and machinery spaces and control stations in relation to cargo piping and cargo vent systems, requirements mentioned in OSV Chemical Code Chapter 4, section 4.1.7 are to be referred to.
- c) For access to cargo tanks, cofferdams, void spaces, cargo pump-room, pump-room, empty tank, or other spaces adjacent to cargo tanks, requirements mentioned in OSV Chemical Code Chapter 4, section 4.1.8 are to be referred to.
- d) High walkways should not be located within the cargo area. Requirements mentioned in OSV Chemical Code Chapter 4, section 4.1.9 are to be referred to.

**2.2.3 Additional requirements for ships granted with notation -FP≤60°C**

In addition to the requirements mentioned in [2.2.1] and [2.2.2], for location of entrances, openings into accommodation, service and machinery spaces and control stations, requirements mentioned in OSV Chemical Code Chapter 4, section 4.2.2 are to be referred to.

**2.2.4 Additional requirements for ships granted with notation -acids**

In addition to the requirements mentioned in [2.2.1] and [2.2.2], the special requirements mentioned in the IBC Code Chapter 15, section 15.11 are to be referred to.

**2.2.5 Additional requirements for ships granted with notation -toxic**

In addition to the requirements mentioned in [2.2.1] and [2.2.2], the following apply:

- a) The special requirements mentioned in the IBC Code Chapter 15, section 15.12 are to be referred to.
- b) For location of entrances, openings into accommodation, passageways, service and machinery spaces and control stations, requirements mentioned in OSV Chemical Code Chapter 4, sections 4.3.2, 4.3.3, 4.3.4, 4.3.5 and 4.3.6, are to be referred to.
- c) For marking of cargo deck areas, requirements mentioned in OSV Chemical Code Chapter 15, section 15.5.5 are to be referred to.

## **3 Arrangement for hull and forecastle openings**

### **3.1 General**

#### **3.1.1 Sidescuttles and windows**

Sidescuttles and windows of opening type are, in general, accepted only in unexposed areas of the deckhouses located immediately above the forecastle and the areas above.

#### **3.1.2 Sidescuttles of gas-safe areas facing hazardous areas**

Sidescuttles of gas-safe areas facing hazardous areas, excluding those of non-opening type, are to be capable of ensuring an efficient gas-tight closure.

Warning plates are to be fitted on access doors to accommodation and service spaces facing the cargo area indicating that the doors and sidescuttles mentioned above are to be kept closed during cargo handling operations.

#### **3.1.3 Freeing ports**

The area of freeing ports is to be increased by 50% with respect to that determined according to Pt B, Ch 11, Sec 12, [6] or NR566, as applicable.

For ships operating in areas where icing is likely to occur, shutters may not be fitted.

#### **3.1.4 Freeing ports through box-bulwarks**

Where box-bulwarks the upper level of which extends to the forecastle deck are fitted in way of the loading area, the freeing ports are to pass through these box-bulwarks and their area is to be increased to take account of the height of the bulwarks.

#### **3.1.5 Miscellaneous**

Air pipes, ventilators, small hatchways, fans and control valves are to be located outside the loading area and protected from possible shifting of the deck cargo.

# Section 3 Stability

## 1 General

### 1.1 Application

1.1.1 Every decked OSV of 24 metres and over is to comply with the provisions of present Section.

Note 1: The requirements of this Section are based on IMO Offshore Supply Vessel Guidelines amended by MSC 335(90).

1.1.2 The intact and damage stability of an OSV of less than 24 metres in length should be to the satisfaction of the Society.

### 1.2 Relaxation

1.2.1 Unless specified in [1.3], relaxation in the requirements of the present Section may be permitted by the Society for ships granted with navigation notation **coastal area**, provided the operating conditions are such as to render compliance with these requirements unreasonable or unnecessary.

### 1.3 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features

1.3.1 No relaxation in the requirements of the present Section shall be accepted for ships assigned with the additional service features **HNLS** and/or **WELLSTIM**.

1.3.2 In addition to the requirements mentioned in this Section, the provisions of OSV Chemical Code Chapter 2, section 2.1, are to be applied.

Note 1: With reference to OSV Chemical Code Chapter 2, section 2.1.2, the stability of ships other than those carrying cargoes containing mixtures and individual products indicated in chapter 17 of the IBC Code and the latest edition of the MEPC.2/Circular will be subject to special consideration.

## 2 Intact stability

### 2.1 General

#### 2.1.1 General stability criteria

The intact stability for the loading conditions defined in Pt B, Ch 3, App 2, [1.2.1] and Pt B, Ch 3, App 2, [1.2.13] with the assumptions in [2.1.5], is to be in compliance with the requirements of Pt B, Ch 3, Sec 2, [2.1] or, as an alternative, with the requirements of [2.1.2]. The additional criteria of [2.1.3] are also to be complied with.

#### 2.1.2 Alternative stability criteria

The following equivalent criteria are recommended where the ship's characteristics render compliance with Pt B, Ch 3, Sec 2, [2.1] impracticable:

- the area, in m-rad, under the curve of righting levers (GZ curve) may not be less than 0,070 up to an angle of 15° when the maximum righting lever (GZ) occurs at 15° and 0,055 up to an angle of 30° when the maximum righting lever (GZ) occurs at 30° or above. Where the maximum righting lever (GZ) occurs at angles of between 15° and 30°, the corresponding area "A", in m-rad, under the righting lever curve is to be:

$$A = 0,055 + 0,001 \cdot (30^\circ - \theta_{\max})$$

where  $\theta_{\max}$  is the angle of heel, in degrees, at which the righting lever curve reaches its maximum

- the area, in m-rad, under the righting lever curve (GZ curve) between the angles of heel of 30° and 40°, or between 30° and  $\theta_i$ ; if this angle is less than 40°, may not be less than 0,03, where  $\theta_i$  is defined in Pt B, Ch 3, Sec 2, [2.1.2]
- the righting lever (GZ), in m, is to be at least 0,20 at an angle of heel equal to or greater than 30°
- the maximum righting lever (GZ) is to occur at an angle of heel not less than 15°
- the initial transverse metacentric height (GM), in m, may not be less than 0,15 m.

#### 2.1.3 Additional criteria

A minimum freeboard at the stern of at least 0,005 L is to be maintained in all operating conditions.

#### 2.1.4 Factors of influence

The stability criteria mentioned in [2.1.1] and [2.1.2] are minimum values; no maximum values are recommended. It is advisable to avoid excessive values, since these might lead to acceleration forces which could be prejudicial to the vessel, its complement, its equipment and the safe carriage of cargo.

Where anti-rolling devices are installed, the stability criteria indicated in [2.1.1] and [2.1.2] are to be maintained when the devices are in operation.

**2.1.5 Assumptions for calculating loading conditions**

If a vessel is fitted with cargo tanks, the fully loaded conditions of Pt B, Ch 3, App 2, [1.2.13] are to be modified, assuming first the cargo tanks full and then the cargo tanks empty.

If in any loading condition water ballast is necessary, additional diagrams are to be calculated, taking into account the water ballast, the quantity and disposition of which are to be stated in the stability information.

In all cases when deck cargo is carried, a realistic stowage weight is to be assumed and stated in the stability information, including the height of the cargo and its centre of gravity.

Where pipes are carried on deck, a quantity of trapped water equal to a certain percentage of the net volume of the pipe deck cargoes is to be assumed in and around the pipes. The net volume is to be taken as the internal volume of the pipes, plus the volume between the pipes. This percentage is 30 if the freeboard amidships is equal to or less than 0,015 L and 10 if the freeboard amidships is equal to or greater than 0,03 L. For intermediate values of the freeboard amidships, the percentage may be obtained by linear interpolation. In assessing the quantity of trapped water, the Society may take into account positive or negative sheer afit, actual trim and area of operation.

A vessel, when engaged in towing operations, may not carry deck cargo, except that a limited amount, properly secured, which would neither endanger the safe working of the crew nor impede the proper functioning of the towing equipment, may be accepted.

Allowance is to be made for the anticipated type of wire or rope on storage reels and wire on the winches when calculating loading conditions.

**2.2 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features**

2.2.1 Requirements mentioned in the OSV Chemical Code Chapter 2, section 2.2, are to be referred to. In any case, requirements mentioned in the OSV Chemical Code shall prevail.

**3 Damage stability**

**3.1 Damage stability when the additional class notation SDS is assigned**

**3.1.1 General**

Taking into account, as initial conditions before flooding, the standard loading conditions as referred to in Pt B, Ch 3, App 2, [1.2.1] and Pt B, Ch 3, App 2, [1.2.13], the vessel is to comply with the damage stability criteria as specified in [3.1.8].

**3.1.2 Damage dimensions**

The assumed extent of damage of supply vessels is to be as indicated in Tab 1.

The extent of damage is to occur anywhere in the vessel’s length between any transverse watertight bulkhead.

**Table 1 : Extent of damage**

Ship length	Longitudinal extent	Transverse extent (1)	Vertical extent (2)
L ≥ 80 m	1/3 L <sup>2/3</sup>	B/20, or 760 mm (3)	Full depth
43 < L < 80 m	3L/100 + 3	760 mm	
L ≤ 43 m	L/10		

(1) Measured inboard from the side of the vessel perpendicularly to the centreline at the level of the summer load waterline.  
 (2) From the underside of the cargo deck, or the continuation thereof.  
 (3) Whichever is the greater.

**3.1.3 Consideration of transverse watertight bulkheads for flooding**

For a vessel with length (L) less than 80 m, a transverse watertight bulkhead extending from the vessel's side to a distance inboard of 760 mm or more at the level of the summer load line joining longitudinal watertight bulkheads may be considered as a transverse watertight bulkhead for the purpose of the damage calculations.

For a vessel with length (L) from 80 m to 100 m, a transverse watertight bulkhead extending from the vessel's side to a distance inboard of B/20 or more (but not less than 760 mm) at the level of the summer load line joining longitudinal watertight bulkheads may be considered as a transverse watertight bulkhead for the purpose of the damage calculations.

Where a transverse watertight bulkhead is located within the transverse extent of assumed damage and is stepped in way of a double bottom or side tank by more than 3,05 m, the double bottom or side tank adjacent to the stepped portion of the bulkhead is to be considered as flooded simultaneously.

If the distance between adjacent transverse watertight bulkheads or the distance between the transverse planes passing through the nearest stepped portions of the bulkheads is less than the longitudinal extent of damage given in [3.1.2], only one of these bulkheads should be regarded as effective for the purpose of the damage assumptions described in Tab 1.

**3.1.4 Progressive flooding**

If pipes, ducts or tunnels are situated within the assumed extent of damage, arrangements are to be made to ensure that progressive flooding cannot thereby extend to compartments other than those assumed to be floodable for each case of damage. The progressive flooding is to be considered in accordance with Pt B, Ch 3, Sec 3, [3.3].

**3.1.5 Minor damage**

If damage of a lesser extent than that specified in [3.1.2] results in a more severe condition, such lesser extent is to be assumed.

**3.1.6 Permeability**

The permeability of spaces assumed to be damaged is to be as indicated in Tab 2.

**Table 2 : Values of permeability**

Spaces	Permeability
Appropriated for stores	0,60
Occupied by accommodation	0,95
Occupied by machinery	0,85
Void spaces, empty tanks	0,95
Intended for dry cargo	0,95
Intended for liquids	(1)
(1) The permeability of tanks is to be consistent with the amount of liquid carried.	

**3.1.7 Survival requirements**

Compliance with the requirements of [3.1.8] is to be confirmed by calculations which take into consideration the design characteristics of the vessel, the arrangements, configuration and permeability of the damaged compartments and the distribution, specific gravities and free surface effect of liquids.

**3.1.8 Damage stability criteria**

- a) The final waterline, taking into account sinkage, heel and trim, is to be below the lower edge of any opening through which progressive flooding may take place. The progressive flooding is to be considered in accordance with Pt B, Ch 3, Sec 3, [3.3].
- b) In the final stage of flooding, the angle of heel due to unsymmetrical flooding may not exceed 15°. This angle may be increased up to 17° if no deck immersion occurs.
- c) The stability in the final stage of flooding is to be investigated and may be regarded as sufficient if the righting lever curve has at least a range of 20° beyond the position of equilibrium in association with a maximum residual righting lever of at least 100 mm within this range. Unprotected openings may not become immersed at an angle of heel within the prescribed minimum range of residual stability unless the space in question has been included as a floodable space in calculations for damage stability. Within this range, immersion of any of the openings referred to in item a) and any other openings capable of being closed weathertight may be authorized.

Note 1: "other openings capable of being closed weathertight" do not include ventilators that have to remain open to supply air to the engine room or emergency generator room for the effective operation of the ship.

- d) The stability is to be sufficient during intermediate stages of flooding. In this regard, the Society applies the same criteria relevant to the final stage of flooding also during the intermediate stages of flooding.

**3.1.9 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features**

Requirements mentioned in the OSV Chemical Code sections 2.4, 2.5, 2.6, 2.7 and 2.8. are to be referred to. In any case, requirements mentioned in the OSV Chemical Code shall prevail.

Requirements mentioned in section 2.9.2 of the OSV Chemical Code are to be applied regarding the protrusion of suction wells installed inside cargo tanks for IBC Code ship types 2 and 3 products when affected compartments are determined flooded after a damage

For the application of these requirements, Tab 3 is to be used to consider together:

- ship type according to the quantity of products carried
- damage assumptions
- standard of damage.

**Table 3 : Damage stability assumptions for ships granted with HNLS and/or WELLSTIM additional service features**

Quantity of product carried, with reference to IBC Code		Ship length	Stability
type 1	type 2 + type 3		
≤ 150 m <sup>3</sup>	< 800 m <sup>3</sup>	> 100 m	<ul style="list-style-type: none"> <li>should be assumed to sustain damage described in section 2.6.2 of the OSV Chemical Code anywhere along the length between transverse watertight bulkheads, and</li> <li>should also comply with SOLAS regulations II-1/6 to II-1/7-3 (probabilistic damage stability standard for a cargo ship).</li> </ul>
		≤ 100 m	should be assumed to sustain damage described in section 2.6.2 of the OSV Chemical Code anywhere along the length between transverse watertight bulkheads.
≤ 150 m <sup>3</sup>	≥ 800 m <sup>3</sup> and ≤ 1200 m <sup>3</sup>	> 100 m	<ul style="list-style-type: none"> <li>should be assumed to sustain damage described in section 2.6.2 of the OSV Chemical Code anywhere along the length, and</li> <li>should also comply with SOLAS regulations II-1/6 to II-1/7-3 (probabilistic damage stability standard for a cargo ship).</li> </ul>
		≤ 100 m	should be assumed to sustain damage described in section 2.6.2 of the OSV Chemical Code anywhere along the length.
≤ 150 m <sup>3</sup>	> 1200 m <sup>3</sup>	> 100 m	should be assumed to sustain damage described in section 2.6.1 of the OSV Chemical Code anywhere along the length.
		≤ 100 m	should be assumed to sustain damage described in section 2.6.1 of the OSV Chemical Code anywhere along the length except involving bulkheads bounding a machinery space of category A.
> 150 m <sup>3</sup>	any quantity	any length	should be assumed to sustain damage described in section 2.6.1 of the OSV Chemical Code anywhere along the length.

## Section 4 Hull Structure

### Symbols

- k : Material factor for steel, defined in Pt B, Ch 4, Sec 1, [2.2]  
b : Breadth of an elementary plate panel (EPP), in mm, as defined in Pt B, Ch 4, Sec 6, [2.1.1].

### 1 Structure design principles

#### 1.1 General

**1.1.1** For ships greater than 24 m in length, it is recommended that a double skin is provided to reinforce the protection of the main compartments in the event of contact with pontoons or platform piles.

#### 1.2 Side structure exposed to bumping

##### 1.2.1 Longitudinally framed side

In the whole area where the side of the ship is exposed to bumping, distribution frames are to be provided at mid-span, consisting of an intercostal web of the same height as the ordinary stiffeners, with a continuous face plate.

Within reinforced areas, scallop welding for all side ordinary stiffeners is forbidden.

##### 1.2.2 Transversely framed side

In the whole area where the side of the ship is exposed to bumping, a distribution stringer is to be fitted at mid-span, consisting of an intercostal web of the same height as the ordinary stiffeners, with a continuous face plate.

Side frames are to be fitted with brackets at ends.

Within reinforced areas, scallop welding for all side ordinary stiffeners is forbidden.

##### 1.2.3 Fenders

Efficient fenders, adequately supported by structural members, are to be fitted on the side, including the forecastle, on the full length of the areas exposed to contact.

#### 1.3 Deck structure

**1.3.1** Local reinforcements are to be fitted in way of specific areas which are subject to concentrated loads.

**1.3.2** Exposed decks carrying heavy cargoes or pipes are to provide protection and means of fastening for the cargo, e.g. inside bulwarks, guide members, lashing points, etc.

#### 1.4 Structure of cement tanks and mud compartments

**1.4.1** Cargo tanks and hoppers intended to carry mud or cement are to be supported by structures which distribute the acting forces as evenly as possible on several primary supporting members.

#### 1.5 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features

##### 1.5.1 Suction wells installed inside cargo tanks

When considering the size of suction wells installed inside the cargo tank, requirements of the OSV Chemical Code, Chapter 2, section 2.9.2 are to be referred to.

##### 1.5.2 Portable tanks used as deck tanks

- Requirements mentioned in OSV Chemical Code Chapter 5, section 5.2.2 are to be referred to regarding the allowable designs of these tanks.
- Requirements mentioned in OSV Chemical Code Chapter 17, section 17.4.2 are to be referred to regarding the securing of the portable tanks to the deck.

**1.6 Additional requirements for ships granted with notation -acids**

1.6.1 In addition to the requirements mentioned in [1.5], the following apply:

- a) The requirements in section 15.11 of the IBC Code are to be applied.
- b) For acid spill protection, requirements mentioned in OSV Chemical Code Chapter 4, sections 4.4.2 and 4.4.6 are to be referred to.

**2 Design loads**

**2.1 Dry uniform cargoes**

**2.1.1 Still water and inertial pressures**

The still water and inertial pressures transmitted to the structure of the upper deck intended to carry loads are to be obtained, in kN/m<sup>2</sup>, as specified in Pt B, Ch 5, Sec 6, [6.1], where the value of P<sub>dl-s</sub> is to be taken not less than 24 kN/m<sup>2</sup>.

**3 Hull scantlings**

**3.1 Plating**

**3.1.1 Minimum net thicknesses**

The net thickness of the side and upper deck plating is to be not less than the values given in Tab 1.

**Table 1 : Minimum net thickness of the side and upper deck plating**

Plating	Minimum net thickness, in mm
Side below freeboard deck	The greater of: <ul style="list-style-type: none"> <li>• <math>2,1 + 0,031 L k^{0,5} + 0,0045 b</math></li> <li>• <math>8 k^{0,5}</math></li> </ul>
Side between freeboard deck and strength deck	The greater of: <ul style="list-style-type: none"> <li>• <math>2,1 + 0,013 L k^{0,5} + 0,0045 b</math></li> <li>• <math>8 k^{0,5}</math></li> </ul>
Upper deck	7,0

**3.1.2 Strength deck plating**

Within the cargo area, the thickness of strength deck plating is to be increased by 1,5 mm with respect to that determined according to Pt B, Ch 7, Sec 4.

However, the above increase in thickness by 1,5 mm may be omitted provided all the following conditions are fulfilled:

- a) Wooden planking provide an efficient protection of the deck at the satisfaction of the society.
- b) The welding of the steel fittings securing the wood protection is performed before coating application.
- c) Full coating application is applied after item b) above.

**3.2 Stiffeners**

**3.2.1 Longitudinally framed side exposed to bumping**

In the whole area where the side of the supply vessel is exposed to bumping, the section modulus of stiffeners is to be increased by 15% with respect to that determined according to Pt B, Ch 7, Sec 5.

**3.2.2 Transversely framed side exposed to bumping**

In the whole area where the side of the supply vessel is exposed to bumping, the section modulus of stiffeners, i.e. side, tweendeck and superstructure frames, is to be increased by 25% with respect to that determined according to Pt B, Ch 7, Sec 5.

**3.3 Primary supporting members**

**3.3.1 Distribution stringers**

The section modulus of the distribution stringer required in [1.2.2] is to be at least twice that calculated in [3.2.2] for stiffeners.

**3.3.2 Cement tanks and mud compartments**

The net scantlings of the primary supporting members of cement tanks and mud compartments are to be calculated taking into account high stresses resulting from vertical and horizontal accelerations due to rolling and pitching.

Secondary moments due to the tendency of materials to tip over are to be considered by the Society on a case-by-case basis.

## 4 Other structure

### 4.1 Aft part

#### 4.1.1 Rollers

At the transom, local reinforcements are to be fitted in way of rollers and other special equipment intended for cargo handling.

#### 4.1.2 Structures in way of rollers

The structures in way of the stern rollers and those of the adjacent deck are considered by the Society on a case-by-case basis, taking into account the relevant loads which are to be specified by the Designer.

### 4.2 Superstructures and deckhouses

#### 4.2.1 Deckhouses

Due to their location at the forward end of the supply vessel, deckhouses are to be reduced to essentials and special care is to be taken so that their scantlings and connections are sufficient to support wave loads.

#### 4.2.2 Minimum net thicknesses

The net thickness of forecastle aft end plating and of plating of deckhouses located on the forecastle deck is to be not less than the values given in Tab 2.

**Table 2 : Plating of forecastle aft end and of deckhouses located on the forecastle deck**

Structure	Plating	Minimum net thickness, in mm
Forecastle	aft end	1,04 (5 + 0,01 L)
Deckhouses located on the forecastle deck	front	1,44 (4 + 0,01 L)
	sides	1,31 (4 + 0,01 L)
	aft end	1,22 (4 + 0,01 L)

#### 4.2.3 Stiffeners

The net section modulus of stiffeners of the forecastle aft end and of deckhouses located on the forecastle deck is to be not less than the values obtained from Tab 3.

Stiffeners of the front of deckhouses located on the forecastle deck are to be fitted with brackets at their ends. Those of side and aft end bulkheads of deckhouses located on the forecastle deck are to be welded to decks at their ends.

**Table 3 : Stiffeners of forecastle aft end and of deckhouses located on the forecastle deck**

Structure	Stiffeners on	Net section modulus, in cm <sup>3</sup>
Forecastle	aft end plating	3 times the value calculated according to Pt B, Ch 11, Sec 5, [3.3]
Deckhouses located on the forecastle deck	front plating	
	sides plating	0,75 times that of the forecastle tweendeck frames
	aft end plating	

### 4.3 Structure of cargo tanks

4.3.1 Scantling of cargo tanks is to be in compliance with the provisions of Part B, Chapter 7.

Refer to Ch 3, Sec 5, [3] to Ch 3, Sec 5, [6] for design details.

## 5 Hull outfitting

### 5.1 Rudders

#### 5.1.1 Rudder stock scantlings

The rudder stock diameter is to be increased by 5% with respect to that determined according to Pt B, Ch 12, Sec 1, [4].

### 5.2 Bulwarks

#### 5.2.1 Plating

In the case of a high bulwark, fitted with a face plate of large cross-sectional area, which contributes to the longitudinal strength, the thickness of the plating contributing to the longitudinal strength is to be not less than the value obtained according to Pt B, Ch 7, Sec 4.

### 5.2.2 Stays

The bulwark stays are to be strongly built with an attachment to the deck reinforced to take account of accidental shifting of deck cargo (e.g. pipes).

## 5.3 Equipment

### 5.3.1 Mooring lines

The mooring lines are given as a guidance, but are not required as a condition of classification.

The length of mooring lines may be calculated according to Pt B, Ch 12, App 2, [2].

However, in the case of supply vessels provided with devices enabling ample manoeuvring characteristics (e.g. supply vessels provided with two or more propellers, athwartship thrust propellers, etc.), the length of mooring lines, in m, may be reduced to  $(L + 20)$ .

### 5.3.2 Chain locker

Chain lockers are to be arranged as gas-safe areas. Hull penetrations for chain cables and mooring lines are to be arranged outside the hazardous areas specified in Ch 3, Sec 1, [1.5.20].

## Section 5 Machinery and Cargo Systems

### 1 Machinery systems

#### 1.1 Cargo heating systems

1.1.1 Where provided, any cargo tank heating system is to comply with the provisions of Pt D, Ch 7, Sec 4, [2.6]

With reference to Ch 3, Sec 1, [1.5.15], particular attention to be provided to the maximum heating temperature of cargo tanks intended for the carriage of oil products.

#### 1.2 Exhaust pipes

1.2.1 Exhaust outlets from diesel engines are to be provided with spark arresters.

#### 1.3 Inert gas system

1.3.1 Where provided, nitrogen/inert gas systems fitted on the ship are to comply with the provision of Pt D, Ch 8, Sec 9, [2].

#### 1.4 Other machinery systems

1.4.1 Fuel oil, lubricating oil tanks, foam forming liquid tanks, oil dispersant tanks and similar tanks which are located inside the cargo area may be served by pumps located outside the cargo area, provided that the piping is directly connected to the associated pump and does not run through cargo tanks.

#### 1.5 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features

##### 1.5.1 Non cargo discharges below the freeboard deck

Requirements mentioned in Pt C, Ch 1, Sec 10, [8] and OSV Chemical Code section 2.3 are to be referred.

##### 1.5.2 Pumps, ballast lines and vent lines serving ballast tanks

Requirements mentioned in OSV Chemical Code, Chapter 3, section 3.1.5 are to be referred to.

#### 1.6 Additional requirements for ships granted with notations -FP $\leq$ 60°C and/or -acids and/or -toxic

1.6.1 In addition to the requirements mentioned in [1.5], the following apply:

- a) For discharge and filling arrangements for ballast or fresh water sited immediately adjacent to cargo tanks certified for products or residues of products, requirements mentioned in OSV Chemical Code Chapter 4, section 4.1.5 are to be referred to.
- b) For bilge pumping systems serving spaces where cargoes or residues of cargoes may occur, requirements mentioned in OSV Chemical Code Chapter 4, section 4.1.6 are to be referred to.
- c) For air intakes and openings into accommodation, passageways, service and machinery spaces and control stations in relation to cargo piping and cargo vent systems, requirements mentioned in OSV Chemical Code Chapter 4, section 4.1.7 are to be referred to.

#### 1.7 Additional requirements for ships granted with notation -FP $\leq$ 60°C

1.7.1 In addition to the requirements mentioned in [1.5] and [1.6], for air inlets and openings to accommodation, service and machinery spaces and control stations, requirements mentioned in OSV Chemical Code Chapter 4, section 4.2.2 are to be referred to.

#### 1.8 Additional requirements for ships granted with notation -toxic

1.8.1 In addition to the requirements mentioned in [1.5] and [1.6], the following apply:

- a) The special requirements mentioned in the IBC Code Chapter 15, section 15.12 are to be referred to.
- b) For air inlets and openings to accommodation, service and machinery spaces and control stations, requirements mentioned in OSV Chemical Code Chapter 4, sections 4.3.2, 4.3.3 and 4.3.4 are to be referred to.

## **1.9 Additional requirements for ships granted with notation -acids**

**1.9.1** In addition to the requirements mentioned in [1.5] and [1.6], the following apply:

- a) For detection of leakage of cargo in adjacent spaces, requirements mentioned in IBC Code Chapter 15, section 15.11.7 are to be referred to.
- b) For cargo pump room bilge pumping and drainage, requirements mentioned in IBC Code Chapter 15, section 15.11.8 are to be referred to.

## **2 Cargo piping design**

### **2.1 Cargo separation**

**2.1.1** For cargo handling, a pumping and piping system independent from the other pumping and piping systems on board is to be provided.

**2.1.2** The piping system serving the non-flammable oil product cargo tanks may be connected to the fuel oil pumping system in engine room, provided that:

- there are suitable means of separation between the branches serving the tanks dedicated for the cargo oil product tanks and the branches serving the fuel oil tanks
- mixing the two different kinds of oils does not jeopardize the intended use of neither the fuel oil nor the cargo.

### **2.2 Design and materials**

**2.2.1** Unless otherwise specified, materials for construction of tanks, piping, fittings and pumps are to be in accordance with Pt D, Ch 7, Sec 4, [3.3.2].

**2.2.2** Unless otherwise specified, cargo piping is to be designed and constructed according to Pt D, Ch 7, Sec 4, [3.3.1].

### **2.3 Piping arrangement**

**2.3.1** The following requirements apply:

- a) Cargo piping conveying non-flammable oil products, need not be located entirely within the cargo area provided that the separation requirements for accommodation spaces, drinking water and stores for human consumption are observed.
- b) *Control of discharge of oil products is to comply with Pt D, Ch 7, Sec 4, [5.3].*

*Note 1: This requirement might not be applied when aggregate capacity does not exceed 1000 m<sup>3</sup>.*

## **2.4 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features**

### **2.4.1 Segregation of cargo**

Requirements mentioned in OSV Chemical Code Chapter 3, sections 3.1.2.2, 3.1.3 and 3.1.4, are to be referred to.

### **2.4.2 Piping scantling, fabrication, joining details, flange connections and testing**

Requirements mentioned in OSV Chemical Code Chapter 6, sections 6.1, 6.2, 6.3 and 6.4, are to be referred to.

### **2.4.3 Piping arrangements**

Requirements mentioned in OSV Chemical Code Chapter 6, section 6.5, are to be referred to.

### **2.4.4 Cargo transfer control system**

Requirements mentioned in OSV Chemical Code Chapter 6, section 6.6, are to be referred to.

### **2.4.5 Ship's cargo hoses**

Requirements mentioned in OSV Chemical Code Chapter 6, section 6.7, are to be referred to.

### **2.4.6 Mechanical ventilation in the cargo area**

Requirements mentioned in the OSV Chemical Code Chapter 10 are to be referred to.

*Note 1: Attention is drawn on the specific requirements to be applied as mentioned in the OSV Chemical Code sections 10.1.1, 10.1.2 and 10.1.3.*

*Note 2: Attention is drawn on the specific requirements to be applied mentioned in the OSV Chemical Code Chapter 10, section 10.3 for spaces normally not entered.*

### **2.4.7 Pollution prevention - no discharge to the sea**

Requirements mentioned in the OSV Chemical Code Chapter 12, section 12.2 are to be referred to.

**2.5 Additional requirements for ships granted with notations -FP≤60°C and/or -acids and/or -toxic**

2.5.1 In addition to the requirements mentioned in [2.4], for cargo piping location, requirements mentioned in OSV Chemical Code Chapter 4, section 4.1.4 are to be referred to.

**3 Cargo tanks**

**3.1 Cargo oil tanks**

3.1.1 Integral and independent gravity tanks are to be constructed and tested according to recognised standards taking into account the carriage temperature and the cargo relative density.

**3.2 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features**

**3.2.1 Tank type requirements for individual products**

Requirements mentioned in OSV Chemical Code Chapter 5, section 5.2.1 are to be referred to.

**3.2.2 Carriage of contaminated backloads**

Requirements mentioned in OSV Chemical Code Chapter 16, section 16.4.2.1 are to be referred to.

**4 Cargo pumping system**

**4.1 General**

4.1.1 The delivery side of cargo pumps is to be fitted with relief valves discharging back to the suction side of the pumps (bypass) in closed circuit. Such relief valves may be omitted in the case of centrifugal pumps with a maximum delivery pressure not exceeding the design pressure of the piping, with the delivery valve closed.

4.1.2 Cargo pumps are to be monitored as required in Tab 1.

**Table 1 : Monitoring of cargo pumps**

Equipment - parameter	Alarm	Indication	Comments
Pump - discharge pressure	L	Local	<ul style="list-style-type: none"> <li>on the pump (1), or</li> <li>next to the unloading control station</li> </ul>
Pump casing - temperature (2)	H		visual and audible, in cargo control room or pump control station
Bearings - temperature (2)	H		visual and audible, in cargo control room or pump control station
Bulkhead shaft gland - temperature (2)	H		visual and audible, in cargo control room or pump control station
(1) And next to the driving machine if located in a separate compartment. (2) Not required for supply vessels intended to carry pollution hazard only substances having a flashpoint above 60°C or oil products having a flashpoint above 60°C only.			

**5 Cargo tank fittings**

**5.1 Level gauging systems and overflow control**

**5.1.1 Cargo oil tanks**

For the cargo tanks intended to carry oil products having a flashpoint above 60°C, the gauging systems may be of the open type provided that the relevant provisions of Pt C, Ch 1, Sec 10, [9] and Pt C, Ch 1 Sec 10, [11] are complied with.

Each cargo tank is to be fitted with a level gauging system in compliance with Pt D, Ch 7, Sec 4, [4.4] and an overflow control system in compliance with Pt D, Ch 7, Sec 4, [4.5].

**5.2 Cargo tank venting systems**

**5.2.1 General**

Cargo tanks are to be provided with a venting system appropriate to the cargo being carried and these systems shall be independent of the air pipes and venting systems of all other compartments of the ship.

**5.2.2 Cargo oil tanks**

The following requirements apply:

- a) general provisions of Pt C, Ch 1, Sec 10, [9] and Pt C, Ch 1, Sec 10, [11] are to be complied with
- b) tank venting systems are to open to the atmosphere at a height of at least 760 mm above the weather deck
- c) tanks may be fitted with venting systems of the open type provided with a flame screen.

### **5.3 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features**

#### **5.3.1 Separated venting systems**

Requirements mentioned in OSV Chemical Code Chapter 3, section 3.1.2.3] are to be referred to.

#### **5.3.2 Cargo tank venting**

Requirements mentioned in OSV Chemical Code Chapter 7, are to be referred to.

#### **5.3.3 Venting of tanks carrying contaminated backloads**

Requirements mentioned in OSV Chemical Code Chapter 16, section 16.4.2.2.1 are to be referred to.

#### **5.3.4 Cargo tank indicators and overflow control**

Requirements mentioned in OSV Chemical Code Chapter 11, sections 11.1, 11.2 and 11.3 are to be referred to.

### **5.4 Additional requirements for ships granted with notation -toxic**

**5.4.1** In addition to the requirements mentioned in [5.3], the following apply:

- a) Special requirements in the section 15.12 of the IBC Code Chapter 15 apply.
- b) For set point of the pressure vacuum valves, requirements mentioned in OSV Chemical Code Chapter 4, section 4.3.7 are to be referred to.
- c) For alarms for pressure indication at cargo control station and cargo area, requirements mentioned in OSV Chemical Code Chapter 15, section 15.4.4 are to be referred to.

### **5.5 Additional requirements for ships granted with notation -acids**

**5.5.1** In addition to the requirements mentioned in [5.3], the following apply:

- a) For spray shields, requirements mentioned in OSV Chemical Code Chapter 4, section 4.4.3 are to be referred to.
- b) For loading manifolds (portable shield covers and drainage arrangements), requirements mentioned in OSV Chemical Code, section 4.4.4 are to be referred to.
- c) For drainage arrangements, requirements mentioned in OSV Chemical Code section 4.4.5 are to be referred to.

## **6 Mechanical ventilation in the cargo area**

### **6.1 Cargo pump-room ventilation**

#### **6.1.1 Ships carrying oil products**

- a) Cargo pump rooms are to be mechanically ventilated. The number of changes of air is to be at least 20 per hour, based upon the gross volume of the space.
- b) Ventilation intakes are to be so arranged as to minimize the possibility of recycling hazardous vapours from ventilation discharge openings.
- c) Ventilation ducts are not to be led through gas-safe spaces, cargo tanks or slop tanks.

### **6.2 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features**

#### **6.2.1 Mechanical ventilation in the cargo area**

Requirements mentioned in the OSV Chemical Code Chapter 10 are to be referred to.

Note 1: Attention is drawn on the specific requirements to be applied mentioned in the OSV Chemical Code, sections 10.1.1, 10.1.2 and 10.1.3.

Note 2: Attention is drawn on the specific requirements to be applied mentioned in the OSV Chemical Code Chapter 10, section 10.3 for spaces normally not entered.

## **7 Discharging and loading of portable tanks on board**

### **7.1 Ships granted with additional service features HNLS and/or WELLSTIM**

#### **7.1.1 Type of tank and quantity limitations**

Requirements mentioned in the OSV Chemical Code Chapter 17, section 17.2 are to be referred to.

Note 1: When the product transported is not included in the list of products in Ch 3, Sec 1, [1.3.2], attention is drawn on requirements in OSV Chemical Code Chapter 17, section 17.2.2: carriage of such product is to be accepted by the Society and the quantity of such product able to be carried is limited.

### **7.1.2 Arrangement of deck spread**

Requirements mentioned in the OSV Chemical Code Chapter 17, section 17.3 are to be referred to.

Arrangement of the deck spread are to be submitted, referring to the OSV Chemical Code Appendix 3, sections 4.1, 4.2 and attachments 3, 4, 5 and 6.

### **7.1.3 Portable tanks used as deck tanks**

Requirements mentioned in the OSV Chemical Code Chapter 17, sections 17.4.4 and 17.4.6 are to be referred to.

## **8 Additional requirements for carriage of liquid carbon dioxide and liquid nitrogen**

### **8.1 Ships granted with notation -LG**

#### **8.1.1 General**

The provisions of this Article does not consider the carriage of other liquefied gases listed in chapter 19 of the IGC Code. When carriage of such liquefied gases are considered, this is to be handled on a case by case basis, referring to the OSV Chemical Code Chapter 18, section 18.12.

The Society may allow adjustments to specific requirements in the IGC Code regarding the cargo containment, materials of construction, vent system for cargo containment and cargo transfer, taking into account existing industry standards and practices, if it is as least as effective as that required by the IGC Code. In any case, these adjustments, if any, are to be submitted to the Administration.

#### **8.1.2 Location of cargo tanks and ship survivability**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.1.4 are to be referred to.

#### **8.1.3 Carriage requirements**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.1.5 are to be referred to.

#### **8.1.4 Accommodation, service and machinery spaces and control stations**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.2 are to be referred to.

#### **8.1.5 Cargo containment**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.3 are to be referred to.

Note 1: Attention is drawn to the specific requirement related to liquid nitrogen

#### **8.1.6 Materials of construction**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.4 are to be referred to.

#### **8.1.7 Vent system for cargo containment**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.5 are to be referred to.

#### **8.1.8 Cargo transfer**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.6 are to be referred to.

#### **8.1.9 Vapour detection**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.7 are to be referred to.

#### **8.1.10 Gauging and level detection**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.8 are to be referred to.

#### **8.1.11 Emergency shutdown system**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.9 are to be referred to.

#### **8.1.12 Carriage on open deck**

Requirements mentioned in the OSV Chemical Code Chapter 18, section 18.11 are to be referred to.

# Section 6 Electrical Installations, Instrumentation and Automation

## 1 Hazardous location and types of equipment

### 1.1 General

1.1.1 OSVs are to comply with the requirements of Pt D, Ch 7, Sec 5.

1.1.2 Electrical equipment, cables and wiring shall not be installed in the hazardous location unless it conforms to IEC 60092-502.

## 2 Additional requirements for ships granted with HNLS and/or WELLSTIM additional service features

### 2.1 General

2.1.1 Requirements mentioned in OSV Chemical Code Chapter 8 are to be referred to.

Note 1: Specific attention should be drawn on the requirements mentioned in OSV Chemical Code, section 8.1.7.

#### 2.1.2 Remote control for loading and unloading

Requirements mentioned in OSV Chemical Code Chapter 11, section 11.1.2 are to be referred to.

### 2.2 Additional requirements for ships granted with notations $-FP \leq 60^{\circ}\text{C}$ and/or -toxic

2.2.1 In addition to the requirements mentioned in [2.1], for vapour detection, requirements mentioned in OSV Chemical Code Chapter 11, section 11.4 are to be referred to.

### 2.3 Additional requirements for ships granted with notation -acid

2.3.1 In addition to the requirements mentioned in [2.1], the following apply:

- a) For hydrogen risk, requirements mentioned in IBC Code Chapter 15, section 15.11.5 are to be referred to.
- b) For detection of leakage of cargo in adjacent spaces, requirements mentioned in IBC Code Chapter 15, section 15.11.7 are to be referred to.

# Section 7 Fire Prevention, Protection and Extinction

## 1 General

### 1.1 Application

1.1.1 Unless otherwise specified, this Section applies to ships intended to carry products as mentioned in Ch 3, Sec 1, [1.1]

1.1.2 For ships intended to carry only liquid identified as non-flammable and not covered by the OSV Chemical Code, the fire-fighting requirements are to be to the satisfaction of the Society.

## 2 Fire prevention and protection

### 2.1 Ships granted with additional service features HNLS and/or WELLSTIM

2.1.1 For ships granted with notation **-FP≤60°C**, with reference to OSV Chemical Code Chapter 4, section 4.2.2, doors to spaces not having access to accommodation, service and machinery spaces and control stations, such as cargo control stations and store-rooms, may be permitted within the deck area mentioned in OSV Chemical Code Chapter 1, Section 1.2.7.3, provided the boundaries of the spaces are insulated to A-60 standard.

## 3 Fire fighting

### 3.1 Ships carrying oil product

3.1.1 For ships of 500 gross tonnage and above, the requirements in Part C, Chapter 4 as they would apply to cargo ships of 2000 gross tonnage and over, are to be complied with.

In addition, the following requirements apply:

- Pt C, Ch 4, Sec 6, [1.2.4], item g)
- Pt D, Ch 7, Sec 6, [3.2] and Pt D, Ch 7, Sec 6, [3.3].

### 3.2 Ships granted with additional service features HNLS and/or WELLSTIM

3.2.1 Requirements mentioned in OSV Chemical Code Chapter 9 are to be referred to.

Note 1: OSV Chemical Code Chapter 9 requirements are referring both to SOLAS II-2 and the IBC Code Chapter 17. Attention is drawn on the OSV Chemical Code Chapter 9, [9.2] and [9.3] that provide specific requirements for the cargo pump-rooms and the cargo area.

Note 2: Attention is drawn on the OSV Chemical Code Chapter 9, sections 9.1.2, 9.1.3 and 9.1.4 about relaxation of requirements for ships carrying non-flammable and/or having a flashpoint equal or greater than 60°C.

## 4 Personnel protection

### 4.1 Ships carrying oil products

#### 4.1.1 Fire-fighters outfits

Two additional fire-fighters outfits are to be provided.

### 4.2 Ships granted with additional service features HNLS and/or WELLSTIM

#### 4.2.1 General

Requirements mentioned in OSV Chemical Code Chapter 14, sections 14.1, 14.2, 14.3 and 14.4 are to be referred to.

#### 4.2.2 Carriage of contaminated backloads

Requirements mentioned in OSV Chemical Code Chapter 16, section 16.4.2.2, are to be referred to.

### 4.3 Additional requirements for ships granted with notation -LG

4.3.1 In addition to the requirements mentioned in [4.2] requirements mentioned in OSV Chemical Code Chapter 18, section 18.10, and consequently, in OSV Chemical Code Chapter 14, sections 14.3 and 14.4 are to be referred to.

### CHAPTER 4

## FIRE FIGHTING SHIPS

---

- Section 1      General
- Section 2      Hull and Stability
- Section 3      Machinery and Systems
- Section 4      Fire Protection and Extinction

# Section 1                      General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **fire-fighting**, as defined in Pt A, Ch 1, Sec 2, [4.11.3].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT
Ship arrangement	L ≥ 90 m	• Part B	• NR566
	L < 90 m	• NR600	• NR566

<p><b>Note 1:</b>            NR566: Hull Arrangement, Stability and Systems for Ships less than 500 GT.            NR600: Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m.</p>			

# Section 2 Hull and Stability

## 1 Stability

### 1.1 Intact stability

#### 1.1.1 General

The stability of the ship for the loading conditions defined in Pt B, Ch 3, App 2, [1.2.11] is to be in compliance with the requirements in Pt B, Ch 3, Sec 2.

#### 1.1.2 Additional criteria

The loading conditions reported in the trim and stability booklet, with the exception of lightship, are also to be checked in order to investigate the ship’s capability to support the effect of the reaction force of the water jet in the beam direction due to the monitors fitted on board.

A fire-fighting ship may be considered as having sufficient stability, according to the effect of the reaction force of the water jet in the beam direction due to the monitors fitted on board, if the heeling angle of static equilibrium  $\theta_0$ , corresponding to the first intersection between heeling and righting arms (see Fig 1), is less than  $5^\circ$ .

The heeling arm may be calculated as follows:

$$b_h = \frac{\sum R_i \cdot h_i + S \cdot (T/2 - e)}{9,81 \cdot \Delta} \cdot \cos\theta$$

where:

- $b_h$  : Heeling arm, in m, relevant to the reaction force of the water jet of the monitors fitted on board, and to the effect of transversal manoeuvring thrusters. The monitors are assumed to be oriented in beam direction parallel to the sea surface, so as to consider the most severe situation
- $R_i$  : Reaction force, in kN, of the water jet of each monitor fitted on board (see Fig 2)
- $h_i$  : Vertical distance, in m, between the location of each monitor and half draught (see Fig 2)
- $S$  : Thrust, in kN, relevant to manoeuvring thruster(s), if applicable (see Fig 2)
- $e$  : Vertical distance, in m, between the manoeuvring thruster axis and keel (see Fig 2)
- $\Delta$  : Displacement, in t, relevant to the loading condition under consideration
- $T$  : Draught, in m, corresponding to  $\Delta$  (see Fig 2).

**Figure 1 : Heeling and righting arm curves**

**Figure 2 : Reaction force of water jet in the beam direction due to monitors**

## **2 Structure design principles**

### **2.1 Hull structure**

**2.1.1** The strengthening of the structure of the ships, where necessary to withstand the forces imposed by the fire-extinguishing systems when operating at their maximum capacity in all possible directions of use, are to be considered by the Society on a case-by-case basis.

### **2.2 Water and foam monitors**

**2.2.1** The seatings of the monitors are to be of adequate strength for all modes of operation.

## **3 Other structures**

### **3.1 Arrangement for hull and superstructure openings**

**3.1.1** Deadlights and shutters are to be provided as requested by Ch 4, Sec 4, [2.2.1].

# Section 3 Machinery and Systems

## 1 General

### 1.1 Application

#### 1.1.1

- a) This Section provides, for ships having the service notations **fire-fighting E**, **fire-fighting 1**, **fire-fighting 2**, and **fire-fighting 3**, specific requirements for:
- machinery systems
  - fire-fighting systems installed on board the ship and intended for fighting of external fires.
- b) The requirements related to the self-protection water-spraying systems fitted to fire-fighting ships having the additional service feature **water spraying** are given in Ch 4, Sec 4.

### 1.2 Documentation to be submitted

1.2.1 The documents listed in Tab 1 are to be submitted.

## 2 Design of machinery systems

### 2.1 Manoeuvrability

#### 2.1.1 General

- a) The ratios between the main ship dimensions and the power of propulsion engines and of engines driving side thrusters are to be adequate and such as to ensure an effective manoeuvrability during fire-fighting operations.
- b) The side thrusters and the main propulsion system are to be capable of maintaining the ship in position in still water and of withstanding the reaction forces of the water monitors even in the most unfavourable combination of operating conditions of such monitors, without requiring more than 80% of the above propulsive power, to prevent engine overload.

**Table 1 : Documents to be submitted**

No.	I/A (1)	Description of the document (2)
1	I	General arrangement showing the disposition of all fire-fighting equipment
2	A	Details of all fire-fighting equipment such as pumps and monitors, including their capacity, range and trajectory of delivery
3	A	Schematic diagram of the water fire-fighting system
4	A	Plan of the water monitor seating arrangements
5	A	Diagram of local control and remote control system for water monitors
6	A	Schematic diagram of the fixed foam fire-extinguishing system
7	A	Plan of the foam monitor seating arrangements (3)
8	A	Diagram of local control and remote control system for foam monitors (3)
9	A	Specification and plan showing the location of fire-fighter's outfits and the location and capacity of the air compressor
10	A	Particulars of the means of keeping the ship in position during fire-fighting operations
11	I	Calculation of the required fuel oil capacity according to [2.2.1] (4)
12	I	Operating manual
<p>(1) A: to be submitted for approval; I: to be submitted for information.</p> <p>(2) Diagrams are also to include, where applicable:</p> <ul style="list-style-type: none"> <li>• the (local and remote) control and monitoring systems and automation systems</li> <li>• the instructions for the operation and maintenance of the piping system concerned (for information).</li> </ul> <p>(3) For ships having the service notation <b>fire-fighting 3</b>.</p> <p>(4) For ships having one of the following service notations: <b>fire-fighting 1</b>, <b>fire-fighting 2</b>, <b>fire-fighting 3</b>.</p>		

### **2.1.2 Power control system**

An operating control system of the power supplied by the engines is to be provided, including:

- an alarm device operating at 80% of the maximum propulsive power available in free navigation, and
- an automatic reduction of power on reaching 100% of the above propulsive power,

to prevent engine overload.

Note 1: Such operating control system may not be required, at the discretion of the Society, in cases where the installed power is redundant.

## **2.2 Fuel oil capacity**

**2.2.1** All ships are to have fuel oil tanks whose capacity is to be sufficient for continuous fighting of fires whilst all the water monitors are operating for a period of time not less than:

- 24 hours in the case of ships having the service notation **fire-fighting 1**
- 96 hours in the case of ships having the service notation **fire-fighting 2** or **fire-fighting 3**.

This capacity is to be additional to that provided for the normal operation of the ship (propulsion, etc.).

Note 1: The determination of such required capacity is the responsibility of the Designer.

## **2.3 Scuppers**

**2.3.1** When the ship is protected by a water-spraying system, suitable scuppers or freeing ports are to be provided to ensure efficient drainage of water accumulating on deck surfaces when such system is in operation.

# **3 General requirements for fire-fighting systems**

## **3.1 General**

**3.1.1** This Article applies to both water fire-extinguishing systems and fixed foam fire-extinguishing systems.

## **3.2 Independence of pumping and piping systems**

**3.2.1** The pumps and piping system serving the water and foam monitors are not to be used for other services except for the water-spraying system referred to in Ch 4, Sec 4 and the hose connections required for the portable fire-fighting equipment referred to in [6.2].

**3.2.2** Where the water or foam monitor pumps are also used for the water-spraying system referred to in Ch 4, Sec 4 or for the hose connections required for the portable fire-fighting equipment referred to in [6.2]:

- it is to be possible to segregate each system from the others by means of valves, so that each system can be operated independently or simultaneously with the others, and
- the pump capacity is sufficient to serve all systems simultaneously.

## **3.3 Design and construction of piping systems**

### **3.3.1 General**

Fire-fighting piping systems are to comply with the provisions of Pt C, Ch 1, Sec 10.

### **3.3.2 Sea suction**

- a) Sea suction for fire-fighting pumps are not to be used for other purposes.
- b) Sea suction and associated sea chest are to be so arranged as to ensure a continuous and sufficient water supply to the fire-fighting pumps, not adversely affected by the ship motion or by water flow to or from bow thrusters, side thrusters, azimuth thrusters or main propellers.
- c) Sea suction are to be located as low as practicable to avoid:
  - clogging due to debris or ice
  - oil intake from the surface of the sea.
- d) Sea water inlets are to be fitted with strainers having a free passage area of at least twice that of the sea suction valve. Efficient means are to be provided for clearing the strainers.

### **3.3.3 Pumps**

- a) Means are to be provided to avoid overheating of the fire-fighting pumps when they operate at low delivery rates.
- b) The starting of fire-fighting pumps when sea water inlet valves are closed is either to be prevented by an interlock system or to trigger an audible and visual alarm.
- c) It is to be demonstrated that the available net positive suction head is more than 1m above the net positive suction head leading to pump cavitation, i.e.  $NPSH_A - 1\text{m water column} > NPSH_R$ .

### **3.3.4 Valves**

- a) If their nominal diameter exceeds 450 mm, sea water suction valves and water delivery valves are to be provided with a power actuation system as well as a manual operation device.
- b) The sea water suction valve and water delivery valve and pump prime movers are to be operable from the same position.

### **3.3.5 Protection against corrosion**

Means are to be provided to ensure adequate protection against:

- internal corrosion, for all piping from sea water inlets to water monitors
- external corrosion, for the lengths of piping exposed to the weather.

### **3.3.6 Piping arrangement**

Suction lines are to be as short and straight as practicable.

## **3.4 Monitors**

### **3.4.1 Design of monitors**

- a) Monitors are to be of an approved type.
- b) Monitors are to be capable of withstanding the reaction forces of the water jet.

## **3.5 Monitor control**

### **3.5.1 General**

Water monitors and foam monitors are to be operated and controlled with a remote control system located in a common control station having adequate overall visibility.

### **3.5.2 Manual control**

In addition to the remote control system, a local manual control is to be arranged for each monitor. It is to be possible to:

- disconnect the local manual control from the control station
- disconnect the remote control system, from a position close to each monitor, to allow the operation with the local manual control.

### **3.5.3 Valve control**

The valve control is to be designed so as to prevent pressure hammering.

### **3.5.4 Control system**

- a) The control system is to comply with the relevant provisions of Pt C, Ch 3, Sec 1 and Pt C, Ch 3, Sec 2.
- b) The control system is to be designed with a redundancy level such that lost function can be restored within 10 minutes.
- c) In the case of a hydraulic or pneumatic control system, the control power units are to be duplicated.

### **3.5.5 Marking**

All control and shut-off devices are to be clearly marked, both locally and in the control station.

## **4 Water fire-fighting system**

### **4.1 Characteristics**

#### **4.1.1**

- a) For ships having the service notation **fire-fighting 1**, **fire-fighting 2** or **fire-fighting 3**, the number of pumps and monitors and their characteristics are to be in accordance with the requirements given in Tab 2.
- b) For ships having the service notation **fire-fighting E**, the characteristics of the water fire-fighting system will be given special consideration by the Society.

### **4.2 Monitors**

**4.2.1** Monitors are to be so arranged as to allow an easy horizontal movement of at least 90° equally divided about the centreline of the ship. The allowed vertical angular movement is to be such that the height of throw required in Tab 2 can be achieved.

**4.2.2** The monitors are to be located such that the water jet is free from obstacles, including ship's structure and equipment.

**4.2.3** The monitors are to be capable of throwing a continuous full water jet without significant pulsations and compacted in such a way as to be concentrated on a limited surface.

**4.2.4** At least two monitors are to be equipped with a device to make the dispersion of the water jet (spray jet) possible.

Table 2 : Number of pumps and monitors and their characteristics

Required characteristics	Service notations		
	fire-fighting 1	fire-fighting 2	fire-fighting 3
minimum number of water monitors	2	3	4
minimum discharge rate per monitor (m <sup>3</sup> /h)	1200	2400	1800
minimum number of fire-fighting pumps	1	2	2
minimum total pump capacity (m <sup>3</sup> /h) (1)	2400	7200	9600
length of throw of each monitor (m) (2) (4)	120	150	150
height of throw of each monitor (m) (3) (4)	45	70	70
<p>(1) Where the water monitor pumps are also used for the self-protection water-spraying system and / or the hose connections for portable fire-fighting, their capacity is to be sufficient to ensure the simultaneous operation of the three systems at the required performances.</p> <p>(2) Measured horizontally from the monitor outlet to the mean impact area.</p> <p>(3) Measured vertically from the sea level, the mean impact area being at a distance of at least 70 m from the nearest part of the ship.</p> <p>(4) The length and height of throw are to be capable of being achieved with the required number of monitors operating simultaneously in the same direction.</p>			

### 4.3 Piping

**4.3.1** The maximum design water velocity is not normally to exceed 4 m/s in the piping between pumps and water monitors. Higher velocity may however be accepted on a case-by-case basis and provided the concerned pipe length remains as short as possible.

## 5 Fixed foam fire-extinguishing system

### 5.1 General

**5.1.1** Ships having the service notation **fire-fighting ship 3** are to be equipped with a fixed low expansion foam monitor system complying with the provisions of [3] and with those of this Article.

**5.1.2** Ships having the service notation **fire-fighting 1**, **fire-fighting 2** or **fire-fighting E** are not required to be equipped with a fixed low expansion foam monitor system. When provided however, such system is to comply with the provisions of [3] and with those of this Article, except that some relaxations in these provisions may be accepted by the Society.

### 5.2 Characteristics

#### 5.2.1 Foam expansion ratio

The foam expansion ratio is not to exceed 12.

#### 5.2.2 Foam monitors

- The ship is to be fitted with two foam monitors, each having a foam solution capacity not less than 300 m<sup>3</sup>/h.
- The height of throw is to be at least 50 m above the sea level, when both monitors are in operation at the maximum foam production rate.

#### 5.2.3 Foam concentrate capacity

Sufficient foam concentrate is to be available for at least 30 min of simultaneous operation of both monitors at maximum capacity.

### 5.3 Arrangement

#### 5.3.1 Foam generating system

The foam generating system is to be of a fixed type with separate foam concentrate tank, foam-mixing units and piping to the monitors.

#### 5.3.2 Pumps

The pumps of the water monitor system may be used for supplying water to the foam monitor system. In such case, it may be necessary to reduce the pump water delivery pressure to ensure correct water pressure for maximum foam generation.

## 6 Portable fire-fighting equipment

### 6.1 Portable high expansion foam generator

**6.1.1** Ships having the service notation **fire-fighting 2** or **fire-fighting 3** are to be equipped with a portable high expansion foam generator having a foam capacity not less than 100 m<sup>3</sup>/min for fighting of external fires.

**6.1.2** The total capacity of foam concentrate is to be sufficient for 30 min of continuous foam production. The foam concentrate is to be stored in portable tanks of about 20 litres capacity.

### 6.2 Hydrants and fire hoses

#### 6.2.1 Hydrants

- Hydrants are to be provided in accordance with Tab 3.
- At least half of the required hydrants are to be arranged on the main weather deck.
- Where hydrants are fed by the pumps serving the monitor supply lines, provision is to be made to reduce the water pressure at the hydrants to a value permitting safe handling of the hose and the nozzle by one man.

**Table 3 : Number of hydrants**

fire-fighting E	fire-fighting 1	fire-fighting 2	fire-fighting 3
4 at each side	4 at each side	8 at each side	8 at each side (1)
(1) May be increased to 10 hydrants at each side, depending on the ship's length.			

#### 6.2.2 Fire hose boxes

- At least one box containing fire hoses is to be provided for every two hydrants.
- Each box is to contain two fire hoses complete with dual-purpose (spray/jet) nozzles.

#### 6.2.3 Fire hoses

- Fire hoses and associated nozzles are to be of a type approved by the Society.
- Fire hoses are to be of 45 to 70 mm in diameter and generally are to be 20 m in length.

## 7 Fire-fighter's outfits

### 7.1 Number and characteristics

**7.1.1** The ship is to be fitted with fire-fighter's outfits in accordance with Tab 4.

Note 1: The number of fire-fighter's outfits required in Tab 4 is the minimum total number of fire-fighter's outfits on-board. Fire-fighter's outfits provided for compliance with e.g. SOLAS II-2/10 may also be counted in this number.

**Table 4 : Number of fire-fighter's outfits**

fire-fighting E	fire-fighting 1	fire-fighting 2	fire-fighting 3
4	4	8	8

**7.1.2** The air breathing apparatuses, protective clothing and electric safety lamps constituting parts of fire-fighter's outfits are to be of a type approved by the Society.

**7.1.3** Breathing apparatuses are to be of the self-contained type. They are to have a capacity of at least 1200 litres of free air. At least one spare air bottle is to be provided for each apparatus.

**7.1.4** The fire-fighter's outfits are to be stored in a safe position readily accessible from the open deck.

### 7.2 Compressed air system for breathing apparatuses

#### 7.2.1 General

Ships are to be equipped with a high pressure air compressor complete with all fittings necessary for refilling the bottles of air breathing apparatuses. The compressor is to be located in a suitable sheltered location.

#### 7.2.2 Capacity

The capacity of the compressor is to be sufficient to allow the refilling of the bottles of all air breathing apparatuses in no more than 30 min.

### **7.2.3 Accessories**

- a) The air suction of the compressor is to be fitted with a suitable filter.
- b) The outlet of the compressor is to be fitted with oil separators and filters capable of preventing passage of oil droplets or vapours to the air bottles.

## **8 Testing**

### **8.1 General**

**8.1.1** The provisions of this Article are related to the certification, workshop and onboard tests to be carried out for:

- machinery systems
- fire-fighting systems.

They supplement those required in Part C, Chapter 1 for machinery systems.

### **8.2 Type testing**

#### **8.2.1 Water monitors**

The following characteristics are to be tested for each type of water monitor and are to comply with the requirements given in Tab 2:

- discharge rate
- length of throw
- height of throw.

### **8.3 Workshop tests**

#### **8.3.1 Tests for material**

- a) Materials used for the housing of fire-fighting pumps are to be subjected to a tensile test at ambient temperature according to the relevant provisions of NR216 Materials and Welding.
- b) Materials used for pipes, valves and other accessories are to be tested in accordance with the provisions of Pt C, Ch 1, Sec 10, [20.4].

#### **8.3.2 Hydrostatic testing**

After completion of manufacture and before installation on board, pipes, valves, accessories and pump housings are to be submitted to a hydrostatic test in accordance with the provisions of Pt C, Ch 1, Sec 10, [20.5].

### **8.4 On board tests**

#### **8.4.1 Fixed fire-fighting systems**

- a) After assembly on board, the water fire-fighting system and the fixed foam fire-extinguishing system are to be checked for leakage at normal operating pressure.
- b) The water fire-fighting system and fixed foam fire-extinguishing system are to undergo an operational test on board the ship, to check their characteristics and performances.

#### **8.4.2 Propulsion and manoeuvring systems**

- a) A test is to be performed to check the manoeuvring capability of the ship.
- b) The capability of the side thrusters and of the main propulsion system to maintain the ship in position with all water monitors in service without requiring more than 80% of the propulsive power is to be demonstrated.

# Section 4 Fire Protection and Extinction

## 1 General

### 1.1 Application

1.1.1 This Section provides, for ships having the service notations **fire-fighting 1**, **fire-fighting 2** and **fire-fighting 3**, specific requirements for:

- fire protection
- self-protection water-spraying system.

These requirements supplement those given in Part C, Chapter 4.

1.1.2 For ships having the service notation **fire-fighting E**, fire protection arrangements will be given special consideration by the Society.

### 1.2 Documents to be submitted

1.2.1 The documents listed in Tab 1 are to be submitted for approval.

**Table 1 : Documents to be submitted**

No.	I/A (1)	Description of the document
1	A	Plan showing the structural fire division, including doors and other closing devices of openings in A and B class divisions
2	I	Fire test reports for insulating materials
3	A	Schematic diagram of the fixed self-protection water-spraying system
(1) A: to be submitted for approval; I: to be submitted for information		

## 2 Fire protection of exposed surfaces

### 2.1 Structural fire protection

2.1.1 On ships having the service notation **fire-fighting 1**, all exterior boundaries above the lightest operating waterline, including superstructures and exposed decks, are to be of steel and are to be internally insulated so as to form A-60 class divisions.

2.1.2 On ships having the service notation **fire-fighting 2** or **fire-fighting 3**, all exterior boundaries are to be of steel but they need not be insulated.

2.1.3 On ships granted with the additional service feature **water spraying**:

- the provisions of [2.1.1] need not apply, and
- aluminium may be accepted as an alternative to steel. No additional fire insulation is required in this case.

Note 1: The allowable arrangements for the external boundaries of fire-fighting ships are summarized in Tab 2 below in order to ease the reading.

**Table 2 : Summary of additional requirements for external boundaries**

Material of the external boundaries	fire-fighting 1	fire-fighting 2 or fire-fighting 3
Steel	Additional requirement: <ul style="list-style-type: none"> <li>• A-60 insulation, or</li> <li>• Self-protection water-spraying system complying with the provisions of Article [3]</li> </ul>	No additional requirement
Aluminium	Additional requirement: Self-protection water-spraying system complying with the provisions of Article [3]	

## **2.2 Deadlights and shutters**

**2.2.1** On ships for which the additional service feature **water spraying** is not assigned, steel deadlights or external steel shutters are to be provided on all windows, sidescuttles and navigation lights, except for the windows of the navigating bridge.

## **3 Self-protection water-spraying system**

### **3.1 General**

**3.1.1** The provisions of this Article apply to the self-protection water-spraying systems fitted to ships having the additional service feature **water spraying**.

### **3.2 Capacity**

**3.2.1** The capacity of the self-protection water-spraying system is to be not less than 10 l/min for each square metre of protected area. In the case of surfaces which are internally insulated, such as to constitute A-60 class divisions, a lower capacity may be accepted, provided it is not less than 5 l/min for each square metre of protected area.

### **3.3 Arrangement**

#### **3.3.1 Areas to be protected**

The fixed self-protection water-spraying system is to provide protection for all vertical areas of the hull and superstructures as well as monitor foundations and other fire-fighting arrangements, and is to be fitted in such a way as not to impair the necessary visibility from the wheelhouse and from the station for remote control of water monitors, also during operation of spray nozzles.

#### **3.3.2 Sections**

The fixed self-protection water-spraying system may be divided into sections so that it is possible to isolate sections covering surfaces which are not exposed to radiant heat.

#### **3.3.3 Spray nozzles**

The number and location of spray nozzles are to be suitable to spread the sprayed water uniformly on areas to be protected.

### **3.4 Pumps**

#### **3.4.1 Use of pumps serving other systems**

The following pumps may be used for the self-protection water-spraying system:

- fire pumps referred to in Pt C, Ch 4, Sec 6, [1.3]
- water monitor system pumps referred to in Ch 4, Sec 3, [4].

In this case, a shut-off valve is to be provided to segregate the systems concerned.

#### **3.4.2 Capacity of the pumps**

- a) The pumps of the self-protection water-spraying system are to have a capacity sufficient to spray water at the required pressure from all spray nozzles of the system.
- b) Where the pumps serving the self-protection water-spraying systems are also used for another service, their capacity is to be sufficient to ensure the simultaneous operation of both systems at the required performances.

### **3.5 Piping system and spray nozzles**

#### **3.5.1 General**

Pipes are to be designed and manufactured according to the requirements of Pt C, Ch 1, Sec 10.

#### **3.5.2 Protection against corrosion**

Steel pipes are to be protected against corrosion, both internally and externally, by means of galvanising or equivalent method.

#### **3.5.3 Drainage cocks**

Suitable drainage cocks are to be arranged and precautions are to be taken in order to prevent clogging of spray nozzles by impurities contained in pipes, nozzles, valves and pumps.

# Part E

## Service Notations for Offshore Service Vessels and Tugs

---

### CHAPTER 5

## OIL RECOVERY SHIPS

---

Section 1	General
Section 2	Hull and Stability
Section 3	Machinery and Systems
Section 4	Electrical Installations
Section 5	Fire Protection, Detection and Extinction

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Rule Note are eligible for the assignment of service notation **oil recovery** as defined in Pt A, Ch 1, Sec 2, [4.11.4].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

#### 1.1.3 Additional service feature OILTREAT

The additional service feature **OILTREAT** may be assigned to the ships designed and equipped to recover polluted water which is subjected to a chemical and/or a physical treatment, in order to separate the oil from the polluted water. The separated oil is to be stored and transported in dedicated tanks.

#### 1.1.4 Additional service feature SECOND-LINE

The additional service feature **SECOND-LINE** may be assigned to the ships designed and equipped to recover polluted water in the event of spills of oils which have, at the time of recovery, a flash point exceeding 60°C (closed cup test).

This service feature is not to be assigned to oil recovery ships carrying heated recovered oils within 15°C of their flash point.

### 1.2 Definitions

#### 1.2.1 Oil recovery ship

An oil recovery ship is a ship specially equipped with a fixed installation and/or a mobile equipment for the removal of oil from the sea surface and its retention on board, carriage and subsequent unloading.

#### 1.2.2 Recovered oil

Recovered oil is the top layers of polluted water collected by means of skimmers, rotating disk, floating pumps or equivalent systems together with sweeping arms, booms or similar devices.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Ships less than 500 GT

(1) Refer to the scope of application of NR600.			
<b>Note 1:</b>			
NR566: Hull Arrangement, Stability and Systems for Ships less than 500 GT.			
NR600: Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m.			

### 1.2.3 Oil recovery tank

An oil recovery tank is a tank intended for the retention and the transportation of recovered oil.

For ships assigned with the additional service feature **OILTREAT**, the oil recovery tanks may be classified in two different categories:

- those intended for the retention of oil removed and separated from sea water, also named accumulation tanks
- those intended for the retention of polluted water only, also named settling tanks.

### 1.2.4 Oil recovery pump room

An oil recovery pump room is a space containing the pumps and their accessories for the handling of recovered oil.

### 1.2.5 Oil recovery area

The oil recovery area is the part of the ship that contains the oil recovery tanks, oil recovery pumps rooms, cofferdams, ballast or void spaces surrounding the integral tanks and hold spaces in which independent tanks are located, and the following deck areas:

- the deck area above the oil recovery tanks
- the deck area extending transversely and longitudinally from the oil recovery tanks over a distance of 3 m, when the rule length is greater than 50 m.

Note 1: Oil recovery area definition is not applicable to oil recovery ships assigned with the additional service feature **SECOND-LINE**.

### 1.2.6 Hazardous areas

The hazardous areas are the areas in which an explosive atmosphere is, or may be, expected to be present in quantities such as to require special precautions for the construction, installation and use of electrical apparatus.

### 1.2.7 Gas-safe areas

The gas-safe areas are the gas areas which are not defined as hazardous.

## Section 2 Hull and Stability

### 1 General

#### 1.1 Documents to be submitted

1.1.1 In addition to the documentation requested in Part B, the documents listed in Tab 1 are to be submitted.

**Table 1 : Documents to be submitted**

No.	A/I (1)	Description of the document
1	A	General arrangement
2	A	General arrangement of access and openings
3	I	Procedure and limiting conditions for recovering oil, oil recovery transfer, tank cleaning, gas freeing and ballasting
4	I	Specification of the oil removal operational test
5	I	General plan showing the location of tanks intended for the retention of oily residues and systems for their treatment
6	I	Plan of the system for treatment of oily residues and specification of all relevant apparatuses
7	A	Supporting structures of the system for treatment of oily residues
8	I	Operating manual
(1) A: to be submitted for approval; I: to be submitted for information		

#### 1.2 General arrangement

##### 1.2.1 Tank arrangement

a) Oil recovery tanks are to be separated from machinery spaces category A, propeller shaft tunnels, dry cargo spaces, accommodations, control stations and service spaces and from drinking water and stores for human consumption by means of a cofferdam or equivalent space. Fuel oil tanks, tanks for ballast water, tanks for liquids used for oil treatment, tanks for anti-pollution liquids, storerooms for oil removal equipment and pump-rooms are considered as spaces equivalent to a cofferdam.

When this cofferdam is impracticable, oil recovery tanks adjacent to the engine room may be accepted provided that:

- boundary bulkheads are accessible for inspection
- the boundary bulkheads are fitted continuously through joining structure to the top of the tank, where full penetration welding is to be carried out
- the tanks are to be pressure tested at each renewal survey.

b) Oil recovery tanks are to be located abaft the collision bulkhead.

c) For ships non-exclusively dedicated to oil recovery operations, the ship may use the following tanks as oil recovery tanks:

- tanks covered by the service notation **supply**, if designed for a cargo mass density of, at least, 1,025 t/m<sup>3</sup>
- water ballast tanks
- fuel oil tanks
- hoppers spaces.

In all cases, the tanks and their associated equipment and piping are to comply with all the requirements for oil recovery tanks.

Fresh water tanks and tanks with a complex inner structure that can lead to obstruction can not be part of the oil recovery tanks.

d) Oil recovery ships assigned with the additional service feature **SECOND-LINE** do not need to comply with the arrangements referred to in item a), provided that the segregation requirements for accommodations, control stations, drinking water and stores for human consumption are observed.

##### 1.2.2 Accommodation, control station, service and machinery spaces

a) Accommodation or service spaces, control stations or machinery spaces category A are to be located outside the oil recovery area.

Note 1: When, instead of a cofferdam, boundaries between oil recovery tanks and machinery spaces of category A are built as described in the second paragraph of [1.2.1], item a), the machinery spaces of category A may be located within the oil recovery area.

- b) Unless they are spaced at least 7 m away from the oil recovery area entrances, air inlets and openings to accommodation, service and machinery spaces category A and control stations should not face the oil recovery area. Doors to spaces not having access to accommodation, service and machinery spaces and control stations, such as oil recovery control stations, storerooms or equipment rooms, may be permitted by the Society within the 7 m zone specified above, provided the boundaries of the spaces are insulated to A-60 standard.
- c) When the additional service feature **SECOND-LINE** is assigned, the arrangement referred to in items a) and b) may be disregarded.

### 1.2.3 Access

- a) Access hatches (at least 600 mm x 600 mm of clear opening) within the oil recovery area are to be direct from the open deck. Such access should be suitable for cleaning and gas-freeing.
- b) For ships assigned with the additional service feature **SECOND-LINE**, the following requirements may apply instead of item a):
- Access to oil recovery tanks is to be direct from the open deck and such as to ensure their complete inspection, except for access to cargo tanks in double bottoms that may be through a cargo pump-room, pump-room, deep cofferdam, pipe tunnel or similar dry compartment, provided the ventilation of these spaces complies with Ch 5, Sec 5, [2.2]
  - Access to oil recovery pump rooms does not need to be from the open deck, provided the access is independent of watertight doors.

### 1.2.4 Oil recovery tank construction

- a) A cargo density of 1,025 t/m<sup>3</sup> is to be considered for calculating the internal pressures and forces in cargo tanks according to Pt B, Ch 5, Sec 6 or NR600 as applicable.
- b) All tank openings and connections to the tank are to terminate above the weather deck and should be located in the tops of the tanks.
- c) The structural design of the tanks should take into account the carriage temperature, and additional strength calculation may be required in case of risk of sloshing induced loads.

## 2 Stability

### 2.1 Intact stability

#### 2.1.1 General

In addition to the standard loading conditions specified in Pt B, Ch 3, App 2, [1.2.1], the following loading cases are to be included in the trim and stability booklet for ships assigned with the service notation **oil recovery**:

- ship in the fully loaded departure to the oil recovery spot having all the oil recovery equipment installed on board
- ship in the worst anticipated operating during oil recovery operation; the worst operating condition regarding free surface effects when the equipment is fitted in the most unfavourable condition (for example, swiping arm extended).

## 3 Hull scantlings

### 3.1 Additional loads

**3.1.1** For the checking of structures supporting oil recovery equipment, the reactions induced by this equipment during oil recovery operations may be calculated assuming that the oil recovery operations take place in moderate sea conditions (accelerations reduced by 10%).

**3.1.2** If lifting appliances are used during oil recovery operations, the scantling of their supporting structures is to be checked according to Pt B, Ch 1, Sec 1, [1.2].

**3.1.3** In case of oil collected in movable tanks fitted on the weather deck, the resulting reactions to be considered for deck scantling are to be calculated, as a rule, according to Pt B, Ch 5, Sec 6 or NR600 as applicable.

## 4 Construction and testing

### 4.1

#### 4.1.1 Oil removal equipment

Tests are to be carried out according to a specification submitted by the Interested Party, in order to check the proper operation of the oil recovery equipment.

These tests may be performed during dry dock or sea trials.

# Section 3 Machinery and Systems

## 1 General

### 1.1 Documents to be submitted

1.1.1 The documents listed in Tab 1 are to be submitted.

**Table 1 : Documents to be submitted**

No.	A/I (1)	Description of the document (2)
1	I	General plan of the system for oil recovery and specification of all relevant apparatuses
2	A	Schematic arrangement of recovered oil piping and pumping systems
3	A	Tank venting arrangement
4	A	Diagram of the bilge and ballast systems serving the spaces located in the oil recovery area
5	A	Specification of the anti-explosion devices (crankcase explosion relief valves, spark arresters) provided for diesel engines
6	A	Location and arrangement of sea chests for engine cooling and fire-fighting purposes
7	A	Diagram of the oil recovery cargo tank level gauging system with overfilling safety arrangement
8	A	Diagram of the cargo heating system, where applicable

(1) A: to be submitted for approval; I: to be submitted for information  
(2) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.

## 2 Machinery installation and piping system other than oil recovery system

### 2.1 Sea water cooling system

2.1.1 One of the suctions serving the sea water cooling system (see Pt C, Ch 1, Sec 10, [10.7.1]) is to be located in the lower part of the hull.

### 2.2 Water fire-extinguishing system

2.2.1 Sea suctions serving the fire water pumps are to be located as low as possible.

### 2.3 Exhaust gas systems

#### 2.3.1

- a) Exhaust lines from engines, gas turbines, boilers and incinerators are to be led outside any hazardous area (as defined in Ch 5, Sec 4) above the deck and are to be fitted with a spark arrester. The spark arrester is not required if the ship is assigned with the additional service feature **SECOND-LINE**.
- b) Where the distance between the exhaust lines of engines and the hazardous areas is less than 3 m, the ducts are to be fitted in a position:
  - near the waterline, if cooled by water injection, or
  - below the waterline, in the other cases.

## 3 Pumping system, piping system and pump-rooms intended for recovered oil

### 3.1 Design of pumping and piping systems

#### 3.1.1 General

The provisions of Pt D, Ch 7, Sec 4, [3] and Pt C, Ch 1, Sec 10 are to be complied with, as far as applicable.

## 3.2 Arrangement of piping systems

### 3.2.1

- a) Piping systems for handling recovered oil are not to pass through:
- accommodation spaces
  - service spaces
  - control stations
  - machinery spaces of category A except for ship assigned with the additional service feature **SECOND-LINE**.
- b) Pumping and piping systems intended for recovered oil are to be independent from the other pumping and piping systems of the ship, except in the following cases:
- If sections of the cargo system covered by the service notation **supply** or if fuel oil tanks are used, means are to be provided to isolate the oil recovery system from any other system from which it may be connected. The connection between the cargo system and the recovered oil transfer piping may consist of movable pipe sections.
  - If water ballast tanks are used as oil recovery tanks when the ship is in oil recovery mode, the water ballast piping is to be blanked-off at the nearest position at the tank before starting the oil recovery operation. The connection between the oil recovery piping and the water ballast tanks is to be done by means of detachable spool pieces.
- c) Piping intended for recovered oil and located below the main deck may run from the tank it serves and penetrate tank bulkheads or boundaries common to longitudinally or transversely adjacent oil recovery tanks, ballast tanks, empty tanks, pump-rooms or oil recovery pump-rooms, provided that inside the tank it serves it is fitted with a stop-valve operable from the weather deck.
- As an alternative, where an oil recovery tank is adjacent to an oil recovery pump-room, the stop valve operable from the weather deck may be situated on the tank bulkhead on the oil recovery pump-room side, provided an additional valve is fitted between the bulkhead valve and the oil recovery pump.
- A totally enclosed hydraulically operated valve located outside the oil recovery tank may also be accepted, provided that the valve is:
- fitted on the bulkhead of the oil recovery tank it serves
  - suitably protected against mechanical damage
  - fitted at a distance from the shell as required for damage protection, and
  - operable from the weather deck.
- d) Transfer of recovered oil through hatches (by means of flexible hoses or movable piping) is not permitted except if the additional service feature **SECOND-LINE** is assigned.

## 3.3 Oil recovery pumps

### 3.3.1

- a) Oil recovery pumps are to comply with the requirements of cargo pumps for **oil tanker, flash point > 60°C** (see Pt D, Ch 7, Sec 4, [3.2]).
- b) Oil recovery pumps are to be capable of being remotely shutdown from a location which is manned during oil recovery operations and from at least one other location outside the oil recovery area.
- c) If an oil recovery pump serves more than one tank, a stop valve is to be fitted in the line of each tank.
- d) For ships non exclusively dedicated to oil recovery operation, the use of portable pumps or pumps serving cargo systems may be permitted, subject to special consideration by the Society.

## 3.4 Oil recovery pump-rooms

### 3.4.1

- a) Pump-rooms containing the pumps for handling the recovered oil are to be provided with a fixed fire-extinguishing system suitable for machinery spaces of category A except if the ship is assigned with the additional service feature **SECOND-LINE**.
- b) Means are to be provided to deal with drainage and any possible leakage from oil recovery pumps and valves in the oil recovery pump-room. Bilge pumping arrangement is to be situated entirely within the oil recovery area. The bilge system is to be operable from outside the oil recovery pump-room. Oil recovery pumps may also be used provided they are connected to the oil recovery pump-room bilge piping through a shut-off valve and a non-return valve arranged in series.
- c) For ventilation of oil recovery transfer pump-rooms, see Ch 5, Sec 5, [2].
- d) Oil recovery pump-rooms are to have no direct communication with machinery spaces of category A, except when the ship is assigned with the additional service feature **SECOND-LINE**.

## **4 Oil recovery tank fittings**

### **4.1 Vent pipes**

#### **4.1.1**

- a) Vent pipes of oil recovery tanks are to lead to the open at least 2,4 m above the weather deck.
- b) Vent pipes are to be located at a distance of at least 5,0 m measured horizontally from the nearest air intake or opening to accommodations, control stations, service and machinery spaces of category A and other gas-safe spaces and from ignition sources.
- c) Openings of vent pipes are to be directed to open deck and fitted with:
  - flameproof wire gauze made of corrosion resistant material easily removable for cleaning, and
  - closing appliances complying with the provisions of Pt C, Ch 1, Sec 10, [9.1]
- d) For ships non exclusively dedicated to oil recovery operations, portable vent pipes may be accepted.

### **4.2 Level gauging and overfilling control**

#### **4.2.1 Level gauging**

Oil recovery tanks are to be fitted with sounding pipes or other level gauging devices of a type approved by the Society.

#### **4.2.2 Overfilling control**

- a) Oil recovery tanks are to be fitted with a high level alarm or an overflow control system except if the oil recovery tank is an open hopper space.
- b) The high level alarm is to be of a type approved by the Society and is to give an audible and visual alarm.

## **5 Heating systems**

### **5.1**

**5.1.1** Heating systems fitted to oil recovery tanks are to comply with the provisions of Pt D, Ch 7, Sec 4, [2.6].

## **6 Additional requirements**

### **6.1 Ships assigned with the additional service feature OILTREAT**

**6.1.1** When the separating system designed to reduce the oil content in the water being discharged into the sea is of a gravity type (single or in series):

- means for locating the oil/water interface in the oil recovery tanks are to be provided
- discharges of processed water from the separating process are to take place above waterline for visual control
- if chemical additives are added, the coating of the oil recovery tanks is to be compatible. The Shipyard is responsible for providing compatibility information to the ship operator and/or the master
- adequate means are to be provided for cleaning the oil recovery tanks.

**6.1.2** Other types of separating system (e.g. gravity type coalescing, centrifugal separator, ...) are to be reviewed on a case-by-case basis.

# Section 4 Electrical Installations

## 1 General

### 1.1 Application

1.1.1 The requirements in this Section apply, in addition to those contained in Part C, Chapter 2.

### 1.2 Documentation to be submitted

1.2.1 In addition to the documentation requested in Pt C, Ch 2, Sec 1, [2.1.1], the documents listed in Tab 1 are to be submitted.

**Table 1 : Documents to be submitted**

No.	AI (1)	Description of the document
1	A	Plan of hazardous areas and location of electrical equipment
2	A	Document giving details of types of cables and safety characteristics of the equipment installed in hazardous areas
(1) A: to be submitted for approval; I: to be submitted for information		

## 2 Design requirements

### 2.1 System of supply

2.1.1 The following systems of generation and distribution of electrical energy are acceptable:

- a) Direct current:
  - two-wire insulated
- b) Alternating current:
  - single-phase, two-wire insulated
  - three-phase, three-wire insulated.

2.1.2 Earthed systems with hull return are not permitted, with the following exceptions to the satisfaction of the Society:

- a) impressed current cathodic protective systems
- b) limited and locally earthed systems, such as starting and ignition systems of internal combustion engines, provided that any possible resulting current does not flow directly through any hazardous area
- c) insulation level monitoring devices, provided that the circulation current of the devices does not exceed 30 mA under the most unfavourable conditions.

2.1.3 Earthed systems without hull return are not permitted, with the following exceptions:

- a) earthed intrinsically safe circuits and the following other systems to the satisfaction of the Society;
- b) power supplies, control circuits and instrumentation circuits in non-hazardous areas where technical or safety reasons preclude the use of a system with no connection to earth, provided the current in the hull is limited to not more than 5 A in both normal and fault conditions; or
- c) earthed systems, provided that any possible resulting hull current does not flow directly through any hazardous area; or
- d) isolating transformers or other adequate means, to be provided if the distribution system is extended to areas remote from the machinery space.

2.1.4 In insulated distribution systems, no current carrying part is to be earthed, other than:

- a) through an insulation level monitoring device
- b) through components used for the suppression of interference in radio circuits.

### 2.2 Earth detection

2.2.1 The devices intended to continuously monitor the insulation level of all distribution systems are also to monitor all circuits, other than intrinsically safe circuits, connected to apparatus in hazardous areas or passing through such areas. An audible and visual alarm is to be given, at a manned position, in the event of an abnormally low level of insulation.

### 3 Hazardous locations and types of equipment

#### 3.1 Electrical equipment permitted in hazardous areas

**3.1.1** In order to facilitate the selection of appropriate electrical apparatus and the design of suitable electrical installation, hazardous areas are classified in zones (zone 0, zone 1 and zone 2), according to Pt C, Ch 2, Sec 1, [3.25.3]. The different spaces are to be classified according to Tab 2 or Tab 3, as applicable.

The types of electrical equipment permitted, depending on the zone where they are installed, are specified in Pt C, Ch 2, Sec 3, [10].

**3.1.2** The explosion group and temperature class of electrical equipment of a certified safe type are to be at least IIA and T3.

#### 3.2 Additional requirements for machinery installations in hazardous areas

**3.2.1** Hazardous areas are not to contain:

- internal combustion engines
- steam turbines and steam piping with a steam temperature in excess of 200°C
- other piping systems and heat exchangers with a surface temperature exceeding 200°
- any other source of ignition.

**Table 2 : Oil recovery ships - Space descriptions and hazardous area zones**

Hazardous area	Spaces	
	No.	Description
Zone 0	1	Oil recovery tanks, pipes and equipment containing the recovered oil
Zone 1	2	Areas on open deck or semi-enclosed spaces on open deck within 3 m of any oil recovery tank outlet, oil recovery manifold valve, oil recovery valve, oil recovery pipe flange, oil recovery hatches
Zone 1	3	Cofferdams and enclosed or semi-enclosed spaces adjacent to or immediately above oil recovery tank which do not contain pipes, valves or other equipment for the handling of recovered oil unless separated by gas-tight boundaries and fitted with forced ventilation capable of giving at least 20 air changes per hour. An alarm on the navigation bridge is to be provided to indicate any loss of the required ventilation capacity. The alarm is to be initiated by fall-out of starter relay fan motor
Zone 1	4	For open hopper dredgers operating as oil recovery ships: the area above the hopper extended to the maximum breath of the ship with an unlimited height
Zone 1	5	Oil recovery pump-rooms
Zone 2	6	Enclosed or semi-enclosed spaces for the storage of floating pumps, associated hoses and equipment for the handling of recovered oil unless acceptable means are provided to drain or empty the equipment after completion of oil recovery operation
Zone 2	7	Double bottoms or duct keels located under oil recovery tanks unless separated by gas-tight boundaries and fitted with forced ventilation capable of giving at least 20 air changes per hour. An alarm on the navigation bridge is to be provided to indicate any loss of the required ventilation capacity. The alarm is to be initiated by fall-out of starter relay fan motor
Zone 2	8	Enclosed or semi-enclosed spaces containing pipes, valves or other equipment for the handling of recovered oil unless made of entirely welded construction except for necessary flanged connections to valves, expansion joints, spool pieces and similar fittings or where required for coating, lining, fabrication, inspection or maintenance
Zone 2	9	Enclosed or semi-enclosed spaces containing pipes, valves or other equipment for the handling of recovered oil unless separated by gas-tight boundaries and fitted with forced ventilation capable of giving at least 20 air changes per hour. An alarm on the navigation bridge is to be provided to indicate any loss of the required ventilation capacity. The alarm is to be initiated by fall-out of starter relay fan motor.
Zone 2	10	Areas on open deck over all oil recovery tanks up to a height of 2,4 m above the deck

**Table 3 : Oil recovery ships, second-line - Space descriptions and hazardous area zones**

Hazardous area	Spaces	
	No.	Description
Zone 2	1	Oil recovery tanks, any pipe work of pressure relief or other venting system for oil recovery tanks, pipes and equipment containing recovered oil

### **3.3 Openings, access and ventilation conditions affecting the extent of hazardous areas**

**3.3.1** There are normally not to be access doors or other openings between a safe space, such as accommodation or service spaces, machinery spaces, control stations and similar spaces, and a hazardous area.

Access (other than access between oil recovery pump-rooms and machinery spaces category A) may, however, be accepted between such spaces and hazardous areas, provided that:

- a) safe spaces are fitted with forced ventilation in order to maintain an overpressure therein
- b) access doors are:
  - 1) of a self-closing type and arranged to swing into the safer space, so that they are kept closed by the overpressure, with the self-closing device capable of shutting the doors against an inclination of 3,5° opposing closure, without hold-back hooks keeping them in an open position, or
  - 2) gas-tight, kept closed during oil recovery operation until gas freeing is carried out, and provided with a warning plate (suitable instructions are given in the oil recovery manual).

# Section 5 Fire Protection, Detection and Extinction

## 1 General

### 1.1 Documents to be submitted

1.1.1 The documents listed in Tab 1 are to be submitted for approval.

**Table 1 : Documents to be submitted**

No.	A/I (2)	Description of the document (1)
1	A	Diagram of mechanical and natural ventilation with indication of inlets and outlets serving: <ul style="list-style-type: none"> <li>spaces within the oil recovery area</li> <li>machinery spaces</li> <li>accommodation spaces</li> </ul>
2	A	Specification of flammable gas detectors and flash point measurement equipment
3	A	Drawing and specification of the fixed, if any, or movable fire-fighting system
<p>(1) Diagrams are also to include, where applicable, the (local and remote) control and monitoring systems and automation systems.  (2) A: to be submitted for approval; I: to be submitted for information</p>		

## 2 Mechanical ventilation in the oil recovery area

### 2.1 General

2.1.1 Spaces considered as hazardous are to have a ventilation system independent from those serving gas-safe spaces.

### 2.2 Ventilation of recovered oil pump rooms

2.2.1 Oil recovery pump rooms are to be provided with a mechanical ventilation system of the extraction type capable of giving at least 20 air changes per hour.

2.2.2 Ventilation intakes are to be so arranged as to minimise the possibility of recycling hazardous vapours from ventilation discharge openings.

2.2.3 Ventilation exhaust ducts are to discharge upwards to a safe area on the weather deck in locations at least 3,0 m from any ventilation intake and opening to accommodations, service and machinery spaces, control stations and other spaces outside the oil recovery area.

2.2.4 Protection screens of not more than 13 mm square mesh are to be fitted on ventilation duct intakes and outlets.

2.2.5 Ventilation fans are to be of non-sparking construction as per Pt C, Ch 4, Sec 1, [2.32].

2.2.6 The ventilation system is to be capable of being controlled from outside the oil recovery pump-room.

2.2.7 Provision is to be made to ventilate such spaces prior to entering the compartment and operating the equipment and a warning notice requiring the use of such a ventilation is to be placed outside the compartment.

2.2.8 Ventilation ducts are not to lead through accommodations, service and machinery spaces or other similar spaces.

### 2.3 Ventilation of enclosed spaces normally entered during oil recovery operation other than recovery oil pump rooms

2.3.1 Enclosed spaces normally entered within the oil recovery area are to be provided with a mechanical ventilation system of the extraction type capable of giving at least 8 air changes per hour.

2.3.2 Ventilation intakes are to be located at a distance of not less than 3,0 m from the ventilation outlets of oil recovery pump-rooms.

### 3 Fire protection and fighting

#### 3.1 Vapor detector

**3.1.1** At least one portable gas detection instrument capable of measuring flammable vapour concentrations in air and an equipment for oil flashpoint measurements are to be provided on board.

Alternatively, instead of a portable gas detection instrument, a fixed system may be accepted provided that the sample is drawn from a point within 6,0 m from the waterline.

#### 3.2 Structural fire protection

**3.2.1** Unless they are located at least 7,0 m from the nearest oil recovery area, exterior boundaries of the superstructures and deckhouses enclosing accommodations and including any overhanging decks which support such accommodations are to be insulated to A-60 standard for the whole of the portions which face the oil recovery areas up to the underside of the navigation bridge deck and for a distance of 3,0 m aft or forward of such areas.

Alternatively to A-60 insulation, a fixed water-spraying system capable of delivering water at a rate of 10 l/m<sup>2</sup>/min may be accepted. This system is to comply with the requirements listed in Ch 4, Sec 4, [3], except that the only protected area is to be the exterior boundaries of the superstructures and deckhouses enclosing accommodations and including any overhanging decks which support such accommodations facing the oil recovery area.

**3.2.2** Windows and sidescuttles fitted within 7,0 m from the nearest oil recovery area are to have the same fire integrity as the bulkhead in which they are fitted. If they have a lower fire rating because they are protected by the fixed water-spraying system mentioned in [3.2.1], windows and sidescuttles are to be fitted with inside covers of steel or other equivalent material having a thickness equal to the bulkhead in which they are fitted. Where they are not of the fixed type, they are to be such as to ensure an efficient gas-tight closure.

**3.2.3** Ships assigned with the additional service feature **SECOND-LINE** do not need to comply with [3.2.1] and [3.2.2].

#### 3.3 Fire-fighting

**3.3.1** For the protection of the oil recovery area, the following fire-fighting equipment is to be provided near the working area:

- two dry powder fire extinguishers, each with a capacity of at least 50 kg or equivalent
- at least one portable foam extinguishing applicator complying with Pt C, Ch 4, Sec 15, [3.2.2].

- Section 2      Hull and Stability
- Section 3      Machinery and Systems
- Section 4      Fire Protection

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **cable laying**, as defined in Pt A, Ch 1, Sec 2, [4.12.8].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT

NR600: Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m.			

# Section 2 Hull and Stability

## 1 General

### 1.1 Application

**1.1.1** The requirements of this Section apply to ships fitted, in general, with one or more continuous decks, suitable holds for the carriage of cables and superstructures extending for most of the ship's length.

The main characteristics of the ship may vary according to the service primarily performed which may be as follows:

- laying (and possibly burying) submarine cables on the sea bed
- hauling and repairing submarine cables.

### 1.2 Documents to be submitted

**1.2.1** In addition to the documentation requested in Part B, the following documents are to be submitted for approval:

- Structural reinforcements in way of load transmitting elements, such as foundations and fastenings of the equipment to the ship structures.

## 2 Stability

### 2.1 Intact stability

#### 2.1.1 General

The stability, the freeboard and the metacentric radius or roll period are to be such as to ensure:

- satisfactory seakeeping performance in working conditions
- a steady working platform in order to facilitate the performance of cable laying and/or repair operations.

Anti-roll tanks or bilge keels of adequate size may be fitted to meet the above requirements.

#### 2.1.2 Tanks intended for liquid consumable

Special attention is to be paid to the arrangement of tanks intended to contain liquid consumables in order to prevent weight variations during service resulting in excessive changes in the ship's trim.

#### 2.1.3 Intact stability criteria

The stability of the ship for the loading conditions in Pt B, Ch 3, App 2, [1.2.1] and for the (departure and arrival) loading conditions corresponding to the maximum draught is to be in compliance with the requirements in Pt B, Ch 3, Sec 2.

### 2.2 Damage stability for ships where the notation SDS has been required

#### 2.2.1 Application

The requirements of this item apply to cable laying ships carrying less than 240 persons.

Damage stability criteria for cable laying ships carrying 240 persons and more are to be considered by the Society on a case-by-case basis.

#### 2.2.2 General

*Cable laying ships are to comply with the survival requirements specified in Pt B, Ch 3, App 3, where the required index R is to be considered as follows in Tab 1 and calculated according to [2.2.3].*

**Table 1 : Index R**

Number of persons: Nb	Index R
Nb ≤ 60	0,8 R
60 < Nb < 240	Linear interpolation between 0,8 R and R <b>(1)</b>
<b>(1)</b> The required index is equal to R for Nb = 240	

#### 2.2.3 Calculation of the required index

$$R = 1 - \frac{5000}{L_s + 2,5N + 15225}$$

where:

$$N = N_1 + 2N_2$$

$N_1$  : Number of persons for whom lifeboats are provided

$N_2$  : Number of persons the ship is permitted to carry in excess of  $N_1$ .

Where the conditions of service are such that compliance with  $R$  on the basis of  $N = N_1 + 2 N_2$  is impracticable and where the Society considers that a suitable reduced degree of hazard exists, a lesser value of  $N$  may be taken, but in no case less than  $N = N_1 + N_2$ . The reduced value of  $N$  is also to be subject to the agreement of the flag administration.

### 3 Hull scantlings

#### 3.1 Cable tanks

**3.1.1** The assessment of primary supporting members is to be made through direct calculations carried out according to Pt B, Ch 8, Sec 1, where the still water and wave loads are to be calculated for the most severe condition of use.

#### 3.2 Connection of the machinery and equipment with the hull structure

**3.2.1** The net scantlings of the structures in way of the connection between the hull structure and the machinery and equipment, constituting the laying or hauling line for submarine cables, are to be obtained through direct calculation to be carried out based on the service loads of such machinery and equipment, as specified by the Designer.

In calculating these above service loads, the Designer is to take into account the inertial loads induced by ship motions in the most severe condition of use.

### 4 Other structures

#### 4.1 Fore part

**4.1.1** In general, a high freeboard is needed in the forward area, where most repair work is carried out, in order to provide adequate safety and protection against sea waves.

### 5 Hull outfitting

#### 5.1 Equipment

##### 5.1.1 Hawse pipes

Hawse pipes are to be integrated into the hull structure in such a way that anchors do not interfere with the cable laying.

##### 5.1.2 Sheaves

Where there is a risk that, in rough sea conditions, sheaves are subjected to wave impact loads, special solutions such as the provision of retractable type sheaves may be adopted.

## Section 3 Machinery and Systems

### 1 General

#### 1.1 Propulsion and manoeuvrability

1.1.1 The main propulsion systems of cable laying and/or repair ships are to be capable of:

- maintaining an adequate speed during the transit condition
- ensuring a satisfactory manoeuvrability at the speed assumed by the Designer for the performance of cable laying and/or repair operations.

#### 1.2 Documents to be submitted

1.2.1 Tab 1 lists the documents which are to be submitted for information.

**Table 1 : Documents to be submitted**

No.	Document
1	General arrangement of the cable laying equipment
2	Design loads on all components of the cable laying equipment transferred to the ship structure
3	Structural plans of seating components of the cable laying equipment, including gears, pressure vessels, hydraulic systems, etc., as applicable, including details of the deck connection
4	Specification of the cable-laying equipment operation test

### 2 Arrangements for cable laying, hauling and repair

#### 2.1 Typical machinery and equipment of cable laying ships

2.1.1 Cable laying ships, in relation to the special service to be performed, are generally to be provided with the following machinery and equipment:

- a main windlass for cable hauling or laying, which generally consists of a drum with a horizontal axis (the surface of which is formed by a series of timed conveyors which fleet the cable axially across the face of the drum) housing the repeaters fitted throughout the cable length without damaging them (see Fig 1 (a))
- a linear tensioner working in conjunction with the main windlass and fitted between it and the cable tank, which maintains the due tension of the cable in relation to the cable type so as to allow effective cable hauling or laying. In order to permit the passage of repeaters, the tensioner may be of the type having either a series of double opposed rubber tyres (see Fig 1 (b)) or pressure-compensated opposed tracks (see Fig 1 (c)).
- a dynamometer, normally fitted between the main windlass and the bow and stern sheaves, which continuously measures the force required to displace the cable under tension
- one or more cable transporters, used to move the cable from the tank(s) and the tensioner.

All the above machinery and equipment form the "cable laying or hauling line". More than one line may be fitted on board in the case of special service requirements.

**Figure 1 : Cable handling machinery**

## **2.2 Design of cable handling machinery and equipment**

**2.2.1** The scantlings of components of machinery and equipment listed in [2.1] and, more generally, of any other machinery and/or equipment to be used for the laying, hauling or repair of submarine cables are outside the scope of classification.

## **2.3 Safety**

**2.3.1** The requirements of this Chapter are based on the assumption that during cable handling all necessary safety measures are taken, due consideration being given to risks connected with the use of machinery and equipment dealt with in [2.1] and that such machinery and equipment are properly used by skilled personnel.

## **2.4 Testing of cable handling machinery and equipment**

### **2.4.1 General**

Machinery covered by [2.1] is to be tested in compliance with the following requirements, with the exception of prime movers and "hydraulic accumulator" type pressure vessels, which are to be tested in compliance with the applicable requirements of the various Sections of the Rules.

### **2.4.2 Testing of materials and components of the machinery**

- a) In general, testing is required for materials intended for shafts, gearing, pressure parts of pumps and hydraulic motors, and plates of foundations of welded construction.
- b) As far as mechanical tests of materials are concerned, internal shop testing certificates submitted by the Manufacturer may be accepted by the Society at its discretion; in such cases, testing operations witnessed by the Surveyor may be limited to visual external inspection associated, where necessary, with non-destructive examinations and hardness tests.

### **2.4.3 Hydrostatic tests**

Pressure parts are to be subjected to hydrostatic tests in accordance with the applicable requirements.

### **2.4.4 Tests on electrical components**

The tests required in Part C, Chapter 2 of the Rules are to be carried out as applicable.

### **2.4.5 Running tests**

- a) Running tests of each individual piece of equipment are to be carried out whenever possible at the Manufacturer's works; as an alternative, the above tests may be performed on board during the trials required after installation of machinery.
- b) On completion and subject to the result of the above tests, the inspection of components may be required, with dismantling where deemed necessary by the Surveyor in charge of the testing.

## **3 On board trials**

### **3.1 Ship trials**

#### **3.1.1**

- a) Upon completion of construction, in addition to conventional sea trials, specific tests may be required at the Society's discretion in relation to the particular service for which the ship is intended or the particular characteristics of machinery and equipment fitted on board and according to a test specification submitted by the interested party.
- b) In particular, as far as propulsion and steering systems are concerned, tests may be required to check the manoeuvring capability and the speed of the ship whilst operating with only directional propellers or active rudders or a combination thereof.
- c) In the case of ships mainly intended for repair of submarine cables, a check of manoeuvring capability whilst running astern or a complete overturning trial may be required to be carried out using the rudder, active rudders or side thrusters only.
- d) In the case of ships provided with a dynamic positioning system, tests to check the capability of holding the desired position or heading are requested.

### **3.2 Equipment trials**

#### **3.2.1**

- a) As far as arrangements for the cable laying, hauling and/or repair lines are concerned, tests are to be carried out to verify the proper operation of all relevant machinery and equipment, by means of the actual hauling and laying of submarine cables, plain or with repeaters, at different ship speeds and, if necessary, in different sea and weather conditions.
- b) Special attention is to be paid during such tests so as to prevent cables being forced to reach their minimum allowed bending radius, both inside and outside the ship.

## Section 4 Fire Protection

### 1 Cable tanks

#### 1.1 Means for fire fighting

**1.1.1** Depending on any special requirements of the Manufacturers of cables, cable tanks may also be required to be protected by a fixed pressure water-spraying or automatic sprinkler fire-extinguishing system.

# Part E

## Service Notations for Offshore Service Vessels and Tugs

---

### CHAPTER 7

## DIVING SUPPORT VESSELS

---

Section 1	General
Section 2	General Arrangement
Section 3	Structural Assessment
Section 4	Machinery and Systems
Section 5	Safety Features
Section 6	Specific Requirements for Ships Assigned with the Service Notation diving support-capable
Section 7	Initial Inspection and Testing

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships intended to support diving operations and complying with the present Chapter are eligible for the assignment of one of the following service notations as defined in Pt A, Ch 1, Sec 2, [4.11.5]:

- **diving support-integrated** when the vessel is fitted with permanently installed diving systems
- **diving support-portable**, when the vessel is fitted with a non-permanent diving system which is installed and operational
- **diving support-capable**, when the vessel is able to be fitted with a non-permanent diving system and the diving equipment is not installed.

Note 1: For non-permanent diving systems, the service notation **diving support-capable** is to be replaced by **diving support-portable** before conducting any diving operations (see Ch 7, Sec 6).

**1.1.2** One of the following additional service features is to be added to service notations **diving support-integrated** and **diving support-portable**:

- **DD** when the diving system installed onboard is a deep diving system (or saturation system) as defined in [2.1.2]
- **SD** when the diving system installed onboard is a shallow diving system (or surface supplied diving system) as defined in [2.1.1].

Note 1: Bounce diving system as defined in [2.1.3] are considered as a shallow diving system for the purpose of this Chapter.

**1.1.3** The present Chapter does not apply to the classification of diving systems which are covered by NR610, as detailed in [2.2].

**1.1.4** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1 and specific requirements for initial inspection and testing as per Ch 7, Sec 7.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT
Ship arrangement	L ≥ 65 or 90 m (1)	<ul style="list-style-type: none"> <li>• Part B</li> <li>• Ch 7, Sec 2 (2)</li> </ul>	<ul style="list-style-type: none"> <li>• NR566</li> <li>• Ch 7, Sec 2 (2)</li> </ul>

<p>(1) Refer to the scope of application of NR600.            (2) Or Ch 7, Sec 6 if the service notation <b>diving support-capable</b> is assigned.  <b>Note 1:</b>            NR566 : Hull Arrangement, Stability and Systems for Ships less than 500 GT.            NR600 : Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m.</p>			

**1.2 Scope**

**1.2.1** The present Chapter addresses the requirements regarding the installations on the supporting ship providing the diving system with auxiliary functions such as: fire safety, electrical power supply, communication means, breathing gas storage, ventilation, structural foundations, station keeping capabilities, etc.

**1.2.2** The present Chapter includes the provisions of IMO Code of Safety for Diving Systems as applicable to the interface between the diving system and the supporting ship.

Note 1: Attention is drawn to the fact that IMO Code of Safety for Diving Systems also covers the diving system itself.

These requirements are reproduced in *Italic type*. In reproducing the text, the word “Administration” is replaced by the word “Society”.

**2 Diving system**

**2.1 Description**

**2.1.1 Shallow or surface supplied diving system**

A surface supplied diving system is a system where interventions by divers are performed at such depth and durations that the descent onto the seabed, the work and the decompression are carried out in the water (without resorting to the use of a closed diving bell).

The breathing gas is supplied from the supporting vessel through an umbilical.

The breathing gas may be:

- pure compressed air, or
- mixed gas with enriched oxygen or helium.

The surface supplied diving installation generally includes as the case may be:

- means of getting into water
- means to recover the divers
- a decompression chamber
- means adapted to the diving method used.

**2.1.2 Deep or saturation diving system**

A saturation diving system is a system where the divers live in a pressurized environment which may be maintained for several days or weeks. Divers are generally decompressed to surface pressure only once, at the end of their tour of duty.

**2.1.3 Bounce diving system**

For the purpose of the present Chapter, a bounce diving system, as defined in [3.2.2], is considered as a shallow diving system.

**2.1.4 Components of the diving system**

Diving systems generally include, but are not limited to, the items listed in Tab 2.

**Table 2 : List of diving equipment**

Items	Deep diving	Shallow diving
Submersible compression chamber (closed diving bell)	X	
Wet diving bell or diver basket		X
Deck decompression chamber	X	X
Deck decompression chamber control panel	X	X
Hyperbaric evacuation system	X	
Breathing supply system	X	X
Handling systems for the diving bell	X	X
Diving control stand	X	X
Clamping and under pressure transfer system	X	
Devices for controlling the atmosphere	X	X
Devices for the recovery and the purification of breathing gases	X	X
Means of production of hot water	X	X

## **2.2 Classification of the diving system**

**2.2.1** The diving system is to be classed and compliant with NR 610 Rules for the Classification of Diving Systems, or with the rules of a recognized Classification Society.

As an alternative, a recognized diving system certificate may be accepted, subject to the Society agreement.

**2.2.2** Classification of the diving support ship and classification of the diving system are independent.

## **3 References**

### **3.1 Acronyms**

**3.1.1** The following acronyms are used:

- DDC : Deck decompression chamber (see [3.2.5])  
HRU : Hyperbaric rescue unit (see [3.2.11])  
LARS : Launch and recovery system (see [3.2.12])  
MSW : Metres of sea water (see [3.2.15])  
SDC : Submersible diving chamber (see [3.2.4])  
SPHL : Self-propelled hyperbaric lifeboat (see [3.2.11]).

### **3.2 Definitions**

#### **3.2.1 Bottle**

Pressure container for the storage and transport of gases under pressure. Also called gas cylinders.

#### **3.2.2 Bounce diving system**

A bounce diving system is a system using a closed diving bell and where the divers are decompressed on-board in a deck decompression chamber after each dive.

#### **3.2.3 Breathing gas**

All gases and mixtures of gases which are used for breathing during diving operations.

#### **3.2.4 Closed diving bell / submersible diving chamber**

Manned underwater compression chamber, including its fitted equipment, for transfer of diving personnel under pressure between the work location and the deck chambers.

Also known as a personnel transfer capsule (PTC) or submersible compression chamber or submersible diving chamber (SDC).

#### **3.2.5 Deck decompression chamber (DDC)**

Pressure vessel for human occupancy which does not go under water and may be used as a living chamber during saturation diving, diver decompression or treatment of decompression illness. Also called compression chamber, recompression chamber, deck chamber or surface compression chamber.

#### **3.2.6 Depth**

Water depth or equivalent pressure to which the diver is exposed at any time during a dive or inside a surface compression chamber or a diving bell.

#### **3.2.7 Diving basket**

Man-riding equipment used for transfer of diving personnel at ambient sea pressure between the work location and the diving support ship.

#### **3.2.8 Hazardous areas**

Those locations in which an explosive gas-air mixture is:

- continuously present, or present for long periods (zone 0)
- likely to occur in normal operation (zone 1)
- not likely to occur and, if it happens, only existing for a short time (zone 2).

#### **3.2.9 Hyperbaric evacuation system (HES)**

The whole plant and equipment necessary for the evacuation of divers in saturation from a deck decompression chamber to the Hyperbaric Reception Facility (HRF) where decompression can be carried out. The main components of a hyperbaric evacuation system include the Hyperbaric Rescue Unit (HRU), its handling system, the Hyperbaric Reception Facility and the evacuation procedures.

#### **3.2.10 Hyperbaric reception facility (HRF)**

Normally a shore based facility (but could be installed offshore) which is capable of accepting a HRU and mating it to a decompression chamber such that the evacuated occupants can be transferred into that chamber and safely decompressed.

### **3.2.11 Hyperbaric rescue unit (HRU)**

Floating unit used to evacuate divers under pressure safely from a ship or a floating structure to a location where decompression can be carried out.

It may be a Hyperbaric Rescue Chamber (HRC) or a Self-Propelled Hyperbaric Lifeboat (SPHL). Also known as Hyperbaric Evacuation Unit (HEU).

### **3.2.12 Launch and recovery system (LARS)**

Plant and equipment necessary for raising, lowering and transporting the diving bell, and/or diving basket, between the work location and the surface compression chamber.

### **3.2.13 Life support system**

Gas supply, breathing gas system, decompression equipment, environmental control system and equipment required to provide a safe environment for the diving crew in the diving bell and the surface compression chamber under all ranges of pressure and conditions they may be exposed to during diving operations.

### **3.2.14 Maximum operating depth**

Depth in metres of seawater equivalent to the maximum pressure for which the diving system is designed to operate.

### **3.2.15 Metres of sea water (MSW)**

Metres of sea water are sometimes used to express a water depth equivalent to a pressure. For the purpose of the design and testing of pressure vessels, the values in MSW are to be converted into pressure units.

### **3.2.16 Portable diving systems**

Portable equipment not remaining onboard but installed periodically for the purpose of specific works related to diving.

### **3.2.17 Pressure vessel**

Container capable of withstanding an internal maximum working pressure greater than or equal to 1 bar.

### **3.2.18 Umbilical**

Link between the diving support ship and the diving bell, or link between the diving bell and divers

It may contain surveillance, communication and power supply cables, breathing gas and hot water hoses.

### **3.2.19 Wet diving bell / open diving bell**

Bell with a closed top section, capable of containing a dry gaseous atmosphere to provide a refuge for the divers. It is not a pressure vessel. Also called an open bell.

## **3.3 Reference rules and regulations**

**3.3.1** The requirements of the present Chapter are generally consistent with the following rules and regulations:

- IMO - Code of Safety for Diving System:  
IMO - Code of Safety for Diving Systems means the Code of Safety adopted by IMO Resolution A.831(19), as amended.
- IMO - Guidelines and Specifications for Hyperbaric Evacuation Systems:  
IMO Guidelines and Specifications for Hyperbaric Evacuation Systems adopted by Resolution A.692(17).
- IMCA publications:  
International Marine Contractors Association (IMCA) is the editor of various publications providing guidelines for commercial diving and dynamic positioning operations. The following IMCA publications are referenced within the present Chapter:
  - IMCA D 014 - IMCA international code of practice for offshore diving
  - IMCA D 018 - Code of practice on the initial and periodic examination, testing and certification of diving plant and equipment
  - IMCA D 039 - FMEA guide for diving systems
  - IMCA D 052 - Guidance on hyperbaric evacuation systems
  - IMCA AODC 055 - Protection of water intake points for diver safety.

## **4 Documents to be submitted**

### **4.1 General**

**4.1.1** The documents listed in Tab 3 are to be submitted.

### **4.2 Diving system documentation**

#### **4.2.1 Specification**

The diving system specification is to include:

- the description of the system

- a design basis including:
  - maximum operating depth (and equivalent design pressure)
  - maximum operating time
  - maximum number of divers in water and in the DDC
  - maximum time of occupancy expected in the DDC
  - maximum operational wave height
  - minimum and maximum sea and air temperature
  - safety concept.
- the list of diving equipment with reference and name of the manufacturer.

**4.2.2 Operating manual**

The manufacturer of the diving equipment is to provide an operating manual with detailed information on the method to use the decompression system.

- the user instructions to operate the system
- operational limitations
- evacuation procedure

**Table 3 : Documents to be submitted**

No.	Documents to be submitted	I/A (1)
1	Diving system documentation (2): <ul style="list-style-type: none"> <li>• diving system certificates</li> <li>• specification (see [4.2.1])</li> <li>• operating manual (see [4.2.2])</li> <li>• equipment and certificate register (see [4.2.3])</li> <li>• service record book (see [4.2.4])</li> <li>• FMEA (see [4.2.5]) and critical spare parts list</li> <li>• planned maintenance system (see [4.2.6])</li> </ul>	I
2	General arrangement of the ship showing the diving system arrangement and including the: <ul style="list-style-type: none"> <li>• locations of equipment</li> <li>• location of breathing gas storage</li> <li>• hazardous zone and hazardous substances locations</li> <li>• interface with the piping arrangement, electrical installations, etc.</li> </ul>	A
Structural assessment

4	Description of the seafastening, if any	I
Electrical installations		
5	General arrangement showing location of electrical installations	I
6	Description of electrical arrangement principles, failure scenarios, redundancy principles, emergency arrangement, etc.	I
7	Single line distribution diagram and detailed diagram of the whole installation	A
8	General arrangement of the diving control room	A
9	Descriptions and details of any communication means as required by the Rules, including single line diagram	A
10	Description and details of the lighting arrangement around the diving system	A
Safety features		
11	Fire protection documentation with definition of the spaces which enclose or surround the diving system items and details of the passive fire protection	A
12	Fire-fighting equipment details	A
13	Fire detection and alarm equipment details	A
14	Breathing gas arrangement details, including piping diagram	A
15	General arrangement showing the hyperbaric evacuation means	A
(1) A : For approval I : For information. (2) Except when not available in case of service notation <b>diving support-capable</b> .		

**4.2.3 Equipment and certificate register**

An equipment and certificate register as defined in IMCA D014 is to be kept on-board.

**4.2.4 Service record book**

The Owner is to establish and maintain a service record book of the diving system which is to be submitted to the Society for in-service inspections.

The service record book is to contain all service and maintenance operations.

The service record book is to be available on-board.

**4.2.5 Failure modes and effects analysis (FMEA)**

A failure modes and effects analysis (FMEA) of the diving installation is to be conducted at an early stage of the new built projects or when a portable diving system is to be installed on-board.

The FMEA should identify the critical components for which spare parts should be provided.

It is recommended to update the FMEA for each modification of the diving system.

Note 1: A guidance to conduct to FMEA is proposed in the document IMCA D039 - FMEA guide for diving systems.

**4.2.6 Planned maintenance system (PMS)**

A planned maintenance system (PMS), as defined in IMCA D 018, should be submitted to the Society.

The PMS should include the requirements for the periodic examinations and testing.

The PMS should ensure the traceability of the maintenance works carried out and the routine replacement of the components on the diving plant.

The PMS is to include the identification markings of the diving equipment.

## Section 2 General Arrangement

### 1 General arrangement

#### 1.1 Diving system arrangements

**1.1.1** *The diving system and breathing gas facilities should be arranged in spaces or locations which are adequately ventilated and provided with suitable electric lighting.*

**1.1.2** *When any part of the diving system is sited on open deck, particular consideration should be given to providing reasonable protection from the sea, icing, heat or any damage which may result from other activities on board the ship or floating structure.*

**1.1.3** *Diving systems are not to be located closed to ventilation outlets and exhausts from machinery spaces or galleys.*

Note 1: In general, a minimum distance of 6 metres between ventilation outlets or exhausts defined above, and diving system ventilation inlets is considered sufficient.

**1.1.4** The diving system arrangement is to comply with the safety features requirements in Ch 7, Sec 5.

#### 1.2 Machinery spaces

**1.2.1** *The diving system and breathing gas storage facilities shall not be located in machinery spaces if the machinery is not associated with the diving system.*

#### 1.3 Hazardous areas

**1.3.1** As far as practicable, diving systems should not be located in hazardous areas.

**1.3.2** Where, due to the requirements of diving operations, the diving equipment is located in hazardous areas zone 1 or zone 2, it has to comply with the requirements for such equipment in hazardous areas, as defined Part C, Chapter 4

**1.3.3** *In any case, diving equipment are not permitted in hazardous areas designated as zone 0.*

#### 1.4 Breathing gas storage

**1.4.1** Particular requirements apply to the storage of the breathing gas, as specified in Ch 7, Sec 5.

#### 1.5 Location of deck decompression chamber

**1.5.1** It is recommended to install deck decompression chambers in the longitudinal direction to limit the effect of rolling motion on the divers.

**1.5.2** The deck decompression chamber of a surface supplied diving system is to be close to the location where the diver is getting out of the water and easily accessible without any trip hazards.

#### 1.6 Diving operations

**1.6.1** The diving system is to be located in such a way that diving operations are not affected by thrusters, propellers or mooring lines.

**1.6.2** The diving operation arrangement should ensure that all deployed umbilicals are physically prevented from coming into contact with any hazard such as thrusters or seawater inlets.

### 2 Access arrangement

#### 2.1 General

**2.1.1** There is to be a sufficient level of access available around the diving system in order to allow operational personnel to safely and efficiently carry out their duties.

#### 2.2 Means of evacuation

**2.2.1** An hyperbaric evacuation system is to be provided for units granted with the additional service feature **DD**, as specified in Ch 7, Sec 5.

## Section 3 Structural Assessment

### 1 Diving equipment foundations

#### 1.1 General

**1.1.1** Provision should be made to ensure that the diving system and auxiliary equipment are securely fastened to the ship or floating structure and that adjacent equipment is similarly secured. Consideration should be given to the relative movement between the components of the system. In addition, the fastening arrangements should be able to meet any required survival conditions of the ship or floating structure.

**1.1.2** Diving equipment are to be permanently secured to the ship primary structure by means of welding or bolting. Normally, a lashing arrangement is considered as not sufficient.

**1.1.3** The fastening arrangement of the pressure vessel has to allow volume variations due to internal pressure variations.

#### 1.2 Design loads

**1.2.1** The deadweight and the maximum operational loads of the diving equipment are to be provided (maximum number of persons, stores and equipment).

**1.2.2** The design loads of pressure vessels for human occupancy are to be especially considered if hydro testing is to be made onboard.

#### 1.3 Allowable deflection

**1.3.1** The deflection of the deck in way of the deck decompression chamber are to be within the allowable limits set by the equipment manufacturer, if any.

### 2 Launching system foundations

#### 2.1 General

**2.1.1** The foundations of the launching appliance are to comply with Pt B, Ch 1, Sec 1, [1.2].

## Section 4 Machinery and Systems

### 1 Sea inlets

#### 1.1 General

**1.1.1** Special considerations are to govern the design of sea inlets fitted in the hull of the ship, in order to protect the divers and the unit seawater systems.

Note 1: Recommendations are provided in IMCA AODC 055.

**1.1.2** Water current in the immediate vicinity of the sea inlet is not to exceed 0,5 m/sec.

**1.1.3** The mesh or aperture size of any protective structure is to be such as to prevent any part of the diver or his equipment from being drawn into the intake.

**1.1.4** The maximum mesh size, or the maximum size of any opening if not a mesh-type construction, is not to exceed an area of 400 cm<sup>2</sup>, equivalent to a square of 20 cm x 20 cm or a rectangle of 28 cm x 14 cm.

### 2 Position keeping

#### 2.1 General

**2.1.1** Ships covered by the present Chapter are to be able to safely maintain their position during diving operations. This may be achieved with a passive mooring or a dynamic positioning system complying with [2.2].

#### 2.2 Dynamic positioning

**2.2.1** When a diving support unit is fitted with a dynamic positioning system used during diving operations, the dynamic positioning system is to comply with IMO class 2 requirements.

In this case, the diving support unit is to be granted with the additional class notation **DYNAPOS AM/AT**, completed by one of the following symbols:

- **R**, when the dynamic positioning is provided with redundancy means. In this case, IMO class 2 equipment is to be used.
- **RS**, when, in addition to symbol **R**, the redundancy is achieved using two systems or alternative means of performing a function physically separated. In this case, IMO class 3 equipment is to be used.

**2.2.2** The dynamic positioning control stand and the diving control room are to have 2-way communication means and a manually operated alarm.

### 3 Electrical installations

#### 3.1 General

**3.1.1** All electrical equipment and installations, including power supply arrangements, should be designed for the environment in which they will operate in order to minimize the risk of fire, explosion, electrical shock and emission of toxic gases to personnel, as well as galvanic corrosion of the deck decompression chamber or diving bell.

**3.1.2** Electrical installations of the diving system are to be considered as secondary essential services according to Pt C, Ch 2, Sec 1.

**3.1.3** Main and automatic emergency lightings are to be provided in spaces containing diving equipment.

**3.1.4** Electrical wires are to be separated from piping installations carrying breathing gas.

#### 3.2 Electrical power supply

**3.2.1** In the event of failure of the main source of electrical power supply to the diving system, an independent source of electrical power is to be available for the safe termination of the diving operation. It is admissible to use the unit's emergency source of electrical power as an emergency source of electrical power if it has sufficient electrical power capacity to supply the diving system and the emergency load for the vessel at the same time.

**3.2.2** The alternative source of electrical power is to be located outside the machinery casings to ensure its functioning in the event of fire or other casualty causing failure to the main electrical installation.

**3.2.3** As a minimum, the emergency source of power is to be of sufficient capacity to supply:

- the life support system (analysis and regeneration)
- the emergency communication system
- the emergency lighting in the deck decompression chamber, the diving bell and the diving control room
- the LARS
- the handling system required for emergency launching of the means of hyperbaric evacuation
- the emergency systems in the diving control room.

**3.2.4** The emergency source of power is to be capable of supplying the systems specified in [3.2.3] for a period in compliance with the National Authorities' regulations, as relevant, and in any case not less than 18 hours.

**3.2.5** When switching from the main source of power to the emergency source of power, an audible and visible alarm is to be actuated in the diving control room with the indication of the source of power connected.

## **4 Diving control station**

### **4.1 General**

**4.1.1** *The diving system should be so arranged as to ensure that centralized control of the safe operation of the system can be maintained under all weather conditions.*

**4.1.2** The diving control station is to provide control of diving operations and of hyperbaric chambers. These functions may be separated in 2 distinct control rooms with suitable means of communication.

### **4.2 Communication and relocation system**

**4.2.1** The communication system should be arranged for direct 2-way communication between the diving control station(s) and:

- the deck decompression chamber control stand, when relevant
- the divers in water
- the diving bell
- each compartment of the deck decompression chamber
- the handling system operating position
- the dynamic positioning control stand
- the bridge
- the hyperbaric evacuation system launch point
- inside the hyperbaric evacuation system.

**4.2.2** *Alternative means of communication with divers in the deck decompression chamber and submersible compression chamber should be available in case of emergency.*

**4.2.3** *Each deck decompression chamber and submersible compression chamber should be connected to a speech unscrambler when used with gas systems, including helium.*

## **5 Diver heating system**

### **5.1 Oil fired heaters**

**5.1.1** When diver heating system includes oil fired heaters, they are to be located such that they present no risk to the dive system in the event of fire.

**5.1.2** The local tank is to be fitted with an overflow system with a capacity greater than the filling supply system (i.e. capable of allowing a rate of overflow greater than the filling rate).

**5.1.3** The overflow system is to dump to a safe area.

## Section 5 Safety Features

### 1 Fire safety

#### 1.1 Personnel protection

**1.1.1** As a minimum, the following fire protection equipment is to be provided in the diving control room for all persons required for the safe operation of the diving equipment, in addition to individual equipment required by the SOLAS Convention:

- emergency breathing masks
- fire-fighter's outfits.

#### 1.2 Structural fire protection

**1.2.1** All materials and equipment used in connection with the diving system should be, as far as practicable, of fire-retardant type in order to minimize the risk of fire and sources of ignition.

**1.2.2** Enclosed spaces in which the diving system or its auxiliary equipment is located are to be provided with structural fire protection A-60 with adjacent spaces.

These enclosed spaces may be subdivided into several compartments containing diving equipment and separated with A-0 bulkheads.

**1.2.3** Doors located in bulkheads forming boundaries with adjacent spaces are to be of self-closing type.

**1.2.4** Piping and cables included in the diving system are to be routed in ducts having the same fire protection than the space containing the diving equipment.

#### 1.3 Detection and alarm

**1.3.1** Interior spaces containing diving equipment such as deck decompression chambers, submersible compression chambers, gas storage, compressors and control stands are to be provided with an automatic fire detection and alarm system.

**1.3.2** The fire detection and alarm system referred to in [1.3.1] is to be independent of those of the other spaces.

**1.3.3** The fire detection panel is to be located in the ship control station and repeated in the engine control room and diving control station(s).

#### 1.4 Fire-fighting equipment

**1.4.1** Interior spaces containing diving equipment such as deck compression chambers, submersible compression chambers, breathing gas storage, compressors and control stands are to be provided with a fixed fire-extinguishing system suitable for machinery spaces of category A.

The fixed fire-extinguishing system is to be:

- either a manually actuated water-spraying system complying with Pt C, Ch 4, Sec 15, [6],
- or a fixed gas fire-extinguishing system using a non-toxic gas, subject to the Society approval.

**1.4.2** When pressure vessels (including gas cylinders) are situated in enclosed spaces, a manually actuated water spray system having an application rate of 10 litres per minute per square metre of the horizontal projected area is to be provided to cool and protect such pressure vessels in the event of an external fire.

Alternative means using water mist may be provided subject to the Society approval.

**1.4.3** Means for cooling windows of pressure vessels for human occupancy are to be provided.

**1.4.4** When pressure vessels are situated on open decks, fire hoses may be considered as providing the necessary protection.

**1.4.5** Portable fire extinguishers of approved types and designs are to be distributed throughout the space containing the diving system.

**1.4.6** One of the portable fire-extinguishers is to be stowed near the entrance to that space.

## 2 Breathing gas system

### 2.1 Storage on board

**2.1.1** Breathing gas storage and associated equipment should not be located in a machinery space not associated with the diving system.

**2.1.2** As a rule, breathing gas should be stored on an open deck.

**2.1.3** If the breathing gas is located in an enclosed space, the following is to be provided:

- a forced ventilation system as defined in [3]
- a type approved continuous monitoring system of the oxygen content in the ambient air
- a type approved audio-visible oxygen alarm (low-high) is to be installed at a manned control station
- any relief valve or bursting disc is to be piped to dump overboard and not into the enclosed space
- the enclosed space is to be gas-tight
- if lighting is provided in the enclosed space containing the breathing gas, it is to be of an approved safe type for operation in the gases likely to be encountered
- signboards as defined in [2.5].

**2.1.4** Breathing gas should not be stored near flammable substances.

**2.1.5** Any gas mixture containing more than 25% oxygen by volume will need to be handled like pure oxygen.

### 2.2 Piping

**2.2.1** Piping containing breathing gas under high pressure is not to be arranged inside the accommodation spaces, machinery spaces or hazardous areas.

**2.2.2** Piping systems containing flammable substances are not to be arranged in the same area as piping systems containing breathing gas.

**2.2.3** Flexible hoses, except for umbilicals, should be reduced to a minimum.

**2.2.4** Exhaust lines should be fitted with an anti-suction device on the inlet side.

**2.2.5** Gases vented from the diving system should be vented into the open air away from sources of ignition, personnel or any area where the presence of those gases could be hazardous.

**2.2.6** All high-pressure piping is to be protected against mechanical damage.

Note 1: Generally piping is considered under high pressure between cylinders or compressors and pressure reducing devices.

**2.2.7** Piping carrying breathing gas is to be kept away from electrical cables.

### 2.3 Oxygen installation

**2.3.1** A recognized standard is to be applied for the design of the oxygen installation and submitted to the Society for approval.

**2.3.2** Any material used in a plant which is intended to carry oxygen is to be compatible with oxygen at working pressure and flow rate.

**2.3.3** The use of high-pressure oxygen piping is to be minimized by the fitting of pressure reducing devices, as close as practicable to the storage cylinders.

**2.3.4** Means of protection against overpressure are to be provided in accordance with Pt C, Ch 1, Sec 10, [2]

**2.3.5** Hoses for oxygen are to be of fire-retardant construction and type-approved.

**2.3.6** Any materials used in a plant which is intended to carry oxygen is to be cleaned of hydrocarbons and debris to avoid explosions. Formal cleaning procedures for such equipment are to be developed and implemented.

### 2.4 Colour code

**2.4.1** For piping systems and gas storage bottles/pressure vessels, the colour codes defined in Tab 1 are to be used.

In addition, each bottle/pressure vessel is to be marked with the name and symbol of the gases it contains. The marking and colour coding of the gas storage bottles is to be visible from the valve end.

Table 1 : Colour code

Name	Symbol	Colour code
Oxygen	O <sub>2</sub>	white
Nitrogen	N <sub>2</sub>	black
Air	Air	white and black
Carbon dioxide	CO <sub>2</sub>	grey
Helium	He	brown
Oxygen-helium mix gas	O <sub>2</sub> -He	white and brown

## 2.5 Signboards

2.5.1 As a minimum, the following signboards are to be displayed in the storage room containing breathing gas:

- NO SMOKING
- diagram of the breathing gas plant.

## 3 Ventilation

### 3.1 General

3.1.1 Enclosed spaces containing the diving equipment are to have a forced ventilation with a rate of 8 air changes per hour with an independent system. The air intake is to be located in a non-hazardous area.

3.1.2 Ventilation fans are to be of non-sparking construction complying with Pt C, Ch 4, Sec 1.

## 4 Means of evacuation of the divers in saturation

### 4.1 Application

4.1.1 Ships having the additional service feature DD are to be provided with an hyperbaric evacuation system.

### 4.2 Hyperbaric evacuation system

4.2.1 *An evacuation system is to be provided having sufficient capacity to evacuate all divers under pressure in the event of the ship having to be abandoned.*

4.2.2 *The hyperbaric evacuation system is to comply with the IMO "Guidelines and Specifications for Hyperbaric Evacuation Systems", adopted by resolution A.692(17).*

### 4.3 Launching arrangement

4.3.1 The hyperbaric evacuation system launching arrangement is to be manufactured, inspected and tested according to SOLAS and IMO International Life-Saving Appliances Code (LSA Code) requirements, as far as practicable.

# Section 6 Specific Requirements for Ships Assigned with the Service Notation diving support-capable

## 1 General

### 1.1 Application

**1.1.1** The present Section provides requirements for ships intended to be fitted with non-permanent diving systems.

**1.1.2** Ships complying with the present Section are eligible for the assignment of the service notation **diving support-capable** defined in Ch 7, Sec 1, [1.1.1].

**1.1.3** Provisions and margins for the diving system are to be considered in the design of the supporting ship. The documents to be submitted are listed in [1.2].

**1.1.4** The service notation **diving support-capable** apply when the diving system is not installed on board.

**1.1.5** When the diving system is installed on board and before diving operations, the service notation **diving support-portable** is to be activated in replacement of **diving support-capable**, as detailed in [1.3].

### 1.2 Documents to be submitted

#### 1.2.1 General

The documents listed in Tab 1 are to be provided, as a minimum. Any additional information deemed necessary may be required by the Society.

**Table 1 : Documents to be submitted**

No.	I/A (1)	Documents to be submitted
1.1	I	Diving operational restrictions (Maximum MSW, limiting environmental conditions, ...)
1.2	I	Provisional characteristics of the diving system: <ul style="list-style-type: none"> <li>• list of equipment</li> <li>• mass estimated</li> <li>• overall dimensions and arrangement</li> <li>• electrical consumers list</li> <li>• quantity of divers</li> </ul>
1.3	A	General arrangement of the ship showing the provisions for diving system arrangement and including the: <ul style="list-style-type: none"> <li>• locations of equipment</li> <li>• location of breathing gas storage</li> <li>• hazardous zones and hazardous substances locations</li> <li>• interface with the piping arrangements, electrical installations, etc.</li> </ul>
1.4	I	Description of the interface between the diving system and the supporting ship as detailed in [1.2.2]
Structural assessment		
2.1	A	Structural arrangement showing the interface between diving equipment and hull structure
Electrical installations		
3.1	I	Description of electrical arrangement principles, when relevant
3.2	A	Electrical balance of the ship considering the diving system
Safety features		
4.1	A	Fire protection documentation with definition of the spaces which enclose or surround the diving system items and details of the passive fire protection, when relevant (2)
4.2	A	Fire-fighting equipment details
4.3	A	Fire detection and alarm equipment details, when relevant
4.4	A	Breathing gas arrangement details including piping diagram, when relevant
(1) A: to be submitted for approval; I: to be submitted for information.		
(2) Not applicable to open deck		

### **1.2.2 Description of the interface between the diving system and the supporting ship**

A description of the interface with the supporting ship is to be provided, including the modifications to be made on the ship where necessary.

The description is to include:

- the electrical power supply
- the fresh water supply
- the sea water supply
- the means for fire fighting, when provided by the ship
- the means of communication and alarms between the bridge of the ship and:
  - the diving control station,
  - the life support control station,
  - the LARS control stand.

### **1.3 Activation of service notation diving support-portable**

**1.3.1** Before any diving operation being conducted, the service notation **diving support-portable** is to be activated. For this purpose, the following requirements are to be complied with:

- documents defined in Ch 7, Sec 1, [4] are to be submitted for information or approval, including a recognized certificate of the diving system, as per Ch 7, Sec 1, [2]
- a survey of the diving system is to be conducted after the installation of the diving equipment on board, as defined in Ch 7, Sec 7, [1.2].

**1.3.2** When the requirements of [1.3.1] are fulfilled, the class certificate of the supporting ship is re-issued with the service notation **diving support-portable**, in replacement of **diving support-capable**.

Note 1: Normally, a minimum of 4 weeks is to be scheduled between the submission of the documents to the Society and the diving operations.

## **2 General arrangement**

### **2.1 General**

**2.1.1** Applicable requirements of Ch 7, Sec 2 are to be complied with, based on the provisional characteristics of the diving system.

## **3 Structural assessment**

### **3.1 General**

**3.1.1** Requirements of Ch 7, Sec 3 are to be complied with, based on the provisional characteristics of the diving equipment.

## **4 Machinery and systems**

### **4.1 Position keeping**

**4.1.1** Requirements of Ch 7, Sec 4, [2] are to be complied with.

### **4.2 Sea inlets**

**4.2.1** Relevant requirements of Ch 7, Sec 4, [1] are to be complied with.

## **5 Electrical installations and automations**

### **5.1 Electrical power supply**

**5.1.1** When the electrical power is supplied by the supporting ship, applicable requirements of Ch 7, Sec 4, [3] are to be complied with.

## **6 Safety features**

### **6.1 Fire safety**

**6.1.1** When a part of the diving system is located in an enclosed space inside the supporting ship, applicable requirements of Ch 7, Sec 5, [1] are to be complied with.

## **6.2 Breathing gas facilities**

**6.2.1** Applicable requirements of Ch 7, Sec 5, [2] are to be complied with, based on the provisional characteristics of the diving system.

## **6.3 Ventilation**

**6.3.1** When a part of the diving system is located in an enclosed space inside the supporting ship, applicable requirements of Ch 7, Sec 5, [3] are to be complied with.

# Section 7 Initial Inspection and Testing

## 1 General

### 1.1 Application

**1.1.1** The present Section provides requirements for initial inspection and testing of the diving equipment when first installed on-board or after re-installation on a supporting ship.

**1.1.2** Upon the installation of the diving system on-board and in addition to conventional sea trials, specific inspection and testing in relation to the particular service for which the ship is intended are required.

**1.1.3** These tests are to be conducted according to an inspection and testing specification to be submitted to the Society by the party applying for classification.

The Society is to be duly informed of the time and place of the commissioning tests of the diving system.

**1.1.4** The commissioning procedures of the diving system should be approved by the certifying authority of the diving system.

**1.1.5** The inspection and testing requirements of the present Section are provided as a minimum and in addition to the requirements of the rules or standards referred to in the diving system certificate.

Any additional testing may be required to the satisfaction of the attending Surveyor.

**1.1.6** The Factory Acceptance Tests (FAT) of the diving equipment are not in the scope of the present Chapter.

### 1.2 Non-permanent diving system

**1.2.1** Non-permanent diving systems should meet inspection and testing requirements defined in [2] after each installation on-board.

**1.2.2** Upon satisfactory completion of [1.2.1], the service notation **diving support-portable** may be activated as defined in Ch 7, Sec 6, [1.3].

## 2 On-board testing

### 2.1 Diving installations

**2.1.1** The inspection and testing of the diving installation should include, as a minimum:

- a) Verification of the presence on-board of the following documents:
  - Diving system specification, as defined in Ch 7, Sec 1, [4.2.1]
  - Operating manual, as defined in Ch 7, Sec 1, [4.2.2]
  - Equipment and certificate register, as defined in Ch 7, Sec 1, [4.2.3]
  - Planned maintenance system, as defined in Ch 7, Sec 1, [4.2.6].
- b) Verification of the structural arrangement and scantling of the foundations of pressure vessels and bell handling system
- c) Verification of the sea fastening arrangement of the diving equipment. If the sea fastening requires any welded fixtures then there is to be Non Destructive Testing reports available confirming these welds were satisfactorily tested
- d) Functional testing of the main source of electrical power, emergency source of electrical power and switching from one to the other. Verification of the satisfactory operation of the alarms and indications
- e) General examination of the electrical cabling
- f) Functional testing of the main and alternative two-way communication system at the dive location, i.e. between divers, chambers, control rooms, launch point and other important locations
- g) Testing of the breathing gas installations:
  - 1) general examination of the storage of the gas cylinders
  - 2) verification of cleanliness of the breathing gas piping system according to the approved procedure
  - 3) testing of the gas-tightness of all sealing devices of the enclosed spaces for breathing gas storage
  - 4) confirmation of the proper operation of the forced ventilation of the enclosed spaces for gas storage
  - 5) verification of the means for the protection against overpressure of the oxygen installation
  - 6) verification of the alarms of oxygen-measuring equipment
  - 7) verification of the signboards in the area containing the gas cylinders.

- h) General examination of the automatic fire detection and alarm system
- i) Verification of the suitable fixed fire-extinguishing system intended for interior spaces containing diving equipment
- j) Confirmation that the fire fighters' outfits, including their self-contained compressed air breathing apparatus, two-way portable communication apparatus and emergency breathing mask, are complete and in good condition and that the cylinders, including the spare cylinders, of any required self-contained breathing apparatus are suitably charged
- k) Functional testing of the self closing systems of the doors located in the bulkheads forming boundaries with the adjacent spaces
- l) General examination of the visible parts of the items forming the structural fire protection, such as bulkheads, decks, doors and trunks, due attention being given to their integrity and that of the insulating material.

**2.1.2** As a rule, all the connections between the supporting ship and the diving installation are to be presented for examination by the Surveyor.

### CHAPTER 8

## LIFTING UNITS

---

Section 1	General
Section 2	General Arrangement
Section 3	Stability and Subdivision
Section 4	Structural Assessment
Section 5	Machinery and Systems
Section 6	Initial Inspection and Testing
Section 7	Self-Elevating Ships

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the present Chapter are eligible for the assignment of the service notation **lifting** as defined in Pt A, Ch 1, Sec 2, [4.12.6].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1 and specific requirements for initial inspection and testing as detailed in Ch 8, Sec 6.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT
Ship arrangement	L ≥ 65 or 90 m (1)	<ul style="list-style-type: none"> <li>• Part B</li> <li>• Ch 8, Sec 2</li> </ul>	<ul style="list-style-type: none"> <li>• NR566</li> <li>• Ch 8, Sec 2</li> </ul>

**1.1.3** The lifting appliance is to be certified as required in [2.1].

### 1.1.4 Ships fitted with legs for self-elevating purposes

When the vessel is fitted with legs for self-elevating purpose, the additional service feature self-elevating is to be assigned in accordance with Pt A, Ch 1, Sec 2, [4.12] and the requirements of Ch 8, Sec 7 are to be complied with.

## 1.2 Scope

**1.2.1** The present Chapter addresses the requirements regarding the installations on the ship providing the lifting equipment with auxiliary functions (power supply, communication means, station keeping capabilities etc.), the stability criteria for lifting operations and the requirements for the structural assessment of the foundations of the lifting equipment.

**1.2.2** Specific requirements for ships fitted with legs for self-elevating purposes are also addressed in Ch 8, Sec 7.

## 2 Lifting equipment

### 2.1 Certification of the lifting equipment

**2.1.1** The lifting equipment is to be certified and included within the scope of classification by assigning to the lifting unit the additional class notation **ALM** or **OHS**, as defined in Pt A, Ch 1, Sec 2, [6.12] and Pt A, Ch 1, Sec 2, [6.25.6] respectively.

## 3 References

### 3.1 Acronyms

3.1.1 The following acronyms are used:

DAF	: Dynamic amplification factor (see [3.2.1])
MBL	: Minimum breaking load (see [3.2.4])
RP	: Rated line pull (see [3.2.6])
SWL	: Safe working load (see [3.2.7])
WLL	: Working load limit (see [3.2.9]).

### 3.2 Definitions

#### 3.2.1 Dynamic amplification factor (DAF)

The dynamic amplification factor (DAF) is applied on the static hook load to account for the effect of the external forces due to vessel motions and accelerations, the self motion of the lifting appliance, and the dynamic effects due to lifting in water in case of subsea lifting.

#### 3.2.2 Geometrical limit

The geometrical limit is the configuration of the lifting appliance for which the SWL is defined. It is possible to specify several SWL corresponding to different geometrical limits.

#### 3.2.3 Handling system

A handling system means any system intended to lifting or pulling of a load.

#### 3.2.4 Minimum breaking load (MBL)

The minimum breaking load of chain, wire ropes and fibre ropes are provided by the manufacturer in accordance with NR216 Materials and Welding.

#### 3.2.5 Nominal pulling load

The nominal pulling load of a handling system is defined as the maximum load which may be pulled by the system in a safe manner, in kN.

When the handling system is a lifting appliance, the nominal pulling load is equivalent to the Safe Working Load.

#### 3.2.6 Rated line pull (RP)

The rated line pull (RP) of a winch is the maximum rope tension, in kN, that the winch can haul at the relevant layer, in normal service condition, when the drum rotates at its maximum service speed.

#### 3.2.7 Safe working load (SWL)

The safe working load (SWL), in kN, is defined as the maximum static load which may be lifted vertically by the appliance under normal use and within its geometrical limits.

#### 3.2.8 Static Load

The static load, in kN, corresponds to the sum of the static mass of the lifted cargo and its rigging, times the gravity acceleration.

#### 3.2.9 Working load limit (WLL)

The working load limit (WLL), in kN, is defined as the maximum load that a lifting accessory (loose gear) is certified to withstand under normal use and in a given configuration.

## 4 Documents to be submitted

### 4.1 General

4.1.1 The documents listed in Tab 2 are to be provided, as a minimum.

### 4.2 Lifting equipment documentation

#### 4.2.1 Operating manual

The operating manual is to contain the user documentation required by the technical standard the lifting equipment is complying to.

In particular, the operating manual is to contain full information concerning:

- the crane utilization chart, taking into account the stability and structural limitations for each relevant wind and sea state

- all limitations during normal and emergency operations:
  - maximum wind and sea state
  - maximum heel and trim
  - design temperature
  - braking systems
- the description of the equipment
- the design technical standard
- the mass and location of centre of gravity of the main components of the lifting equipment
- all safety devices, including overload protection system, when relevant
- the description of the motion compensation system, when relevant
- the user instructions to operate, erect, dismantle and transport the system
- the factory acceptance tests specification
- the inspection and testing programme of the equipment when installed on-board
- the testing specification of the emergency lowering system for personnel transfer, when relevant
- the diagrams of electrical, hydraulic and pneumatic systems and equipment
- the materials used in construction, welding procedures and extent of non-destructive testing

Note 1: The party applying for classification may also refer to the IMO MODU Code Chapter 12 for the description of the manual content.

**4.2.2 Calculation notes**

Calculation notes including the items listed below are to be provided for information:

- loading conditions and design loads applied on the lifting equipment
- loads lowering in the foundations
- structural assessment of the connecting bolts between the lifting equipment and its foundations.

**Table 2 : Documents to be submitted**

## Section 2                      General Arrangement

### 1 General

#### 1.1 Location of lifting appliances

**1.1.1** *Lifting appliances should be so located and protected as to reduce to a minimum any danger to personnel, due regard being paid to moving parts or other hazards. Adequate provisions should be made to facilitate cleaning, inspection and maintenance.*

#### 1.2 Position of the crane during navigation

**1.2.1** When the lifting appliance is a crane, it is to be possible and to secure it during transit.

## Section 3 Stability and Subdivision

### Symbols

LCG	: Longitudinal centre of gravity
TCG	: Transversal centre of gravity
VCG	: Vertical centre of gravity.

### 1 General

#### 1.1 Application

**1.1.1** The provisions of this Section are to be applied to operations involving the lifting of the ship's own structures or for lifts in which the maximum heeling moment due to the lift is greater than that given in the following:

$$M_L = 0,67 \cdot \Delta \cdot GM \cdot \left(\frac{f}{B}\right)$$

Where:

$M_L$	: Threshold value for the heeling moment, in t.m, induced by the lifting equipment and load in the lifting equipment.
$GM$	: Initial metacentric height, in m, with free surface correction, including the effect of the lifting equipment and load in the lifting equipment.
$f$	: Minimum freeboard, in m, measured from the upper side of the weather deck to the waterline.
$B$	: Moulded breadth of the ship, in m.
$\Delta$	: Displacement of the ship, including the lift load, in t.

The stability criteria of this Section also apply to ships which are engaged in lifting operations where no transverse heeling moment is induced and the increase of the ship's vertical centre of gravity (VCG) due to the lifted weight is greater than 1%.

The calculations are to be completed at the most unfavourable loading conditions for which the lifting equipment shall be used.

**1.1.2** This Section provides additional stability criteria to be met during lifting operations in exposed or in non-exposed waters.

#### 1.2 Definitions

##### 1.2.1 Exposed/non-exposed waters

For the purpose of this Section, waters that are not exposed are those where the environmental impact on the lifting operation is negligible. Otherwise, waters are to be considered exposed. In general, waters that are not exposed are calm stretches of water, i.e. estuaries, roadsteads, bays, lagoons; where the wind fetch is six nautical miles or less.

Note 1: Wind fetch is an unobstructed horizontal distance over which the wind can travel over water in a straight direction.

#### 1.3 Loading conditions

**1.3.1** The stability criteria stated in this Section shall be satisfied for all loading conditions intended for lifting and with the hook load at the most unfavourable positions. For each loading condition, the weight and centre of gravity of the load being lifted, the lifting appliance, and counter ballast, if any, should be included. The most unfavourable position may be obtained from the load chart and is chosen at the position where the total of the transverse and vertical moment is the greatest. Additional loading conditions corresponding to various boom positions and counter ballast with different filling level, if applicable, may need to be checked.

**1.3.2** In lifting operations involving a lifting appliance such as a crane, derrick, sheerlegs or any other similar lifting device:

- the magnitude of the lifted load ( $P_L$ ) shall be the maximum allowed static load at a given outreach of the lifting appliance
- the transverse distance ( $y$ ) is the transverse distance between the point at which the vertical load is applied to the lifting appliance and the ship centreline in the upright position
- the vertical height of the load ( $KG_{load}$ ) is taken as the vertical distance from the point at which the vertical load is applied to the lifting appliance to the baseline in the upright position
- the change of centre of gravity of the lifting appliance(s) need to be taken into account.

**1.3.3** In lifting operations not involving a lifting appliance consisting of a crane, derrick, sheerlegs, a-frame or similar, which involve lifting of fully or partially submerged objects over rollers or strong points at or near a deck-level:

- the magnitude of the lifted load ( $P_L$ ) shall be the winch brake holding load

- the transverse distance ( $y$ ) is the transverse distance between the point at which the vertical load is applied to the ship and the ship centreline in the upright position
- the vertical height of the load ( $KG_{load}$ ) is taken as the vertical distance from the point at which the vertical load is applied to the ship to the baseline in the upright position.

**1.3.4** Allowance is to be made for the anticipated type of wire or rope on storage reels and wire on the winches when calculating loading conditions.

## **1.4 Trim and stability booklet**

**1.4.1** Loading conditions reflecting the operational limitations of the ship, while engaged in lifting shall be included in the stability booklet.

Use of counter ballast, if applicable, shall be clearly documented, and the adequacy of the ships stability in the event of the sudden loss of the hook load shall be demonstrated.

**1.4.2** The following information is to be included in the trim and stability booklet in addition to the information required in Part B, Chapter 3:

- a) Maximum heeling moment for each direction of lift/inclination as a function of the counter-ballast heeling moment, if used, the draught, and vertical centre of gravity.
- b) Where fixed counter ballast is used the following information shall be included:
  - mass of the fixed counter ballast
  - centre of gravity (LCC, TCC, VCC) of the fixed counter ballast.
- c) Loading conditions over the range of draughts for which lifting operations may be conducted with the maximum vertical load of the lift. Where applicable, righting lever curves for both before and after load drop should be presented for each loading condition.
- d) Limitations on cranes operation including permissible heel angles.
- e) operational limitations, such as:
  - maximum safe working load (SWL)
  - maximum radius of operation of all derricks and lifting appliances
  - maximum load moment
  - environmental condition affecting the stability of the ship.
- f) Instructions related to normal operations, including use of counter-ballast.
- g) Instructions such as ballasting/de-ballasting procedures to righting the ship following an accidental load drop.
- h) identification of critical down-flooding openings.
- i) recommendations on the use of roll reduction systems.
- j) drawing of the crane showing the weight and centre of gravity, including heel/trim limitations established by the crane manufacturer.
- k) a crane load chart, with appropriate de-ratings for wave height.
- l) Load chart for lifting operations covering the range of operational draughts related to lifting and including a summary of the stability results.
- m) A crane specification manual provided by the manufacturer shall be submitted separately for information.
- n) the lifting appliance load, radius, boom angle limit table, including identification of offlead and sidelead angle limits and slewing angle range limits and reference to the ship's centreline.
- o) a table that relates the ship trim and heel to the load, radius, slewing angle and limits, and the offlead and sidelead limits.
- p) procedures for calculating the offlead and sidelead angles and the ship VCC with the load applied.
- q) if installed, data associated with a Load Moment Indicator system and metrics included in the system.
- r) if lifting appliance (crane) offlead and sidelead determine the maximum ship equilibrium angle, the stability booklet should include a note identifying the lifting appliance as the stability limiting factor during lifting operations.
- s) information regarding the deployment of (stability) pontoons to assist a lifting operation, if fitted.

The information listed above may be included in other ship specific documentation on board the ship. In that case, a reference to these documents shall be included in the stability booklet.

## **1.5 Model tests or direct calculations**

**1.5.1** Model tests or direct calculations, performed in accordance with a methodology acceptable to the Society, that demonstrate the survivability of the ship after sudden loss of hook load, may be allowed as an alternative to complying with the requirements of [2.3] or [3.2.3], provided that:

- the effects of wind and waves are taken into account, and
- the maximum dynamic roll amplitude of the ship after loss of load will not cause immersion of unprotected openings.

**1.6 Operational procedures against capsizing**

1.6.1 *Ships should avoid resonant roll conditions when engaged in lifting operations.*

**1.7 Guidance on wind force**

1.7.1 The curves of wind heeling moments may be drawn for wind forces calculated by the following formula:

$$F = 0,5 C_s C_H P V^2 A$$

where:

- F : Wind force, in N
- C<sub>s</sub> : Shape coefficient depending on the shape of the structural member exposed to the wind (refer to Tab 1)
- C<sub>H</sub> : Height coefficient depending on the height above sea level of the structural member exposed to wind (refer to Tab 2)
- P : Air specific mass (1,222 kg/m<sup>3</sup>)
- V : Wind speed, in m/s
- A : Projected area of the exposed surface of the structural member in either the upright or the heeled condition, in m<sup>2</sup>.

**Table 1 : Shape coefficient C<sub>s</sub>**

Shape	C <sub>s</sub>
Spherical	0,40
Cylindrical	0,50
Large flat surface (hull, deckhouse, smooth underdeck areas)	1,00
Drilling derrick	1,25
Wires	1,20
Exposed beams and girders under deck	1,30
Small parts	1,40
Isolated shapes (crane, beam, etc.)	1,50
Clustered deckhouses or similar structures	1,10

**Table 2 : Height coefficient C<sub>H</sub>**

Height above sea level, in m	C <sub>H</sub>
0 - 15,3	1,00
15,3 - 30,5	1,10
30,5 - 46,0	1,20
46,0 - 61,0	1,30
61,0 - 76,0	1,37
76,0 - 91,5	1,43
91,5 - 106,5	1,48
106,5 - 122,0	1,52
122,0 - 137,0	1,56
137,0 - 152,5	1,60
152,5 - 167,5	1,63
167,5 - 183,0	1,67
183,0 - 198,0	1,70
198,0 - 213,5	1,72
213,5 - 228,5	1,75
228,5 - 244,0	1,77
244,0 - 259,0	1,79
above 259	1,80

**1.7.2** Wind forces are to be considered in the transversal direction relative to the ship axis and the value of the wind speed is to be taken as follows:

- a) In general, a minimum wind speed of 10 m/s (20 knots) is to be used for normal working conditions.
- b) When the ship is limited in operation, the maximum wind velocity is to be clearly stated in the crane utilization manual.

**1.7.3** In calculating the projected areas to the vertical plane, the area of surfaces exposed to wind due to heel or trim such as under decks surfaces, etc., are to be included using the appropriate shape factor. Open truss work may be approximated by taking 30% of the projected block area of both the front and back section, i.e., 60% of the projected area of one side. In the case of columns, the projected areas of all columns is to be included.

**1.7.4** The lever for the wind heeling moment is to be taken vertically from the centre of the lateral resistance or, if available, the centre of hydrodynamic pressure, of the underwater body to the centre of pressure of the areas subject to wind loading. When the installation is fitted with dynamic positioning system, the thrusters effect in [1.7.7] is to be considered.

**1.7.5** The curve of wind heeling moments may be assumed to vary as the cosine function of ship heel (see Fig 1).

**1.7.6** Wind heeling moments derived from wind tunnel tests on a representative model of the ship may be considered as alternatives to the method given in [1.7.1] to [1.7.5]. Such heeling moment determination is to include lift and drag effects at various applicable heel angles.

#### **1.7.7 Thrusters effect**

When deemed necessary, for ships on which dynamic positioning is installed, the thrusters negative effect on stability is to be taken into account.

## **2 Intact stability**

### **2.1 General stability criteria**

**2.1.1** The stability criteria included herein, or the criteria contained in [2.2], [2.3] or [3], as applicable, is to be satisfied for all loading conditions intended for lifting with the lifting appliance and its load at the most unfavourable positions.

For the purpose of this Section, the lifting appliance, its load(s) and their centre of gravity (COG) should be included in the displacement and centre of gravity of the ship, in which case no external heeling moment/heeling lever is applied.

**2.1.2** For the loading conditions stated in [1.3], the following intact stability criteria are to be complied with:

- a) the equilibrium heeling angle  $\varphi_1$  shall not be greater than the maximum static heeling angle for which the lifting device is designed and which has been considered in the approval of the loading gear.
- b) during lifting operations in non-exposed waters, the minimum distance between the water level and the highest continuous deck enclosing the watertight hull, taking into account trim and heel at any position along the length of the ship, shall not be less than 0,50 m.
- c) during lifting operations in exposed waters, the residual freeboard shall not be less than 1,00 m or 75% of the highest significant wave height  $H_s$ , in (m), encountered during the operation, whichever is greater.

### **2.2 Lifting operations conducted under environmental and operational limitations**

**2.2.1** For lifting conditions carried out within clearly defined limitations set forth in a), the intact criteria set forth in b) may be applied instead of the criteria included in [2.1]:

a) The limits of the environmental conditions should specify at least the following:

- the maximum significant wave height
- the maximum wind speed (1 minute sustained at 10 m above sea level), see guidance in [1.7]

The limits of the operational conditions should specify at least the following:

- the maximum duration of the lift
- limitations in ship speed
- limitations in traffic/traffic control

b) The following stability criteria apply with the lifted load is at the most unfavourable position:

- the corner of the highest continuous deck enclosing the watertight hull shall not be submerged
- $A_{RL} \geq 1,40 \times A_{HL}$

Where:

$A_{RL}$  : The area under the net righting lever curve, corrected for crane heeling moment and for the righting moment provided by the counter ballast, if applicable, extending from the angle  $\varphi_1$  to the angle  $\varphi_2$ , see Fig 1

$A_{HL}$  : The area below the wind heeling lever curve due to the wind force applied to the ship at the maximum wind speed specified in a), see Fig 1

$\varphi_1$  : Equilibrium heeling angle

$\varphi_2$  : The lesser between the angle of down flooding ( $\varphi_F$ ), the angle of vanishing stability ( $\varphi_R$ ), and the second intersection of the righting lever curve with the wind heeling lever curve.

c) The area under the net righting lever curve from the equilibrium heel angle,  $\varphi_1$ , to the down flooding angle,  $\varphi_F$ , or  $20^\circ$ , whichever is less, shall be at least 0,03 m rad.

**Figure 1 : Intact criteria under Environmental and Operational limitations**

**2.3 Intact stability criteria in the event of sudden loss of the lifted load**

**2.3.1** A ship engaged in a lifting operation and using counter ballasting should be able to withstand the sudden loss of the hook load, considering the most unfavourable point at which the hook load may be applied to the ship (i.e. largest heeling moment). In this case, the following intact stability criteria are to be complied with in addition to those in [2.1] and [2.2].

**2.3.2** For this purpose, the area on the side of the ship opposite to the lift (Area 2) is to be greater than the residual area on the side of the lift (Area 1), as shown in Fig 2, by an amount given by the following:

- Area 2 > 1,4 × Area 1, for lifting operations in waters that are exposed
- Area 2 > 1,0 × Area 1, for lifting operations in waters that are not exposed

Where:

$GZ_1$  : Net righting lever (GZ) curve for the condition before loss of crane load, corrected for crane heeling moment and for the righting moment provided by the counter ballast if applicable.

$GZ_2$  : Net righting lever (GZ) curve for the condition after loss of crane load, corrected for the transverse moment provided by the counter ballast if applicable.

$\varphi_{e2}$  : The angle of static equilibrium after loss of crane load.

$\varphi_f$  : The angle of down-flooding or the heel angle corresponding to the second intersection between heeling and righting arm curves, whichever is less.

The term “net righting lever” means that the calculation of the GZ curve includes the ship's true transverse centre of gravity as function of the angle of heel.

Note 1: When, after the loss of the lifted load, the ship still heels to the same side, there is no need to comply with above criteria.

**Figure 2 : Righting moment curve after sudden loss of load**

### 3 Intact stability - alternative method

#### 3.1 General

**3.1.1** The criteria in this Article may be applied to a ship engaged in a lifting operation, as an alternative to the criteria in [2.1] to [2.3], as applicable.

For the purpose of this section and the alternative stability criteria set out in [3.2], the lifted load which causes the ship to heel is translated for the purpose of stability calculation to a heeling moment/heeling lever which is applied on the righting lever curve of the ship.

**3.1.2** The heeling moment applied to the ship due to a lift and the associated heeling lever should be calculated using the following formulae:

$$HM_{\varphi} = P_L \cdot y \cdot \cos \varphi$$

$$HL_{\varphi} = HM_{\varphi} / \Delta$$

where:

$HM_{\varphi}$  : heeling moment, in t.m, due to the lift at  $\varphi$

$P_L$  : vertical load, in t, of the lift, as defined in [1.4.2]

$y$  : transverse distance, in m, of the lift, metres, as defined in [1.4.2]

$\varphi$  : angle of heel

$HL_{\varphi}$  : heeling lever, in m, due to the lift at  $\varphi$

$\Delta$  : displacement, in t, of the ship with the load of the lift.

#### 3.2 Alternative stability criteria

**3.2.1** The equilibrium heel angle  $\varphi_e$  referred to in this Article means the angle of first intersection between the righting lever curve and the heeling lever curve.

**3.2.2** During the lifting operation, the following stability criteria apply:

- a) the residual righting area below the righting lever and above the heeling lever curve between  $\varphi_e$  and the lesser of 40° or the angle of the maximum residual righting lever should not be less than:
  - 0,080 m rad, if lifting operations are performed in waters that are exposed, or
  - 0,053 m rad, if lifting operations are performed in waters that are not exposed.
- b) in addition, the equilibrium angle is to be limited to the lesser of the following:
  - 10 degrees
  - the angle of immersion of the highest continuous deck enclosing the watertight hull
  - the lifting appliance allowable value of trim/heel (data to be derived from sidelead and offlead allowable values obtained from manufacturer).

**3.2.3** For application of the criteria contained in [2.3] involving the sudden loss of load of the lift in which counter-ballast is used, the heeling levers that include the counter-ballast should be calculated using the following formulae (see Fig 3):

$$CHL_1 = \frac{(P_L \cdot y - CBM)}{\Delta} \cos \varphi$$

$$CBHL_2 = \frac{CBM \cdot \cos \varphi}{\Delta - P_L}$$

Where:

$CBM$  : the heeling moment, in t.m, due to the counter-ballast

$CHL_1$  : combined heeling lever, in m, due to the load of the lift and the counter-ballast heeling moment at the displacement corresponding to the ship with the load of the lift

$CBHL_2$  : heeling lever, in m, due to the counter-ballast heeling moment at the displacement corresponding to the ship without the load of the lift.

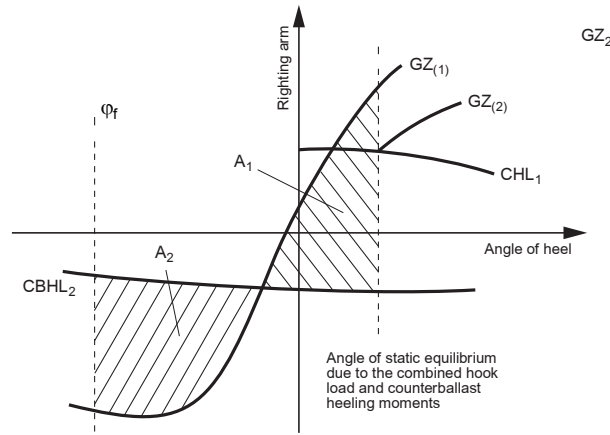

For this purpose, the area on the side of the ship opposite from the lift (Area 2) in Fig 3 should be greater than the residual area on the side of the lift (Area 1) by an amount given by the following:

$$\text{Area 2} - \text{Area 1} > K$$

where

- $K = 0,037$  m.rad, for a lifting operation in waters that are exposed, and
- $K = 0,0$  m.rad, for a lifting operation in waters that are not exposed.

Figure 3 : Alternative criteria - sudden loss of load

## 4 Additional intact stability criteria for crane overload test

### 4.1 General

4.1.1 Intact stability check during crane overload testing may be deemed necessary.

As guidance, ships which have onboard cranes of significant size compared to the ship general particulars or/and in case the intact stability particulars during normal crane operations are deemed marginal, the residual intact stability during crane overload test is to be checked and is in principle not to be less than that required by [2.1] and [2.3] as applicable.

## 5 Alternative damage stability for lifting operations for ships where additional class notation SDS is assigned

### 5.1 Application

5.1.1 The damage stability criteria specified in this Article may apply to ships operating within a field such as a windfarm and within the limiting conditions as defined in [5.1.2], in lieu of the damage stability criteria applicable as per Pt B, Ch 3, Sec 3, subject to Society agreement.

5.1.2 These alternative damage stability criteria may be applied when the following conditions are satisfied:

- the ship is operating in an area subject to fully controlled traffic (e.g. wind farm)
- maximum wave significant height and wind speed is limited

### 5.2 Data to be submitted

5.2.1 The following data are to be submitted:

- limits of the environmental conditions:
  - the maximum significant wave height
  - the maximum wind speed (1 minute sustained at 10 m above sea level)
- limits of the operational conditions:
  - the maximum duration of the lift
  - limitations in ship speed
  - limitations in traffic/traffic control

### 5.3 Extent of damage

5.3.1 The following extent of damage is to be assumed to occur between effective watertight bulkheads:

- vertical extent: from the baseline upwards without limit
- horizontal penetration measured inboard from the side of the ship perpendicularly to the centre line at the summer load waterline level: 1,5 m.

5.3.2 The distance between effective watertight bulkheads or their nearest stepped portions which are positioned within the assumed extent of horizontal penetration are not to be less than 3 m; where there is a lesser distance, one or more of the adjacent bulkheads are to be disregarded.

5.3.3 Where damage of a lesser extent than defined in [5.3.1] results in a more severe condition, such lesser extent is to be assumed.

**5.3.4** All piping, ventilation systems, trunks, etc., within the extent of damage referred to in [5.3.1] are to be assumed to be damaged. Positive means of closure are to be provided at watertight boundaries to prevent the progressive flooding of other spaces which are not managed.

#### **5.4 Alternative damage stability criteria**

**5.4.1** The following stability criteria in the final stage of flooding are to be complied with:

- The final waterline is to be below the lower edge of any opening through which progressive flooding may occur.
- The equilibrium heeling angle is to be less than 15 degrees, or 17 degrees if no deck immersion occurs
- the righting lever curve is to have a range of positive stability of at least 16° and the GZ max is not to be less than 0.12 m within this range
- unprotected openings are not to become immersed within the prescribed minimum range of positive stability unless the space in question has been included as a floodable space in calculations for damage stability.

# Section 4 Structural Assessment

## 1 General

### 1.1 Application

**1.1.1** This Section provides requirements for the structural assessment of the foundations of the lifting equipment, the devices for stowage during transit and the connecting bolts between the lifting equipment and the foundations.

**1.1.2** In addition, when the lifting operations are inducing significant hull girder stresses, the hull girder loads due to the lifting operations are to be considered in the hull scantling verification, as specified in Article [4].

## 2 Structural design principles

### 2.1 General

**2.1.1** The foundations of the lifting equipment are considered as integral part of hull.

**2.1.2** The foundations means the structural elements permanently connected by welding to the hull (for instance crane pedestals, masts, derrick seatings, etc...) to the exclusion of the cranes themselves, derrick booms, ropes, rigging accessories, slewing rings and, generally, any dismantlable parts.

**2.1.3** In general, ships performing lifting operations are to be longitudinally framed.

### 2.2 Materials

#### 2.2.1 Structural category and steel grades for the foundations of the lifting equipment

The steel grade of the structural elements of the foundation is to comply with Pt B, Ch 4, Sec 1, taking into account the structural categories given in Tab 1.

**Table 1 : Guidance for structural categories**

Category / Class	Structural elements
Secondary / Class I	crane resting support
Primary / Class II	crane pedestal and its foundation
Special / Class III	insert plate of deck plating in way of crane pedestal

### 2.3 Crane pedestal

**2.3.1** In general, crane pedestal is to be continuous through the deck.

In this case, the pedestal is to be checked against through thickness stress in accordance with Pt B, Ch 4, Sec 1, [2.6].

**2.3.2** If the pedestal is interrupted on deck, the continuous deck plate is to be made of Grade Z steel quality in way of the crane pedestal.

### 2.4 Mobile lifting equipment

**2.4.1** When the lifting equipment is fastened on deck with a lashing arrangement, the description of the sea fastening is to be submitted.

**2.4.2** A cargo securing manual, as defined in NI429, Guidelines for the Preparation of the Cargo Securing Manual, is to be submitted.

### 2.5 Devices for equipment stowage

**2.5.1** The structure of the locking device used for the stowage of the lifting equipment during transit is to comply with the relevant provisions of Part B.

Environmental loads during transit are to be considered.

**2.5.2** The hull is to be strengthened in way of the crane stowage device.

### 3 Design loads

#### 3.1 General

3.1.1 The design loads defined in [3.2] to [3.6] are to be provided by the Interested Party.

#### 3.2 Hull girder loads

##### 3.2.1 Still water loads

The still water bending moment and shear forces due to lifting operations are to be added to the moment and shear forces due to the ship weight distribution.

##### 3.2.2 Wave loads

The wave hull girder loads corresponding to the maximum sea state defined in the operational limitations of the lifting equipment are to be obtained through an hydrodynamic analysis.

When an hydrodynamic analysis is not performed, the wave hull girder loads are to be evaluated through assumptions to be defined in agreement with the Society.

##### 3.2.3 Torsional moment

When deemed necessary, the hull girder strength is to be checked against torsion.

#### 3.3 Loading conditions

3.3.1 The loading conditions and associated design loads to be considered for the calculation of the foundations are given in Tab 2.

**Table 2 : Guidance for the design loading conditions**

Loading condition	Load case	Design loads		Environmental load	Basic allowable stress factor (1)
		hoisting load	Hull girder loads		
Transit	Design	none	still water + wave	extreme situation	(2)
Operating - static	Static	SWL	still water only	none	$\alpha = 0,6$
Operating - dynamic	Design	SWL x DAF	still water + wave	operating conditions	$\alpha = 0,8$
Accidental situation	Accidental	Maximum holding load	still water + wave	accidental situation	$\alpha = 1,0$
Testing condition	Testing	Overload test	still water only	none	$\alpha = 0,9$

(1) Factor  $\alpha$  is given in this Table as an indication of safety level for each design loading condition.  
 (2) Structural assessment is to comply with Part B, Chapter 7.

#### 3.4 Load cases

3.4.1 The foundations of the lifting appliance and the stowage device are to be designed for at least the load cases defined in [3.4.2] to [3.4.5].

##### 3.4.2 Load cases 1 “static” (still water)

These load cases refer to the most unfavourable combinations of the fixed and operational loads.

The most severe arrangement of operational loads, in particular with respect to moving equipment and dynamic operational loads, is to be considered.

For these load cases no environmental load is taken into account.

##### 3.4.3 Load cases 2 “design” (with environment)

These load cases refer to the most unfavourable combinations of the fixed, operational and environmental loads, including:

- the extreme (severe storm) environmental loads with fixed and associated operational loads
- environmental loads specified by the Operating Manual as constituting limits for a condition of operation of the unit or for the operation of a particular equipment or system, with corresponding fixed and operational loads.

##### 3.4.4 Load cases 3 “accidental”

The accidental loads are to be combined with the fixed, operational and associated environmental loads corresponding to the nature of each accidental load.

##### 3.4.5 Load cases 4 “testing”

Testing loads are to be considered for the design of structures being tested and of the structures supporting the items to be tested, and also, as necessary, for design of overall structure.

### 3.5 Lifting loads

#### 3.5.1 Vertical loads

As a minimum, the following vertical loads, referring to the coordinate system of the ship, are to be considered:

- the maximum static load equal to the Safe Working Load (SWL) in calm sea, within the geometrical limits of the crane utilisation chart
- the maximum dynamic hoisting loads equal to the maximum Dynamic Amplification Factor (DAF) times the SWL associated with the most severe sea state allowed, within the geometrical limits of the crane utilisation chart
- the maximum holding load corresponding to either the maximum brake capacity or the overload release value

Note 1: The foundation of the lifting equipment is to withstand the design overload value referred to in the rules for certification applicable to the lifting equipment.

- the overload test value of the lifting equipment.

#### 3.5.2 Horizontal loads

Horizontal loads, referring to the coordinate system of the ship, due to lifting operations are to be accounted for in the structural assessment of the foundation.

#### 3.5.3 Dynamic amplification factor

Dynamic amplification factors are applied on static loads to account for the effect of:

- lifting equipment self-motions
- ship motions and accelerations.

The dynamic amplification factors are to be based on the technical standard used for the certification of the lifting equipment.

Additional requirements applicable to subsea lifting are to be complied with, when relevant.

#### 3.5.4 Boom configuration

The design loads are to be applied at the most unfavourable positions of the crane boom within the geometrical limits of the crane utilisation chart.

### 3.6 Environmental loads

3.6.1 The environmental loads include:

- wind loads acting on the crane and the lifted cargo, as specified in [3.6.2]
- the ship acceleration and motion corresponding to the allowable sea state for a given operation (DAF) as defined in [3.5.3]
- the hull girder wave loads corresponding to the allowable sea state for a given operational limitation, as specified in [3.2.2].

#### 3.6.2 Wind loads

The wind velocity to consider for structural assessment of the foundation are given in Tab 3.

Note 1: the design wind velocity corresponds to an average velocity over 1 minute and taken at 10 m above sea level.

The wind loads acting on the lifted cargo are also to be considered.

**Table 3 : Wind velocity**

Condition of operation	Wind velocity
Transit	51,5 m/s
Operating	20 m/s or from lifting equipment operating manual, whichever is the greatest

## 4 Hull girder strength

### 4.1 Principles

4.1.1 The hull girder strength is to be checked in accordance with Pt B, Ch 6, Sec 1 with the loads due to lifting operations defined in [3.2].

### 4.2 Hull girder stress

#### 4.2.1 General

The stresses due to hull girder loads are to be considered in the longitudinal members of the lifting equipment foundations.

## 5 Allowable stress

### 5.1 General

**5.1.1** For lifting conditions, the foundations of the lifting equipment are to comply with allowable stress criteria defined in the present Article.

**5.1.2** Allowable stress for transit conditions are to be taken as per the rules applicable to the hull in Part B.

### 5.2 Criteria

**5.2.1** The equivalent stress  $\sigma_{VM}$  is not to exceed the allowable stress  $\sigma_{perm}$ , for the loading condition considered, according to the following formula:

$$\sigma_{VM} \leq \sigma_{perm}$$

where:

$\sigma_{perm}$  : Allowable stress, given by:

$$\sigma_{perm} = 1,1 \alpha R_f$$

$\alpha$  : Basic allowable stress factor defined in [5.3].

$R_f$  : Material reference stress defined in [5.4]

$\sigma_{VM}$  : Equivalent stress defined in [5.5]

**5.2.2** When the stresses are obtained through a fine mesh Finite Element Model, the Society may give consideration to small hot spot areas not satisfying above stress criteria, providing that the following criteria are fulfilled:

- Equivalent Von Mises stress  $\sigma_{VM}$  at the centroid of elements of a peak stress region of no more than  $2t \times 2t$ , with  $t$  being the thickness of the elements, is to comply with the following criteria:

$$\sigma_{VM} \leq 1,3 \alpha R_f$$

- outside the peak stress region of  $2t \times 2t$ , the Von Mises stress is to comply with [5.2.1]
- a plastic stress redistribution should be demonstrated to the satisfaction of the Society or obvious from engineering judgement.

### 5.3 Basic allowable stress factor

**5.3.1** The basic allowable stress factor  $\alpha$  is to be taken as follows:

a) In general:

- for load case 1 ("static"):  
 $\alpha = 0,6$
- for load case 2 ("design"):  
 $\alpha = 0,8$
- for load case 3 ("accidental"):  
 $\alpha = 1,0$

b) For specific calculations:

- for load case 4 ("testing"):  
 $\alpha = 0,9$

Note 1: The definitions of the above load cases are provided in Article [3].

### 5.4 Material strength

**5.4.1** The reference stress of material,  $R_f$ , is defined by:

$$R_f = \min\left(R_{eG}, \frac{R}{1,2}\right)$$

where:

$R_{eG}$  : Minimum specified yield stress of the material

$R$  : Tensile strength of the material.

**5.4.2** For hull steels, as defined in NR216 Materials and Welding,  $R_f$  is equal to the minimum specified yield strength of steel.

**5.4.3** For light alloy materials (aluminium), when used in non-welded constructions,  $R_f$  is to be defined taking into account the material properties in the specified condition of delivery. For welded aluminium,  $R_f$  is to be taken based on  $R_{eG}$  in the annealed condition (refer to NR216 Materials and Welding).

## 5.5 Equivalent stress

**5.5.1** For uniaxial stress condition (e.g. obtained by beam calculation), the following stress components are to be calculated:

- the normal stress  $\sigma_1$  in the direction of the beam axis
- the shear stress  $\tau_{12}$  in the direction of the local loads applied to the beam
- the Von Mises equivalent stress, obtained from the following formula:

$$\sigma_{VM} = \sqrt{\sigma_1^2 + 3\tau_{12}^2}$$

Above stresses are the result of the addition of overall stresses and grillage stresses.

**5.5.2** For biaxial stress condition (e.g. obtained by finite element calculation with plate elements), the following stress components are to be calculated at the centroid of the mid-plane layer of each element:

- the normal stresses  $\sigma_1$  and  $\sigma_2$  in the directions of the element co-ordinate system axes
- the shear stress  $\tau_{12}$  with respect to the element co-ordinate system axes
- the Von Mises equivalent stress, obtained from the following formula:

$$\sigma_{VM} = \sqrt{\sigma_1^2 + \sigma_2^2 - \sigma_1\sigma_2 + 3\tau_{12}^2}$$

The stresses in the element under study, include the effects of both overall and local loads.

## 6 Buckling

### 6.1 General

**6.1.1** As possible, the risk of instability (buckling) of structural elements is to be avoided or minimised by adequate structural arrangement (e.g. by avoiding large unstiffened panels or members with high slenderness, by the proper orientation of stiffeners with respect to direction of compressive stresses, etc.) and by detailing (e.g. by providing lateral restraint by tripping brackets, or additional members).

**6.1.2** The buckling strength of structural elements is to be ascertained considering the most unfavourable combinations of loads likely to occur, with respect to possible modes of failure.

**6.1.3** For unstiffened or ring-stiffened cylindrical shells, both local buckling and overall buckling modes are to be considered for buckling strength assessment.

**6.1.4** For stiffened panels, buckling check is to be performed in accordance with NR615 Buckling Assessment of Plated Structures.

The buckling of tubular members is to be checked according to recognized codes or standards.

### 6.2 Buckling strength criteria

**6.2.1** The buckling strength of structural elements is to be ascertained for the effect of stresses resulting from:

- compression induced by axial loads
- compression induced by bending in flanges and web of members
- shear
- external pressure
- localised compression loads.

**6.2.2** The buckling capacity of structural elements for each failure mode is to be evaluated following recognised techniques, taking into account:

- potential overall and local failure mode(s)
- due allowance for the manufacturing and/or construction tolerances and residual stresses
- interaction of buckling with yielding
- when relevant, the interaction between overall and local buckling.

**6.2.3** The buckling utilisation factor  $\eta$  of a structural element subject to lifting induced stresses is to satisfy the following criterion:

$$\eta \leq \eta_{ALL}$$

with:

$$\eta_{ALL} = \alpha$$

$\alpha$  : Basic allowable stress factor defined in [5.3.1].

The buckling utilisation factor  $\eta$  of the structural member is defined as the highest value of the ratio between the applied loads and the corresponding ultimate capacity or buckling strength obtained for the different buckling modes.

## **7 Fatigue**

### **7.1 General**

**7.1.1** Structural details located between the connection flange with the lifting equipment and the strength deck are to be checked in accordance with NI 611 Guidelines for Fatigue Assessment of Ships and Offshore Units.

**7.1.2** The justification of the long term distribution of fluctuating stress is to be provided.

Note 1: In the absence of data on loading conditions, assumptions may be taken from a recognized standard, e.g. API SPEC 2C Specification for Offshore Pedestal-mounted Cranes.

## **8 Welding**

### **8.1 Welding**

**8.1.1** As a rule, full penetration welding is to be provided between crane pedestal and deck plate.

# Section 5 Machinery and Systems

## 1 General

### 1.1 Essential service

1.1.1 Electrical installations related to the lifting equipment are to be considered as essential services according to Part C, Chapter 2.

### 1.2 Hazardous areas

1.2.1 As far as practicable, electrical installations intended for the lifting equipment should not be located in hazardous areas.

1.2.2 Where, due to the operational requirements, some electrical equipment is located in hazardous areas zone 1 or zone 2, it has to comply with the requirements for such equipment in hazardous areas, as defined in Pt C, Ch 2, Sec 1.

## 2 Position keeping

### 2.1 General

2.1.1 Vessels granted with the service notation **lifting** are to be able to safely maintain their position during lifting operations. This may be achieved with a passive mooring or a dynamic positioning system in accordance with [2.2].

### 2.2 Dynamic positioning

2.2.1 When the unit is fitted with a dynamic positioning system, it may be assigned the additional class notation **DYNAPOS** defined in Part A of the classification rules used for the supporting unit.

In this case, lifting units are to be granted with the additional class notation **DYNAPOS AM/AT**, completed by one of the following symbols:

- **R**, when the dynamic positioning is provided with redundancy means. In this case, IMO class 2 equipment is to be used.
- **RS**, when, in addition to symbol **R**, the redundancy is achieved using two systems or alternative means of performing a function physically separated. In this case, IMO class 3 equipment is to be used.

## 3 Power supply

### 3.1 General

3.1.1 When the ship main power plant is used to supply the lifting equipment, it shall have sufficient power to run simultaneously:

- the lifting equipment at its maximum rated load and nominal hook velocity
- the essential services
- the dynamic positioning system, when relevant
- the ballast system, when relevant.

3.1.2 The description of the power supply is to be submitted.

## 4 Lifting equipment controls

### 4.1 General

4.1.1 The commands on the lifting equipment operating position are to comply with NR526 or another recognized standard.

### 4.2 Overload prevention

4.2.1 *Each lifting appliance should be fitted, to the satisfaction of the Society, with a safety device to give the operator a continuous indication of hook load and rated load for each radius. The indicator should give a clear and continuous warning when approaching the rated capacity of the crane.*

### **4.3 Emergency system**

**4.3.1** Emergency lowering system and emergency stops are to comply with the requirements of the NR526 Certification of lifting appliances onboard ships and offshore units, or another recognized standard.

### **4.4 Communication means**

**4.4.1** The communication system is to be arranged for direct 2-way communication between the lifting equipment operating position and:

- the bridge or command centre of the supporting unit
- the dynamic positioning control stand.

## Section 6 Initial Inspection and Testing

### 1 General

#### 1.1 Application

**1.1.1** The present Section provides requirements for inspection and testing of the lifting installations when first installed onboard or after re-installation.

**1.1.2** The inspection and testing requirements of the present Section are provided as a minimum and in addition to the requirements of the rules or standards referred to in the lifting equipment certificate.

Any additional testing may be required to the satisfaction of the attending Surveyor.

**1.1.3** These tests are to be conducted according to an inspection and testing specification which is to be submitted to the Society by the interested party.

The Society is to be duly informed of the time and place of the commissioning tests of the lifting equipment.

**1.1.4** The specification of the commissioning tests of the lifting equipment should be approved by the certifying authority of the equipment.

### 2 Onboard testing

#### 2.1 Lifting installations

**2.1.1** Before putting into service, the inspection and testing of the lifting equipment is to include, as a minimum:

- a) Verification of the presence onboard of the operating manual as defined in Ch 8, Sec 1.
- b) Inspection of the structural arrangement and scantling of the foundations of the lifting equipment
- c) General examination of the electrical cabling
- d) Functional testing of the main and alternative two-way communication system at the lifting operating position.
- e) Testing of the hydraulic installations
- f) Load tests in accordance with the rules and standards referred to in the lifting equipment certificate:
  - Functional tests
  - Overload tests.

**2.1.2** As a rule, all the connections between the supporting unit and the lifting equipment are to be presented for examination by the Surveyor.

# Section 7 Self-Elevating Ships

## 1 General

### 1.1 Application

**1.1.1** The present Section is applicable to ships or barges fitted with legs and capable of being lowered to the sea bed and of raising the hull above the sea level, hereafter defined as self-elevating ships (see [3.1]).

The present Section addresses the requirements regarding structural assessment of the hull in elevated position, the elevating system and the specific fire safety features.

**1.1.2** Self-elevating ships complying with the requirements of this Section are eligible for the assignment of the additional service feature **self elevating** to complete the service notations assigned to the ship as defined in Pt A, Ch 1, Sec 2, [4.12].

**1.1.3** The Party applying for classification is to provide the most unfavourable environmental conditions for which the self-elevating ship is designed, as stipulated in Article [6]. These conditions are to be reported in the Design Criteria Statement defined in [2.2].

All changes of the stipulated environmental conditions are to be submitted to the examination of the Society and the design criteria statement may be modified accordingly after approval of the design for the new conditions and, if applicable, execution of the necessary reinforcements.

### 1.2 Applicable rules and regulations

**1.2.1** In addition to the requirements that ships are to comply with for granting a service notation defined in Pt A, Ch 1, Sec 2, [4.12], ships assigned with the additional service feature **self elevating** are to comply with:

- the requirements for hull structure listed in [1.2.2], taking into account the specific structural requirements for elevated position
- the requirements for machinery, electrical installations, and automation listed in [1.2.2], taking into account the specific requirements for jacking system
- the requirements for fire safety listed in Article [9].

**1.2.2** Self-elevating ships are to comply with the relevant requirements of NR534, as specified in:

- Article [5] for structure design principles
- Article [6] for design and environmental conditions
- Article [7] for structural analysis, in elevated position (see [7.1]) or transit and installations conditions (see [7.2])
- Article [8] for jacking system
- Article [10] for construction survey.

Note 1: NR534 Rules for the classification of self elevating units - jackups and liftboats, as amended.

**1.2.3** The attention is drawn to certain national or international regulations that may be required by the Administration.

Note 1: e.g. IMO MODU Code (IMO Resolution A.1023(26) - Code for the construction and equipment of mobile offshore drilling unit) applicable to self-elevating units.

## 2 Classification principles

### 2.1 Classification limits

#### 2.1.1 Site conditions

It is incumbent to the owner or operator:

- to perform the necessary investigations, including environmental and geotechnical surveys, prior to operating the unit at a given site
- to ascertain that the actual conditions met at the contemplated operating site remain on the safety side when compared to the design data and assumptions (particularly those listed in the design criteria statement, as defined in [2.2]). Such site assessment is not part of the classification.

Classification does not cover the following items:

- assessment of sea bottom conditions and geotechnical investigations
- prediction of footing penetration during preloading

- the stability of the foundation after preloading
- assessment of the possible sea floor movement.

**2.1.2 Operating procedures**

Classification does not cover the procedures to be used for the unit positioning, leg jacking (lowering or elevating), preloading, jacking and other procedures related to operations.

It is the responsibility of the owner operator to ascertain that the said procedures and their implementation satisfy the design criteria of the ship and the design of the related equipment.

**2.2 Design criteria statement**

**2.2.1** Classification is based upon the design data or assumptions specified by the party applying for classification in accordance with [1.1.3].

A design criteria statement is to list the service(s) performed by the ship and the design conditions and other assumptions on the basis of which class is assigned.

The design criteria statement is issued by the Society, based on the information provided by the party applying for classification.

The design criteria statement is to be incorporated in the operating manual (see [4.2]).

**2.2.2** The description of the most unfavourable environmental conditions for which the ship is designed to operate in elevated position, as defined in [1.1.3] is to be included in the design criteria statement as per Article [6].

**3 Definitions**

**3.1 Self-elevating ship**

**3.1.1** A self-elevating ship is a ship or a barge fitted with legs and capable of being lowered to the sea bed and of raising the hull above the sea level (see Fig 1).

The legs may be:

- of a shell or truss type
- equipped with a lower mat, a spudcan, a gravity-based structure or with footings designed to penetrate the sea bed
- vertical or slanted.

**Figure 1 : Self-elevating ship**

## **3.2 Modes of operation**

**3.2.1** A self-elevating ship is designed to resist to the loads occurring during working, survival, transit, installation and retrieval modes:

- working mode: the ship is on location, supported on the sea bed to operate, and combined environmental and operational loading are within the appropriate design limits established for such operations
- survival mode: the ship is on location, supported on the sea bed and may be subjected to the most severe environmental loading for which it is designed
- transit mode: the ship moves from one location to another within the appropriate limits the ship is designed to
- installation mode: period when the ship is firstly lowering legs to the sea bed, secondly elevating hull at the required elevation above the sea level, and then preloading the legs to the extreme loading
- retrieval mode: period when the ship is lowering the hull and then elevating legs to be ready for transit mode.

## **3.3 Water levels, crest elevation and water depth**

**3.3.1** The reference water levels and crest elevation are defined as follows in the present Section (see Fig 1):

- mean water level (MWL): mean level between the highest astronomical tide (HAT) and the lowest astronomical tide (LAT)
- astronomical tidal range: range between the highest astronomical tide (HAT) and the lowest astronomical tide (LAT)
- maximum still water level (SWL): level at the highest astronomical tide (HAT) including storm surge
- crest elevation: height of wave crest above the SWL.

**3.3.2** Except otherwise specified, the reference water depth to be considered is the distance between the sea bed and the SWL.

## **3.4 Configuration of a self-elevating unit in elevated position**

**3.4.1** The configuration of a self-elevating ship in elevated position is to be defined based on the site data associated with the ship's services, as specified in accordance with [1.1.3].

**3.4.2** The configuration is defined with the following parameters (see Fig 1):

- leg penetration length: the leg penetration length is the maximum leg penetration into the sea bed, including the spudcan if any
- leg length reserve: the leg length reserve is the reserve above the upper guide to avoid any soil settlement or punch through and to provide a contingency in case the penetration exceeds the predicted one
- air gap: the air gap is defined as the distance between the underside of the hull and the lowest astronomical tide (LAT)
- wave crest clearance: the wave crest clearance is defined as the distance between the highest wave crest and the underside of the hull.

## **4 Documents to be submitted**

### **4.1 General**

**4.1.1** Documents listed in Tab 1 are to be submitted for approval or information.

### **4.2 Operating manual**

**4.2.1** An operating manual, including instructions regarding the safe operation of the ship and of the elevating systems is to be placed on board.

The operating manual is to be, at all times, made available to all concerned. A copy of the operating manual is to be retained ashore by the owner of the ship or by his representatives.

The operating manual is to incorporate a dedicated section containing all the information relating to classification, particularly the environmental, loading and other design criteria, as well as the classification restrictions. The operating manual of a self-elevating ship is also to stipulate the instructions related to the transit conditions, the preloading and the emergency procedures in case of punch through.

It is the responsibility of the party applying for classification to prepare the contents of the operating manual.

**4.2.2** The operating manual is to be submitted to the Society for review, this review being limited to check that the classification related material as mentioned above is consistent with the data given in the design criteria statement defined in [2.2].

**4.2.3** The operating manual is to include the following information, where applicable:

- design limitations:
  - during transit (leg arrangement, rig and other equipment sea fastening)
  - during installation (leg lowering, preloading)

- on site
- during retrieval (hull lowering, leg retrieval)
- emergency procedures in case of punch through
- preload procedure
- or normal operation, information regarding the preparation of the ship to avoid structural damage during the setting or retraction of legs on or from the seabed, or during extreme weather conditions while in transit, including the positioning and securing of legs
- jacking gear main loading capacity in operating conditions
- maximum loading capacity in case of engaged fixation system
- design criteria statement including the classification restrictions, if any.

**Table 1 : Documents to be submitted**

No.	Document	A/I (1)
1	Operating manual as defined in [4.2]	A
2	Descriptions of the environmental loads including forces and moments from wind, waves, currents, ice, snow, earthquakes, as applicable as per [6.1]	I
3	Structural analysis of the unit in elevated position	I
4	Calculations of the unit resistance against overturning while resting on the sea bed in elevated position	I
5	Leg strength calculation in floating condition	I
6	Local strength calculations of: <ul style="list-style-type: none"> <li>• legs</li> <li>• leg/hull connection</li> <li>• spudcans or bottom mat, if relevant</li> <li>• leg/spudcan or leg/mat connection, if relevant</li> </ul>	I
7	Fatigue calculations of structural details, when relevant	I
8	Calculations of jacking systems and, if any, fixation systems	I
9	Calculations of segregation of loads between jacking and fixation systems, if relevant	I
10	General arrangement in elevated position	I
11	Drawings of the legs including: <ul style="list-style-type: none"> <li>• for lattice legs: racks, chords, bracings and their connections</li> <li>• for shell type legs: shell plating, stiffeners, stringers, struts, connections of racks with shell plating and supporting leg rack members, potential openings, where relevant</li> </ul>	A
12	Detailed drawings of the racks, if any, including their arrangement in transit and elevating conditions	A
13	Drawings of the footings (spudcans) or mats	A
14	Drawing of the leghouses and their attachments with the hull	A
15	Description of the jacking system as required in NR534, Section 10	(2)
16	Arrangement of the fire-fighting system in elevated position	A
(1) A : for approval; I : for information		
(2) As per NR534, Sec 10, Tab 1		

## 5 Structure design principles

### 5.1 General

5.1.1 The structure design principles applicable for the legs, the leghouses and the spudcans or bottom mat are to be in accordance with NR534, Section 2.

## 6 Design conditions

### 6.1 General

6.1.1 The design conditions applicable for the design of the legs, the leghouses, the spudcans or bottom mat and the elevating system, are to be in accordance with NR534, Section 3 as amended by [6.2] for elevated configuration, [6.3] for transit configuration and [6.4] for installation conditions.

## **6.2 Design conditions in elevated configuration**

**6.2.1** The most unfavourable wave, current and wind loads to be considered in elevated configuration are to be provided for both working and survival modes.

The area of operation and the description of sea state are to be provided in accordance with NR534, Section 4.

**6.2.2** Environmental loads to be considered for accidental conditions such as a broken bracing on a lattice leg may be specially considered subject to the agreement of the Society.

## **6.3 Transit conditions**

### **6.3.1 Simplified approach**

The structural assessment of the legs, the leghouses, the spudcans or bottom mat and the elevating system in transit conditions, is to be based on the motions and accelerations derived from Part B, Chapter 5.

The greatest transversal and longitudinal metacentric heights (GMt ad GML) are to be taken from the trim and stability booklet for the calculation of the roll and pitch motions and accelerations.

Note 1: When the condition  $L/B > 5$  is not met, a direct assessment of the environmental loads as per [6.3.2] is recommended.

### **6.3.2 Direct calculation approach**

Subject to the agreement of the Society, specific environmental conditions may be considered for the structural assessment of the legs, the leghouses and the spud cans or bottom mat in transit conditions.

In that case, a hydrodynamic analysis is to be performed in accordance with NR534, Appendix 1.

## **6.4 Installation conditions**

**6.4.1** The impact loads during installation are to be taken into account as per NR534, Sec 6, [5].

## **7 Structural analysis**

### **7.1 Structural analysis in elevated position**

**7.1.1** The structural analysis in elevated position of the legs, the leghouses, the spudcans or bottom mat, the elevating system and the hull, are to be conducted in accordance with NR534, Section 5, considering the wave and wind loads defined in [6.2].

**7.1.2** When the self-elevating ship is fitted with lifting appliances intended to be used in elevated position, the lifting loads, defined in Sec 4, [5] are to be taken into consideration for the structural assessment of the elevated hull, the legs and the leghouses.

**7.1.3** When fatigue calculations are to be submitted in accordance with NR534, Sec 5, [6.5], the damage ratio criteria are to be selected among the ones applicable to the details accessible for dry inspection.

### **7.2 Structural analysis in transit conditions and installations conditions**

**7.2.1** The legs, the leghouses, the spudcans or bottom mat and the self-elevating system are to be designed to sustain the loads induced by the ship motions and accelerations in transit considering the design loads defined in [6.3] and the loads induced by impact, preloading and punch through during installation phase.

**7.2.2** The leg structure is to be examined in transit according to the inertia and wind loads distributed along the legs.

**7.2.3** The forces and moments induced by the legs are to be considered for the verification of local reinforcements in way of the guides.

**7.2.4** The structural assessment to be performed on the legs, the leghouses and the spudcans or bottom mat, are described in NR534, Sec 6, [3], exclusive of the hull and superstructure design requirements.

**7.2.5** Spudcans and bottom mat scantling is also to comply with requirements from NR534, Sec 6, [7.2].

## **8 Jacking system**

### **8.1 General**

**8.1.1** The design and construction of the jacking system is to comply with the requirements of NR534, Section 10.

### **8.2 Electricity and automation**

**8.2.1** The jacking system is to be considered as an essential service.

## **9 Fire and safety**

### **9.1 Firefighting water supply**

**9.1.1** At least two water supply sources (sea chests, valves, strainers and pipes) are to be provided and be so arranged that one supply source failure will not put all supply sources out of action.

The following additional fire water supply measures are to be provided:

- in elevated position, water is to be supplied from sea water main filled by at least two submersible pumping systems. One system failure is not to put the other system(s) out of function
- water is to be available while the ship is lifting or lowering. The water stored is to be not less than 40 m<sup>3</sup> plus the engines cooling water consumptions before the ship is lifting or lowering. Alternatively, water may be supplied from buffer tank(s) in which the sea water stored is not less than the quantity mentioned above.

## **10 Construction survey**

### **10.1 Self-elevating system**

**10.1.1** The construction survey of the self-elevating system, the legs, the leghouses and the spudcans or the bottom mat is performed in accordance with NR534, Section 9.

# Part E

## Service Notations for Offshore Service Vessels and Tugs

---

### **CHAPTER 9**

## **SEMI-SUBMERSIBLE CARGO SHIPS**

---

Section 1	General
Section 2	General Arrangement
Section 3	Stability, Subdivision and Load Line
Section 4	Hull Structure
Section 5	Machinery and Systems
Section 6	Electrical Installations and Controls
Section 7	Safety Features

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the present Chapter are eligible for the assignment of the service notation **semi-submersible cargo ships**, as defined in Pt A, Ch 1, Sec 2, [4.2.9].

The service notation **semi-submersible cargo ship** is to be completed by:

- the additional service feature **heavycargo** [AREA1, X1 kN/m<sup>2</sup> - AREA2, X2 kN/m<sup>2</sup> - ...] as defined in Pt A, Ch 1, Sec 2, [4.16.10]
- one of the additional class notations **LI-HG-S2** or **LI-HG-S3**, as defined in Pt A, Ch 1, Sec 2, [6.16.1], in compliance with Ch 9, Sec 3, [1].
- the additional class notation **SDS**, as defined in Pt A, Ch 1, Sec 2, [6.17.1], in compliance with the damage stability requirements specified in Ch 9, Sec 3.

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1 and specific requirements for initial inspection and testing as defined in Ch 9, Sec 8.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT

## **1.2 Scope**

### **1.2.1 General**

This Chapter addresses specific requirements to:

- load line and stability criteria for transit and temporary submerged conditions
- ballast system and auxiliary equipment
- structural assessment of the hull in the temporary submerged conditions
- electrical installations
- safety features
- sea trials.

### **1.2.2 Submerged conditions**

#### a) Stability:

The stability verification required in this Chapter is limited to the assumptions made on some typical floating cargoes as mentioned in the stability booklet.

As a rule, the stability and buoyancy are to be checked before any submersion operation with the actual description of the floating cargo, as specified in Ch 9, Sec 3.

#### b) Bottom contact:

For units requiring sea bottom contact when submerging, the soil is to be surveyed to obtain information on the character of the soil and to localize obstacles possibly present.

#### c) Environmental conditions:

Limitations on the environmental conditions (waves, wind and current) to carry out the submersion procedure in a safe and controllable manner, taking into account the actual behaviour of the ship and the floating cargo, are under the responsibility of the operator of the ship.

## **1.3 Definitions**

### **1.3.1 Transit condition**

Transit condition means all ship movements from one geographical location to another.

### **1.3.2 Temporary submerged condition**

Temporary submerged condition means any situation where the semi-submersible cargo ship has its cargo deck under the sea surface.

### **1.3.3 Maximum submerged draft**

The maximum submerged draft is the distance, in m, measured vertically from the moulded base line to the uppermost considered waterlines in temporary submerged conditions at the relevant longitudinal position.

The maximum submerged draft may be:

- the maximum submerged draft at midship taking into account the uppermost considered waterline with no trim, or
- the maximum submerged draft at fore end (FE) taking into account the maximum negative trim of the ship, or
- the maximum submerged draft at aft end (AE) taking into account the maximum positive trim of the ship.

### **1.3.4 Cargo deck**

The cargo deck is the deck on which the floating cargo is being transported. It is generally equivalent to the freeboard deck as defined in the International Convention on Load Lines 1966, as amended.

### **1.3.5 Central ballast control station**

The central ballast control station is a control station from which the submersion operations are performed.

## **2 Documents to be submitted**

### **2.1 General**

#### **2.1.1** The documents listed in Tab 2 are to be submitted.

Relevant additional drawings and calculation notes may be requested by the Society in complement to the hereafter mentioned documents.

**2.2 Submersion operating manual**

**2.2.1** A submersion operating manual including the following is to be submitted:

- stability assessment method
- procedure for ballast operations including the filling sequence and the designation of the pumps and tanks used simultaneously
- definition of the ballast capacity with respect to associated type of operation (float-on/float-off or load-on/load-off) and for the different failure modes defined in Ch 9, Sec 5, [2.2]
- commissioning procedure
- contingency plan.

**Table 2 : Document to be submitted**

No.	Documents to be submitted	I/A (1)

## Section 2 General Arrangement

### 1 General

#### 1.1 Draft marks

**1.1.1** Accurate draft marks are to be positioned on the hull and casings in order to remain visible in temporary submerged conditions and with the maximum trim.

The draft marks and gauges are to be positioned sufficiently at the ends of the ship in order that the trim can be read accurately.

As a rule, the draft scales are to extend above the maximum submerged draft with a height equal to:

- 1,0 m, or
- 0,75L / 100,

whichever is the greater

Draft marks above the summer load line should be highly visible with indicating figures 0,5 m in height, 0,5 m apart.

**1.1.2** The maximum submerged draft is to be clearly indicated with a mark near each draft scale.

**1.1.3** In addition to the above, automatic draft gauges and alarms are to be provided as defined in Ch 9, Sec 6.

### 2 Ballast system arrangement

#### 2.1 General

**2.1.1** Requirements for the ballast system are given in Ch 9, Sec 5.

**2.1.2** Special arrangement to reduce the air entrapped in the ballast tanks are to be considered.

#### 2.2 Central ballast control station

**2.2.1** A central ballast control station is to be provided.

**2.2.2** The central ballast control station is to be located above the maximum submerged draft and in a space not within the assumed extent of damage referred to in Ch 9, Sec 3, [6].

**2.2.3** The central ballast control station is to contain all means necessary to conduct the submersion operation as defined in Ch 9, Sec 5.

## Section 3 Stability, Subdivision and Load Line

### 1 General

#### 1.1 Loading instrument

##### 1.1.1 General

A loading instrument is to be provided on-board and accessible from the central ballast control station.

The loading instrument is to comply with Pt B, Ch 1, Sec 5, according to the assigned additional class notation **LI-HG-S2** or **LI-HG-S3**, and also with the additional requirements of the present Section.

Note 1: When the loading instrument allows the definition of a buoyant cargo and/or damage cases, the approval is to be specially considered.

##### 1.1.2 Ballast gauging system

It is recommended that the loading instrument be connected to the ballast tank monitoring system so as to check the stability using the actual filling level values.

##### 1.1.3 Transit conditions

When the cargo is considered buoyant in transit conditions, a procedure describing the input of the new set of data into the loading instrument is to be submitted.

The procedure should include the definition of the new buoyant volume and of the new damage cases under the provisions of [4.2].

##### 1.1.4 Temporary submerged conditions

The loading instrument should be able to perform simulations of the ballast loading sequence and to check the stability criteria for the intermediate conditions during submersion operation.

The loading instrument is to be able to perform stability verification up to the maximum submerged draft and the maximum trim.

#### 1.2 Stability verification in temporary submerged conditions

1.2.1 In addition to the typical loading conditions assumed for the temporary submerged condition in the trim and stability booklet defined in [2.2], specific stability calculations are to be performed before any submersion operation.

A description of the method used for the assessment of stability in the temporary submerged conditions is to be submitted to the Society.

#### 1.3 Submersion procedure

1.3.1 A detailed procedure of the ballasting operation during submersion operation is to be submitted to the Society for the typical loading conditions assumed in the trim and stability booklet.

The procedure should include the sequence of ballast tank filling and stability verification for several intermediate stages.

### 2 Loading conditions

#### 2.1 Transit conditions

2.1.1 The trim and stability booklet is to include the loading conditions specified in Part B, Chapter 3 for the transit conditions. Loading conditions with typical cargoes are to be submitted, including the full draft condition.

The windage area of the deck cargo is to be considered.

Buoyancy of the deck cargo may be considered subject to the provisions detailed in Articles [3] and [4].

#### 2.2 Temporary submerged conditions

2.2.1 The trim and stability booklet is to include the following temporary submerged conditions:

- no cargo on deck
- typical loading conditions including buoyant cargo(es) on deck.

The loading conditions are to include initial transit draft and maximum submerged draft with several intermediate stages.

Several trim values are to be considered, including maximum trim.

The free surface effect resulting from partial filling of the ballast tanks is to be considered.

The buoyant volume of the cargo is to be included in the hydrostatic calculations.

Note 1: The stability in temporary submerged conditions is to be checked before any loading or unloading operation.

### **3 Intact stability in transit conditions**

#### **3.1 General**

**3.1.1** The intact stability in transit condition is to comply with the requirements of Part B, Chapter 3.

#### **3.2 Buoyancy of the cargo**

**3.2.1** Buoyancy of the cargo may be considered in the stability calculations, on case-by-case basis.

Note 1: Special agreement from the Administration should be granted.

The buoyancy and the watertight integrity of the cargo is to be documented.

**3.2.2** For any loading condition involving the buoyancy of the deck cargo, stability calculations with the buoyancy data are to be performed prior to the operation.

#### **3.2.3 Lift-off of buoyant cargo**

When the cargo is considered buoyant, assessment of the lift-off of the cargo at heel is to be submitted.

The cargo should not lift-off at an angle of heel less than 20°.

Note 1: Lift-off occurs when the cargo is partially floating, i.e. the tilting moment due to hydrostatic pressure on the cargo is higher than the moment due to gravity.

### **4 Damage stability in transit conditions**

#### **4.1 General**

**4.1.1** For assignment of the additional class notation **SDS**, semisubmersible cargo ships are to comply with the applicable requirements of Pt B, Ch 3, Sec 3 taking into account the provisions of:

- [4.2] for the buoyancy of cargo
- [4.3] for type B freeboard
- [4.4] for reduced freeboard.

#### **4.2 Buoyancy of the cargo**

**4.2.1** Buoyancy of the cargo may be considered in the stability calculations on case-by-case basis.

Note 1: Special agreement from the Administration should be granted.

The buoyancy and the watertight integrity of the cargo is to be documented.

**4.2.2** For any loading condition involving the buoyancy of the deck cargo, stability calculations with the buoyancy data are to be performed prior to the operation.

#### **4.3 Type B freeboard**

**4.3.1** For ships with type B freeboard, damage stability is to comply with the requirements of Pt B, Ch 3, Sec 3 as applicable to cargo ships..

Note 1: When the criteria on the maximum allowable vertical centre of gravity (KG) are not met, compliance with Pt B, Ch 3, App 4 may be considered as an alternative subject to acceptance by the Society. Special agreement from the Administration should also be granted.

Note 2: When the buoyancy of the cargo is taken into account, the damage stability is to comply with the requirements of Pt B, Ch 3, App 4 and the provisions specified in [4.2].

#### **4.4 Type B-60 and B-100 freeboard**

**4.4.1** For ships which have been assigned reduced freeboard as permitted by Regulation 27 of the International Convention on Load Lines, damage stability is to comply with the requirements specified in Pt B, Ch 3, App 4, taking into account [4.4.2], [4.4.3] and the provisions of IACS UI LL65.

Therefore, compliance with the requirements in [4.3.1] is not required.

Note 1: Note 1: When the buoyancy of the cargo is taken into account, the damage stability is to comply with the provisions specified in [4.2].

#### **4.4.2 Extent of damage**

Units with a type B-60 freeboard are to comply with the requirements of ICLL for one compartment damaged.

Units with a type B-100 freeboard are to comply with the requirements of ICLL for two compartments damaged.

**4.4.3 Extent of damage with protruding cargo**

When the cargo is considered buoyant and is protruding from the side shell of the ship, the transversal penetration may include the cargo overhang as shown in Fig 1.

In that case, the cargo is considered part of the hull providing the vertical distance between the cargo and the sea level is small, typically less than 4,5 m, and the cargo structure is considered strong enough.

The transverse extent of damage is to be in accordance with ICLL, measured inboard from the side of the ship or from the side of the cargo, on a line perpendicular to the ship's centreline, whichever is the farthest.

Note 1: In specific cases, the definition of the extent of damage may need to be supported by a collision analysis in order to assess the effective protection of the hull provided by the cargo.

**Figure 1 : Extent of damage with protruding buoyant cargo**

**5 Intact stability in temporary submerged conditions**

**5.1 Criteria**

5.1.1 The intact stability in temporary submerged conditions is to be checked with the following criteria:

- a) The metacentric height GM is to be not less than 0,30 m
- b) The range of stability is to be positive over a range of at least 15°
- c) Within the range of GZ curve of 15°, the GZ lever maximum is to be not less than 0,10 m
- d) The maximum GZ value shall not occur at an angle of heel less than 10°
- e) In equilibrium condition, the distance between the waterline and any weathertight opening through which progressive flooding can occur is to be at least 1,0 m or, with a heel angle of 5°, the weathertight opening is to be above the waterline, whichever is the greatest (see Fig 2).

**Figure 2 : Zone of weathertight integrity**

- A : 1.0m - Zone of weathertightness
- B : 5 degrees - Zone of weathertightness

## 6 Damage stability in temporary submerged conditions

### 6.1 General

**6.1.1** For the assignment of the additional class notation **SDS**, the requirements of the present Article are to be complied with in lieu of Pt B, Ch 3, Sec 3.

**6.1.2** Damage stability during temporary submerged conditions as a result of a collision with the cargo or flooding due to a failure of the water ballast system is to be considered.

### 6.2 Extent of damage

#### 6.2.1 Horizontal penetration

A one-compartment extent of damage is to be assumed on vertical surface adjacent to the exposed deck with:

- longitudinal/ transversal extent of 5,00 m

Note 1: One-compartment extent with a damage length of 5 m imply that a watertight bulkhead may be considered to remain intact provided that the distance with adjacent bulkheads exceeds 5m.

- penetration of 0,76 m
- vertical extent 3,0 m occurring at any level between the exposed deck and 5 m above the maximum submerged draft.

This includes all sides of casings, superstructure bulkheads and hull surface adjacent to the exposed deck within a distance of 2,5 m measured from the superstructure bulkhead.

#### 6.2.2 Vertical penetration

A one-compartment extent of damage is to be assumed on the exposed deck with:

- longitudinal extent of 5,00 m
- transversal extent of 5,00 m
- vertical penetration of 0,76 m.

Note 1: One-compartment extent with a damage length of 5 m imply that a watertight bulkhead may be considered to remain intact provided that the distance with adjacent bulkheads exceeds 5 m.

### 6.3 Compartment permeability

**6.3.1** The permeability of damaged compartments (voids and water ballast) is to be taken as 0,95. The permeability of machinery spaces is to be taken as 0,85.

### 6.4 Damage criteria

**6.4.1** The following damage stability criteria are to be complied with:

- a) The final waterline after flooding is to be below any non-watertight opening through which progressive flooding may take place
- b) The equilibrium angle is not to exceed 15° of heel
- c) The righting lever curve is to have a positive range of at least 7° beyond the equilibrium angle
- d) The maximum righting lever is to be at least 0,05 m within the range of positive stability.

### 6.5 Intermediate stage of flooding

**6.5.1** Damage stability at intermediate stages of flooding is to be verified.

## 7 Temporary submersion

### 7.1 International Load Line Certificate

**7.1.1** Attention is drawn to the temporary submerged condition, for which an exemption with regard to the provisions of ICLL Article 6 should be granted by the Administration.

### 7.2 Reserve buoyancy

#### 7.2.1 Criteria

The reserve buoyancy at maximum submerged draft is to be assessed.

The reserve buoyancy volume, i.e. the volume with weathertight integrity above the maximum submerged waterline, is to be at least 4,5% higher than the submerged volume.

The reserve buoyancy ratios of the fore end and aft end structures considered separately are to be at least 1,5% higher than the submerged volume.

### **7.2.2 Alternative**

As an alternative to the reserve buoyancy criteria, the ship is to provide sufficient buoyancy and stability at the maximum submerged draft in order to withstand the accidental flooding of any watertight compartment wholly or partially below the waterline in submerged conditions, which is a ballast pump room or a room containing ballast system piping, in compliance with the following criteria:

- a) the angle of inclination after flooding should not be greater than 25°
- b) any opening below the final waterline should be made watertight
- c) a range of positive stability should be provided, beyond the calculated angle of inclination in these conditions, of at least 7°

### **7.3 Watertight openings**

**7.3.1** Openings which could be submerged during temporary submerged conditions are to be closed with two effective watertight means to maintain the watertight integrity if one means fails.

The fitting of a second door or hatch of equivalent strength and watertightness is an acceptable arrangement.

A leakage detection device shall be provided in the compartment between the two doors. Drainage of this compartment to the bilges, controlled by a readily accessible screw-down valve, is to be arranged. The outer door is to open outwards.

### **7.4 Openings**

**7.4.1** Openings which are to remain open during the temporary submerged conditions, such as the engine room air intakes, are to be provided with remote controlled quick-closing appliances.

# Section 4 Hull Structure

## Symbols

- $T_S$  : Maximum submerged draft, in m, defined in Ch 9, Sec 1, [1.3.3]
- $H_S$  : Wave parameter defined in Pt B, Ch 5, Sec 3, calculated using:
- the coefficients given in Tab 1
  - the reference length  $L_{ref}$  calculated with  $\alpha$  and  $f_\alpha$  values as defined in Pt B, Ch 5, Sec 3 or Pt B, Ch 5, Sec 4, as applicable
- $n_S$  : Navigation coefficient for the temporary submerged conditions, as defined in Pt B, Ch 5, Sec 3, [1.1.2], using  $H_S$  instead of H.

## 1 General

### 1.1 Application

1.1.1 This Section provides specific requirements for:

- structural assessment of semi-submersible cargo ships in temporary submerged conditions
- ballast tanks pressure when using overflow tanks.

### 1.2 Internal ballast pressure when using overflow tanks

1.2.1 In order to limit the pressure head in the tanks, the cargo ship may be fitted with an overflow system.

When overflow tanks complying with the relevant provisions of Ch 9, Sec 5 are installed, the pressure head may be taken at the top of the overflow tank instead of the top of the air pipe.

## 2 Loading conditions

### 2.1 General

2.1.1 In addition to the design load scenarios defined in Pt B, Ch 5, Sec 7, the structural assessment is to be performed against temporary submerged scenario considering draught  $T_S$  and the navigation coefficient  $n_S$ .

2.1.2 As a minimum, the loading conditions during temporary submerged conditions defined in Tab 1 are to be considered.

Note 1: As an alternative to the rule-based formulae, a direct hydrodynamic analysis may be performed in order to obtain the design wave loads.

**Table 1 : Wave parameter  $H_S$  coefficients**

Loading condition	Assessment	$A_0$	$A_1$	$e_1$	$A_2$	$e_2$	$L_c$
Temporary submerged conditions in sheltered area	Strength	0,25	1,29	2,38	0,32	1,71	239
	Fatigue	0,1	1,91	2,13	0,51	1,56	233
Temporary submerged conditions in harbour	Strength	0,16	1,27	2,42	0,3	1,65	206
	Fatigue	0,07	2,0	2,22	0,49	1,43	206

## 3 Design loads

### 3.1 Vertical wave bending moments

3.1.1 The vertical wave bending moments during temporary submerged conditions  $M_{wv-h,S}$  and  $M_{wv-s,S}$  at any hull transverse section are to be obtained, in kN·m, according to Pt B, Ch 5, Sec 4, [3.1.1], replacing n by  $n_S$ :

### 3.2 Horizontal wave bending moments

3.2.1 The horizontal wave bending moment during temporary submerged conditions  $M_{wh,S}$  at any hull transverse section is to be obtained, in kN·m, according to Pt B, Ch 5, Sec 4, [3.3.1], replacing H by  $H_S$  and  $T_{LC}$  by  $T_S$ .

### **3.3 Vertical wave shear forces**

**3.3.1** The vertical wave shear forces during temporary submerged conditions  $Q_{wv-pos,S}$  and  $Q_{wv-neg,S}$  at any hull transverse section are to be obtained, in kN, according to Pt B, Ch 5, Sec 4, [3.2.1], replacing  $n$  by  $n_S$ :

### **3.4 Still water and dynamic pressures**

#### **3.4.1 External boundaries**

For temporarily submerged conditions, the hydrostatic and hydrodynamic pressures at any point of the hull are to be the calculated according to Pt B, Ch 5, Sec 5, [1] considering the wave parameter  $H_S$ .

#### **3.4.2 Watertight boundaries**

The static pressure  $P_{is}$ , in kN/m<sup>2</sup> acting on structural watertight elements defined as per the Internal Watertight Plan and located below the deepest equilibrium waterline (excluding side shell structural elements) which constitute boundaries intended to stop vertical and horizontal flooding is to be based on the deepest equilibrium waterline in damaged transit or damaged temporary submerged conditions.

#### **3.4.3 Internal pressure**

In order to limit the pressure head in the tanks, the cargo ship may be fitted with an overflow system.

When overflow tanks complying with the relevant provisions of Ch 9, Sec 5 are installed, the pressure head may be taken at the top of the overflow tank instead of the top of the air pipe.

## **4 Hull girder strength**

### **4.1 General**

**4.1.1** The hull girder strength is to be checked in temporary submerged conditions with the hull girder loads defined in [3].

Note 1: Due to the low depth of the hull girder, special attention is to be paid to the requirement regarding the moment of inertia. This requirement is to be satisfied over a minimum length of 0,40 L in the midship area.

## **5 Hull scantlings**

### **5.1 General**

**5.1.1** Hull scantlings are to be checked in temporary submerged conditions with the design loads defined in [3].

Where intermediate situations are considered more severe due to specific loading conditions of the cargo ship, the scantlings are to be determined according to the most severe situation.

## **6 Connection of the buoyancy casings**

### **6.1 General**

**6.1.1** The scantlings of the structures in way of the connection between the hull structure and the buoyancy casings are to be obtained through direct calculations.

### **6.2 Design loads**

#### **6.2.1 Still water loads**

Static pressures are to be calculated taking into account the maximum draught at the location of the buoyancy casing.

#### **6.2.2 Wave loads**

Hydrodynamic pressures at any point of the hull is to be the calculated according to Pt B, Ch 5, Sec 5, [1] considering the wave parameter  $H_S$ .

Note 1: As an alternative to the rule-based formulae, a direct hydrodynamic analysis may be performed in order to obtain the design wave loads.

### **6.3 Strength criteria**

**6.3.1** The local stresses in the elements of the buoyancy casings and in connections with the hull structure are to satisfy the following conditions:

$$\sigma \leq 0, 8R_y$$

$$\tau \leq 0, 4R_y$$

## **7 Fatigue strength assessment**

### **7.1 General**

**7.1.1** Fatigue assessment may be required on ships less than 150m in length if deemed necessary by the Society.

**7.1.2** The fatigue life and sea conditions of the ship are to be specified by the Owner, and to be indicated on the midship section drawing.

**7.1.3** Fatigue calculations are to be provided to the Society for review.

# Section 5 Machinery and Systems

## 1 General

### 1.1 Sea pressure

1.1.1 Any equipment on the hull and submitted to the sea pressure is to withstand the pressure due to the maximum submerged draft.

## 2 Ballast system

### 2.1 Failure modes and effects analysis

2.1.1 A failure modes and effects analysis (FMEA) is to be performed regarding the ballast system, including its control and monitoring systems.

2.1.2 The FMEA is to address the ballast functions with reference to the different modes of operation defined in [2.2], and regarding float-on / float-off or load-on / load-off operations.

2.1.3 The FMEA method described in Pt F, Ch 2, App 1 may be used as a guidance.

### 2.2 Failure modes

2.2.1 The ballast system is to be designed in order to meet the safety principles defined in [2.4] in the following failure modes:

- Normal conditions, refer to [2.3.1]
- Degraded conditions, refer to [2.3.2]
- Emergency conditions, refer to [2.3.3].

### 2.3 Definitions

#### 2.3.1 Normal ballast functions

The normal ballast functions means the design ballast capacity, control and monitoring functions allowing to perform ballasting and de-ballasting procedure of the semi-submersible cargo ship in the intended manner regarding float-on / float-off or load-on / load-off operations.

#### 2.3.2 Degraded ballast functions

The degraded ballast functions means the ballast capacity, control and monitoring functions which remain available in case of a single failure on any active component of the ballast system, as defined in [2.3.4].

The degraded ballast functions are to be defined by the Owner and addressed in the FMEA.

#### 2.3.3 Emergency ballast functions

The emergency ballast functions means the ballast capacity, control and monitoring functions available in case of main source of electrical power failure.

The emergency ballast functions are to be defined by the Owner and addressed in the FMEA.

#### 2.3.4 Active component of the ballast system

An active component of the ballast system means any component of the ballast system which is not a pipe, an electrical cable, a manually controlled valve or a tank.

Active components include the machinery items (pumps, remote controlled valves, filters, etc.) and the control system items (gauges, sensors, switchboards).

## 2.4 Safety principles

### 2.4.1 Degraded conditions

Any single failure on an active component in the ballast system is not to lead to a situation where the degraded ballast functions are not met or to unintended flooding.

Note 1: Duplicate of components of the ballast control system may be required.

### 2.4.2 Emergency conditions

Failure of the main source of electrical power is not to lead to a situation where the emergency ballast functions are not met or to unintended flooding.

## 2.5 Air pipes

### 2.5.1 General

Effective means to reduce the air entrapped in the ballast tanks while filling up are to be provided, such as:

- sufficient air holes in tank internal structures, and
- air pipe connected to the highest point during the ballast operations.

Note 1: If the venting system requires operational restrictions (i.e. no trim by the bow when submersing), this should be specifically noted in the submersion operating manual.

### 2.5.2 Valves

Installation of valves on ballast tank air pipes may be accepted, subject to the following conditions:

- the layout of the air pipe system and of the control and supply systems is to be of fail-safe design. In this design, both the risk of flooding and pressurisation are to be taken into account
- an interlock system is provided between filling tank lines and air vent valves.

## 2.6 Overflow tanks

### 2.6.1 General

When overflow tanks are fitted to reduce tank pressures in case of overfilling, means are to be provided to drain the overflow tank with sufficient capacity to allow uninterrupted ballasting in normal conditions.

### 2.6.2 Design pressure and alarms

The design head of pressure considered for the ballast tanks structural assessment may be taken as the overflow tank top level, instead of the top of the air pipe, providing that the following alarms are fitted:

- High level alarm or overflow alarm
- High-High level alarm at max 98% level with shut-down of ballast pumps.

### 2.6.3 Overflow tank capacity

The overflow tanks are to have a capacity  $V_{\text{overflow}}$  in m<sup>3</sup>, not less than:

$$V_{\text{overflow}} = \frac{T_{\text{filling}}}{60} \times (Q_{\text{normal}} - Q_{\text{draintotal}} + Q_{\text{drainpump}})$$

Where:

$T_{\text{filling}}$  : Filling time, in minute, to be taken the lesser of:

- 10 min, or
- time matching the design ballast philosophy, or
- when alarms in compliance with [2.6.2] and an automatic draining system are provided, the greatest of:
  - the time elapsed before the drain system is switched on, and
  - 3 min.

$Q_{\text{normal}}$  : Ballast rate in normal conditions, in m<sup>3</sup>/hr

$Q_{\text{draintotal}}$  : Total drain pump rate, in m<sup>3</sup>/hr

$Q_{\text{drainpump}}$  : Rate of the largest drain pump, in m<sup>3</sup>/hr.

Note 1: The rate of the largest pump is considered in order to cope with the single failure of a drain pump.

## 2.7 Valves and actuators

**2.7.1** Every ballast tank is to be provided with remote isolating valves for filling and/or emptying purposes.

The valves are to be able to be operated from the central ballast control station.

An emergency system is to be provided to operate the remote ballast valves.

The isolating ballast tank valves should be closed in case of loss of power.

The flow may be controlled by isolating valve when this valve is designed to reduce the wear associated with sealing surface contact and to maintain the sealing integrity. Other means may be provided to ensure tightness of the valve.

The arrangement for hydraulic and pneumatic controlled valves is to be submitted to the Society.

A speed control system is to be installed for remote valves in order to adjust the operating time. The operating time is to be long enough to avoid any water hammering in the valve and pipe, whilst being in accordance with the manufacturer's recommendation.

The valves and actuators are to be certified as sea side valves.

## **2.8 Pressurized ballast tanks**

**2.8.1** Compressed air systems used to fill or empty the ballast tanks are to be specially considered. Adequate means to control and to mitigate the risks of overpressure are to be provided. A description of the air pressure system is to be submitted.

## **2.9 Control and monitoring**

### **2.9.1 Central ballast control station**

The central ballast control station defined in Ch 9, Sec 2, [2.2] is to include the following:

- a ballast pump control system
- a ballast pump status-indicating system
- a ballast valves control system
- a ballast valves position-indicating system
- a ballast tank level indicating and monitoring system as defined in Ch 9, Sec 6
- a ballast valve status monitoring system as defined in Ch 9, Sec 6
- a draught indicating system, indicating the draught at each draft scale of the unit or at presentative positions as required by the Society
- a power availability indicating system (main and emergency)
- a ballast system hydraulic / pneumatic pressure-indicating system
- a permanently installed means of communication, independent of the unit's main source of electrical power, between the control station and those spaces containing the ballast pumps and valves or their manual controls, or other spaces that may contain equipment necessary for the operation of the ballast system.

## **3 Scuppers and sanitary discharges**

### **3.1 Arrangement of scuppers and sanitary discharges**

**3.1.1** The requirements for scuppers and sanitary discharges are to consider the maximum submerged waterline in lieu of the summer waterline.

## Section 6 Electrical Installations and Controls

### 1 Emergency source of power

#### 1.1 Essential service

1.1.1 The emergency source of power is to be able to supply the emergency ballast functions defined in Ch 9, Sec 5, [2.3.3] in addition to the other essential services.

### 2 Controls

#### 2.1 Draft mark automatic gauges

2.1.1 An automatic draft gauging system is to be fitted and the information is to be displayed on the central ballast control station. In case of submersion to the maximum draft, an automatic visible and audible alarm is to be provided in the central ballast control station.

Note 1: The alarm should be triggered when the mean sea level is higher than the maximum submerged draft.

#### 2.2 Ballast tanks gauging system

2.2.1 The ballast tanks are to be provided with effective means of measuring the filling level. The variations of water ballast level are to be able to be directly observed.

2.2.2 An automatic gauging system is to be provided with the information accessible from the central ballast control station.

2.2.3 The ballast tank filling level is to be continuously monitored during ballasting operations and compared with the provisional values.

#### 2.3 Ballast valves monitoring

2.3.1 The open/close status of valves is to be continuously monitored.

#### 2.4 Communication means

2.4.1 The communication system should be arranged for direct 2-way communication between the central ballast control station and:

- the bridge or command centre of the ship
- the dynamic positioning control stand, when relevant.

## Section 7 Safety Features

### 1 Fire safety

#### 1.1 General

1.1.1 The cargo deck is to be protected by a fire-fighting system readily accessible in case of fire during a transit.

#### 1.2 Fire hydrants

1.2.1 Fire hydrant located forward and aft of the cargo deck on both sides and with sufficient hose length to reach all the cargo deck area may be considered acceptable as an alternative to requirements of Pt C, Ch 4, Sec 6, [1.2.5].

### 2 Means of escape

#### 2.1 Transit conditions

2.1.1 Means of safe transfer between aft and fore parts of the ship are to be provided and to be practical in transit conditions.

#### 2.2 Temporary submerged conditions

2.2.1 Internal spaces of buoyancy towers are normally unmanned during temporary submerged conditions.

### 3 Life-saving appliances

#### 3.1 Temporary submerged conditions

3.1.1 If buoyancy casings are manned during temporary submerged conditions, they should be provided with life-saving appliances suitable for the intended number of persons present on the casing in case of ship abandonment.

# Section 8 Initial Inspection and Testing

## 1 General

### 1.1 Application

**1.1.1** The present Section provides requirements for initial inspection and testing specific to the submersion function of the ship at new build stage or after substantial modifications or repair.

The submersion testing is to be conducted according to the submersion procedure submitted to the Society by the Interested Party.

The Society is to be duly informed of the time and place of the commissioning tests of the ballasting equipment and of the submersion trials.

Any additional testing not mentioned in the present Section may be required, to the satisfaction of the attending Surveyor.

## 2 Commissioning

### 2.1 At quay

**2.1.1** Before putting the equipment into service, the inspection and testing should include, as a minimum, the:

- a) verification of the presence on board of the submersion procedure as defined in Ch 9, Sec 1
- b) examination of the connection of the buoyancy casings with the hull
- c) functional testing of the ballasting system including its control and monitoring system for the different modes of operation defined in Ch 9, Sec 5, [2.2]
- d) functional testing of the interface between the ballast system and the loading instrument
- e) examination of ballast tank gauging system.

### 2.2 Sea trials

**2.2.1** Submersion trials are to be performed under survey of the Society.

# Part E

## Service Notations for Offshore Service Vessels and Tugs

---

### CHAPTER 10

## STANDBY RESCUE VESSELS

---

Section 1	General
Section 2	Rescue Arrangement, Accommodation and Equipment
Section 3	Hull and Stability
Section 4	Machinery
Section 5	Electrical Installations
Section 6	Fire Protection

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the requirements of this Chapter are eligible for the assignment of the service notation **standby rescue** as defined in Pt A, Ch 1, Sec 2, [4.12.9].

This service notation is to be completed by the number of survivors that the vessel is intended to carry.

Depending on the vessel operation area, the Society may adapt the requirements regarding the survivors accommodation and / or the safety equipment. In such a case, the service notation is to be completed by the vessel operation area.

For example:

**standby rescue (150 survivors)**

**standby rescue (150 survivors, Guinea Gulf)**

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT
Ship arrangement	L ≥ 90 m	<ul style="list-style-type: none"> <li>• Part B</li> <li>• Ch 10, Sec 2 (1)</li> </ul>	<ul style="list-style-type: none"> <li>• NR566</li> <li>• Ch 10, Sec 2 (1)</li> </ul>

<p><b>(1)</b> In addition to rescue and accommodation arrangement, Ch 10, Sec 2 includes requirements for safety and medical equipment.</p> <p><b>Note 1:</b>            NR566: Hull Arrangement, Stability and Systems for Ships less than 500 GT            NR600: Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m.</p>			

### 1.1.3 Other standards

In order to ensure consistency with other applicable standards (e.g. national authorities, industry bodies), the requirements of this chapter may be completed or replaced, as necessary, by the following recognized standards upon agreement of the Society:

- Canada Atlantic Standby Vessel Guidelines (June 2015 or later)
- DMA Guidance on standby vessels (July 1997 or later)
- NMA Regulation N°853 on standby vessels (December 2014 or later)
- NMA Instructions to Class regarding Standby Vessels (February 2014 or later)

- NOGEPa Industry Guideline n°6 (V1 - June 2004 or later)
- Oil & Gas UK - Emergency Response & Rescue Vessel - Management Guidelines (Issue 5 - April 2013 or later)
- Oil & Gas UK - Emergency Response & Rescue Vessel - Survey Guidelines (Issue 6 - April 2013 or later)

Standards not listed above may be considered by the Society on a case-by-case basis.

Deviations from the requirements of this chapter and/or application of additional requirements based on recognized standards are to be specified in a memorandum.

### 1.2 Documents to be submitted

**1.2.1** In addition to the provisions of Pt B, Ch 1, Sec 4, the following documents are to be submitted to the Society for approval:

- Arrangement of rescue areas
- Rescue and safety equipment plan showing position and quantity of all life safety rescue equipment on board
- Towing arrangement, if applicable
- Structural arrangement of the winch and its remote control of the quick-release device for opening under load, if applicable
- Structural arrangement of the hook and its remote control of the quick-release device for opening under load, if applicable
- Connection of the towing system (winch and hook) with the hull structures, if applicable
- Arrangement of windows with information on type of glass, frames, including references of standards and deadlights where applicable.

## Section 2 Rescue Arrangement, Accommodation and Equipment

### 1 General

#### 1.1 Wheelhouse

##### 1.1.1 Manoeuvrability

The vessel is to be easily manoeuvrable from the wheelhouse by one person only.

##### 1.1.2 Visibility

The wheelhouse is to be designed to offer an unobstructed view at all times on:

- the rescue zone, including ship's sides
- the helicopter winching area
- the areas where the fast rescue crafts (FRCs) are launched and recovered

### 2 Rescue equipment and facilities

#### 2.1 Rescue zone

**2.1.1** The vessel is to be arranged on both sides with a rescue zone extending minimum 8 m in length.

**2.1.2** The rescue zone is to be located sufficiently far away from the propellers or thrusters and clear of any ship side discharges up to 2 m below the summer waterline.

**2.1.3** It should be arranged so that the necessity of vertical transfer is kept to a minimum.

**2.1.4** The area is to be clearly marked on the ship's side in contrasting colours.

**2.1.5** The ship's side in way of the rescue zone shall be free of any obstruction like fenders or anything which may harm climbing survivors.

**2.1.6** Dedicated lighting is to be provided along the rescue zone.

**2.1.7** Deck area in way of the rescue zone should preferably be free from air pipes, valves, smaller hatches, etc., and covered with anti-slip coating. However, when this becomes impractical, proper arrangement is to be provided as protection against personnel injury.

**2.1.8** Bulwarks and railing in way of the rescue zone shall be of the type that are easy to open or remove, to enable direct boarding on the deck.

**2.1.9** Unobstructed stretcher access from the rescue zone to the accommodation is to be provided and covered with anti-slip coating.

#### 2.2 Scrambling net

**2.2.1** Each rescue zone is to be provided with a scrambling net made for climbing the ship's side from the sea or from the Fast Rescue Craft.

It is to be made of corrosion resistant and non-slip material, hang clear of the ship's side and extend below the waterline level at lightest draught.

#### 2.3 Retrieval device

**2.3.1** The vessel is to be equipped with a power-assisted device operated from the vessel and capable of recovering at least 5 able or disabled persons from sea directly onto the vessel.

This could be achieved by means of a crane with a rescue basket. In such case, attention is drawn to Flag State requirements that may have to be complied with for the crane.

#### 2.4 Rescue hooks

**2.4.1** At least two poles with rounded-off hooks at ends are to be provided to assist survivors alongside the vessel.

## **2.5 Fast Rescue Craft (FRC)**

**2.5.1** The vessel is to be equipped with at least one SOLAS approved fast rescue boat for standby duties, arranged and maintained to be permanently ready for use under severe weather conditions, and which may be accepted as forming part of the ship's life saving appliances. The launching arrangement shall also be SOLAS approved.

## **2.6 Safety equipment**

**2.6.1** Vessels having a gross tonnage lower than 500 are to be provided with the following minimum safety equipment:

- 1 line-throwing appliance with not less than 4 projectiles and 4 lines
- 1 daylight signalling lamp
- 6 lifebuoys, 4 being with self-igniting electric light and buoyant line (SOLAS type approved)
- 1 SOLAS type approved immersion suit for each crew member
- 1 SOLAS type approved lifejacket for each crew member plus 25% of the number of survivors for which the vessel is intended to carry
- 1 whistle and 1 bell
- Equipment for at least 2 surface swimmers.

## **2.7 Helicopter winching area**

**2.7.1** The vessel is to be arranged with a designated helicopter winching area on deck for transferring personnel or stretchers.

**2.7.2** The area is to be at least 5 m in diameter and free of any obstructions. It is to be arranged away from superstructures.

**2.7.3** The area is to be painted in yellow colour and illuminated so that it remain visible by the helicopter at all times.

**2.7.4** Unobstructed stretcher access from the accommodation to the helicopter winching area is to be provided.

**2.7.5** The winching area and the passage leading thereto are to be provided with anti-slip coating.

## **3 Survivors spaces**

### **3.1 General**

**3.1.1** A dedicated space is to be available for treatment, reception and accommodation of survivors. The space is to be sheltered from bad weather and direct sun radiation and provided with lighting, ventilation, or heating according to the intended zone of operation.

### **3.2 Decontamination area**

**3.2.1** An area equipped with a shower system for cleaning survivors and crew before proceeding to the reception area is to be arranged.

### **3.3 Reception area**

**3.3.1** An enclosed area with access to accommodations is to be arranged for medical assessment and registration of survivors, as well as for the distribution of supplies.

### **3.4 Treatment room**

**3.4.1** A dedicated room of at least 15 m<sup>2</sup> is to be equipped to provide first-aid to injured persons.

### **3.5 Accommodations**

**3.5.1** 10% of the number of survivors the vessel is rated for are to be able to lie down. Permanent seating is to be provided for the rest of them.

**3.5.2** In an emergency, survivors may be accommodated in crew accommodation except for sanitary accommodation, galley, berths for the master and 2 crew members, the radio room, the wheelhouse and main access passageways which should be kept clear.

**3.5.3** Sanitary facilities are to be available exclusively for the survivors. At least one installation comprising a toilet, a wash basin and a shower is to be provided per group of 50 survivors.

### **3.6 Non-survivors**

**3.6.1** Facilities to store corpses out of sight of survivors in a cool and ventilated space, with arrangements for shelving and securing, is to be provided. This storage space should permit maximum discretion for other survivors.

## **4 Medical equipment and supplies**

### **4.1 Water**

**4.1.1** Per group of 50 survivors, there is to be a minimum of 0,85 tonnes of fresh water for washing, showering, etc., and a minimum of 0,7 tonnes of potable water.

**4.1.2** Water heating facilities are to be able to feed all the showers dedicated to the survivors with 40°C water for at least 2 hours.

### **4.2 Meals**

**4.2.1** It should be possible to serve soup or stew to the rated number of survivors for at least 2 days.

### **4.3 Sundries**

**4.3.1** The vessel is to be provided with blankets, towels, socks and disposable coveralls in sufficient quantity for the number of survivors the vessel is intended to carry.

### **4.4 Medical equipment**

**4.4.1** The treatment room is to be adequately equipped and furnished to perform the largest possible scope of medical operations on board. Typical required medical equipment are listed below for guidance:

- surgical instruments and suture materials
- resuscitation equipment
- various examination, surveillance and treatment equipment
- dressings and bandages
- stretchers
- medicaments.

## Section 3 Hull and Stability

### 1 Stability

#### 1.1 General

1.1.1 The stability of the ship is to be in compliance with the requirements in Ch 3, Sec 3.

1.1.2 The requirement in Pt D, Ch 11, Sec 3, [2.2.4] addressing the crowding of passengers is to be complied with, considering the number of survivors that the vessel is intended to carry as passengers.

#### 1.2 Additional requirements for towing operations

1.2.1 The stability of vessels intended to perform towing operations is to be in compliance with Ch 1, Sec 2, [2].

#### 1.3 Additional requirements for water spraying

1.3.1 Vessels fitted with a water spraying system are to meet the stability requirements of Ch 4, Sec 2.

### 2 Hull

#### 2.1 Vessels intended for towing operations

2.1.1 Vessels intended to perform towing operations are to comply with the requirements of Ch 1, Sec 3, [2.2] to Ch 1, Sec 5, [2.1].

#### 2.2 Lifeboat towing

2.2.1 In addition to the optional towing capabilities mentioned in [2.1.1], the vessel is to be fitted with simple and suitable arrangements for connecting and towing lifeboats and liferafts, such as towing points and towlines.

## Section 4 Machinery

### 1 General

#### 1.1 Application

1.1.1 In addition to the present Section, the relevant requirements of Ch 3, Sec 5 are to be applied.

#### 1.2 Ship propulsion and manoeuvrability

##### 1.2.1 Propulsion redundancy

The vessel shall be equipped with at least two independent propulsion systems, which may be either:

- single screw propulsion with variable pitch or reversible gearbox and a 360° azimuth thruster unit
- twin screw propulsion and a side thruster
- two azimuth thrusters
- any equivalent system approved by the Society on a case-by-case basis.

##### 1.2.2 Minimum speed

During sea trials, it is to be verified that in calm water conditions, the vessel is to be capable of attaining an ahead speed of at least 10 knots, and 4 knots with the most powerful propulsion system out of action.

##### 1.2.3 Stationary position and manoeuvring capabilities

The vessel is to be capable of manoeuvring at low speed and maintaining position in currents, waves and winds expected in the operations areas.

#### 1.3 Exhaust pipes

1.3.1 The exhaust outlets from engines are to be fitted as high as practicable above the upper deck and are to be provided with spark arresters.

## Section 5 Electrical Installations

### 1 General

#### 1.1 Electrical installations

**1.1.1** The electrical installations are to allow the simultaneous use of all the electric equipment needed for rescue operations.

**1.1.2** The vessel is to be provided with sufficient emergency power sources to allow the rescue operations to continue for at least 1 hour after failure of the main power supply.

#### 1.2 Searchlight

**1.2.1** A searchlight is to be available on each side of the vessel and operated from the navigation bridge. The searchlights are to be able to provide an illumination of 50 lux at a distance of 250 m.

## Section 6 Fire Protection

### 1 General

#### 1.1 Additional requirements for water spraying

1.1.1 Vessels fitted with a water spraying system are to meet the applicable requirements of Ch 4, Sec 4.

# Part E

## Service Notations for Offshore Service Vessels and Tugs

---

### CHAPTER 11

## ACCOMMODATION UNITS

---

Section 1	General
Section 2	Electrical Installations and Automation
Section 3	Fire Protection, Detection and Extinction
Section 4	Specific Requirements for Ships Assigned with the Additional Service Feature SPxxx-capable

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the present Chapter are eligible for the assignment of the service notation **accommodation**, as defined in Pt A, Ch 1, Sec 2, [4.12.5].

The service notation **accommodation** is to be completed by at least one of the following additional service features:

- **SPxxx**, as detailed in [1.1.2], when the ship complies with the SPS Code
- **SPxxx-capable**, as detailed in [1.1.3], when accommodation facilities may be added as separate modules during the service life of the ship, with a view to complying with the SPS Code.

The additional service feature **SPxxx** or **SPxxx-capable** are completed by the additional service feature **MOU**, as detailed in [1.1.4], when the ship complies with IMO MODU Code.

Examples of notations are given below:

**accommodation SP70**

**accommodation SP120-capable**

**accommodation SP80 SP240-capable MOU**

#### 1.1.2 Additional service feature SPxxx

Ships intended for the accommodation of industrial personnel and provided with all facilities for this purpose are to be assigned with the additional service feature **SPxxx**, as defined in Pt A, Ch 1, Sec 2, [4.16.8] where **xxx** is the total number of persons onboard.

Industrial personnel carried on board ships assigned with the service notation **accommodation** and the additional service feature **SPxxx** may be regarded as special personnel for the purpose of IMO Code of Safety for Special Purpose Ships.

#### 1.1.3 Additional service feature SPxxx-capable

Ships on which facilities for the accommodation of industrial personnel may be added as separate modules are to be assigned with the additional service feature **SPxxx-capable**, where **xxx** is the total number of persons onboard once the modules have been added.

Industrial personnel carried on board ships assigned with the service notation **accommodation** and the additional service feature **SPxxx-capable** may be regarded as special personnel for the purpose of IMO Code of Safety for Special Purpose Ships.

Ships assigned with the additional service feature **SPxxx-capable** are to comply with the requirements of Ch 11, Sec 4.

#### 1.1.4 Additional service feature MOU

Ships complying with the relevant requirements of IMO MODU Code are to be assigned the additional service feature **MOU**.

Note 1: IMO MODU Code means the Code for the Construction and Equipment of Mobile Offshore Drilling Units, published by the International Maritime Organization.

The requirements for the assignment of this additional service feature consist of IMO MODU Code Ch.2 to 9 and Ch.13.

## 1.2 Applicable rules

**1.2.1** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- Applicable requirements according to Tab 1.

**1.2.2** Ships less than 500 GT will be specially considered by the Society.

## 1.3 Definitions

### 1.3.1 Crew

Crew means all persons carried on board the ship to provide navigation and maintenance of the ship, its machinery, systems and arrangements essential for propulsion and safe navigation or to provide services for other persons on board.

**1.3.2 Industrial personnel**

Industrial personnel means all persons who are transported or accommodated on board for the purpose of offshore industrial activities performed on board other vessels and/or other offshore facilities. Industrial personnel are:

- Not less than 16 years of age, and
- Physically fit, and
- Properly equipped and familiarized with ship general layout, ship safety procedures and ship safety equipment as detailed in IMO Resolution MSC.418(97).

**Table 1 : Applicable requirements**

## Section 2 Electrical Installations and Automation

### 1 Interaction with operational ships or units

#### 1.1 Application

1.1.1 The requirements of this article apply to ships that may be located close to drilling or oil or gas production units.

#### 1.2 Emergency Shutdown

1.2.1 Arrangements are to be provided to ensure the selective disconnection of the following equipment, in the event of an emergency situation where explosion hazard may extend up to the ship:

- Ventilation systems
- Non-essential electrical apparatuses
- Essential electrical apparatuses
- Main generator prime movers
- Emergency apparatuses, including the emergency generators, except those certified for installation in Zone 1

Note 1: In the case of ships with dynamic positioning systems as a sole means of position keeping, special consideration may be given to the selective disconnection or shutdown of machinery and equipment associated with maintaining the operability of the dynamic positioning system.

1.2.2 Disconnection or shutdown is to be possible from at least two widely separated locations.

1.2.3 Shutdown systems that are provided to comply with [1.2.1] are to be so designed that the risk of unintentional stoppages caused by malfunction in a shutdown system and the risk of inadvertent operation of a shutdown are minimized.

#### 1.2.4 Services to be operable after emergency shutdown

Equipment which is located in spaces other than enclosed spaces and which is capable of operation after shutdown as given in [1.2.1] are to be suitable for installation in zone 2 locations. Such equipment which is located in enclosed spaces is to be suitable for its intended application to the satisfaction of the Society. At least the following facilities are to be operable for half an hour after an emergency shutdown:

- a) emergency lighting:
  - at every muster and embarkation station on deck and over sides
  - in all service and accommodation alleyways, stairways and exits, personnel lift cars and personnel lift trunks
  - in the machinery spaces and main generating stations including their control positions
  - in all control stations, machinery control rooms, and at each main and emergency switchboard
- b) navigation aids
- c) general alarm system
- d) public address system
- e) battery-supplied radiocommunication installations.

## Section 3 Fire Protection, Detection and Extinction

### 1 Interaction with operational ships or units

#### 1.1 Application

1.1.1 The requirements of this article apply to ships that may be located close to drilling or oil or gas production units.

#### 1.2 Structural integrity

1.2.1 The superstructures and deckhouses containing accommodation spaces are to have external boundaries made of steel.

1.2.2 In addition, if the ship may be located within 100m of a drilling or oil or gas production unit, the external boundaries of superstructures or deckhouses containing accommodation spaces are to have fire integrity as follows:

- If the boundary is located within 30m of the centre of the rotary table of a drilling unit or of the process or storage area of a production unit, it is to have A-60 fire integrity
- If the boundary is located within 100m of the centre of the rotary table of a drilling unit or of the process or storage area of a production unit, it is to have A-0 fire integrity.

#### 1.3 Installation layout

1.3.1 Accommodation spaces and control stations are to be located outside hazardous areas, taking into account hazardous areas on drilling or oil or gas production units in close proximity.

1.3.2 Ventilation intakes are to be located so as to minimize the risk of ingress of gas or smoke in the event of a gas release or of a fire on drilling or production units in close proximity.

# Section 4 Specific Requirements for Ships Assigned with the Additional Service Feature SPxxx-capable

## 1 General

### 1.1 Application

**1.1.1** The present Section provides requirements for ships on which accommodation modules are intended to be added at a later stage.

**1.1.2** Ships complying with the present Section are eligible for the assignment of the additional service feature **SPxxx-capable** defined in Ch 11, Sec 1, [1.1.3].

**1.1.3** The additional service feature **SPxxx-capable** applies when the accommodation modules are not installed on board.

**1.1.4** When the accommodation modules are installed on board, the additional service feature **SPxxx** is to be activated in replacement of **SPxxx-capable**. For this purpose, the Society will check that the additional modules and the ship including the additional modules are in compliance with the applicable requirements.

**1.1.5** In case xxx is above 240, the feasibility of granting the additional service feature **SPxxx-capable** will be assessed on a case-by-case basis by the Society. In this respect, specific attention is to be paid to the requirements of [2.3].

**1.1.6** Provisions applicable to the ship in general are to be considered during the ship design and construction, although the additional accommodation modules are not installed on board yet.

### 1.2 Documents to be submitted

**1.2.1** A description of a likely arrangement of the ship with the additional accommodation modules is to be provided for information, including the following information as a minimum:

- List of equipment to be added onboard together with the accommodation modules, if any
- General description of the modules, number and arrangement onboard
- Assumed electrical power balance

**1.2.2** For the purpose of the stability assessment, the following documents are to be provided by the ship designer, taking into account a likely arrangement for the accommodation modules:

- General Arrangement
- Intact and damage stability calculations

## 2 Design review

### 2.1 Specific requirements

**2.1.1** The requirements of Part B and Part C of the present Rules are to be complied with, as applicable.

**2.1.2** The ship without the additional accommodation module is to comply with the specific requirements listed in Tab 1.

### 2.2 Stability assessment

**2.2.1** When the accommodation modules are installed onboard and in order to activate the additional service feature **SPxxx**, it is to be demonstrated that the actual module arrangement, if different from the initially assumed arrangement, is properly covered by the initial stability assessment.

### 2.3 Safe Return to Port

**2.3.1** The provisions of [2.3] apply to ships assigned with the additional service feature **SPxxx-capable** and for which:

- xxx is greater than 240 and
- $L_{LL}$  as defined in Pt B, Ch 1, Sec 3, [2.1.2] is greater than or equal to 120m or the ship includes three or more main vertical zones as defined in Pt C, Ch 4, Sec 1, [2.30]

**2.3.2** Special attention is to be given to redundancies on at least the following systems, with a view to complying with the requirements for **SRTP** additional service feature:

- propulsion
- steering systems and steering-control systems
- navigational systems
- systems for fill, transfer and service of fuel-oil
- internal communication
- external communication
- fire main system
- fixed fire-extinguishing systems
- fire and smoke detection system
- bilge and ballast system
- power-operated watertight and semi-watertight doors
- systems intended to support safe areas
- flooding detection systems

**2.3.3** When the accommodation modules are installed onboard and together with the activation of the additional service feature **SPxxx**, compliance with the requirements for the additional service feature **SRTP** is to be demonstrated.

**Table 1 : Applicable requirements for notation SPxxx-capable**

Item	Reference requirement	Provisions to be applied depending on the total number of persons on board (POB) (1)		
		POB < 240		240 ≤ POB
Arrangement	<ul style="list-style-type: none"> <li>• Pt B, Ch 2, Sec 1, [1.1]</li> <li>• Pt B, Ch 2, Sec 1, [6.1.2]</li> <li>• Pt B, Ch 2, Sec 2, [1.1]</li> </ul>	<ul style="list-style-type: none"> <li>• Pt B, Ch 2, Sec 1, [1] to Pt B, Ch 2, Sec 1, [5],</li> <li>• Pt B, Ch 2, Sec 2,</li> </ul> considering the industrial personnel as crew		<ul style="list-style-type: none"> <li>• Pt B, Ch 2, Sec 1, [1] to Pt B, Ch 2, Sec 1, [5]</li> <li>• Pt D, Ch 11, Sec 2,</li> <li>• Pt B, Ch 2, Sec 2</li> </ul> considering the industrial personnel as passengers
		Pt B, Ch 3, Sec 1, [1.2]	<ul style="list-style-type: none"> <li>• Part B, Chapter 3</li> <li>• Pt D, Ch 11, Sec 3, [2.3.14]</li> </ul> considering the industrial personnel as crew

## Service Notations for Offshore Service Vessels and Tugs

---

### CHAPTER 12

## PIPE LAYING UNITS

---

Section 1	General
Section 2	Stability and Subdivision
Section 3	Structural assessment
Section 4	Initial Inspection and Testing

# Section 1 General

## 1 General

### 1.1 Application

**1.1.1** Ships complying with the present Chapter are eligible for the assignment of the service notation **pipe laying** as defined in Pt A, Ch 1, Sec 2, [4.12.7].

**1.1.2** Ships dealt with in this Chapter are to comply with:

- Part A of the Rules
- NR216 Materials and Welding
- applicable requirements according to Tab 1 and specific requirements for initial inspection and testing as detailed in Ch 12, Sec 4.

**Table 1 : Applicable requirements**

Item		Greater than or equal to 500 GT	Less than 500 GT
Ship arrangement	L ≥ 65 or 90 m (1)	• Part B	• NR566
	L < 65 or 90 m (1)	• NR600	• NR566
Stability		• Part B • Ch 12, Sec 2	• NR566 • Ch 12, Sec 2
Structural assessment	L ≥ 65 or 90 m (1)	• Part B • Ch 12, Sec 3	• Part B • Ch 12, Sec 3
	L < 65 or 90 m (1)	• NR600 • Ch 12, Sec 3	• NR600 • Ch 12, Sec 3
Machinery and systems		• Part C	• NR566
Electrical installations and automation		• Part C	• NR566
Fire protection, detection and extinction		• Part C	• NR566
(1) Refer to the scope of application of NR600			
<b>Note 1:</b>			
NR566: Hull Arrangement, Stability and Systems for Ships less than 500 GT			
NR600: Hull Structure and Arrangement for the Classification of Cargo Ships less than 65 m and Non Cargo Ships less than 90 m			

### 1.2 Scope

**1.2.1** The present Chapter addresses the requirements regarding the structural assessment of the foundations of the pipe laying equipment and the stability of the ship during pipe laying operations.

**1.2.2** The certification of the pipe laying system is not covered by the present Chapter. Certification of pipe laying system pieces of equipment may be considered independently as detailed in [2.2].

## 2 Pipe laying system

### 2.1 General

**2.1.1** The term pipe laying system is used herein to designate the system used for assembling and installing rigid or flexible pipelines to the seabed.

Pipe laying systems include:

- S lay systems
- J lay systems
- Flex lay systems
- Reel lay system

with the following typical pieces of equipment:

- stingers, towers, ramps and tensioners
- wheels, reels, davits and chutes

- carousels, baskets and pipe racks
- winches, ropes and sheaves
- pipe handling systems and clamps.

**2.2 Certification of the pipe laying equipment**

**2.2.1** At the request of the Party applying for classification, the pipe laying system pieces of equipment may be certified and covered under the scope of classification, provided that the additional class notation **OHS** is assigned to the ship.

**3 Documents to be submitted**

**3.1 General**

**3.1.1** The documents listed in Tab 2 are to be provided.

**Table 2 : Documents to be submitted**

No.	Documents to be submitted	I / A (1)
1	Pipe laying operational restrictions (pay load, limiting environmental conditions, ...)	I
2	Pipe laying equipment documentation: <ul style="list-style-type: none"> <li>• operating manual (see [3.2.1])</li> <li>• calculation notes (see [3.2.2])</li> </ul>	I
3	General arrangement of the ship showing the pipe laying equipment position during transit and operations	I
4	General arrangement of the pipe laying equipment showing the control stations	I
Stability		
5	Loading conditions during transit and pipe laying operations	A
6	Trim and stability booklet including operational loading conditions, when relevant	A
Structural assessment		
7	Structural arrangement showing the foundations of the equipment and the hull structure reinforcements (stinger, lay tower, winches, etc.)	A
8	Scantlings and steel grades of the connecting bolts between the equipment and its foundations	I
9	Material specification of the foundations of the equipment	A
10	Welding procedure and welding book of the foundation	A
(1) A : For approval ; I : For information.		

**3.2 Pipe laying equipment documentation**

**3.2.1 Operating manual**

The operating manual is to contain full information concerning:

- the pipe laying operational limitations, for each relevant wind and sea state
- all limitations during normal and emergency operations taking into account the ship stability and structure:
  - maximum wind and sea state
  - maximum heel and trim
  - design temperature
  - maximum pay load on the pipe lay equipment
- the description of the equipment
- the design technical standard, if any
- the description of the safety devices
- the user instructions to operate, erect, dismantle and transport the system
- the inspection and testing programme of the equipment.

**3.2.2 Calculation notes**

Calculation notes including the items listed below are to be provided for information:

- loading conditions and design loads applied on the supporting structure of the pipe laying equipment including:
  - maximum safe working loads with respect to environmental conditions
  - dynamic amplification factors
  - maximum holding loads
- the mass and location of centre of gravity of the main components of the pipe laying equipment
- loads lowering in the foundations
- structural assessment of the connecting bolts between the lifting equipment and its foundations.

## Section 2                      Stability and Subdivision

### 1 General

#### 1.1 Application

**1.1.1** The stability requirements described in this Section may be applied to ships when the pipe laying operation induces significant heeling moment.

**1.1.2** In that case, the stability criteria required for lifting operation and described in Ch 8, Sec 3 are to be applied in order to check the residual stability during pipe laying operations.

For that purpose, the term “lifting” is to be replaced by “pipe laying”.

#### 1.2 Loading conditions

**1.2.1** When relevant, the stability criteria are to be satisfied for all pipe laying operational conditions and with the pipe laying load at the most unfavourable positions.

## Section 3 Structural assessment

### 1 General

#### 1.1 Application

**1.1.1** This Section provides requirements for the structural assessment of the foundations of pipe laying equipment supported by the hull structure, such as stingers, lay tower, ramps, reels, davits, chutes, carousels, pipe racks, winches and sheaves.

### 2 Hull girder strength

#### 2.1 Principles

**2.1.1** When the pipe laying operations induce significant hull girder stresses, the hull girder loads due to the pipe laying operations are to be considered in the hull scantling verification, as defined in Ch 8, Sec 4, [3].

Note 1: For that purpose, the term “lifting” is to be replaced by “pipe laying”.

### 3 Materials and welding

#### 3.1 Structural category and steel grades for the foundations of the pipe laying equipment

**3.1.1** The steel grade of the structural elements of the foundation is to comply with Pt B, Ch 4, Sec 1, taking into account the structural categories given in Tab 1.

**Table 1 : Guidance for structural categories**

Category / Class	Structural elements
Primary / Class II	Hull supporting structure
Special / Class III	Insert plate of deck plating or hull shell in way of stingers, davits or lay tower

### 4 Pipe laying equipment foundations

#### 4.1 General

**4.1.1** The foundations of the pipe laying equipment and the connecting bolts between the equipment and the foundations are to comply with the relevant requirements applicable to lifting units defined in Part E, Chapter 8, i.e.:

- for design loads: Ch 8, Sec 4, [3]
- for loading conditions: Ch 8, Sec 4, [3.3]
- for allowable stress: Ch 8, Sec 4, [5]
- for buckling: Ch 8, Sec 4, [6]
- for fatigue: Ch 8, Sec 4, [7].

Note 1: For that purpose, the term “lifting” is to be replaced by the term “pipe laying”.

#### 4.2 Connecting bolts

**4.2.1** The arrangement and scantling of the connecting bolts between the pipe laying equipment and the foundations are to comply with a recognized standard.

**4.2.2** The manufacture, steel grades and installation of bolts and nuts used for the connection of the lifting equipment on the foundation are to comply with a recognized standard.

## Section 4 Initial Inspection and Testing

### 1 General

#### 1.1 Application

**1.1.1** The present Section provides requirements for inspection and testing of the pipe laying installations when first installed onboard or after re-installation.

**1.1.2** These tests are to be conducted according to an inspection and testing specification to be submitted to the Society by the interested party.

The Society is to be duly informed of the time and place of the commissioning tests of the pipe laying equipment.

**1.1.3** Any additional testing may be required to the satisfaction of the attending Surveyor.

### 2 Onboard testing

#### 2.1 Pipe laying installations

**2.1.1** Before putting into service, the inspection and testing of the pipe laying installations should include, as a minimum:

- a) Verification of the presence onboard of the operating manual as defined in Ch 12, Sec 1
- b) Inspection of the structural arrangement and scantlings of the foundations of the pipe laying equipment
- c) Load tests in accordance with the pipe laying equipment testing program.

**2.1.2** As a rule, all the connections between the supporting ship and the pipe laying equipment are to be presented for examination by the Surveyor.

## Chapter 5 Monitoring Equipment

### Section 1 Hull Stress and Motion Monitoring (MON-HULL)

<b>1</b>	<b>General</b>	<b>163</b>
	1.1 Application	
	1.2 Documentation	
<b>2</b>	<b>Sensors design</b>	<b>164</b>
	2.1 General	
	2.2 Measurements ranges and tolerances	
	2.3 On-site calibration of sensors	
	2.4 Environmental and EMC requirements	
<b>3</b>	<b>System design</b>	<b>164</b>
	3.1 General	
	3.2 Data processing	
	3.3 Data displaying	
	3.4 Alarms	
	3.5 Data storage	
	3.6 Exploitation of stored data	
	3.7 Checking facility	
	3.8 Power supply	
<b>4</b>	<b>Installation and testing</b>	<b>166</b>
	4.1 General	
	4.2 Installation of sensors	
	4.3 Testing of Hull Monitoring System	

### Section 2 Shaft Monitoring (MON-SHAFT)

<b>1</b>	<b>General</b>	<b>167</b>
	1.1 Applicability of MON-SHAFT notation	
	1.2 Documentation to be submitted	
<b>2</b>	<b>Requirements for oil lubricated shafts</b>	<b>167</b>
	2.1 Arrangement	
	2.2 Lubricating oil analysis	
<b>3</b>	<b>Requirements for water lubricated shafts</b>	<b>168</b>
	3.1 General requirements	
	3.2 Additional requirements for forced water lubrication systems	
	3.3 Data to be recorded	

### Section 3 Real-Time Carbon Intensity Indicator (CII-REALTIME)

<b>1</b>	<b>General</b>	<b>170</b>
	1.1 Application	
	1.2 Definitions	
	1.3 Type approval of CII ODS and CII SDS	
	1.4 Documentation to be submitted	
<b>2</b>	<b>CII Onboard Digital Solution (CII ODS)</b>	<b>173</b>
	2.1 Requirements to inputs	
	2.2 Requirements to functions	
<b>3</b>	<b>CII Shore Digital Solution (CII SDS)</b>	<b>174</b>
	3.1 Requirements to functions	
<b>4</b>	<b>Test datasets</b>	<b>175</b>
	4.1 Information to be submitted	
	4.2 Verification	

# Table of Content

5	Initial Survey	175
5.1	CII Onboard Digital Solution (ODS)	
5.2	CII Shore Digital Solution (SDS)	

## Chapter 6 Comfort on Board and Habitability

### Section 1 COMF Notations - General Requirements

1	General	177
1.1	Application	
1.2	Basic principles	
1.3	Regulations, Standards	
1.4	Definitions	
1.5	Document to be submitted	
2	Conditions of attribution	179
2.1	Measurements	
2.2	Determination of comfort rating number	
2.3	Measuring locations	
3	Testing conditions	180
3.1	General	
3.2	Harbour test conditions	
3.3	Sea trial conditions	

### Section 2 COMF Notations - Additional Requirements for Ships of Less than 1600 GT

1	General	182
1.1	Application	
2	COMF-NOISE	182
2.1	Measurement procedure	
2.2	Noise levels	
2.3	Sound insulation measurements	
3	COMF-VIB	183
3.1	Measurement procedure	
3.2	Vibration levels	

### Section 3 COMF Notations - Additional Requirements for Crew Areas - Ships Greater than or Equal to 1600 GT

1	General	185
1.1	Application	
2	COMF-NOISE	185
2.1	Measurement procedure	
2.2	Noise levels	
2.3	Sound insulation measurements	
3	COMF-VIB	187
3.1	Measurement procedure	
3.2	Vibration levels	

### Section 4 COMF Notations - Additional Requirements for Passenger Areas - Ships Greater than or Equal to 1600 GT

1	General	189
1.1	Application

## Chapter 7 Refrigerating Installations (REF)

### Section 1 General Requirements

1	General	214
1.1	Application	
1.2	Temperature conditions	
1.3	Definitions	
2	Design criteria	215
2.1	Reference conditions	
3	Documentation	215
3.1	Refrigerating installations	
3.2	Controlled atmosphere installations	
3.3	Ships assigned with the notation QUICKFREEZE	
4	General technical requirements	217
4.1	Refrigeration of chambers	
4.2	Defrosting	
4.3	Prime movers and sources of power	
4.4	Pumps	
4.5	Sea connections	
4.6	Refrigerating machinery spaces	
4.7	Exemptions for small plants	
4.8	Personnel safety	
5	Refrigerated chambers	219
5.1	Construction of refrigerated chambers	
5.2	Penetrations	
5.3	Access to refrigerated spaces	
5.4	Insulation of refrigerated chambers	
5.5	Protection of insulation	
5.6	Miscellaneous requirements	
5.7	Installation of the insulation	
5.8	Drainage of refrigerated spaces	
6	Refrigerants	221
6.1	General	
6.2	Rated working pressures	
7	Refrigerating machinery and equipment	222
7.1	General requirements for prime movers	
7.2	Common requirements for compressors	
7.3	Reciprocating compressors	
7.4	Screw compressor bearings	
7.5	Pressure vessels	
7.6	General requirements for piping	
7.7	Accessories	
7.8	Refrigerating plant overpressure protection	
8	Specific requirements for direct and indirect refrigerating systems	224
8.1	Specific requirements for refrigerating systems	
8.2	Specific requirements for air cooling systems and distribution and renewal of air in cargo spaces	

# Table of Content

9	Instrumentation, alarm, monitoring	225
9.1	General	
9.2	Instrumentation, alarm and monitoring arrangement	
10	Material tests, inspection and testing, certification	226
10.1	Material testing	
10.2	Shop tests	
10.3	Pressure tests at the workshop	
10.4	Thermometers and manometers	
10.5	Shipboard tests	
10.6	Defrosting system	
<b>Section 2</b>	<b>Additional Requirements for Notation REF-CARGO</b>	
1	General	229
1.1	Application	
1.2	Refrigeration of cargo spaces	
1.3	Heating	
2	Refrigerated cargo spaces	229
2.1	Insulation	
3	Instrumentation	229
3.1	Thermometers in cargo spaces	
4	Additional requirements for AIR-CONT notation	230
4.1	General	
4.2	Controlled atmosphere cargo spaces and adjacent spaces	
4.3	Gas systems	
4.4	Miscellaneous equipment	
4.5	Gas detection and monitoring equipment	
4.6	Instrumentation, alarm and monitoring arrangement	
4.7	Safety	
4.8	Tests and trials	
5	Additional requirements for notations PRECOOLING and QUICKFREEZE	236
5.1	General	
5.2	Shipboard tests	
<b>Section 3</b>	<b>Additional Requirements for Notation REF-CONT</b>	
1	General	237
1.1	Application	
2	Ships supplying electrical power to self-refrigerated containers	237
2.1	Electrical equipment	
2.2	Installation of containers	
<b>Section 4</b>	<b>Additional Requirements for Notation REF-STORE</b>	
1	General	238
1.1	Application	

## Chapter 8 Navigation in Cold Environment

### Section 1 ICE Class Notations - General Requirements

1	General	240
1.1	Application	
1.2	Owner's responsibility	
1.3	Documents to be submitted	

# Table of Content

	2	Ice class draughts and ice thickness	240
	2.1	Definitions	
	2.2	Draught limitations in ice	
	2.3	Ice thickness	
	3	Output of propulsion machinery	242
	3.1	Required engine output for ICE CLASS IA SUPER, ICE CLASS IA, ICE CLASS IB and ICE CLASS IC	
<b>Section 2</b>	<b>ICE Class Notations - Hull and Stability</b>		
	1	General	245
	1.1	Application	
	1.2	Hull regions	
	1.3	Ice strengthened area	
	2	Structure design principles	247
	2.1	General framing arrangement	
	2.2	Transverse framing arrangement	
	2.3	Bilge keels	
	3	Design loads	248
	3.1	General	
	3.2	Ice loads	
	4	Hull scantlings	250
	4.1	Gross scantlings	
	4.2	Plating	
	4.3	Stiffeners	
	4.4	Primary supporting members	
	5	Other structures	253
	5.1	Application	
	5.2	Fore part	
	5.3	Aft part	
	5.4	Deck strips and hatch covers	
	5.5	Sidescuttles and freeing ports	
	6	Hull outfitting	254
	6.1	Rudders and steering arrangements	
	6.2	Bulwarks	
	7	Additional class notations YOUNG ICE 1 and YOUNG ICE 2	255
	7.1	Area to be strengthened	
	7.2	Design loads	
	7.3	Plating	
	7.4	Stiffeners and primary supporting members	
	7.5	Sidescuttles and freeing ports	
<b>Section 3</b>	<b>ICE Class Notations - Machinery</b>		
	1	Requirements for propulsion machinery of the class notation ICE CLASS IA SUPER, ICE CLASS IA, ICE CLASS IB and ICE CLASS IC	258
	1.1	Scope	
	1.2	Design ice conditions	
	1.3	Materials	
	1.4	Design loads	
	1.5	Propeller blade design	
	1.6	Controllable pitch propeller and built-up propeller	
	1.7	Propulsion line design	
	1.8	Coupling	
	1.9	Gear	
	1.10	Chockfast calculation	
	1.11	Azimuthing main propulsors	

# Table of Content

	<b>2</b>	Requirements for propulsion machinery of ICE CLASS ID	281
		2.1 Ice torque	
		2.2 Propellers	
		2.3 Shafting	
	<b>3</b>	Miscellaneous requirements	283
		3.1 Starting arrangements	
		3.2 Sea inlets, ballast systems and cooling water systems of machinery	
		3.3 Steering gear	
		3.4 Fire pumps	
		3.5 Transverse thrusters	
		3.6 Test and certification for propellers	
<b>Section 4</b>		<b>COLD Notations - Cold Weather Conditions</b>	
	<b>1</b>	General	285
		1.1 Application	
		1.2 Documentation to be submitted	
		1.3 Testing	
	<b>2</b>	Machinery installations	286
		2.1 General	
		2.2 Principles	
		2.3 Design requirements	
	<b>3</b>	Electrical installations	287
		3.1 General	
		3.2 System design	
		3.3 Protection	
	<b>4</b>	Additional requirements	288
		4.1 De-icing of deck areas	
		4.2 De-icing tools	
		4.3 Protection of deck machinery	
		4.4 Closing appliances and doors	
		4.5 HVAC	
		4.6 Other protections	
	<b>5</b>	Specific requirements for COLD (H tDH, E tDE)	289
		5.1 Hull	
		5.2 Stability	
	<b>6</b>	Additional requirements for machinery installations for COLD (H tDH, E tDE)	290
		6.1 General	
		6.2 Principles	
		6.3 Design requirements	
	<b>7</b>	Other additional requirements for COLD (H tDH, E tDE)	291
		7.1 General	
		7.2 Cableways supports	
		7.3 Navigation and communication equipment	
		7.4 Fire safety systems	
		7.5 Others protections	
	<b>8</b>	Additional requirements for COLD CARGO	292
		8.1 General	
		8.2 Arrangements	
		8.3 Design and arrangement of the cargo heating means	
		8.4 Risk analysis	
		8.5 Materials	

## Chapter 9 Environmental Protection

### Section 1 General Requirements

1	Scope and application	295
1.1	General	
2	Definitions and abbreviations	296
2.1	Definitions related to sea pollution	
2.2	Definitions related to air pollution	
2.3	Abbreviations	

### Section 2 Notations CLEANSHIP and CLEANSHIP SUPER

1	General	299
1.1	Application	
1.2	Documents to be submitted	
2	Design requirements for the additional class notation CLEANSHIP	302
2.1	Waste management and monitoring	
2.2	Oily wastes	
2.3	Wastewaters	
2.4	Garbage and hazardous wastes	
2.5	Hull anti-fouling systems	
2.6	Prevention of pollution by oil spillage and leakage	
2.7	Refrigeration systems	
2.8	Fire-fighting systems	
2.9	Emission of nitrogen oxides (NO <sub>x</sub> )	
2.10	Emission of sulphur oxides (SO <sub>x</sub> )	
3	Additional design requirements for the additional class notation CLEANSHIP SUPER	310
3.1	Waste minimization and recycling program	
3.2	Oily wastes	
3.3	Wastewaters	
3.4	Food wastes	
3.5	Prevention of pollution by oil spillage and leakage	
3.6	Protection against oil pollution in the event of collision or grounding	
3.7	Prevention of air pollution	
4	Onboard tests and measurements	312
4.1	Application	
4.2	Periodical tests and measurements done by the Shipowner	

### Section 3 Notations AWT-A, AWT-B and AWT-A/B

1	General	313
1.1	Application	
1.2	Documents to be submitted	
2	Additional class notations AWT-A, AWT-B and AWT-A/B	313
2.1	Scope	
2.2	Definitions and abbreviations	
2.3	Design of the AWT plant	
3	Onboard tests and measurements	314
3.1	Periodical tests and measurements done by the Shipowner	

### Section 4 Notations BWE and BWT

1	General	316
1.1	Application	
1.2	Documents to be submitted	

# Table of Content

	2	Additional class notation BWE	316
	2.1	Scope	
	2.2	Design requirements	
	3	Additional class notation BWT	317
	3.1	Scope	
	3.2	Design and installation requirements	
<b>Section 5</b>		<b>Notations GWT, NDO-x days and OWS-x ppm</b>	
	1	General	318
	1.1	Application	
	1.2	Documents to be submitted	
	2	Additional class notation GWT and GWT-B	318
	2.1	Scope	
	2.2	Design of the grey water treatment plant	
	3	Additional class notation NDO-x days	319
	3.1	Scope	
	3.2	Design requirements	
	4	Additional class notation OWS-x ppm	319
	4.1	Scope	
	4.2	Design requirements	
<b>Section 6</b>		<b>Notations NOX-x% and SOX-x%</b>	
	1	General	321
	1.1	Application	
	1.2	Documents to be submitted	
	2	Additional class notation NOX-x%	321
	2.1	Scope	
	2.2	Design requirements	
	3	Additional class notation SOX-x%	322
	3.1	Scope	
	3.2	Design requirements	
<b>Section 7</b>		<b>EGCS-SCRUBBER and SCRUBBER READY</b>	
	1	General	323
	1.1	Application	
	2	Additional class notation EGCS-SCRUBBER	323
	2.1	Scope	
	2.2	Documents to be submitted	
	2.3	Design and installation requirements	
	3	Requirements for the additional class notation SCRUBBER-READY	324
	3.1	Scope of this notation	
	3.2	Documentation to be submitted	
	3.3	General arrangement	
	3.4	Hull items	
	3.5	Machinery items	
	3.6	Electricity items	
	3.7	Safety items	
	3.8	Stability items	

# Table of Content

<b>Section 8</b>	<b>Ultra-Low Emission Vessel (ULEV)</b>	
1	General	328
	1.1 Scope	
	1.2 Application	
	1.3 Documents to be submitted	
2	Definitions	329
	2.1	
3	Requirements for ULEV additional class notation	329
	3.1 Requirements for the engines	
	3.2 Emission levels	
	3.3 Emission control monitoring	
	3.4 ULEV Mode	
4	Emission measurements	331
	4.1 Pollutants to be measured	
	4.2 Measurements	
	4.3 Fuel specification	
	4.4 Deterioration factors	
	4.5 Control areas	
5	Onboard surveys	334
	5.1 Initial survey	
<b>Section 9</b>	<b>Methane Emission Measurements (MEM)</b>	
1	General	335
	1.1 Scope	
	1.2 Application	
	1.3 Documents to be submitted	
2	Definitions and abbreviations	336
	2.1	
3	Requirements for the MEM notation	336
	3.1 Engines	
4	Emission measurements	337
	4.1 Values to be measured	
	4.2 Measurement methodology	
	4.3 Test fuel	
	4.4 Data evaluation for methane emissions	
	4.5 Calculation of the methane emissions	
5	Onboard surveys	337
	5.1 Initial survey	
<b>Section 10</b>	<b>Vapour Control System (VCS)</b>	
1	General	338
	1.1 Application	
	1.2 Definitions	
	1.3 Documentation to be submitted	
2	Vapour system	339
	2.1 General	
	2.2 Vapour manifold	
	2.3 Vapour hoses	
	2.4 Vapour overpressure and vacuum protection	

# Table of Content

	<b>3 Instrumentation</b>	<b>341</b>
	3.1 Cargo tank gauging equipment	
	3.2 Cargo tank high level alarms	
	3.3 Cargo tank overfill alarms	
	3.4 High and low vapour pressure alarms	
	<b>4 Instruction manual</b>	<b>342</b>
	4.1 General	
	4.2 Content	
	<b>5 Testing and trials</b>	<b>343</b>
	5.1	
	5.2 Shipboard trials	
	<b>6 Additional requirements for notation "TRANSFER"</b>	<b>343</b>
	6.1 Application	
	6.2 Equipment	
<b>Section 11</b>	<b>Protected FO Tanks (PROTECTED FO TANKS)</b>	
	<b>1 General</b>	<b>344</b>
	1.1 Application	
	1.2 Definitions	
	<b>2 Design requirements</b>	<b>344</b>
	2.1 Distance from the bottom shell plating	
	2.2 Distance from the side shell plating	
	2.3 Oil fuel piping lines	
	2.4 Suction wells	
<b>Section 12</b>	<b>Fast Oil Recovery System (FORS)</b>	
	<b>1 General</b>	<b>346</b>
	1.1	
	1.2 Documents to be submitted	
	1.3 Definitions	
	<b>2 Requirements for the design and installation of the connectors</b>	<b>347</b>
	2.1 General	
	2.2 Number of connectors	
	2.3 Design of the connectors	
	2.4 Installation and access	
	<b>3 Additional requirements for -NS notation</b>	<b>348</b>
	3.1 General	
	3.2 Requirements	
<b>Section 13</b>	<b>BIOFUEL READY</b>	
	<b>1 General</b>	<b>349</b>
	1.1 Scope	
	1.2 Application	
	1.3 Documents to be submitted	
	1.4 Definitions and abbreviations	
	<b>2 Requirements for the BIOFUEL READY notation</b>	<b>350</b>
	2.1 Technical analysis	
	2.2 Onboard arrangement	
	2.3 Biofuel specification	
	2.4 Engine testing

## Chapter 10 CBRN and BIORISK

### Section 1 CBRN Notations - General Requirements

1	<b>General</b>	<b>357</b>
1.1	Scope	
1.2	Application	
1.3	CBRN operation specification	
2	<b>Definitions and abbreviations</b>	<b>357</b>
2.1	Citadel	
2.2	CBRN	
2.3	CBRN Mode	
2.4	CBRN Operation	
2.5	Collective protection system	
2.6	Shelter	
2.7	PPE	
3	<b>Documents to be submitted</b>	<b>358</b>
3.1		
4	<b>Construction testing and inspection</b>	<b>358</b>
4.1	General	
4.2	Tightness test	
4.3	Collective protection ventilation test	
4.4	CBRN detection test	
4.5	Pre-wetting and wash down test	

### Section 2 CBRN Notations - Ship Arrangement

1	<b>Citadel</b>	<b>360</b>
1.1	Spaces to be included in the citadel	
1.2	Spaces where explosive atmosphere may occur	
1.3	Boundaries of the citadel	
1.4	Openings in the citadel boundaries	
1.5	Means of access to the citadel	
2	<b>CBRN Control station</b>	<b>360</b>
2.1	Function	
2.2	Location	
3	<b>Space for rescued people</b>	<b>361</b>
3.1	Accommodation for rescued people	
3.2	Means of escape	
4	<b>Shelter</b>	<b>361</b>
4.1	Sheltered spaces	
4.2	Openings in shelter boundary	

# Table of Content

	<b>5</b>	<b>Airlock</b>	<b>361</b>
	5.1	Arrangement	
	5.2	Doors	
	5.3	Purging	
	<b>6</b>	<b>Cleansing station</b>	<b>361</b>
	6.1	Arrangement	
	6.2	Doors	
	<b>7</b>	<b>Machinery space arrangement</b>	<b>362</b>
	7.1	Allowable arrangements for engine room and internal combustion machinery spaces	
	7.2	Machinery space included in the citadel	
	7.3	Sheltered machinery space	
	7.4	Unprotected machinery space	
	7.5	Fire protection	
	7.6	Engine room cooling	
	<b>8</b>	<b>Superstructure design</b>	<b>363</b>
	8.1	Precautions for decontamination	
	<b>9</b>	<b>Marking</b>	<b>363</b>
	9.1	Openings	
	9.2	Equipment	
<b>Section 3</b>		<b>CBRN Notations - CBRN Protection</b>	
	<b>1</b>	<b>Detection system</b>	<b>364</b>
	1.1	Detection	
	1.2	Alarm and monitoring	
	<b>2</b>	<b>Collective Protection system</b>	<b>364</b>
	2.1	Citadel ventilation	
	2.2	Ventilation of machinery spaces included in the citadel	
	2.3	CBRN Protection plant	
	2.4	Airlocks and cleansing stations	
	<b>3</b>	<b>Personal protective equipment (PPE)</b>	<b>366</b>
	3.1	General	
	3.2	Self-contained breathing apparatus	
	<b>4</b>	<b>Monitoring and Controls</b>	<b>366</b>
	4.1		
	<b>5</b>	<b>Onboard procedures</b>	<b>366</b>
	5.1	CBRN operation manual	
	5.2	Fire control plan	
	5.3	Fire procedures	
<b>Section 4</b>		<b>CBRN Notations - Piping and Electrical Equipment</b>	
	<b>1</b>	<b>Piping systems</b>	<b>368</b>
	1.1	General	
	1.2	Scupper and bilge systems	
	1.3	Air, sounding and overflow pipes	
	<b>2</b>	<b>Electrical equipment</b>	<b>368</b>
	2.1	Environmental protection	
	2.2	Emergency source of power	
<b>Section 5</b>		<b>CBRN Notations - Pre-Wetting and Washdown System</b>	
	<b>1</b>	<b>General</b>	<b>370</b>
	1.1	Application	
	1.2	Ventilation openings	

# Table of Content

2	Pre-wetting and washdown system	370
2.1	System arrangement	
2.2	System equipment	
<b>Section 6</b>	<b>Biological Risk Management (BIORISK)</b>	
1	General	371
1.1	Application	
1.2	Documents to be submitted	
2	BIORISK MANAGED	371
2.1	Biological risk assessment	
2.2	Outbreak Management Plan	
2.3	Personal Protective Equipment (PPE)	
2.4	Signs and marking	
3	Additional requirements for BIORISK SECURED	373
3.1	General	
3.2	Quarantine area	
3.3	Ventilation of accommodation spaces and normally manned control stations	
3.4	Other equipment	
4	Onboard testing	374
4.1	Initial survey	

## Chapter 11 Manoeuvring, Mooring, Anchoring and Position Keeping

<b>Section 1</b>	<b>Ship Manoeuvrability (MANOVR)</b>	
1	General	377
1.1	Application	
1.2	Manoeuvre evaluation	
2	Definitions	377
2.1	Geometry of the ship	
2.2	Standard manoeuvres and associated terminology	
3	Requirements	378
3.1	Foreword	
3.2	Conditions in which the requirements apply	
3.3	Criteria for manoeuvrability evaluation	
4	Additional considerations	379
4.1	Trials in different conditions	
4.2	Dynamic instability	
<b>Section 2</b>	<b>Heading Control in Adverse Conditions</b>	
1	General	380
1.1	Application	
1.2	Definitions	
1.3	Documents to be submitted	
2	Heading control analysis	382
2.1	General	
2.2	Environmental adverse conditions	
2.3	Loading conditions	
2.4	Performance criteria	

# Table of Content

	<b>3</b>	<b>Requirements for duplicated propulsion and steering systems</b>	<b>383</b>
	3.1	Principles	
	3.2	Failure and casualty scenarios	
	3.3	Propulsion and steering systems	
	3.4	Propulsion auxiliary systems	
	3.5	Steering systems	
	3.6	Electrical installations	
	3.7	Automation	
	<b>4</b>	<b>Requirements for independent propulsion and steering systems</b>	<b>384</b>
	4.1	General design requirements	
	4.2	Propulsion and steering systems	
	4.3	Electrical installations	
	4.4	Automation	
	4.5	Compartment arrangement	
	4.6	Propulsion auxiliary systems	
	4.7	Ventilation system	
	<b>5</b>	<b>Tests on board</b>	<b>386</b>
	5.1	Operating tests	
	5.2	Sea trials	
<b>Section 3</b>		<b>Single Point Mooring (SPM)</b>	
	<b>1</b>	<b>General</b>	<b>387</b>
	1.1	Application	
	<b>2</b>	<b>Documentation</b>	<b>387</b>
	2.1	Documentation for approval	
	2.2	Documentation for information	
	<b>3</b>	<b>General arrangement</b>	<b>387</b>
	3.1	General provision	
	3.2	Typical layout	
	3.3	Equipment	
	<b>4</b>	<b>Number and safe working load of chain stoppers</b>	<b>389</b>
	4.1	General	
	<b>5</b>	<b>Mooring components</b>	<b>389</b>
	5.1	Bow chain stopper	
	5.2	Bow fairleads	
	5.3	Pedestal roller fairleads	
	5.4	Winches or capstans	
	<b>6</b>	<b>Supporting hull structures</b>	<b>391</b>
	6.1	General	
	<b>7</b>	<b>Strength criteria</b>	<b>391</b>
	7.1	General	
<b>Section 4</b>		<b>Unsheltered Anchoring</b>	
	<b>1</b>	<b>General</b>	<b>392</b>
	1.1	Application	
	<b>2</b>	<b>Anchoring equipment</b>	<b>392</b>
	2.1	Equipment number for deep and unsheltered water	
	2.2	Anchors	
	2.3	Chain cables for bower anchors	
	2.4	Anchor windlass and chain stopper	

# Table of Content

## Section 5 Dynamic Positioning (DYNAPOS)

<b>1</b>	<b>General</b>	<b>394</b>
1.1	Application	
1.2	Definitions	
1.3	Dynamic positioning sub-systems	
1.4	Additional and optional class notation	
1.5	Installation survey during construction	
1.6	List of documents to be submitted	
<b>2</b>	<b>Performance analysis</b>	<b>398</b>
2.1	General	
2.2	Condition of analysis	
2.3	Modelling and simulations	
2.4	Failure mode and effects analysis	
<b>3</b>	<b>Equipment class</b>	<b>400</b>
3.1	General	
3.2	Equipment class according to single failure	
<b>4</b>	<b>Functional requirements</b>	<b>401</b>
4.1	General	
4.2	Power system	
4.3	Monitoring and management of the electricity production and propulsion	
4.4	Thruster system	
4.5	Thruster control	
4.6	Thruster monitoring and protection	
4.7	DP operator station	
4.8	DP control system	
4.9	Computers	
4.10	Networks	
4.11	Independent joystick system	
<b>5</b>	<b>Position reference systems and environmental sensors</b>	<b>408</b>
5.1	General	
5.2	Arrangement and performance of reference systems	
5.3	Type of position reference system	
5.4	Other reference systems	
5.5	Environmental sensors	
<b>6</b>	<b>Installation requirements</b>	<b>410</b>
6.1	Cables and piping systems	
6.2	Thruster location	
<b>7</b>	<b>Operational requirements</b>	<b>410</b>
7.1	General	
<b>8</b>	<b>Tests and trials</b>	<b>411</b>
8.1	Inspection at works	
8.2	Trials	
<b>9</b>	<b>Environmental station keeping index ESKI</b>	<b>411</b>
9.1	Definition	
9.2	Environmental conditions	
9.3	Condition of ESKI estimation	
9.4	Documentation to be submitted and example	
<b>10</b>	<b>Enhanced DP system</b>	<b>413</b>
10.1	General	
10.2	DP Control system	
10.3	Position reference system	
10.4	Other vessel sensors	

# Table of Content

11	Digital DP survey	414
11.1	General	
11.2	Definitions	
11.3	Documentation and test attendance	
11.4	Recorded parameters	
11.5	Data Communication and Management	
11.6	Hardware requirements	
11.7	Cyber security	
11.8	Validation	
11.9	Verification	
11.10	Qualification

## Chapter 12 Cargo Operation, Securing and Safety

### Section 1 SINGLEPASSLOADING

1	General	423
1.1	Application	
1.2	Definitions	
2	Documentation to be submitted	423
2.1	Design loading rate	
2.2	Loading sequences	
2.3	Hold mass curves	
3	Loading instrument and alternative loading	424
3.1	Loading instrument	
3.2	Alternative loading	
4	Hull requirements	424
4.1	General	
4.2	Hull structure	
4.3	Control and monitoring	
5	System requirements	425
5.1	General	
5.2	Ballast piping	
5.3	Control and monitoring	

### Section 2 Bow and Stern Loading / Unloading Systems

1	General	426
1.1	Application	
1.2	Class notations	
1.3	Scope of classification	
1.4	Definitions	
1.5	Documents to be submitted	
1.6	Operating Manual	
2	Materials	427
2.1	General	
3	General design	427
3.1	Mooring system	
3.2	Cargo piping system	
3.3	Ventilation	
3.4	Hazardous areas and electrical installations	
3.5	Positioning	
3.6	Emergency Disconnection System (EDS)	
3.7	Control station	
3.8	Communications	
3.9	Safety features	

# Table of Content

<b>Section 3</b>	<b>Supply at Sea (SAS)</b>	
1	General	430
1.1	Application	
1.2	Documents to be submitted	
1.3	Definitions	
2	Design and construction	431
2.1	SAS equipment	
2.2	Steering capability	
3	Arrangement and installation	432
3.1	General	
3.2	Arrangement of SAS stations	
3.3	SAS control station arrangement	
3.4	Communication	
3.5	Fluid transfer	
3.6	Solid transfer	
3.7	Electrical installation	
4	Certification, inspection and testing	435
4.1	Type approval procedure	
4.2	Inspection at works of the SAS equipment	
4.3	Prototype tests	
4.4	Tests on board	
<b>Section 4</b>	<b>Centralised Cargo and Ballast Water Handling Installations (CARGOCONTROL)</b>	
1	General	437
1.1	Application	
1.2	Documents to be submitted	
2	Design and construction requirements	437
2.1	Control station	
2.2	Remote control, indication and alarm systems	
3	Inspection and testing	438
3.1	Equipment and systems	
3.2	Testing on board	
<b>Section 5</b>	<b>Container Lashing Equipment</b>	
1	General	439
1.1	Additional class notations	
1.2	Documentation to be submitted	
1.3	Materials	
2	Arrangement of containers	441
2.1	General	
2.2	Stowage in holds within cell guides	
2.3	Stowage in holds without cell guides	
2.4	Stowage on exposed deck	
2.5	Uniform line load stowage on deck or hatch covers	
3	Approval of the fixed and portable lashing equipment	444
3.1	General	
3.2	Type tests	
3.3	Additional functional test for fully automatic twistlocks	
3.4	Inspection at works of the fixed and portable lashing equipment	
3.5	Reception on board of the lashing equipment	

# Table of Content

<b>4</b>	<b>Forces applied to containers</b>	<b>448</b>
	4.1 General	
	4.2 Definitions	
	4.3 Still water and inertial forces	
	4.4 Passive free-surface anti-roll tank	
	4.5 Wind forces	
	4.6 Forces imposed by lashing and securing arrangements	
<b>5</b>	<b>Resulting loads in lashing equipment and container frames</b>	<b>453</b>
	5.1 Calculation hypothesis	
	5.2 Distribution of forces	
	5.3 Containers only secured by locking devices	
	5.4 Containers secured by means of lashing devices or buttresses	
	5.5 Stiffness values	
<b>6</b>	<b>Strength criteria</b>	<b>457</b>
	6.1 Maximum stack weight	
	6.2 Permissible loads on containers	
	6.3 Permissible loads induced by lashing on container corners	
	6.4 Permissible loads on lashing equipment	
<b>7</b>	<b>Lashing software</b>	<b>460</b>
	7.1 General	
	7.2 Requirements for lashing software	
	7.3 Approval of a lashing software	
 <b>Section 6 OPEN-HATCH</b>		
<b>1</b>	<b>General</b>	<b>462</b>
	1.1 Application	
	1.2 Definitions	
<b>2</b>	<b>Loading conditions</b>	<b>462</b>
	2.1 Intact flooded condition	
<b>3</b>	<b>Freeboard</b>	<b>463</b>
	3.1 General	
<b>4</b>	<b>Stability</b>	<b>463</b>
	4.1 Intact stability without water ingress	
	4.2 Intact stability considering water ingress	
	4.3 Damage Stability	
<b>5</b>	<b>Hull</b>	<b>464</b>
	5.1 Hull girder ultimate strength	
	5.2 Hull scantlings	
<b>6</b>	<b>Procedure of model tests</b>	<b>464</b>
	6.1 General	
<b>7</b>	<b>Ship arrangement</b>	<b>465</b>
	7.1 Hold bilge dewatering system and freeing ports	
<b>8</b>	<b>Fire protection</b>	<b>466</b>
	8.1 Fire insulation	
	8.2 Water-spray system	
	8.3 Dangerous goods	
<b>9</b>	<b>Testing</b>	<b>467</b>
	9.1 Onboard tests	

# Table of Content

<b>Section 7</b>	<b>Efficient Washing of Cargo Tanks (EWCT)</b>	
1	General	468
	1.1 Application	
	1.2 Documents to be submitted	
2	Design requirements	468
	2.1 Cargo tanks	
	2.2 Cargo piping system	
	2.3 Cargo tank cleaning system	
<b>Section 8</b>	<b>Increased Admissible Cargo Tank Pressure (IATP)</b>	
1	Application	469
	1.1 Ships covered by this section	
	1.2 Scope	
2	Documentation to be submitted	469
	2.1 Drawings and documents to be submitted to the Society	
3	Definitions	469
	3.1	
4	General design requirements	470
	4.1 Ship design	
	4.2 Cargo tanks pressure relieving system	
	4.3 Boil-off gas management system	
5	Control, monitoring and safety systems	471
	5.1 Cargo tanks pressure alarms	
	5.2 Indication of the cargo tanks pressure setting	
6	Other	471
	6.1 Shop and gas trials	
	6.2 Ship to ship transfer	
<b>Section 9</b>	<b>Electric Vehicle Onboard Charging (EVOC)</b>	
1	General	472
	1.1 Application	
	1.2 Definitions and abbreviations	
	1.3 Documents to be submitted	
2	Arrangement and safety assessment	473
	2.1 Recharging area arrangement	
	2.2 Risk assessment	
3	Electrical installation	473
	3.1 General	
	3.2 Sockets and outlets	
	3.3 Electrical cables and connections	
	3.4 Charging station	
4	Fire safety	475
	4.1 Fire detection	
	4.2 Fixed fire-extinguishing systems	
	4.3 Portable equipment	
5	Prevention of explosion and limitation of the consequences of toxicity	476
	5.1 Sources of ignition	
	5.2 Ventilation	
6	Testing	477
	6.1 Type testing	
	6.2 Workshop tests	
	6.3 Shipboard test	

# Table of Content

Appendix 1	Definition of Specific Routes for the Notation LASHING-RSSA	
1	General	478
1.1	Definition of the reference specific routes and crossed areas	
1.2	Allowance criterion for deviations from the reference specific routes	

## Chapter 13 Additional Notation for Fire Protection

### Section 1 Enhanced Fire Protection (EFP-AMC)

1	General	488
1.1	Application	
2	Protection of accommodation spaces (EFP-A)	488
2.1	Application	
2.2	Prevention of fire	
2.3	Detection and alarm	
2.4	Containment of fire	
2.5	Escape	
3	Protection of machinery spaces (EFP-M)	489
3.1	Application	
3.2	Machinery spaces general arrangement	
3.3	Detection and alarm	
3.4	Ventilation system	
3.5	Fixed water-based local application fire-fighting system	
3.6	Escape	
3.7	Central control station	
4	Protection of cargo decks and cargo spaces (EFP-C)	490
4.1	Cargo ships	
4.2	Ro-ro cargo ships, PCTC and PCC	
4.3	Oil tankers, FLS tankers and chemical tankers	
4.4	Liquefied gas carriers	
5	Onboard testing	492
5.1	Hot spot verification	

### Section 2 Enhanced Cargo Fire Protection for Container Ships (ECFP)

1	General	493
1.1	Application	
1.2	Innovative technologies	
1.3	Documents to be submitted	
2	Requirements for the notation ECFP-1	494
2.1	General	
2.2	Portable equipment	
2.3	Compressed air system for breathing apparatuses	
3	Additional requirements for the notation ECFP-2	495
3.1	General	
3.2	Central control station	
3.3	Fire detection	
3.4	Water supply systems	
3.5	Mobile water monitors	
3.6	Fixed water monitors covering the on-deck cargo stowage area	
3.7	Water-spray system below hatch cover	
3.8	Flooding system for the cargo holds	
3.9	Water-spray system for the protection of the superstructure block	
3.10	Design of the ventilation system	

# Table of Content

4	Additional requirements for the notation ECFP-3	501
4.1	General	
4.2	Central control station	
4.3	Portable equipment	
4.4	Fire detection	
4.5	Water-spray system below hatch cover	
4.6	Design of the ventilation system	
5	Certification and testing	503
5.1	Type approval of portable fire-fighting devices for stacked containers	
5.2	Onboard tests	
<b>Section 3</b>	<b>Cofferdam Ventilation (COVENT)</b>	
1	General	505
1.1	Application	
1.2	Documents to be submitted	
2	Design and construction	505
2.1	Arrangement	
2.2	Other technical requirements	
3	Inspection and testing	506
3.1	Equipment and systems	
3.2	Testing on board	

---

## Chapter 14 Electric Propulsion or Power Supply

### Section 1 Battery System

1	General	508
1.1	Application	
1.2	Documents to be submitted	
2	Definitions and acronyms	508
2.1	System considered	
2.2	Definitions	
3	Safety and design issues	510
3.1	Battery compartment	
3.2	Battery pack	
4	Availability of power	512
4.1	Ship configuration	
4.2	Case 1: global battery system failure leads to loss of propulsion or of main electrical sources	
4.3	Case 2: global battery system failure does not lead to any loss regarding ship propulsion and main source of power	
5	Test and certification process for batteries	513
5.1	Battery cells	
5.2	Equipment used in battery systems	
5.3	Battery packs and associated BMS	
5.4	Onboard tests of battery compartment and fire-extinguishing system	

### Section 2 Electric Hybrid

1	General	516
1.1	Application	
1.2	Documents to be submitted	
1.3	Definitions	

# Table of Content

	2		519
	2.1	Quality of power supply	
	2.2	Power distribution	
	3	<b>Electric Energy Storage System (ESS)</b>	519
	3.1	ESS battery pack	
	3.2	ESS semiconductor converter	
	3.3	ESS transformer	
	3.4	Energy Control System (ECS)	
	3.5	ESS capacity	
	3.6	ESS charging	
	3.7	ESS control and instrumentation	
	4	<b>Installation on board</b>	521
	4.1	Safety and design of battery system	
	5	<b>Testing</b>	521
	5.1	Factory acceptance tests	
	5.2	Onboard tests	
	5.3	Tests of battery compartment and fire-extinguishing system	
<b>Section 3</b>	<b>Electric Hybrid Prepared</b>		
	1	<b>General</b>	523
	1.1	Application	
	1.2	Definitions and abbreviations	
	1.3	Documents to be submitted	
	1.4	Conversion to electric hybrid	
	2	<b>System design</b>	525
	2.1	Ship design	
	2.2	Cables	
	3	<b>Electric energy storage system (ESS)</b>	525
	3.1	ESS Batteries
