BUREAU VERITAS
RULES FOR THE CLASSIFICATION OF NAVAL SHIPS

NR483 - JANUARY 2024

This document contains the consolidated January 2024 edition, Part A to Part E.

This document is for documentation only.

The PDF electronic version of this document available on the Bureau Veritas Marine & Offshore website https://marine-offshore.bureauveritas.com/ is the official version and shall prevail if there are any inconsistencies between the PDF version and any other available version.

These rules are provided within the scope of the Bureau Veritas Marine & Offshore General Conditions, enclosed at the end of Part A of NR467, Rules for the Classification of Steel Ships. The latest version of these General Conditions is available on the Bureau Veritas Marine & Offshore website.

RULES FOR THE CLASSIFICATION OF NAVAL SHIPS

Part A
Classification and Surveys

Chapter 1	Principles of Classification and Class Notations
Chapter 2	Assignment, Maintenance, Suspension and Withdrawal of Class
Chapter 3	Scope of Surveys (all ships)
Chapter 4	Scope of Surveys in Respect of the Different Services of Ships
Chapter 5	Scope of Surveys Related to Additional Class Notations

January 2024

Chapter 1 Principles of Classification and Class Notations

Section 1 General Principles of Classification

1 Principles of classification 14

1.1 Purpose of the Rules
1.2 General definitions
1.3 Meaning of classification, scope and limits
1.4 Request for services
1.5 Register of ship

2 Rules 15

2.1 Effective date
2.2 Equivalence
2.3 Novel features
2.4 Interpretation
2.5 Disagreement and appeal

3 Duties of the Interested Parties 16

3.1 International and national regulations
3.2 Surveyor's intervention
3.3 Operation and maintenance of ships
3.4 Use of measuring equipment and of service suppliers
3.5 Spare parts

Section 2 Classification Notations

1 General 18

1.1 Purpose of the classification notations
1.2 Types of notations assigned

2 Main class symbol 18

2.1 Main class symbol

3 Construction marks 19

3.1 General
3.2 List of construction marks

4 Service notations 19

4.1 General
4.2 Frigate
4.3 Aircraft carrier
4.4 Corvette
4.5 Auxiliary naval vessel
4.6 Amphibious vessel
4.7 Military OPV
4.8 Landing craft
4.9 Unmanned Surface Vessel (USV)
4.10 Special service

5 Navigation notations 21

5.1 Navigation notations
5.2 List of navigation notations

6 Additional class notations 21

6.1 General
6.2 Military environment
6.3 System of Trace and Analysis of Records (STAR)
6.4 Availability of machinery (AVM)
6.5 Automated machinery systems (AUT)
6.6 Integrated and digital systems
6.7 Monitoring equipment (MON)
6.8 Comfort on board (COMF)
6.9 Refrigerating installations
6.10 Environmental protection
6.11 Protection against chemical, biological, radiological or nuclear risks (CBRN)
6.12 Manoeuvring, stability and sea-keeping
6.13 Safety equipment and installations
6.14 Lifting appliances
6.15 Other additional class notations

7 Other notations 29

7.1

8 Explicit request of the Naval Authority 29

8.1

Chapter 2 Assignment, Maintenance, Suspension and Withdrawal of Class

Section 1 Assignment of Class

1 General 31

1.1 Criteria
1.2 Confidentiality

2 New building procedure 31

2.1 Ships surveyed by the Society during construction
2.2 Other cases
2.3 Documentation

3 Ships classed after construction 32

3.1 Class admission process and requirements

4 Date of initial classification 33

4.1 Definitions

5 Reassignment of class 34

5.1 Conditions

Section 2 Maintenance of Class

1 Foreword 35

1.1 Terminology

2 General principles of surveys 35

2.1 Survey types
2.2 Change of periodicity, postponement or advance of surveys
2.3 Extension of scope of survey
2.4 General procedure of survey
2.5 Appointment of another Surveyor
2.6 Alterations or additions to approved systems

Table of Content

3	Definitions and procedures related to surveys	36
	3.1 General	
	3.2 Terminology related to hull survey	
	3.3 Procedures for thickness measurements	
	3.4 Agreement for in-water survey	
	3.5 Conditions for surveys	
	3.6 Access to structures	
	3.7 Equipment for surveys	
	3.8 Surveys at sea and anchorage	
	3.9 Repairs and maintenance during voyage	
	3.10 Repairs	
4	Certificate of Classification: issue, validity, endorsement and renewal	40
	4.1 Issue of Certificate of Classification	
	4.2 Validity of Certificate of Classification, maintenance of class	
	4.3 Endorsement of Certificate of Classification	
	4.4 Status of surveys and recommendations	
5	Class renewal survey	41
	5.1 General principles	
	5.2 Normal system	
	5.3 Continuous survey system	
	5.4 Planned maintenance scheme (PMS) for machinery	
	5.5 STAR-MACH survey system	
6	Other periodical surveys	43
	6.1 General	
	6.2 Annual surveys	
	6.3 Intermediate surveys	
	6.4 Ship lightweight and stability check	
	6.5 Bottom survey	
	6.6 Tailshaft survey	
	6.7 Boiler survey	
	6.8 Links between anniversary dates and annual surveys, intermediate surveys and class renewal surveys	
7	Occasional surveys	46
	7.1 General	
	7.2 Damage and repair surveys	
	7.3 Conversions, alterations and repairs	
	7.4 Quality System audits	
8	Change of ownership	47
	8.1	
9	Lay-up and re-commissioning	47
	9.1 General principles	

Section 3 Suspension and Withdrawal of Class

1	General	49
	1.1 Discontinuance of class	
	1.2 Suspension of class	
	1.3 Withdrawal of class	
	1.4 Suspension/withdrawal of additional class notations	

Appendix 1 Planned Maintenance Scheme

1	General	51
	1.1	

Table of Content

2	Conditions and procedures for the approval of the system	51
	2.1 General 2.2 Documentation 2.3 Information on board 2.4 Annual report	
3	Implementation of the system	52
	3.1	
4	Retention and withdrawal of the system	52
	4.1	
5	Surveys	53
	5.1 Implementation survey 5.2 Annual audit 5.3 Damage and repairs	
6	Machinery items surveyed on the basis of condition monitoring	54
	6.1	

Appendix 2 CSM and PMS Systems: Surveys Carried out by the Chief Engineer

1	Conditions	55
	1.1	
2	Limits of the interventions	55
	2.1	
3	Procedure for carrying out surveys	55
	3.1 General 3.2 Main diesel engines 3.3 Auxiliary diesel engines 3.4 Reciprocating compressors 3.5 Coolers, condensers, heaters 3.6 Electrical switchboard 3.7 a.c. and d.c. generators 3.8 Other items (pumps, electric motors, etc.)	
4	Records of surveys carried out	57
	4.1	
5	Confirmatory survey	57
	5.1	
6	Suspension of the Chief Engineer’s authorization	58
	6.1	

Appendix 3 Thickness Measurements: Extent, Determination of Locations, Acceptance Criteria

1	General	59
	1.1 Aim of the Appendix 1.2 Scope of the Appendix	
2	Rule requirements for the extent of measurements	59
	2.1 General 2.2 Class renewal survey	
3	Number and locations of measurements	60
	3.1 General 3.2 Locations of points	

4 Acceptance criteria for thickness measurements 62
4.1 General
4.2 Criteria
4.3 Local and global strength criteria
4.4 Buckling strength criterion
4.5 Pitting

Chapter 3 Scope of Surveys (all ships)

Section 1 Annual Survey

1 General 68
1.1

2 Hull 68
2.1 Hull and hull equipment
2.2 Hatch covers and coamings

3 Machinery and systems 69
3.1 General machinery installations
3.2 Boilers
3.3 Electrical machinery and equipment
3.4 Fire protection, detection and extinction

Section 2 Intermediate Survey

1 General 72
1.1 Application

2 Hull 72
2.1 Surveys and testings

Section 3 Class Renewal Survey

1 General 73
1.1

2 Stability and ship lightweight 73
2.1 Ship lightweight check
2.2 Hull girder deflection
2.3 Stability check

3 Hull and hull equipment 73
3.1 Bottom survey in dry condition
3.2 Decks, hatch covers and equipment
3.3 Dry compartments
3.4 Tanks
3.5 Thickness measurements

4 Machinery and systems 76
4.1 General
4.2 Main and auxiliary engines and turbines
4.3 Reduction gears, main thrust and intermediate shaft(s)
4.4 Pumps and other machinery items
4.5 Systems in machinery spaces
4.6 Electrical equipment and installations
4.7 Controls, commands
4.8 Fire protection, detection and extinction

Table of Content

Section 4 Bottom Survey

1 General 81

1.1 Conditions

2 Bottom survey in dry condition 81

2.1 General requirements
2.2 Bottom survey held within the scope of class renewal survey

3 Bottom in-water survey 81

3.1 General

Section 5 Tailshaft Survey

1 Survey of tailshafts 83

1.1 General
1.2 Complete survey
1.3 Modified survey

2 Periodical survey of other propulsion systems 84

2.1 Rotating and azimuth thrusters
2.2 Vertical axis propellers
2.3 Ventilated propellers
2.4 Pump jet systems

Section 6 Boiler Survey

1 Steam boilers 85

1.1

2 Thermal oil heaters 85

2.1

Appendix 1 Class Requirements and Surveys of Laid-up Ships

1 General 86

1.1

2 Safety conditions 86

2.1

3 Preservation measures for lay-up and maintenance 87

3.1 General
3.2 Exposed parts of the hull
3.3 Internal spaces
3.4 Deck fittings
3.5 Machinery
3.6 Electrical installations
3.7 Steering gear
3.8 Boilers
3.9 Automated installation

4 Lay-up site and mooring arrangements 90

4.1 General
4.2 Recommendations for the lay-up site
4.3 Recommendations for the mooring arrangements
4.4 Review of the mooring arrangements

5 Surveys 91

5.1 Laying-up survey
5.2 Annual lay-up condition survey
5.3 Re-commissioning survey

Chapter 4 Scope of Surveys in Respect of the Different Services of Ships

Section 1 General

1	General	94
	1.1	
2	Service notations subject to additional surveys	94
	2.1	

Section 2 Frigate, Corvette and Military OPV

1	General	95
	1.1	
2	Annual survey	95
	2.1 Watertight bulkheads	
	2.2 Openings in shell plating	
	2.3 Shell and inner doors	
	2.4 Fire protection, detection and extinction	
	2.5 Emergency escapes	
	2.6 Ballast equipment and installation	
3	Class renewal survey	97
	3.1 Stability	
	3.2 Lighting	
	3.3 Shell and inner doors	
	3.4 Fire protection, detection and extinction	

Section 3 Aircraft Carrier

1	General	98
	1.1	
2	Annual survey	98
	2.1 Inner doors	
	2.2 Internal platforms and ramps	
	2.3 Fire protection, detection and extinction	
	2.4 Emergency escapes	
3	Class renewal survey	99
	3.1 Stability	
	3.2 Lighting	
	3.3 Inner doors	
	3.4 Internal platforms and ramps	
	3.5 Fire protection, detection and extinction	

Section 4 Auxiliary Naval Vessel

1	General	101
	1.1 Application	
	1.2 Documentation on board	
	1.3 Reporting and evaluation of surveys	
	1.4 Conditions for survey	
	1.5 Access to structures	
2	Annual survey - Hull items - Liquid cargo area	102
	2.1 Weather decks	
	2.2 Cargo pump rooms and pipe tunnels	
	2.3 Ballast tanks	
	2.4 Safe access to tanker bows	

3	Annual survey - Hull items - Dry cargo area	103

3.1 Watertight bulkheads
3.2 Openings in shell plating
3.3 Shell and inner doors

4	Annual survey - Machinery items - Liquid cargo area	104

4.1 Cargo area and cargo pump rooms
4.2 Instrumentation and safety devices
4.3 Fire-fighting systems in cargo area
4.4 Inert gas system

5	Annual survey - Machinery items - Dry cargo area	106

5.1 Fire protection, detection and extinction
5.2 Emergency escapes
5.3 Ballast equipment and installation

6	Intermediate survey - Hull items	106

6.1 General
6.2 Ships between 5 and 10 years of age
6.3 Ships between 10 and 15 years of age
6.4 Ships over 15 years of age

7	Intermediate survey - Machinery items - Liquid cargo area	107

7.1 Cargo area and cargo pump rooms
7.2 Inert gas system

8	Class renewal survey - Hull items - Liquid cargo area	107

8.1 Survey planning meeting
8.2 Scope of survey
8.3 Overall surveys
8.4 Thickness measurements
8.5 Tank testing
8.6 Cargo piping, area and pump rooms

9	Class renewal survey - Hull items - Dry cargo area	113

9.1 Stability
9.2 Shell and inner doors

10	Class renewal survey - Machinery items - Liquid cargo area	114

10.1 Cargo area and cargo pump rooms
10.2 Fire-fighting systems in cargo area
10.3 Inert gas system

11	Class renewal survey - Machinery items - Dry cargo area	114

11.1 Lighting
11.2 Fire protection, detection and extinction

Section 5 Amphibious Vessel

1	General	115

1.1

2	Annual survey	115

2.1 Shell and inner doors
2.2 Internal platforms and ramps
2.3 Watertight bulkheads
2.4 Openings in shell plating
2.5 Fire protection, detection and extinction
2.6 Means of escape

3 Class renewal survey 117

3.1 Lightweight survey
3.2 Shell and inner doors
3.3 Internal platforms and ramps
3.4 Fire protection, detection and extinction
3.5 Means of escape

Chapter 5 Scope of Surveys Related to Additional Class Notations

Section 1 General

1 General 120

1.1

2 Additional class notations subject to additional surveys 120

2.1

Section 2 Military environment

1 General 122

1.1 Application

2 ARMOUR 122

	2.2 Class renewal survey	

Part A
Classification and Surveys

CHAPTER 1
PRINCIPLES OF CLASSIFICATION AND CLASS NOTATIONS

Section 1 General Principles of Classification

Section 2 Classification Notations

Section 1 General Principles of Classification

1 Principles of classification

1.1 Purpose of the Rules

1.1.1 The Rules published by the Society give the requirements for the assignment and the maintenance of class for seagoing surface naval ships, in particular frigates.

Class assigned to a ship reflects the discretionary opinion of the Society that the ship, for declared conditions of use and within the relevant time frame, complies with the Rules applicable at the time the service is rendered. Class requirements can be temporarily suspended under emergency conditions (war, terrorist attack,...) declared by the Naval Authority.

Note 1: The general conditions of classification are laid down in the Preamble.

1.1.2 The application criteria of the different parts of the present Rules are the following:

- Part A - Classification and Surveys applies to all ships.
- Part B - Hull and Stability, Part C - Machinery, Systems and Fire Protection, Part D - Service Notations and NR216 - Materials and Welding apply to seagoing ships whose hull is of welded steel construction. Where necessary, the extent of application is more precisely defined in each chapter of these parts of the Rules.
- Part E - Additional Class Notations applies, at the request of the Interested Party, to all ships.

The classification of ships other than those dealt with in the above-mentioned Part B, Part C, Part D, Part E and NR216 is covered by specific Rules published by the Society.

1.2 General definitions

1.2.1 The following general definitions are used in these Rules :

- Society means the Classification Society with which the ship is classed.
- Rules means these Rules for the Classification of Ships and documents issued by the Society serving the same purpose.
- Surveyor means technical staff acting on behalf of the Society to perform tasks in relation to classification and survey duties.
- Survey means an intervention by the Surveyor for assignment or maintenance of class as defined in Part A, Chapter 2, or interventions by the Surveyor within the limits of the tasks delegated by the Naval Authorities.
- Interested Party means a party, other than the Society, having responsibility for the classification of the ship, such as the Owner of the ship and his representatives, or the Shipbuilder, or the Engine Builder, or the Supplier of parts to be tested.
- Navy means the Governmental Body to whom the State or the Defence Department of the State has delegated responsibility for ownership of naval ships. The Navy is responsible for the requirement, procurement and through life support and maintenance of the naval ship.
- Naval Authority means the authority nominated by the Navy responsible for providing regulation associated with procurement and support of the ship. The Naval Authority may also be responsible for identifying appropriate standards, auditing and classification. The Naval Authority could be a Navy department, Statutory Authority or an independent organization with appropriate standing.
- Owner means the party having the responsibility to keep the ship seaworthy, having particular regard to the provisions relating to the maintenance of class laid down in Part A, Chapter 2.
- Shipbuilder means the party having the responsibility of the construction of the ship and of her classification at the assignment phase.
- Approval means the examination and acceptance by the Society of documents, procedures or other items related to classification, verifying solely their compliance with the relevant Rules requirements, or other referentials where requested.
- Type approval means an approval process for verifying compliance with the Rules of a product, a group of products or a system, and considered by the Society as representative of continuous production.
- Essential service is intended to mean a service necessary for a ship to proceed at sea, be steered or manoeuvred, or undertake activities connected with its operation, and for the safety of life, as far as class is concerned.
- The gross tonnage (GT) is the measure of the overall size of a ship as determined in accordance with the provisions of the 1969 International Convention on Tonnage Measurement of Ships. It is expressed as a figure without units.

1.3 Meaning of classification, scope and limits

1.3.1 The classification consists of:

- the development of Rules, guidance notes and other documents relevant to the ship, structure, material, equipment, machinery and any other item covered by such documents

- the examination of plans and calculations and the surveys, checks and tests intended to ensure that the ship meets the Rules (refer to Ch 2, Sec 1)
- the assignment of class (see Ch 2, Sec 1) and issue of a Certificate of Classification, where the above Rules are met
- the periodical, occasional and class renewal surveys performed to verify that the ship in service meets the conditions for maintenance of class (see Ch 2, Sec 2).

1.3.2 The Rules, surveys performed, reports, certificates and other documents issued by the Society, are in no way intended to replace or alleviate the duties and responsibilities of other parties such as Navy, Naval Authority, Designers, Shipbuilders, Manufacturers, Repairers, Suppliers, Contractors or Sub-contractors, actual or prospective Owners or Operators, Charterers, Brokers, Cargo-owners and Underwriters. The Society cannot therefore assume the obligations arising from these functions, even when the Society is consulted to answer inquiries concerning matters not covered by its Rules, or other documents.

The activities of such parties which fall outside the scope of the classification as set out in the Rules, such as design, engineering, manufacturing, operating alternatives, choice of type and power of machinery and equipment, number and qualification of crew or operating personnel, lines of the ship, trim, hull vibrations, spare parts including their number, location and fastening arrangements, life-saving appliances, and maintenance equipment, remain therefore the responsibility of those parties, even if these matters may be given consideration for classification according to the type of ship or additional class notation assigned.

The classification-related services and documents performed and issued by the Society do not relieve the parties concerned of their responsibilities or other contractual obligations expressed or implied or of any liability whatsoever, nor do they create any right or claim in relation to the Society with regard to such responsibilities, obligations and liabilities. In particular, the Society does not declare the acceptance or commissioning of a ship or any part of it, this being the exclusive responsibility of the Owner.

1.3.3 Unless otherwise specified, the Rules do not deal with structures, pressure vessels, machinery and equipment which are not permanently installed and used solely for operational activities such as dredging or heavy load lifting, workshops or welding equipment, except for their effect on the classification-related matters, as declared by the Interested Party the Naval Authority or the Owner, such as fire protection and ship's general strength.

During periods of construction, modification or repair, the unit is solely under the responsibility of the builder or the repair yard. As an example, the builder or repair yard is to ensure that the construction, modification or repair activities are compatible with the design strength of the ship and that no permanent deformations are sustained.

Note 1: Refer to [3.3] as regards the Owner's responsibility for maintenance and operation of the ship in relation to the maintenance of class.

1.4 Request for services

1.4.1 Requests for interventions by the Society, such as surveys during construction, surveys of ships in service, tests, etc., are in principle to be submitted in writing and signed by the Interested Party. Such request implies that the applicant will abide by all the relevant requirements of the Rules, including its Preamble.

The Society reserves the right to refuse or withdraw the class of any ship for which any applicable requirement of the Rules is not complied with.

1.5 Register of ship

1.5.1 Except when otherwise stated by the Owner, the Ship is published in the Register of Ships. This publication, which is updated by the Society, contains the names of ships which have received the Certificate of Classification, as well as particulars of the class assigned and non classified information concerning each ship.

Referring the additional notations, only these which publication is authorized by the Owner are mentioned in the Register.

2 Rules

2.1 Effective date

2.1.1 The effective date of entry into force of any amendments to the Rules is indicated on the inside front page of each Part of the Rules.

2.1.2 In principle, the applicable Rules for assignment of class to a new ship are those in force at the date when the contract between the Owner and the shipyard is signed.

2.1.3 Special consideration may be given to applying new or modified rule requirements which entered into force subsequent to the date of the contract, at the discretion of the Society and in the following cases:

- when a justified written request is received from the parties applying for classification
- when the keel is not yet laid and more than one year has elapsed since the contract was signed
- where it is intended to use existing previously approved plans for a new contract.

2.1.4 The above procedures for application of the Rules are, in principle, also applicable to existing ships in the case of major conversions and, in the case of alterations, to the altered parts of the ship.

2.1.5 The rule requirements related to assignment, maintenance and withdrawal of the class of ships already in operation, as detailed in Part A, Chapter 2 to Part A, Chapter 5, are applicable from the date of their entry into force.

2.2 Equivalence

2.2.1 The Society may consider the acceptance of alternatives to these Rules, provided that they are deemed to be equivalent to the Rules to the satisfaction of the Society.

2.2.2 Except when the alternative design and arrangements are:

- already approved by the Society on a ship with similar characteristics and operating conditions, or
- based on novel principles and features as indicated in [2.3.1],

a justificative engineering analysis of the alternative design and arrangements is to be submitted to the Society.

2.2.3 The engineering analysis submitted to the Society shall include, as a minimum, the following elements:

a) determination of the ship type and arrangement concerned

b) identification of the rule requirements with which the ship or the arrangement will not comply

c) identification of the potential hazards of the ship or arrangement concerned

d) identification of the relevant alternative standard or regulations, functional requirements and operating conditions

e) detailed technical description of the proposed alternative design and arrangements

f) technical justification or analysis of previous in service experience on ships of similar characteristics and operating conditions showing that the proposed design and arrangements comply with the alternative standard in d).

2.3 Novel features

2.3.1 The Society may consider the classification of ships based on or applying novel design principles or features, to which the Rules are not directly applicable, on the basis of experiments, calculations or other supporting information provided to the Society. The specific limitations may then be indicated on the Certificate of Classification.

2.4 Interpretation

2.4.1 The Society alone is qualified to decide upon the meaning, interpretation and application of the Rules and other classification-related documents. No reference to the Rules or other classification-related documents has any value unless it involves, accompanies or follows the intervention of the Society.

2.5 Disagreement and appeal

2.5.1 Any technical disagreement with the Surveyor in connection with the performance of his duties should be raised by the Interested Party as soon as possible.

The Interested Party may appeal in writing to the Society, which will subsequently consider the matter and announce its decision according to its established procedure.

3 Duties of the Interested Parties

3.1 International and national regulations

3.1.1 The classification of a ship does not absolve the Interested Party from compliance with any requirements issued by the Naval Authority.

3.1.2 When authorized by the Naval Authority concerned, the Society will act on its behalf within the limits of such authorization. In this respect, the Society will take into account the relevant requirements, survey the ship, report and issue or contribute to the issue of the corresponding certificates.

The above surveys do not fall within the scope of the classification of ships, even though their scope may overlap in part and may be carried out concurrently with surveys for assignment or maintenance of class.

3.2 Surveyor's intervention

3.2.1 Except for secrecy or operational restrictions, Surveyors are to be given free access at all times to ships in service which are classed or being classed, shipyards and works, to carry out their interventions within the scope of assignment or maintenance of class, or within the scope of interventions carried out on behalf of the Naval Authority, when so delegated.

3.2.2 Interested Parties are to take the necessary measures for the Surveyors' inspections and testing to be carried out safely. Interested Parties - irrespective of the nature of the service provided by the Surveyors of the Society or others acting on its behalf - assume with respect to such Surveyors all the responsibility of an employer for his workforce such as to meet the provisions of applicable legislation. As a rule, the Surveyor is to be constantly accompanied during surveys by personnel of the Interested Party.

Refer also to Ch 2, Sec 2, [2.5].

3.2.3 The Certificate of Classification and/or other documents issued by the Society remain the property of the Society. All certificates and documents necessary to the Surveyor's interventions are to be made available by the Interested Party to the Surveyor on request.

3.2.4 During the phases of ship design and construction, due consideration should be given to rule requirements in respect of all necessary arrangements for access to spaces and structures with a view to carrying out class surveys. Arrangements of a special nature are to be brought to the attention of the Society.

3.3 Operation and maintenance of ships

3.3.1 The classification of a ship is based on the understanding that the ship is loaded and operated in a proper manner by competent and qualified crew or operating personnel according to the loading, environmental, operating and other criteria on which classification is based.

In particular, it will be assumed that the draught maximum displacement of the ship in operating conditions will not exceed the maximum approved for the classification, that the ship will be properly loaded taking into account both its stability and the stresses imposed on its structures and that cargoes will be properly stowed and suitably secured and that the speed and course of the ship are adapted to the prevailing sea and weather conditions, and that the ship is operated in accordance with the applicable international and national regulations for the prevention and containment of marine pollution.

3.3.2 Any document issued by the Society in relation to its interventions reflects the condition of the ship as found at the time and within the scope of the survey. It is the Owner's responsibility to ensure proper maintenance of the ship until the next survey required by the Rules. It is the duty of the Owner to inform the Surveyor when he boards the ship of any events or circumstances affecting the class.

3.4 Use of measuring equipment and of service suppliers

3.4.1 General

Firms providing services on behalf of the Interested Party, such as measurements, tests and servicing of safety systems and equipment, the results of which may form the basis for the Surveyor's decisions, are subject to the acceptance of the Society, as deemed necessary.

The equipment used during tests and inspections in workshops, shipyards and on board ships, the results of which may form the basis for the Surveyor's decisions, is to be customary for the checks to be performed. Firms are to individually identify and calibrate to a recognized national or international standard each piece of such equipment.

3.4.2 Simple measuring equipment

The Surveyor may accept simple measuring equipment (e.g. rulers, tape measures, weld gauges, micrometers) without individual identification or confirmation of calibration, provided it is of standard commercial design, properly maintained and periodically compared with other similar equipment or test pieces.

3.4.3 Shipboard measuring equipment

The Surveyor may accept measuring equipment fitted on board a ship (e.g. pressure, temperature or rpm gauges and meters) and used in examination of shipboard machinery and/or equipment based either on calibration records or comparison of readings with multiple instruments.

3.4.4 Other equipment

The Surveyor may request evidence that other equipment (e.g. tensile test machines, ultrasonic thickness measurement equipment, etc.) is calibrated to a recognized national or international standard.

3.5 Spare parts

3.5.1 It is the Owner's responsibility to decide whether and which spare parts are to be carried on board.

3.5.2 As spare parts are outside the scope of classification, the Surveyor will not check that they are kept on board, maintained in a satisfactory condition, or suitably protected and lashed.

However, in the case of repairs or replacement, the spare parts used are to meet the requirements of the Rules as far as practicable; refer to Ch 2, Sec 2, [7.3.2].

Section 2 Classification Notations

1 General

1.1 Purpose of the classification notations

1.1.1 The classification notations give the scope according to which the class of the ship has been based and refer to the specific rule requirements which are to be complied with for their assignment. In particular, the classification notations are assigned according to the type, service and navigation of the ship and other criteria which have been provided by the Interested Party, when applying for classification.

The Society may change the classification notations at any time, when the information available shows that the requested or already assigned notations are not suitable for the intended service, navigation and any other criteria taken into account for classification.

Note 1: Reference should be made to Ch 1, Sec 1, [1.3] on the limits of classification and its meaning.

1.1.2 The classification notations assigned to a ship are indicated on the Certificate of Classification.

1.2 Types of notations assigned

1.2.1 The types of classification notations assigned to a ship are the following:

a) main class symbol

b) construction marks

c) service notations with additional service features, as applicable

d) navigation notations

e) additional class notations (optional).

The different classification notations and their conditions of assignment are listed in [2] to [6], according to their types.

1.2.2 As an example, the classification notations assigned to a ship may be as follows (the kind of notation shown in brackets does not form part of the classification notation indicated the Certificate of Classification:

I ✠ HULL • MACH

(main class symbol, construction marks)

frigate

(service notation)

unrestricted navigation

(navigation notation)

✠ AUT-CCS

(additional class notation).

2 Main class symbol

2.1 Main class symbol

2.1.1 The main class symbol expresses the degree of compliance of the ship with the rule requirements as regards its construction and maintenance. There is one main class symbol, which is compulsory for every classed ship.

2.1.2 The main class symbol **I** is assigned to ships built in accordance with the requirements of the Rules or other rules recognized as equivalent, and maintained in a condition considered satisfactory by the Society. The period of class (or interval between class renewal surveys) assigned to a ship is maximum 5 years; see Ch 2, Sec 2, [5].

Except for special cases, class is assigned to a ship only when the hull, propulsion and auxiliary machinery installations, and equipment providing essential services have all been reviewed in relation to the requirements of the Rules.

2.1.3 The class symbol **II** is assigned to ships which do not meet all requirements for class symbol **I**, but are deemed acceptable to be entered into the Register of Ships.

The period of class assigned to class symbol **II** ships is maximum 3 years, see Ch 2, Sec 2, [5].

3 Construction marks

3.1 General

3.1.1 The construction mark identifies the procedure under which the ship and its main equipment or arrangements have been surveyed for initial assignment of the class. The procedures under which the ship is assigned one of the construction marks are detailed in Ch 2, Sec 1.

3.1.2 One of the construction marks defined below is assigned separately to the hull of the ship and its appendages, to the machinery installation, and to some installations for which an additional classification notation (see [6] below) is assigned.

The construction mark is placed before the symbol **HULL** for the hull, before the symbol **MACH** for the machinery installations, and before the additional class notation granted, when such a notation is eligible for a construction mark.

When the same construction mark is assigned to both hull and machinery, the construction mark is assigned globally to the ship without indication **HULL** and **MACH** after the main class symbol.

If the ship has no machinery installations covered by classification, the symbol **MACH** is not granted and the construction mark will be placed before the symbol **HULL**.

3.1.3 The construction marks refer to the original condition of the ship. However, the Society may change the construction mark where the ship is subjected to repairs, conversion or alterations.

3.2 List of construction marks

3.2.1 The mark ✠ is assigned to the relevant part of the ship, when it has been surveyed by the Society during its construction in compliance with the new building procedure detailed in Ch 2, Sec 1, [2.1].

3.2.2 The mark • is assigned to the relevant part of the ship, where the procedure for the assignment of classification is other than those detailed in [3.2.1], but however deemed acceptable.

4 Service notations

4.1 General

4.1.1 The service notations define the type and/or service of the ship which have been considered for its classification, according to the request for classification signed by the Interested Party. At least one service notation is to be assigned to every classed ship.

4.1.2 The assignment of any service notation to a new ship is subject to compliance with general rule requirements laid down in Part B and Part C of the Rules, in NR216 Materials and Welding and, for some service notations, in the additional requirements laid down in Part D.

4.1.3 A ship may be assigned several different service notations. In such case, the specific rule requirements applicable to each service notation are to be complied with. However, if there is any conflict in the application of the requirements applicable to different service notations, the Society reserves the right to apply the most appropriate requirements or to refuse the assignment of one of the requested service notations.

4.1.4 A service notation may be completed by one or more additional service features, giving further precision regarding the type of service of the ship, for which specific rule requirements are applied.

4.1.5 The different service notations which may be assigned to a ship are listed in [4.2] to [4.10].

4.2 Frigate

4.2.1 The service notation **frigate** is assigned to ships designed for world wide operations and used either as centres of command or as a part of a task force or as an independent unit. They may have a variety of roles as air defence, anti submarine, sea defence or shore support.

They typically have displacement of more than 2000 tonnes, a length of more than 90 meters and comply with severe requirements.

The additional requirements of Ch 4, Sec 2 and Part D, Chapter 1 are applicable to these ships.

4.3 Aircraft carrier

4.3.1 The service notation **aircraft carrier** is assigned to ships designed for world wide operations and used either as centres of command or as a part of a task force or as an independent unit. They have the role of supporting aircraft operations at sea, with the capability to launch, recover and accommodate airplanes, unmanned aerial vehicles and helicopters.

They typically have displacement in excess of 20 000 tonnes, a length of more than 170 meters and comply with severe requirements.

The additional requirements of Ch 4, Sec 3 and Part D, Chapter 2 are applicable to these ships.

4.4 Corvette

4.4.1 The service notation **corvette** is assigned to ships designed for worldwide operations and used either as part of a task force or as an independent unit. They may have a variety of roles as anti-air, anti-submarine and sea defence and they generally have a helicopter capability.

They typically have displacement between 1000 and 2500 tonnes, a length between 60 and 90 meters and a maximum speed of more than 25 knots.

The additional requirements of Ch 4, Sec 2 and Part D, Chapter 3 are applicable to these ships.

4.5 Auxiliary naval vessel

4.5.1 The service notation **auxiliary naval vessel** is assigned to ships designed for world wide operations and are intended for underway replenishment vessels and fleet support vessels which carry and may transfer at sea oil, and possibly other solid and liquid supplies, like freshwater, stores, spare parts and ammunition.

The additional requirements of Ch 4, Sec 4 and Part D, Chapter 4, are applicable to these ships.

4.6 Amphibious vessel

4.6.1 The service notation **amphibious vessel** is assigned to ships designed for world wide operations and used either as centres of command, or as a part of a task force, or as an independent unit. They have the role of supporting helicopter and landing craft operations together with the transport of troops and vehicles.

They typically have a displacement in excess of 20 000 tonnes but smaller units can also be considered for this service notation.

The additional requirements of Ch 4, Sec 5 and Part D, Chapter 5 are applicable to these ships.

4.7 Military OPV

4.7.1 The service notation **military OPV** is assigned to ships dedicated to patrol and combat missions, serving as an independent unit, possessing a weapons system and generally having no operational limits based on weather conditions or sea state.

They have a variety of roles such as protection of the Economic Exclusive Zone, defense against terrorist attacks and other surveillance duties. These vessels patrol at either low or high speed.

The additional requirements of Ch 4, Sec 2 and Part D, Chapter 6 are applicable to these ships.

4.8 Landing craft

4.8.1 The service notation **landing craft** is assigned to craft designed for delivering troops and equipment ashore and restricted to vessels that can be docked in an amphibious mothership (length <60m).

They typically have a versatile deck structure to accommodate a range of vehicles and other loads. They are usually equipped with loading / unloading ramps, have structure reinforced for beaching loads and have mooring and towing capability.

The notation **landing craft** is completed by **-MOTHERSHIP (name of mother ship class)** when the mothership is already known and the limits for overall dimensions of the landing craft are mentioned inside the request for classification.

Note 1: Navigation notations to be assigned to landing craft are restricted to **coastal area** or **sheltered area**.

The requirements of Part D, Chapter 7 are applicable to these ships.

4.9 Unmanned Surface Vessel (USV)

4.9.1 The service notation **USV** is assigned to unmanned surface units.

The type of service is to be specified after the service notation.

Example: **USV / minehunter**.

The scope of application and the requirements for the assignment of the service notation **USV** are given in NR681 Unmanned Surface Vessels.

4.10 Special service

4.10.1 The service notation **special service** is assigned to naval ships for which, by reason of their design or mission, the granting of a specific service notation mentioned in Part D is not considered relevant, but where NR483 can nevertheless be applied.

Specific Rules of the Society and in particular the Rules for the Classification of Steel Ships (NR467) may also be applied to these ships.

An additional service feature may be specified after the notation (e.g. **special service - hospital vessel**) to identify the particular service the ship is intended for. The scope and criteria of classification of such units are indicated in a memoranda.

5 Navigation notations

5.1 Navigation notations

5.1.1 Every classed ship is to be assigned one navigation notation as listed in [5.2].

5.1.2 The assignment of a navigation notation, including the reduction of scantlings or specific arrangements for restricted navigation notations, is subject to compliance with the requirements laid down in Part B, Part C and Part D of the Rules and in NR216 Materials and Welding.

5.1.3 The assignment of a navigation notation does not absolve the Interested Party from compliance with any international and national regulations established by the Naval Authority for a ship operating in national waters, or a specific area, or a navigation zone. Neither does it waive the requirements in Ch 1, Sec 1, [3.3.1].

5.2 List of navigation notations

5.2.1 The navigation notation **unrestricted navigation** is assigned to a ship intended to operate in any area and any period of the year.

5.2.2 The navigation notations **coastal area** or **sheltered area** are only assigned to ships with the service notation **landing craft** as defined in [4.8].

The navigation notation **coastal area** is assigned to ships intended to operate only within 20 nautical miles from the shore and with a maximum sailing time of six hours from a place of refuge, including a mother ship, or a safe sheltered anchorage.

The navigation notation **sheltered area** is assigned to ships intended to operate in sheltered waters, i.e. harbours, estuaries, roadsteads, bays, lagoons and generally calm stretches of water and when the wind force does not exceed 6 Beaufort scale.

6 Additional class notations

6.1 General

6.1.1 An additional class notation expresses the classification of additional equipment or specific arrangement, which has been requested by the Owner.

6.1.2 The assignment of such an additional class notation is subject to the compliance with additional rule requirements, which are detailed in Part E of the Rules.

6.1.3 Some additional class notations, due to the importance of relevant equipment or arrangements, are assigned a construction mark, according to the principles given in [3.1.2]. This is indicated in the definition of the relevant additional class notations.

6.1.4 The different additional class notations which may be assigned to a ship are listed in [6.2] to [6.15], according to the category to which they belong. These additional class notations are also listed in alphabetical order in Tab 1.

Additional class notations from other Bureau Veritas Rules, such as NR467 Rules for the Classification of Steel Ships for example, can also be applied to Naval ships subject to specific agreement of the Society on case by case basis.

Table 1 : List of additional class notations

Additional class notation	Reference for definition	Reference in NR483 or to other Rule Notes	Remarks
ALM **(ALM)** **ALM-EN** **ALM-SUBSEA** **ALP** **(ALP)**	[6.15]	NR526	**ALP**, **ALM**, **ALM-EN** and A**LM-SUBSEA** may be completed by **-MR** **(1)**
ARMOUR	[6.2.1]	Pt E, Ch 1, Sec 1	
AUT-QAS	[6.5.2]	Pt E, Ch 4, Sec 1	**(1)**
AUT-PORT	[6.5.3]	Pt E, Ch 4, Sec 2	**(1)**
AUT-IAS	[6.5.4]	Pt E, Ch 4, Sec 3	**(1)**
AVM-APM	[6.4.2]	Pt E, Ch 3, Sec 1	**(1)**
AVM-DPS	[6.4.3]	Pt E, Ch 3, Sec 2	**(1)**

(1) A construction mark is added to this notation.
(2) This notation may be completed by the suffix **-IMO**, **-MIL** (see [6.12.1])

Additional class notation	Reference for definition	Reference in NR483 or to other Rule Notes	Remarks
AVM-IPSx-(V)	[6.4.4]	Pt E, Ch 3, Sec 3	
AWT	[6.10.4]	Part E, Chapter 7	
BWE	[6.10.5]	Part E, Chapter 7	
BWT	[6.10.6]	Part E, Chapter 7	
CBRN **CBRN-AIR BLAST RESISTANCE**	[6.11.1]	Part E, Chapter 8	
CLEANSHIP **CLEANSHIP SUPER ( )**	[6.10.2] [6.10.3]	Part E, Chapter 7	between brackets, at least 3 eligible notations are to be assigned among the following ones: **AWT**, **BWT**, **GWT**, **HVSC**, **NDO -x days**, **NOX-x%**, **OWS-x ppm**, **SOX-x%**
COMF-NOISE	[6.8.2]	Pt E, Ch 6, Sec 2	
COMF-VIB	[6.8.3]	Pt E, Ch 6, Sec 3	
FFS	[6.2.4]	Pt E, Ch 1, Sec 4	
FIRE()	[6.13.3]	Pt E, Ch 10, Sec 3	The additional class notation **FIRE()** is to be completed, between brackets, by one, more or all of the following notations: **F**, **T**, **S**
GWT	[6.10.7]	Part E, Chapter 7	
HELICOPTER	[6.15.2]	Pt E, Ch 11, Sec 2	
INTERNAL CONNECTIVITY	[6.15.4]	NR688	
INWATERSURVEY	[6.15.1]	Pt E, Ch 11, Sec 1	
LSA	[6.13.1]	Pt E, Ch 10, Sec 1	
MANOVR	[6.12.1]	Pt E, Ch 9, Sec 1	**(2)**
MON-HULL	[6.7.2]	Pt E, Ch 5, Sec 1	
MON-SHAFT	[6.7.3]	Pt E, Ch 5, Sec 2	
NDO-x days	[6.10.8]	Part E, Chapter 7	
NOX-x%	[6.10.9]	Part E, Chapter 7	
NSC **NSC()**	[6.15.3]	–	When partial compliance with the Naval Ship Code, the list of the chapters complied with is indicated between brackets
OWS-x ppm	[6.10.10]	Part E, Chapter 7	
REF-STORE	[6.9.1]	Pt E, Ch 11, Sec 3	**(1)**
RS-P	[6.2.3]	Pt E, Ch 1, Sec 3	
SEA-KEEP	[6.12.3]	Pt E, Ch 9, Sec 3	To be completed by notations for the capabilities assessed along with their limiting sea states, amongst the notations listed in Tab 2
SHOCK **SHOCK STRENGTH** **SHOCK EQUIPMENT**	[6.2.2]	Pt E, Ch 1, Sec 2	
SOX-x%	[6.10.11]	Part E, Chapter 7	as an alternative, equivalent arrangements (e.g. exhaust gas cleaning systems) may be accepted
STAR	[6.3.4]	Part E, Chapter 2	This cumulative notation supersedes the notations **STAR-HULL** and **STAR-MACH**, when both are assigned **(1)**
STAR-HULL	[6.3.2]	Pt E, Ch 2, Sec 1	**(1)(2)**
STAR-MACH	[6.3.3]	Pt E, Ch 2, Sec 2	**(1)**
STAR-MACH-PMS	[6.3.3]	Pt E, Ch 2, Sec 2	
SYS-NEQ **SYS-NEQ-1**	[6.6.1]	Pt E, Ch 11, Sec 4	**(1)**
TOW	[6.13.2]	Pt E, Ch 10, Sec 2	
VLS	[6.12.2]	Pt E, Ch 9, Sec 2	Restricted to auxiliary naval vessels

(1) A construction mark is added to this notation.
(2) This notation may be completed by the suffix **-IMO**, **-MIL** (see [6.12.1])

6.2 Military environment

6.2.1 ARMOUR

The additional class notation **ARMOUR** is assigned to ships fitted with a protection by armour, when the requirements of Pt E, Ch 1, Sec 1, [2] to Pt E, Ch 1, Sec 1, [4] are complied with.

The requirements for the assignment and maintenance of this notation are provided in Pt E, Ch 1, Sec 1 and Ch 5, Sec 2, [2] respectively.

According to Ch 1, Sec 1, [1.5.1], this additional class notation is mentioned in the Register only after the Owner has authorized the publication. When this notation is not mentioned in the Register, an attestation is issued by the Society.

6.2.2 SHOCK

The following additional class notations are assigned to ship for which shock-resistance capability measures are taken:

- The additional class notation **SHOCK STRENGTH** is granted to ship for which measures are taken to increase their survivability following threat damage to the structures from an assigned underwater non-contact explosion in compliance with the requirements of Pt E, Ch 1, Sec 2.
- The additional class notation **SHOCK EQUIPMENT** is granted to ship for which a list of specified pieces of equipment have been satisfactorily shock tested and subsequently fulfill the shock resilience criteria specified by the Naval Authority for the applicable design shock level in compliance with the requirements of Pt E, Ch 1, Sec 2.
- The additional class notation **SHOCK** is granted to ship for which hull strength and equipment are in compliance with both notations **SHOCK STRENGTH** and **SHOCK EQUIPMENT**.

6.2.3 Residual strength (RS-P)

The additional class notation **RS-P** is assigned to ships for which the residual hull girder ultimate strength under damage condition is evaluated according to minimum hull damage scenari and rule wave hull girder loads.

The requirements for the assignment of this notation are provided in Pt E, Ch 1, Sec 3.

6.2.4 Flooding fighting systems (FFS)

The additional notation **FFS** is assigned to ship fitted with pumping facilities able to cope with the ingress of a great amount of water resulting from a hull damage or a sea water pipe break.

The requirements for the assignment and maintenance of this notation are given Pt E, Ch 1, Sec 4 and in Ch 5, Sec 2, [3] respectively.

6.3 System of Trace and Analysis of Records (STAR)

6.3.1 General

STAR is a System of Trace and Analysis of Records integrating rational analysis with data and records from ship-in-service concerning planned inspection and ship maintenance.

In compliance with [6.1.3], these notations are assigned a construction mark, as defined in Article [3].

The requirements for the assignment of these notations are given in Part E, Chapter 2.

6.3.2 STAR-HULL

The additional class notation **STAR-HULL** is assigned to ships on which an Inspection and Maintenance Plan (IMP) for the hull is implemented.

The notation may be completed by the suffix **NB** when a structural tridimensional analysis has been performed for the hull structures, as defined in Pt B, Ch 7, App 1 or Pt B, Ch 7, App 2 or Pt B, Ch 7, App 3, as applicable, at the new building stage. The suffix **NB** is removed when the ship enters the **STAR-HULL** survey programme through the implementation of the Inspection and Maintenance Plan (IMP).

6.3.3 STAR-MACH

The additional class notation **STAR-MACH** is assigned to ships on which an Inspection and Maintenance Plan (IMP) for the machinery is implemented. This plan is based on a risk analysis review of the installation.

Where only a Planned Maintenance Scheme approved by the Society is implemented, the additional class notation **STAR-MACH-PMS** is assigned.

6.3.4 STAR notation (STAR)

When ships are granted both **STAR-HULL** and **STAR-MACH**, the two separate notations are superseded by the cumulative additional class notation **STAR**.

6.4 Availability of machinery (AVM)

6.4.1 General

The notations dealt with under this heading are relevant to systems and/or arrangements enabling the ship to carry on limited operations when single failure affects propulsion or auxiliary machinery or when an external event such as fire or flooding involving machinery spaces affects the availability of the machinery.

In compliance with [6.1.3], these notations are assigned a construction mark, as defined in Article [3].

The requirements for the assignment of these notations are given in Part E, Chapter 3.

6.4.2 AVM-APM (Alternative propulsion mode)

The additional class notation **AVM-APM** is assigned to ships which are fitted with systems and/or arrangements enabling them to maintain operating conditions during the normal service with some limitations in speed, range and comfort, in the case of any single failure of items relative to the propulsion or power generating system.

The limitations in operation and the types of single failure covered by this notation are specified in Pt E, Ch 3, Sec 1.

6.4.3 AVM-DPS (Duplicated propulsion system)

The additional class notation **AVM-DPS** is assigned to ships which are fitted with a duplicated propulsion system enabling them to maintain operating conditions with some limitations in power (but 50% of the main power necessary for nominal speed, booster not included is to be maintained), speed, range and comfort, in the case of any single failure of items relative to the propulsion or power generating system.

The loss of one compartment due to fire or flooding is not considered as a single failure case.

The limitations in operation and the types of failure which are covered by this notation are specified in Pt E, Ch 3, Sec 2.

6.4.4 AVM-IPSx-(V) Independent propulsion system

The additional class notation **AVM-IPSx-(V)** is assigned to ships which are fitted with an independent propulsion system enabling them to maintain operating conditions with some limitations in power (but 50% of the main power is to be maintained), speed, range and comfort, in the case of single failure of items relative to the propulsion or power generating system, where x indicates the number of flooded compartments and V the minimum speed in case of single failure.

The limitations in operation and the types of failure which are covered by this notation are specified in Pt E, Ch 3, Sec 3, [1.2].

Note 1: The loss of one compartment due to fire or flooding is considered as a single failure case.

6.5 Automated machinery systems (AUT)

6.5.1 General

The notations dealt with under this heading are relevant to automated machinery systems installed on board ships.

In compliance with [6.1.3], these notations are assigned a construction mark, as defined in Article [3].

The requirements for the assignment of these notations are given in Part E, Chapter 4.

6.5.2 Unattended machinery space (AUT-QAS)

The additional class notation **AUT-QAS** is assigned to ships which are fitted with automated installations enabling machinery spaces to remain periodically unattended in all sailing conditions including manoeuvring.

6.5.3 Automated operation in port (AUT-PORT)

The additional class notation **AUT-PORT** is assigned to ships which are fitted with automated installations enabling the ship’s operation in port or at anchor without personnel specially assigned for the watch-keeping of the machinery in service.

6.5.4 Integrated machinery system (AUT-IAS)

The additional class notation **AUT-IAS** is assigned to ships fitted with automated installations enabling periodically unattended operation of machinery spaces and additionally with integrated systems for the control and monitoring of platform systems.

6.6 Integrated and digital systems

6.6.1 Centralised navigation equipment (SYS-NEQ)

The additional class notation **SYS-NEQ** is assigned to ships fitted with a centralized navigation control system so laid out and arranged that it enables normal navigation and manoeuvring operation of the ship by two persons in cooperation.

The additional class notation **SYS-NEQ-1** is assigned when, in addition, the installation is so arranged that the navigation and manoeuvring of the ship can be operated under normal conditions by one person for periodical one man watches. This notation includes specific requirements for prevention of accidents caused by the operator’s unfitness.

The requirements for the assignment of these notations are provided in Pt E, Ch 11, Sec 4.

6.7 Monitoring equipment (MON)

6.7.1 General

The notations dealt with under this heading are relevant to hull and tailshaft monitoring equipment installed on board ships.

The requirements for the assignment of these notations are given in Part E, Chapter 5.

6.7.2 Hull stress monitoring (MON-HULL)

The additional class notation **MON-HULL** is assigned to ships which are fitted with equipment continuously monitoring ship's dynamic loads through measurements of motions in waves and stresses/deformations in the hull structure.

The notation may be completed by the suffix **+S** if the measurements are stored for further exploitation by the Owner.

6.7.3 Tailshaft monitoring system (MON-SHAFT)

The additional class notation **MON-SHAFT** is assigned to ships which are fitted with a temperature monitoring system for the tailshaft sterntube aft bearing. The assignment of this notation allows the ship to be granted a reduced scope for complete tailshaft surveys, see Ch 2, Sec 2, [6.6.4].

6.8 Comfort on board (COMF)

6.8.1 General

The notations dealt with under this heading are relevant to the assessment of comfort on board ships with regard to the noise and/or vibration.

The parameters which are taken into consideration for the evaluation of the comfort, such as the level of noise, the level of vibration, is indicated in a memoranda.

The requirements for the assignment and maintenance of these notations are given in Part E, Chapter 6.

6.8.2 Comfort with regard to noise (COMF-NOISE)

The additional class notation **COMF-NOISE** is assigned to ships satisfying levels of noise defined in Pt E, Ch 6, Sec 2. The assessment of noise levels is only carried out through design review and sea trials.

6.8.3 Comfort with regard to vibration (COMF-VIB)

The additional class notation **COMF-VIB** is assigned to ships satisfying levels of vibration defined in Pt E, Ch 6, Sec 3. The assessment of vibration levels is only carried out through design review and sea trials.

6.9 Refrigerating installations

6.9.1 Refrigerating installations for domestic supply (REF-STORE)

The additional class notation **REF-STORE** is assigned to ships fitted with refrigerating plants and spaces exclusively intended for the preservation of ship's domestic supply.

The requirements for the assignment of this notation is given in Pt E, Ch 11, Sec 3.

6.10 Environmental protection

6.10.1 General

The notations dealt with under this heading are assigned to ships fitted with equipment and arrangements enabling them to control and limit the emission of polluting substances in the sea and the air.

The requirements for the assignment of these notations are given in Part E, Chapter 7.

6.10.2 Pollution prevention (CLEANSHIP)

The additional class notation **CLEANSHIP** is assigned to ships so designed and equipped as to control and limit the emission of polluting substances in the sea and the air in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 2.

6.10.3 Pollution prevention (CLEANSHIP SUPER)

The additional class notation **CLEANSHIP SUPER** is assigned to ships so designed and equipped as to control and limit the emission of polluting substances in the sea and the air in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 2.

Note 1: At least 3 eligible notations are to be assigned among the following ones:

AWT, **BWT**, **GWT**, **HVSC**, **NDO-x days**, **NOX-x%**, **OWS-x ppm**, **SOX-x%**.

Example:

CLEANSHIP SUPER (AWT, NOX-80%, SOX-60%)

6.10.4 Advanced Wastewater Treatment (AWT)

The additional class notations **AWT** is assigned to ships fitted with an Advanced Wastewater Treatment plant in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 3.

6.10.5 Ballast Water Exchange (BWE)

The additional class notation **BWE** is assigned to ships designed for ballast water exchange complying with the requirements of BWM convention (2004) and in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 3.

6.10.6 Ballast Water Treatment (BWT)

The additional class notation **BWT** is assigned to ships fitted with a Ballast Water Treatment plant in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 3.

6.10.7 Grey Water Treatment (GWT)

The additional class notation **GWT** is assigned to ships fitted with a treatment installation for grey waters in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 3.

6.10.8 No Discharge Operation (NDO-x days)

The additional class notation **NDO-x days** is assigned to ships designed for no discharge operation during x days, in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 3.

Note 1: **x days** is the number of consecutive days the ship is able to operate with the full complement of on-board people, including crew and passengers, without the need for discharging any substances into the sea. This number cannot be less than one day (24 hours).

6.10.9 NOx emissions control (NOX-x%)

The additional class notation **NOX-x%** is assigned to ships for which the average NOx emissions of engines are not to exceed x% of IMO Tier II limit in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 3.

6.10.10 High-performance Oily Water Separator (OWS-x ppm)

The additional class notation **OWS-x ppm** is assigned to ships fitted with an oily water separator producing effluents having a hydrocarbon content not exceeding x ppm (parts per million) in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 3.

6.10.11 SOx emissions control (SOX-x%)

The additional class notation **SOX-x%** is assigned to ships for which the oil fuels used within and outside SECAs have a sulphur content not exceeding x% of the relevant IMO limit in accordance with the provisions of Pt E, Ch 7, Sec 1 and Pt E, Ch 7, Sec 3.

Note 1: As an alternative, equivalent arrangements (e.g. exhaust gas cleaning systems) may be accepted.

6.11 Protection against chemical, biological, radiological or nuclear risks (CBRN)

6.11.1 CBRN protection

The additional class notation **CBRN** may be assigned to ships intended for operations in atmospheres contaminated by chemical, biological or nuclear hazardous material and equipped with a citadel with a collective protection system that protects people inside from contamination thanks to its dedicated ventilating system.

The additional class notation **CBRN-AIR BLAST RESISTANCE** may be assigned to ships which, in addition to the above features, have their collective protection system designed to withstand air blast.

The requirements for the assignment and maintenance of these notations are given respectively in Part E, Chapter 8 and in Ch 5, Sec 10.

6.12 Manoeuvring, stability and sea-keeping

6.12.1 Ship manoeuvrability

The additional class notation **MANOVR** may be assigned to ships complying with manoeuvring capability standards.

The above is completed by the following notations according to the specified performance assured:

- **-IMO**, for performance complying with IMO resolution A.751(18)
- -**MIL**, for performance complying with a higher level of manoeuvring standards.

The requirements for the assignment of this notation are given in Pt E, Ch 9, Sec 1.

6.12.2 VLS

The additional notation **VLS** may be assigned to auxiliary naval vessels, the stability of which is in compliance with military criteria, based on the V-lines method with 2 flooded compartments.

The requirements for the assignment of this notation are provided in Pt E, Ch 9, Sec 2.

6.12.3 SEA-KEEP

The confidential additional class notation **SEA-KEEP** is assigned to ships whose specified performance levels are assured up to a certain sea state, according to criteria given in NATO STANAG 4154 Ed. 4.

The **SEA-KEEP** notation is to be completed between brackets, by at least one of the following notations indicating the type of ship capability for which the sea-keeping performance has been evaluated:

- **FLY** for flight operations
- **RAS** for replenishment at sea
- **WEAP** for weapon systems operations
- **CREW** for crew capability
- **BOAT** for small craft operations.

These notations are to be completed, as applicable, by at least one notation detailing the specific capabilities assessed as given in Tab 2.

The notations detailing the specific capabilities assessed are to be completed by a notation **-X(L,M,H)** where **X** specifies the limiting sea state number and **L**, **M** and **H** further specify the degree of severity (Low, Medium, High) of the sea state considered among those characterized by the number, up to and including which the required sea-keeping performance is maintained.

Note 1: for assessment of crew capability, the limiting sea state notation **-X(L,M,H)** is to be added directly to the notation indicating the type of ship capability (e.g. **CREW-2(M)**)

For example, the additional notation **SEA-KEEP(FLY-CTOL-3(H)-FWAH-1(L)**, **RAS-CONREP-2(M))** is assigned to a ship that can satisfy the flight operation limits for “Conventional Take-Off and Landing” in seas up to and including high sea state 3, the flight operation limits for “Fixed Wing Aircraft Handling” in seas up to and including low sea state 1 and the replenishment at sea limits for “Connected replenishment” in seas up to and including medium sea state 2.

The requirements for the assignment of this notation are given in Pt E, Ch 9, Sec 3.

Table 2 : Additional class notations for sea-keeping assessment

Type of ship capability	Specific capability assessed	Notation **(1)**
Flight operations (**FLY**)	Conventional Take-Off and Landing	**-CTOL**
	Fixed Wing Aircraft Handling	**-FWAH**
	Helicopter and short take-off and vertical landing (STOVL) aircraft launch and recovery	**-HELOL**
	Helicopter and short take-off and vertical landing (STOVL) aircraft handling	**-HELOH**
Replenishment at sea (**RAS**)	Connected replenishment	**-CONREP**
	Fuelling at sea	**-FAS**
	Vertical replenishment	**-VERTREP**
Weapon systems operations (**WEAP**)	Radars	**-R**
	Sonar	**-S**
	Trainable missiles	**-TM**
	Vertical launch systems	**-VM**
	Torpedo systems	**-T**
	Support equipment	**-E**
	Guns	**-G**
Crew **(CREW)**	Crew performance	N.A.
Small craft operations (**BOAT**)	Stern and davit (or side) launch and recovery of small craft	**-DECK**
	Stern ramp launch and recovery of small craft	**-RAMP**

(1) To be completed in each case by the limiting sea state notation **-X(L,M,H)** where **X** indicates the limiting sea state number and one of **L**, **M** and **H** is to be specified to indicate the degree of severity (Low, Medium, High) of the limiting sea state.

Note 1: N.A. = Not applicable. In such cases the limiting sea state notation is assigned directly to the notation indicating the type of ship capability.

6.13 Safety equipment and installations

6.13.1 Life saving appliances (LSA)

The additional class notation **LSA** may be assigned to ships the life-saving equipment of which complies with the applicable provisions of Pt E, Ch 10, Sec 1.

Note 1: It is reminded that, except if **LSA** additional class notation is to be granted, life-saving appliances are out of the scope of classification.

6.13.2 Towing

The additional class notation **TOW** is assigned to ships fitted with towing and emergency towing equipment.

The requirements for the assignment and maintenance of this notation are given in Pt E, Ch 10, Sec 2 and Ch 5, Sec 12, [2] respectively.

6.13.3 Enhanced fire protection (FIRE)

The additional class notation **FIRE** may be assigned to ships provided with enhanced fire protection features. It is always completed between brackets by one, or by a combination, of the following notations:

- **F**, for ships equipped with a sprinkler system in accommodation spaces, service spaces and control stations
- **T**, for ships on which the low flame-spread characteristics of surface materials have been assessed taking into account the layer combination
- **S**, for ships on which fire doors located on smoke extraction paths are planned to be kept open.

Examples:

FIRE(F)

FIRE(T, S)

FIRE(F, T, S)

The requirements for the assignment of these notations are given in Pt E, Ch 10, Sec 3.

Note 1: Ships assigned the additional class notation **FIRE** before 1st November 2023, are to be assigned the additional class notation **FIRE(F)** at the first renewal survey held after 1 November 2023, or before upon request from the Owner.

6.14 Lifting appliances

6.14.1 Ships fitted with lifting appliances meeting the requirements of the NR526 "Rules for the Certification of Lifting Appliances onboard Ships and Offshore Units" may be assigned the following additional class notations:

- **ALP** for lifting appliances intended to be used in harbours or similarly sheltered areas
- **ALM** for lifting appliances intended to be used in offshore conditions.

6.14.2 The additional class notations **(ALP)** or **(ALM)** may be assigned by the Society in lieu of the notations **ALP** or **ALM** respectively, when the corresponding lifting appliances meet the requirements of specific National Regulations under the conditions defined in NR526.

6.14.3 The additional class notation **ALM** may be completed by:

- **-EN**, when lifting appliances are in compliance with additional specific safety requirements as defined in NR526
- **-SUBSEA**, when lifting appliances are intended to be used for lifting of subsea equipment in compliance with some specific requirements.

6.14.4 The additional class notations **ALP**, **ALM**, **ALM-EN** and **ALM-SUBSEA** may be completed by **-MR** when, in addition, lifting appliances are intended to be used for lifting of personnel.

6.14.5 The additional class notations **ALP**, **ALM**, **(ALP)**, **(ALM)**, A**LM-EN** and **ALM-SUBSEA** are optional. However, the Society may require the compliance of lifting appliances with the assigning conditions of one of the above mentioned additional class notations for the classification of ships, when the lifting appliance or appliances are of a primary importance to the operation of the ship.

6.14.6 In compliance with [6.1.3], these notations are assigned a construction mark as defined in Article [3].

6.14.7 The requirements for assignment and maintenance of these notations are given in NR526.

6.15 Other additional class notations

6.15.1 In-water survey

The additional class notation **INWATERSURVEY** may be assigned to ships provided with suitable arrangements to facilitate the in-water surveys as provided in Ch 2, Sec 2, [3.4].

The requirements for the assignment of this notation are given in Pt E, Ch 11, Sec 1.

6.15.2 Helicopter deck

The additional class notation **HELICOPTER** may be assigned to ships provided with a helicopter deck when the requirements of Pt E, Ch 11, Sec 2 are complied with.

The requirements for the assignment and maintenance of this notation are given in Pt E, Ch 11, Sec 2 and Ch 5, Sec 13, [2] respectively.

6.15.3 Naval Ship Code (NSC)

The additional class notation **NSC** is assigned to ships complying with the Naval Ship Code published by NATO as ANEP 77 (Allied Naval Engineering Publication).

When only partial compliance is required, the additional class notation **NSC ()** is to be assigned, indicating between brackets the chapters of the Naval Ship Code that are complied with. Chapters detailing the definitions, the use of the NSC and the certification process are deemed to apply automatically and are not needed to be indicated between brackets.

For example, **NSC (II, VI, VII)** means that Chapters II, VI and VII of the Naval Ship Code have been reviewed for assignment of the notation.

The documents to be submitted for review in order to assign additional class notation **NSC** or **NSC ()** are those required by the relevant chapters of the Naval Ship Code.

When the ship is assigned an additional class notation **NSC** or **NSC ()**, a Naval Ship Safety Certificate, indicating the applicable version of the Code, may be issued by the Society on behalf of the Naval Authority, when delegated.

6.15.4 Internal Connectivity

The additional class notation **INTERNAL CONNECTIVITY** may be assigned to ships for which the on-board network infrastructure enables internal connectivity.

The requirements for the assignment and the maintenance of this notation are given in Rule Note NR688 Internal Connectivity.

Note 1: The scope of the notation is limited to a list of Internal Connectivity Areas (ICAs) to be specified by the applicant. This list of ICAs is to be indicated in a memorandum.

7 Other notations

7.1

7.1.1 The Society may also define other notations by means of provisional requirements and guidelines, which may then be published in the form of tentative rules.

8 Explicit request of the Naval Authority

8.1

8.1.1 Some non compulsory requirements of the Rules are applicable only upon explicit request of the Naval Authority.

Same as for the additional class notations, these requirements are to be listed on the request for classification to be applicable.

Example: see Pt C, Ch 1, Sec 6, Tab 5: Value of K_A.

Part A
Classification and Surveys

CHAPTER 2
ASSIGNMENT, MAINTENANCE, SUSPENSION AND WITHDRAWAL OF CLASS

Section 1	Assignment of Class
Section 2	Maintenance of Class
Section 3	Suspension and Withdrawal of Class
Appendix 1	Planned Maintenance Scheme
Appendix 2	CSM and PMS Systems: Surveys Carried out by the Chief Engineer
Appendix 3	Thickness Measurements: Extent, Determination of Locations, Acceptance Criteria

Section 1 Assignment of Class

1 General

1.1 Criteria

1.1.1 Class is assigned to a ship upon a survey, with the associated operations, which is held in order to verify whether it is eligible to be classed on the basis of the Rules of the Society (see Ch 1, Sec 1, [1.3.1]). This may be achieved through:

- the completion of the new building, during which a survey has been performed
- a specific admission to class survey, in cases where a ship is classed by a recognized Classification Society or is not classed at all.

Special consideration will be given to ships transferring class from another recognized Classification Society who have appropriate Military or Navy Ship Rules.

1.2 Confidentiality

1.2.1 The drawing approval activities and the necessary interventions for the class assignment are performed by authorized persons.

The drawings and documents required for the classification of a ship are dealt with according to the level of confidentiality required by the Owner or Naval Authority.

2 New building procedure

2.1 Ships surveyed by the Society during construction

2.1.1 When a ship is surveyed by the Society during construction, it is to comply with those requirements of the Rules which are in force and applicable depending on the class of the ship, taking into account the provisions of Ch 1, Sec 1, [2.1] and Ch 1, Sec 1, [2.5].

2.1.2 The Society:

- approves the plans and documentation submitted as required by the Rules
- proceeds, if required, with the appraisal of the design of materials and equipment used in the construction of the ship and their inspection at works
- carries out surveys or obtains appropriate evidence to satisfy itself that the scantlings and construction meet the rule requirements in relation to the approved drawings
- attends tests and trials provided for in the Rules
- assigns the construction mark ✠; refer to Ch 1, Sec 2, [3.2.1].

2.1.3 The Society defines in specific Rules which materials and equipment used for the construction of ships built under survey are, as a rule, subject to appraisal of their design and to inspection at works, and according to which particulars.

2.1.4 As part of his interventions during the ship's construction, the Surveyor will:

- conduct an overall examination of the parts of the ship covered by the Rules
- examine the construction methods and procedures when required by the Rules
- check selected items covered by the rule requirements
- attend tests and trials where applicable and deemed necessary.

2.1.5 Use of materials, machinery, appliances and items

As a general rule, all materials, machinery, boilers, auxiliary installations, equipment, items etc. (generally referred to as "products") which are covered by the class and used or fitted on board ships surveyed by the Society during construction are to be new and, where intended for essential services as defined in Ch 1, Sec 1, [1.2.1], tested by the Society.

Second hand materials, machinery, appliances and items may be used subject to the specific agreement of the Society and the Owner.

The requirements for the selection of materials to be used in the construction of the various parts of a ship, the characteristics of products to be used for such parts and the checks required for their acceptance are to be as stated in Part C and NR216 Materials and Welding, as applicable, or in other Parts of the Rules or as specified on approved plans. In particular, the testing of products manufactured according to quality assurance procedures approved by the Society and the approval of such procedures are governed by the requirements of NR216 Materials and Welding, Ch 1, Sec 1, [3] of the Rules.

2.1.6 Defects or deficiencies and their repair

The Society may, at any time, reject items found to be defective or contrary to rule requirements or require supplementary inspections and tests and/or modifications, notwithstanding any previous certificates issued.

All repairs are subject to the preliminary agreement of the Society. When the limits of tolerance for defects are specified in the Rules concerned or by the Manufacturer, they are to be taken into account for repairs.

It is incumbent upon the Interested Party to notify the Society of any defects noted during the construction of the ship and/or of any item not complying with the applicable requirements or in any case unsatisfactory. Proposals regarding remedial actions intended to be adopted to eliminate such defects or unsatisfactory items are to be submitted to the Society and, if accepted, carried out to the Surveyor's satisfaction.

2.1.7 Equivalence of Rule testing under certain conditions

Notwithstanding the provisions of [2.1.4], the Society may, at its discretion and subject to conditions and checks deemed appropriate, accept certain materials, appliances or machinery which have not been subjected to rule testing.

2.2 Other cases

2.2.1 When the procedure adopted does not comply with that detailed in [2.1] but the Society deems that it is acceptable for the assignment of class, the construction mark • is assigned in accordance with Ch 1, Sec 2, [3.2.2].

2.3 Documentation

2.3.1 Documentation relevant to the class applied for is to be submitted for the approval of the Society.

2.3.2 The documentation to be submitted is specified in the relevant chapters of the Rules.

The lists of requested plans, documents and other items related to classification are not exhaustive and are intended as guidance for specifying the set of information to be submitted, rather than lists of actual titles. The Society may require that additional information be submitted if deemed necessary for the verification of rule requirements, especially in the case of non-conventional design.

2.3.3 The documentation submitted to the Society is examined in relation to the class applied for in the request for classification.

Note 1: Should the Interested Party subsequently wish to have the class, in particular the service notation or navigation notation, granted to the ship modified, plans and drawings are generally to be re-examined.

2.3.4 A copy of the submitted plans will be returned duly stamped, with remarks related to the compliance with the rule requirements should the need arise.

2.3.5 As a rule, modifications of the approved plans regarding items covered by classification are to be submitted.

2.3.6 Design data to be submitted to the Society are to incorporate all information necessary for the assessment of the design of the ship for the purpose of assignment of class. It is the responsibility of the Interested Party to ascertain that the design data are correct, complete and compatible with the use of the ship.

2.3.7 Design calculations are to be provided, when called for, as supporting documents to the submitted plans.

2.3.8 Design data and calculations are to be adequately referenced. It is the duty of the Interested Party to ascertain that the references used are correct, complete and applicable to the design of the ship.

2.3.9 The submitted plans are to contain all necessary information for checking the compliance with the requirements of the Rules.

2.3.10 In the case of conflicting information, submitted documentation will be considered in the following order of precedence: design data, plans, design calculations.

2.3.11 It is the responsibility of the Interested Party to ascertain that drawings used for the procurement, construction and other works are in accordance with the approved plans.

2.3.12 Upon specific agreement between the Society and the Interested Parties, three-dimensional models may be submitted in place of two-dimensional plans. In this case, the Society may require that additional documentation containing information that cannot be specified in three-dimensional models be submitted.

3 Ships classed after construction

3.1 Class admission process and requirements

3.1.1 The class of the ship will be assigned upon a preliminary review of the documentation listed in [3.1.3] and subsequent satisfactory completion of the surveys, the extent and scope of which are given below.

3.1.2 Surveys

The extent and scope of the admission to class survey is to be not less than those required at the class renewal survey of a ship of the same age and type; in addition all other periodical surveys should be performed together with those inspections which are linked to specific service notations and/or additional class notations and/or special installations the ship is provided with.

Special consideration will be given to ships transferring class from another recognized Classification Society who have appropriate Military or Navy Ship Rules.

3.1.3 Documentation

As a general rule, the documentation to be supplied to the Society is not to be less than the following.

a) Main plans:
   - general arrangement
   - capacity plan
   - loading cases, calculations of still water bending moments, and relevant documents, particulars of loading calculator and instruction booklet as per Society's requirements, according to the case
   - stability documents, if applicable (refer to Part B, Chapter 3).

b) Hull structure plans:
   - midship section
   - profile and deck plan
   - watertight bulkheads
   - rudder and rudder stock
   - shell expansion
   - hatch covers.

c) Machinery plans:
   - engine room general arrangement
   - diagram of fuel- (transfer, service), bilge-, ballast-, lubricating oil-, cooling-, steam- and feed-, general service and starting compressed air piping
   - diagram of fire-fighting systems
   - drawings of boilers and air receivers
   - drawings of shaft line, reduction gear and propeller
   - drawings of steering gear
   - torsion vibration calculations as per conditions laid down in Pt C, Ch 1, Sec 9. Such documents are required only for ships less than 2 years old or for older ships the propelling system of which has been modified during the two years preceding the classification.

d) Electrical installation plans:
   - master plan of power distribution, lighting and emergency power circuits
   - single line diagram of networks and switchboards
   - location and arrangement of electrical equipment in hazardous areas.

Alternative technical data may be accepted by the Society in lieu of specific items of the listed documentation not available at the time of the transfer of class.

3.1.4 Where appropriate within reasonable limits, a proven service record (log book) of satisfactory performance during a period of adequate length may be used as a criterion of equivalence. Special consideration will be given to ships of recent construction.

3.1.5 For installations or equipment covered by additional service and/or class notations, the Society will determine the documentation to be submitted.

3.1.6 In addition, the Society may base its judgement upon documentation such as certificates issued or accepted by the former Classification Society, if any, and certificates issued by the flag Administration or by a recognized organization on its behalf; moreover, other documents and/or plans may be specifically required to be supplied to the Society in individual cases.

4 Date of initial classification

4.1 Definitions

4.1.1 Date of build

For a new building the date of build is the year and month at which the new construction survey process is completed. Where there is a substantial delay between the completion of the construction survey process and the ship commencing active service, the date of commissioning may be also specified.

If modifications are carried out, the date of build remains assigned to the ship. Where a complete replacement or addition of a major portion of the ship (e.g. forward section, after section, main cargo section) is involved, the following applies:

- the date of build associated with each major portion of the ship is indicated on the classification certificate
- survey requirements are based on the date of build associated with each major portion of the ship.

4.1.2 Date of initial classification for new buildings

As a general rule, for new buildings the date of initial classification coincides with the date of issuance of classification certificates which is close to the date of the transfer of property between the Shipbuilder and the Owner.

4.1.3 Date of initial classification for existing ships

In principle, for existing ships the date of initial classification is the date of completion of the admission to class survey.

5 Reassignment of class

5.1 Conditions

5.1.1 At the request of the Owner, a ship which was previously classed with the Society, subsequently withdrawn from class and has not been classed since may have the class reassigned subject to an admission to class survey. If applicable and appropriate, account may be taken of any periodical surveys held in the former period of class with the Society.

Section 2 Maintenance of Class

1 Foreword

1.1 Terminology

1.1.1 Boilers

As the rules do not apply to nuclear propulsion ships, when the word boiler(s) is used in the present chapter, it concerns boilers using fuel or coal.

1.1.2 Expert

The word Surveyor in this chapter means authorized surveyor (see Ch 1, Sec 1, [1.2.1]).

2 General principles of surveys

2.1 Survey types

2.1.1 Classed ships are submitted to surveys for the maintenance of class. These surveys include the class renewal survey, intermediate and annual survey, bottom survey (either survey in dry condition or in-water survey), tailshaft survey, boiler survey, and surveys for the maintenance of additional class notations, where applicable. Such surveys are carried out at the intervals and under the conditions laid down in this Section. In addition to the above periodical surveys, ships are to be submitted to occasional surveys whenever the circumstances so require; refer to [6].

2.1.2 The different types of periodical surveys are summarized in Tab 1. The intervals at which the periodical surveys are carried out are given in the items referred to in the second column of Tab 1. The relevant extent and scope are given in Part A, Chapter 3 and Part A, Chapter 4 for all ships and for service notations, respectively, while surveys related to additional class notations are given in Part A, Chapter 5.

Where there are no specific survey requirements for additional class notations assigned to a ship, equipment and/or arrangements related to these additional class notations are to be examined, as applicable, to the Surveyor's satisfaction at each class renewal survey for the main class.

The surveys are to be carried out in accordance with the relevant requirements in order to confirm that the hull, machinery, equipment and appliances comply with the applicable Rules and will remain in satisfactory condition based on the understanding and assumptions mentioned in Ch 1, Sec 1, [3.3].

Where the conditions for the maintenance of main class, service notations and additional class notations are not complied with, the main class and/or the service notation and/or the additional class notations as appropriate will be suspended and/or withdrawn in accordance with the applicable Rules given in Ch 2, Sec 3.

Note 1: It is understood that requirements for surveys apply to those items that are required according to the Rules or, even if not required, are fitted on board.

Table 1 : List of periodical surveys

Type of survey	Reference in this Section	Reference to scope of survey
Class renewal - hull	[5]	Ch 3, Sec 3 and Part A, Chapter 4 **(1)**
Class renewal - machinery	[5]	Ch 3, Sec 3 and Part A, Chapter 4 **(1)**
Class renewal - additional class notations	[2.1]	Part A, Chapter 5 **(2)**
Annual - hull	[6.2]	Ch 3, Sec 1 and Part A, Chapter 4 **(1)**
Annual - machinery	[6.2]	Ch 3, Sec 1 and Part A, Chapter 4 **(1)**
Annual - additional class notation	[2.1]	Part A, Chapter 5 **(2)**
Intermediate - hull	[6.3]	Ch 3, Sec 2 and Part A, Chapter 4 **(1)**
Intermediate - machinery	[6.3]	Ch 3, Sec 2 and Part A, Chapter 4 **(1)**
Stability and lightweight check	[6.4]	Ch 3, Sec 3, [2]
Bottom - dry condition	[6.5]	Ch 3, Sec 4
Bottom - in water	[6.5]	Ch 3, Sec 4
Tailshaft - complete	[6.6]	Ch 3, Sec 5
Tailshaft - modified	[6.6]	Ch 3, Sec 5
Boiler - complete	[6.7]	Ch 3, Sec 6

(1) As applicable, according to the service notation assigned to the ship
(2) As applicable, according to the additional class notations assigned to the ship.

2.1.3 Unless specified otherwise, any survey other than bottom survey and tailshaft survey may be effected by carrying out partial surveys at different times to be agreed upon with the Society, provided that each partial survey is adequately extensive. The splitting of a survey into partial surveys is to be such as not to impair its effectiveness.

2.2 Change of periodicity, postponement or advance of surveys

2.2.1 The Society reserves the right, after due consideration, to change the periodicity, postpone or advance surveys, taking into account particular circumstances.

2.2.2 When a survey becomes overdue during a voyage, the following applies:

a) In the case of a class renewal survey, the Society may, under exceptional circumstances, grant an extension to allow for completion of this survey provided there is documented agreement to such an extension prior to the expiry date of the Certificate of Classification, adequate arrangements have been made for the attendance of the Surveyor at the first port of call and the Society is satisfied that there is technical justification for such an extension. Such an extension will be granted only until arrival at the first port of call after the expiry date of the Certificate of Classification.

b) In the case of annual and intermediate surveys, no postponement is granted. Such surveys are to be completed within their prescribed windows; see [3.1.3].

c) In the case of all other periodical surveys and recommendations, extension of class may be granted until the arrival of the ship at the port of destination.

2.3 Extension of scope of survey

2.3.1 The Society and/or its Surveyors may extend the scope of the provisions in Part A, Chapter 3 to Part A, Chapter 5, which set forth the technical requirements for surveys, whenever and so far as considered necessary, or modify them in the case of special ships or systems.

2.3.2 The extent of any survey also depends upon the condition of the ship and its equipment. Should the Surveyor have any doubt as to the maintenance or condition of the ship or its equipment, or be advised of any deficiency or damage which may affect the class, then further examination and testing may be conducted as considered necessary.

2.4 General procedure of survey

2.4.1 The general procedure of survey consists in:

- an overall examination of the parts of the ship covered by the rule requirements
- checking selected items covered by the rule requirements
- attending tests and trials where applicable and deemed necessary by the Surveyor.

2.4.2 When a survey results in the identification of significant corrosion, structural defects or damage to hull, machinery and/or any piece of its equipment which, in the opinion of the Surveyor, affect the ship's class, remedial measures are to be implemented before the ship continues in service (see also [3.10]).

Note 1: The Society's survey requirements cannot be considered as a substitute for specification and acceptance of repairs and maintenance, which remain the responsibility of the Owner.

Note 2: During the surveys, the Surveyor does not check that the spare parts are kept on board, maintained in working order and suitably protected and lashed.

2.5 Appointment of another Surveyor

2.5.1 In compliance with the provisions of Ch 1, Sec 1, [2.5.1], should a disagreement arise between the Owner and the Surveyor during a survey, the Society may, at the request of the Owner, designate another Surveyor.

2.6 Alterations or additions to approved systems

2.6.1 When an alteration or addition to an approved system is proposed, documentation is to be submitted and approved by the Society before the work of alteration or addition is commenced.

2.6.2 Where the modifications may affect compliance with the rules, they are to be carried out under survey and the installation and testing are to be to the Surveyor's satisfaction.

3 Definitions and procedures related to surveys

3.1 General

3.1.1 Period of class

Period of class means the period starting either from the date of the initial classification, see Ch 2, Sec 1, [4], or from the credited date of the last class renewal survey, and expiring at the limit date assigned for the next class renewal survey.

3.1.2 Anniversary date

Anniversary date means the day of the month of each year in the period of class which corresponds to the expiry date of the period of class.

3.1.3 Survey time window

Survey time window, or more simply window, mean the fixed period during which annual and intermediate surveys are to be carried out.

3.1.4 Overdue surveys

Each periodical survey is assigned a limit date specified by the relevant requirements of the Rules (end of survey interval or end date of window) by which it is to be completed.

A survey becomes overdue when it has not been completed by its limit date.

Examples:

- Anniversary date: 15th April

  The 2000 annual survey can be validly carried out from 16th January 2000 to 15th July 2000. If not completed by 15th July 2000, the annual survey becomes overdue.
- Last bottom survey 20th October 2000 (periodicity 3 years)

  The next bottom survey is to be carried out before 20th April 2003. If not completed by 20th April 2003, the bottom survey becomes overdue.

3.1.5 Recommendations

Any defect and/or deficiency affecting the class and to be dealt with within a specific period of time is indicated as a recommendation. A recommendation is pending until it is cleared. Where it is not cleared by its limit date, the recommendation is overdue.

3.1.6 Memoranda

Those defects and/or deficiencies which do not affect the maintenance of class and which may therefore be cleared at the Owner's convenience and any other information deemed noteworthy for the Society's convenience are indicated as memoranda. Memoranda are not to be regarded as recommendations.

3.1.7 Exceptional circumstances

"Exceptional circumstances" means:

- unavailability of dry-docking facilities, or
- unavailability of repair facilities, or
- unavailability of essential materials, equipment or spare parts, or
- delays incurred by action taken to avoid severe weather conditions.

3.2 Terminology related to hull survey

3.2.1 Ballast tank

A ballast tank is a tank which is used solely for salt water ballast.

3.2.2 Spaces

Spaces are separate compartments such as holds and tanks.

3.2.3 Overall survey

An overall survey is a survey intended to report on the overall condition of the hull structure and determine the extent of additional close-up surveys.

3.2.4 Close-up survey

A close-up survey is a survey where the details of structural components are within the close visual inspection range of the Surveyor, i.e. normally within reach of hand.

3.2.5 Transverse section

A transverse section includes all longitudinal members contributing to longitudinal hull girder strength, such as plating, longitudinals and girders at the deck, side shell, bottom, inner bottom, longitudinal bulkheads, and sloped plating in upper and lower side tanks, as well as relevant longitudinals, as applicable for the different ships. For a transversely framed ship, a transverse section includes adjacent frames and their end connections in way of transverse sections.

3.2.6 Representative tanks or spaces

Representative tanks or spaces are those which are expected to reflect the condition of other tanks or spaces of similar type and service and with similar corrosion protection systems. When selecting representative tanks or spaces, account should be taken of the service and repair history on board and identifiable suspect areas.

3.2.7 Substantial corrosion

Substantial corrosion is an extent of corrosion such that assessment of the corrosion pattern indicates a wastage in excess of 75% of allowable margins, but within acceptable limits.

3.2.8 Suspect areas

Suspect areas are locations showing substantial corrosion and/or considered by the Surveyor to be prone to rapid wastage.

3.2.9 Coating

A corrosion prevention system is normally considered either:

- a full hard coating, or
- a full hard coating supplemented by anodes.

Protective coating should usually be epoxy coating or equivalent. Other coating systems may be considered acceptable as alternatives provided that they are applied and maintained in compliance with the Manufacturer's specifications.

Refer to [3.5.7] for access to tanks with soft coating.

3.2.10 Coating condition

Coating condition is defined as follows:

- good: condition with only minor spot rusting
- fair: condition with local breakdown at edges of stiffeners and weld connections and/or light rusting over 20% or more of areas under consideration, but less than as defined for poor condition
- poor: condition with general breakdown of coating over 20% or more of areas or hard scale at 10% or more of areas under consideration.

3.2.11 Cargo area (oil replenishment ships)

The cargo area is that part of the ship which contains cargo tanks, slop tanks and cargo/ballast pump rooms, cofferdams, ballast tanks and void spaces adjacent to cargo tanks and also deck areas throughout the entire length and breadth of the part of the ship over the above-mentioned spaces.

3.2.12 Cargo area (dry cargo ships)

The cargo area is that part of the ship which includes all cargo holds and adjacent areas including fuel tanks, cofferdams, ballast tanks and void spaces.

3.2.13 Prompt and thorough repair

A “Prompt and Thorough Repair” is a permanent repair completed at the time of survey to the satisfaction of the Surveyor, therein removing the need for the imposition of any associated recommendation. See also [3.10].

3.3 Procedures for thickness measurements

3.3.1 When required as per the scope of surveys defined below, thickness measurements are normally to be carried out under the responsibility of the Owner, in the presence of the Surveyor.

However, the Surveyor may accept thickness measurements not carried out under his supervision.

3.3.2 The thickness measurements are to be carried out by a company authorised by the Society.

The Society reserves the right to limit the scope of authorisation of the Company.

Note 1: The specific Rules of the Society give details about the authorisation.

3.3.3 A thickness measurement report is to be prepared. The report is to give the location of measurements, the thickness measured and the corresponding original thickness. Furthermore, the report is to include the date when the measurements were carried out, the type of measuring equipment, the names and the qualification of the operators and their signatures.

The report is validated by the Surveyor.

3.4 Agreement for in-water survey

3.4.1 The in-water surveys referred to in the Rules are to be carried out by a certified company accepted by the Society and authorized.

Note 1: Rule Note NR533 gives details about the certification.

3.4.2 On the Owner request, a survey program based on close-up in-water hull surveys can be applied with the Society agreement.

For the program application, an on-board person with appropriated professional qualification has to be responsible of the program management.

The surveys of the hull elements and components covered by the program can be performed by on-board divers who have been given by the Society an authorization note, after receiving an appropriated training.

3.5 Conditions for surveys

3.5.1 The Owner is to provide the necessary facilities for the safe execution of the surveys, as per Ch 1, Sec 1, [3.2.2].

3.5.2 For their internal examination, tanks and spaces are to be safe for access, i.e. gas freed, ventilated, etc.

Tanks and spaces are to be sufficiently illuminated, clean and free from water, scale, dirt, oil residues, etc. to reveal significant corrosion, deformation, fractures, damage or other structural deterioration.

3.5.3 A tank entry permit is to be issued prior to entering the tank. Adequate ventilation is to be maintained during the survey, and the required ventilation is to be specified on the entry permit. If the tanks are connected by a common venting system or an IG system, the tank inspected is to be isolated to prevent a transfer of gas from other tanks.

3.5.4 A communication system is to be arranged between the survey party in the tank and the responsible officer on deck.

3.5.5 Rescue and safety equipment such as explosimetre, breathing apparatus, resuscitators, smoke masks, rescue lines, stretcher, etc. is to be provided at the tank hatch, or, if more than one tank is being surveyed, at a central location on deck.

3.5.6 Surveys of tanks by means of boats or rafts may only be undertaken at the discretion of the Surveyor. In such case, the following additional conditions apply:

- a safety meeting is to be held prior to entering the tank, and applicable safety procedures and responsibilities are to be discussed to ensure that the survey is carried out under controlled conditions, in particular concerning the movement of the surface of the water in the tank
- the surface of the water in the tank should be calm (under all foreseeable conditions the expected rise of water within the tank should not exceed 0,25 m) and the water level either stationary or falling. On no account is the level of the water to be rising while the boat is in use
- the tank is to contain clean ballast water only. Even a thin sheen of oil on the water is not acceptable
- at no time should the water be allowed within one metre of the deepest under-deck web face flat so that the survey team is not isolated from a direct escape route to the tank hatch. Filling to levels above the deck transverses should be contemplated only if a deck access manhole is fitted in the bay being examined, so that an escape route for the survey party is available at all times
- only rough duty, inflatable life boats, having residual buoyancy and stability even if one chamber is ruptured, are to be used
- the work-boat is to be tethered to the access ladder and an additional person stationed down the access ladder with a clear view of the work-boat
- all personnel in the compartment are to be provided with personal flotation devices.

3.5.7 When examination of associated structure is required, the following applies:

- ceilings in holds and floors in the engine room are to be lifted to the necessary extent for examination of the structure
- cement or other protective sheathing is to be removed when there is any doubt as to the condition of the plating underneath or when adherence to plating is not tight
- in the case of solid ballast spaces, the solid ballast is to be partially removed for examination of the condition of the structure in way. Should doubts arise, the Surveyor may require more extensive removal of the solid ballast
- where soft coatings have been applied, safe access is to be provided for the Surveyor to verify the effectiveness of the coating and to carry out an assessment of the conditions of internal structures which may include spot removal of the coating. When safe access cannot be provided, the soft coating is to be removed.

3.6 Access to structures

3.6.1 For overall survey, means are to be provided to enable the Surveyor to examine the structure in a safe and practical way.

3.6.2 For close-up survey, one or more of the following means for access, acceptable to the Surveyor, is to be provided:

- permanent staging and passages through structures
- temporary staging and passages through structures
- hydraulic arm vehicles such as conventional cherry pickers, lifts and movable platforms
- portable ladders
- boats or rafts
- other equivalent means.

3.7 Equipment for surveys

3.7.1 One or more of the following fracture detection methods may be required if deemed necessary by the Surveyor:

- radiography (X or γ rays)
- ultrasonic test
- magnetic particle test
- dye penetrant test.

3.8 Surveys at sea and anchorage

3.8.1 Surveys at sea or at anchorage may be accepted provided the Surveyor is given the necessary assistance by the personnel on board. Precautions and procedures for carrying out the survey are to be in accordance with [3.5], [3.6] and [3.7].

3.9 Repairs and maintenance during voyage

3.9.1 Where repairs to hull, machinery or other equipment, which affect or may affect the class, are to be carried out by a riding crew during a voyage, they are to be planned in advance. A complete repair procedure including the extent of proposed repair and the need for the Surveyor's attendance during the voyage is to be submitted to the Society for approval sufficiently in advance. Failure to notify the Society in advance of the repairs may result in the suspension of class of the ship.

3.9.2 The above is not intended to include maintenance to and overhaul of the hull, machinery and equipment in accordance with the Manufacturer's recommended procedures and established marine practice, which does not require the Society's agreement. However, any repair resulting from such maintenance and overhauls which affects or may affect the class is to be noted in the ship's log and submitted to the attending Surveyor for use in determining further survey requirements.

3.10 Repairs

3.10.1 Any damage in association with wastage over the allowable limits (including buckling, grooving, detachment or fracture), or extensive areas of wastage over the allowable limits, which affects or, in the opinion of the Surveyor, will affect the ship's structural, watertight or weathertight integrity, is to be promptly and thoroughly (see [3.2.13]) repaired.

Areas to be considered include:

- side shell frames, their end attachments or adjacent shell plating
- deck structure and deck plating
- bottom structure and bottom plating
- watertight or oiltight bulkheads, or
- hatch covers or hatch coamings.

3.10.2 For locations where adequate repair facilities are not available, consideration may be given to allow the ship to proceed directly to a repair facility. This may require discharging the cargo and/or temporary repairs for the intended voyage.

4 Certificate of Classification: issue, validity, endorsement and renewal

4.1 Issue of Certificate of Classification

4.1.1 A Certificate of Classification, bearing the class notations assigned to the ship and an expiry date, is issued to any classed ship.

4.1.2 A Provisional Certificate of Classification may serve as a Certificate of Classification in some cases, such as after an admission to class survey, after a class renewal survey, or when the Society deems it necessary.

4.1.3 The Certificate of Classification is to be made available to the Society's Surveyors upon request.

4.1.4 Issuance of the first Certificate of Classification is notified to the Classification Committee for its advice.

4.2 Validity of Certificate of Classification, maintenance of class

4.2.1 According to Ch 1, Sec 1, [2.4], the Society alone is qualified to confirm the class of the ship and the validity of its Certificate of Classification.

4.2.2 During the class period, a Certificate of Classification is valid when it is not expired.

The class is maintained during a certain period or at a given date, when during the said period or at such date the conditions for suspension or withdrawal of class are not met.

4.2.3 At the request of the Owner, a statement confirming the maintenance of class may be issued by the Society based on the information in its records for that ship at the time.

This statement is issued on the assumption that the Owner has complied with the Rules, in particular with [7].

Should any information which would have prevented the Society from issuing the statement and which was not available at the time subsequently come to light, the statement may be cancelled.

Attention is drawn to Ch 2, Sec 3, [1.2], whereby the Society, upon becoming aware of a breach of the Rules, is empowered to suspend class from the date of the breach, which may be prior to the date of the statement.

4.2.4 According to the same conditions as in [4.2.3], a statement declaring that the class is maintained "clean and free from recommendation" may be issued by the Society when there is no pending recommendation at that date.

4.2.5 Classification-related documents and information are liable to be invalidated by the Society whenever their object is found to differ from that on which they were based or to be contrary to the applicable requirements. The Owner is liable for any damage which may be caused to any third party from improper use of such documents and information.

4.3 Endorsement of Certificate of Classification

4.3.1 Text of endorsement

When surveys are satisfactorily carried out, the Certificate of Classification is generally endorsed accordingly.

Each endorsement normally consists of sections for the description of:

- the surveys held
- the imposed, deleted and postponed recommendations (including the assigned limit date as applicable)
- the unchanged existing recommendations (given for information only).

Where applicable, memoranda are also endorsed in the Certificate of Classification.

4.3.2 Possible modifications to endorsements

The Society reserves the right to modify the endorsements made by Surveyors.

4.4 Status of surveys and recommendations

4.4.1 Information given in the Certificate of Classification, associated endorsements, Rules and specific documents enables the Owner to identify the status of surveys and recommendations.

4.4.2 The omission of such information does not absolve the Owner from ensuring that surveys are held by the limit dates and pending recommendations are cleared to avoid any inconvenience which is liable to result from the suspension or withdrawal of class; see Ch 2, Sec 3.

5 Class renewal survey

5.1 General principles

5.1.1 Class renewal surveys are to be carried out at five-year (class symbol **I**) or three-year (class symbol **II**) intervals.

5.1.2 For surveys completed within three months before the limit date of the class renewal survey, the next period of class will start from this limit date. For surveys completed more than three months before the limit date, the period of class will start from the survey completion date.

In cases where the vessel has been laid up or has been out of service for a considerable period because of a major repair or modification and the Owner elects to carry out only the overdue surveys, the next period of class will start from the expiry date of the renewal survey. If the Owner elects to carry out the next due renewal survey, the period of class will start from the survey completion date.

5.1.3 A new period of class is assigned to the ship after the satisfactory completion of the class renewal survey, and a new Certificate of Classification is issued for the new period of class.

5.1.4 Concurrent crediting to both Intermediate Survey and Class Renewal Survey for surveys and thickness measurements of spaces is not acceptable.

5.2 Normal system

5.2.1 When the normal system is applied to ships with a 5 year period of class, the class renewal survey may be commenced at the fourth annual survey and continued during the following year with a view to completion by its due date. In this case the survey may be carried out by partial surveys at different times. The number of checks to be performed at each partial survey and the interval between partial surveys are to be agreed by the Society. In general, the first partial survey should include a significant number of thickness measurements, where required by the Rules.

5.2.2 A class renewal survey may be commenced before the fourth annual survey at the request of the Owner. In this case, the survey is to be completed within fifteen months. The conditions for the execution of partial surveys are the same as those referred to in [5.2.1].

5.3 Continuous survey system

5.3.1 The request by the Owner for admission to the continuous survey system will be considered by the Society and agreement depends on the type and age of hull and machinery. This system may apply to the class renewal survey of hull, machinery or other installations such as refrigerating installations covered by an additional class notation.

5.3.2 The continuous survey system is not applicable to the class renewal survey of the hull of ships over 20 years old. However, consideration may be given, at the discretion of the Society, to the applicability of the continuous survey system to the class renewal survey of the hull of ships over 20 years old.

5.3.3 When the continuous survey system is applied, appropriate notations are entered in the Certificate of Classification and the Register of Ships.

5.3.4 Ships subject to the continuous survey system are provided with lists of items to be surveyed under this system; these lists are attached to the Certificate of Classification.

5.3.5 For items inspected under the continuous survey system, the following requirements generally apply:

a) the interval between two consecutive surveys of each item is not to exceed five years
b) the items are to be surveyed in rotation, so far as practicable ensuring that approximately equivalent portions are examined each year
c) the Society may credit for continuous survey results of inspections carried out before the admission to the continuous survey scheme
d) each item is to be surveyed at one time, as far as practicable; the Society may, however, allow possible repair work to be carried out within a certain period.

5.3.6 For ships under continuous survey, items not included in the continuous survey cycle are to be inspected according to the provisions given in [5.2].

5.3.7 Upon application by the Owner, the Society may agree, subject to certain conditions, that some items of machinery which are included in the continuous survey cycle are examined by the Chief Engineer where the Society is not represented. The Chief Engineer is to be certified for this purpose by the Society and his examination is to be followed by a confirmatory survey carried out by a Surveyor. The conditions for the application of this procedure are given in Ch 2, App 2.

5.3.8 The continuous survey system does not supersede the annual surveys and other periodical and occasional surveys.

5.3.9 A general examination of the ship, as detailed in Ch 3, Sec 1 for annual surveys, is to be carried out at the end of the period of class.

5.3.10 For laid-up ships, specific requirements given in [9.1] apply.

5.3.11 The continuous survey system may be discontinued at any time at the discretion of the Society, or at the request of the Owner, and a specific arrangement devised.

5.4 Planned maintenance scheme (PMS) for machinery

5.4.1 A planned maintenance scheme may be considered as an alternative to the continuous survey system for machinery and is limited to components and systems covered by it. When such a system approved by the Society is implemented, a survey scheme other than those normally adopted and with intervals different from those of the continuous survey system as detailed in [5.3] may be accepted.

5.4.2 The conditions for approval of the planned maintenance scheme, the determination of survey item intervals and the general scope of surveys are detailed in Ch 2, App 1.

5.4.3 When the planned maintenance scheme is applied, appropriate notations are entered on the Certificate of Classification and in the Register of Ships.

5.4.4 The planned maintenance scheme does not supersede the annual surveys and other periodical and occasional surveys.

5.4.5 A general examination of the machinery, as detailed in Ch 3, Sec 1 for annual surveys, is to be carried out at the end of the period of class.

5.4.6 The planned maintenance scheme may be discontinued at any time at the discretion of the Society, or at the request of the Owner, and a specific arrangement devised.

5.5 STAR-MACH survey system

5.5.1 When the additional class notation **STAR-MACH** is assigned, the class renewal survey covering machinery installation and other arrangement covered by the notation is replaced by the survey system described in Pt E, Ch 2, Sec 2 for the maintenance of this notation.

5.5.2 When the survey system linked to **STAR-MACH** notation is applied, appropriate notations are entered on the Certificate of Classification and in the Register of Ships.

5.5.3 This survey system does not supersede the annual surveys and other periodical and occasional surveys.

5.5.4 A general examination of the installation covered by the notation, as detailed in Ch 3, Sec 1 for annual surveys, is to be carried out at the end of the period of class.

6 Other periodical surveys

6.1 General

6.1.1 The different types of periodical surveys are summarized in Tab 1.

6.2 Annual surveys

6.2.1 Annual surveys are to be carried out within three months before or after each anniversary date.

6.3 Intermediate surveys

6.3.1 An intermediate survey, where applicable, is to be carried out within the window from three months before the second to three months after the third anniversary date.

6.3.2 The intermediate survey is applicable at any period of class to ships which are five years old and over.

6.3.3 The intermediate survey is not applicable to ships with class symbol **II**.

6.3.4 Concurrent crediting to both Intermediate Survey and Class Renewal Survey for surveys and thickness measurements of spaces is not acceptable.

6.4 Ship lightweight and stability check

6.4.1 The ship lightweight and stability check aim to verify the that the ship is in conformity with respect to the state defined by the design drawings.

The checking is performed through a verification of the light ship mass, of the hull girder deformation in still water and of the stability.

6.4.2 The verification of the light ship mass is performed through a displacement measurement as defined in Pt B, Ch 3, App 1.

6.4.3 The verification of the hull girder deformation is performed through a measurement of the global vertical hull girder deformation by the way of reading aft, forward and midship draught marks or a method defined in agreement between the Owner and the Society.

This measurement is performed in still water and generally at the same time than the ship lightweight check.

6.4.4 The verification of the stability is performed through the determination of the initial righting lever arm by a stability check as defined in Pt B, Ch 3, App 1.

6.5 Bottom survey

6.5.1 Bottom survey means the examination of the outside of the ship’s bottom and related items. This examination may be carried out with the ship either in dry dock (or on a slipway) or afloat: in the former case the survey will be referred to as dry-docking survey, while in the latter case as in-water survey.

6.5.2 The Owner is to notify the Society whenever the outside of the ship’s bottom and related items can be examined in dry dock or on a slipway.

6.5.3 For ships classed with the class symbol **I**, there are to be two examinations of the outside of the ship’s bottom and related items in each period of class of five years.

In all cases, the interval between any two such examinations is not to exceed 36 months.

An extension of examination of the ship's bottom of three months beyond the due date can be granted in exceptional circumstances, as defined in [3.1.7].

6.5.4 For ships under the normal survey system, one of the bottom surveys to be performed in each period of class is to be carried out in conjunction with the class renewal survey and is to be a dry-docking survey.

The Society may allow the bottom survey carried out between class renewal surveys to be replaced by an in-water survey, subject to the provisions of Ch 3, Sec 4. Special consideration is to be given to ships of 15 years of age and over before being permitted to have such in-water examinations.

6.5.5 For ships under the continuous survey system of hull (CSH), one of the bottom surveys to be performed in each period of class is to be carried out in conjunction with the end of class period.

This bottom survey may be an in-water survey, subject to the provisions of Ch 3, Sec 4 and provided that the previous bottom survey performed in the period of class was a dry-docking survey. Special consideration is to be given to ships of 15 years of age and over before being permitted to have such in-water examinations.

6.6 Tailshaft survey

6.6.1 Definition

Tailshaft survey means survey of propeller shafts and tube shafts (hereafter referred to as tailshafts) as well as survey of other propulsion systems.

6.6.2 Tailshaft complete survey

Tailshafts are to be submitted to complete examination at the periodicity specified below and summarized in Fig 1, based on the type of shaft and its design.

a) Where the tailshaft is fitted with continuous liners or equivalent protective coating, or approved oil sealing glands, or made of corrosion-resistant material, the periodicity of complete surveys is:
   - three years for single shafting arrangements
   - four years for multi-shafting arrangements.

b) These periodicities may be increased to five years in the following cases:
   - where the propeller is fitted keyless to the shaft taper, the shaft is protected from sea water, the design details are approved, and a non-destructive examination of the forward part of the aft shaft taper is performed at each survey by an approved crack-detection method
   - where the propeller is fitted to a keyed shaft taper the design details of which comply with the applicable requirements in Pt C, Ch 1, Sec 7, and a non-destructive examination of the after end of the cylindrical part of the shaft (from the after end of the liner, if any), and of about one third of the length of the taper from the large end is performed at each survey by an approved crack-detection method
   - where the propeller is fitted to a solid flange coupling at the aft end of the shaft, the shaft and its fittings are not exposed to corrosion, the design details are approved, and a non-destructive examination of the after flange fillet area of the shaft is performed at each survey by an approved crack-detection method.

c) In all other cases the periodicity of complete surveys is three years.

6.6.3 Tailshaft modified survey

A modified survey of the tailshaft is an alternate way of examination whose scope is given in Ch 3, Sec 5. It may be accepted for tailshafts described in [6.6.2] provided that:

For oil lubricated shafts:

- they are fitted with oil lubricated bearings and approved oil sealing glands
- the shaft and its fittings are not exposed to corrosion
- the design details are approved
- the clearances of the aft bearing are found to be in order
- the oil and the oil sealing arrangements prove effective
- lubricating oil analyses are carried out regularly at intervals not exceeding six months and oil consumption is recorded at the same intervals.

The modified survey is to be carried out five years from the last complete survey with a window period of plus or minus six months.

The next complete survey is to be carried out ten years from the last complete survey.

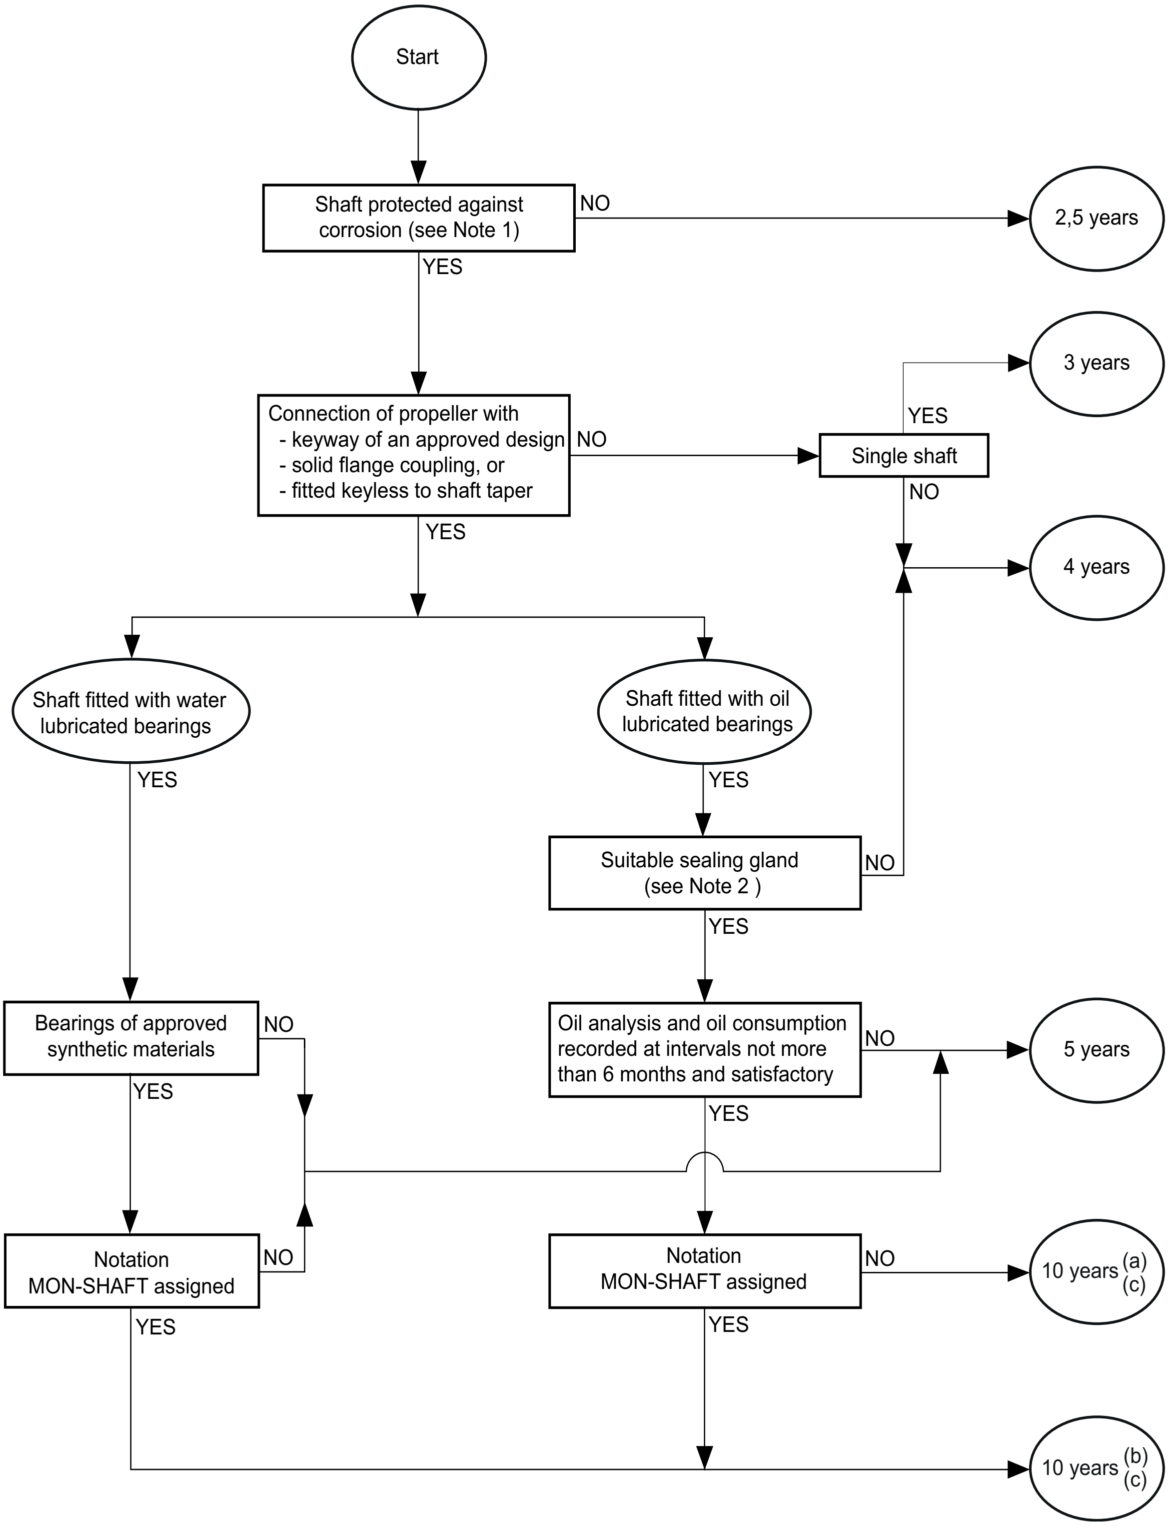
For water lubricated shafts:

- the design details are approved
- the integrity of the coating and the watertightness of its junctions to liners are found to be in order
- the bearings arrangement allows the liners surfaces to be visually checked in way of bearings without shaft removal
- the liners are found to be in order in way of bearings.

The modified survey is to be carried out five years from the last complete survey with a window period of plus or minus six months.

The next complete survey is to be carried out ten years from the last complete survey.

Figure 1 : Periodicity of complete survey of tailshaft



(a) : with shaft withdrawn, subject to modified survey at 5 years plus minus 6 months

(b) : with shaft in place, subject to modified survey at 5 years plus minus 6 months.

(c) : the periodicity cannot exceed the maximum recommended by the designer and manufacturer of the tailshaft and bearing system.

Note 1: Shafts protected against corrosion are those:

- made of corrosion resistant material, or
- fitted with continuous liners or systems considered as equivalent, or
- fitted with oil lubricated bearings and oil sealing glands.

Note 2: Suitable sealing glands are glands which are type approved by the Society with regard to protection of the sterntube against ingress of water.

6.6.4 Tailshaft Monitoring System (MON-SHAFT)

Where, in addition to the conditions stated in [6.6.3] for modified survey, the additional class notation **MON-SHAFT** is assigned, the tailshaft need not be withdrawn at both the complete and modified survey provided that all condition monitoring data is found to be within permissible limits and the remaining requirements for the respective surveys are complied with.

6.6.5 Other propulsion systems

Driving components serving the same purpose as the tailshaft in other propulsion systems, such as directional propellers, vertical axis propellers, water jet units, dynamic positioning systems and thruster assisted mooring systems, are to be submitted to periodical surveys at intervals not exceeding five years.

6.7 Boiler survey

6.7.1 Boilers and thermal oil heaters are to be surveyed twice in every five-year period. The periodicity of the boiler survey is three years (36 months).

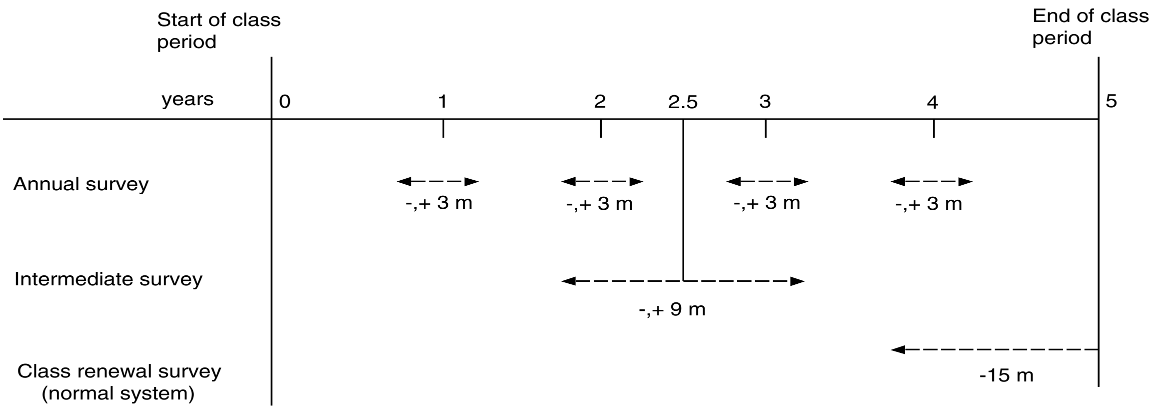
6.7.2 For ships of eight years of age and over fitted with one single boiler supplying steam for main propulsion, the interval between two boiler surveys may be specially considered.

6.7.3 Boilers are also submitted to an external inspection as a part of the annual survey of machinery.

6.8 Links between anniversary dates and annual surveys, intermediate surveys and class renewal surveys

6.8.1 The link between the anniversary dates, the class renewal survey (when carried out according to the normal system), and the annual and intermediate surveys is given in Fig 2.

Figure 2 : Links between anniversary date and annual, intermediate and class renewal surveys



7 Occasional surveys

7.1 General

7.1.1 An occasional survey is any survey which is not a periodical survey. The survey may be defined as an occasional survey of hull, machinery, boilers, refrigerating plants, etc., depending on the part of the ship concerned.

Where defects are found, the Surveyor may extend the scope of the survey as deemed necessary.

7.1.2 Occasional surveys are carried out at the time of, for example:

- updating of classification documents (e.g. change of the Owner, name of the ship, flag)
- damage or suspected damage
- repair or renewal work
- alterations or conversion
- quality system audits
- postponement of surveys or recommendations.

7.2 Damage and repair surveys

7.2.1 In the event of damage which affects or may affect the class of the ship, the Owner is to apply to the Society for a survey. Such application is to be made as soon as possible to enable the Surveyor to ascertain the extent of the damage and necessary repairs, if any.

Note 1: Whenever a ship is fitted with an helicopter platform which is made in aluminium or other low melting metal construction which is not made equivalent to steel, and a fire occurred on the said platform or in close proximity, the platform is to be subject to a structural survey to determine its suitability for further use.

7.2.2 If, after sustaining damage, the ship calls at a port where the Society is not represented, the Owner is to notify the Society forthwith, supply all available information regarding the damage and make arrangements for the ship to be surveyed in the nearest port where the Society is represented.

7.2.3 All repairs to hull, machinery and equipment which may be required in order for a ship to retain its class are to be to the satisfaction of the Surveyor.

During repairs or maintenance work, the Owner is to arrange so that any damage, defects or non-compliance with the rule requirements are reported to the Surveyor during his survey.

7.2.4 Damages and partial or temporary repairs considered acceptable by the Surveyor for a limited period of time are the subject of an appropriate recommendation.

7.2.5 Damages or repairs required by the Surveyor to be re-examined after a certain period of time are the subject of an appropriate recommendation.

7.3 Conversions, alterations and repairs

7.3.1 Conversions, alterations or repairs of/to structures and arrangements affecting the class are to be carried out in accordance with the requirements of the Society and to its satisfaction. Where necessary, documentation is to be submitted to the Society and/or made available to the attending Surveyor.

7.3.2 Materials and equipment used for conversions, alterations or repairs are generally to meet the requirements of the Rules for new ships built under survey; see Ch 2, Sec 1, [2.1.5].

7.4 Quality System audits

7.4.1 The Society reserves the right to carry out occasional surveys in order to conduct audits either as deemed necessary in pursuance of its internal Quality System.

7.4.2 These surveys may also be attended by auditors external to the Society.

7.4.3 The scope of these surveys is determined by the Society.

8 Change of ownership

8.1

8.1.1 In the case of change of ownership, the ship retains its current class with the Society provided that:

- the Society is informed of the change sufficiently in advance to carry out any survey deemed appropriate, and
- the new Owner signs the appropriate request, involving acceptance of the Society's general conditions and Rules. This request covers inter alia the condition of the ship when changing ownership.

Note 1: The ship's class is maintained without prejudice to those provisions in the Rules which are to be enforced in cases likely to cause suspension or withdrawal of the class such as particular damages or repairs to the ship of which the Society has not been advised by the former or, as the case may be, new Owner.

Note 2: No information whatsoever related to the class of the ship will be provided or confirmed to any third party, unless the appropriate request for information is duly completed and signed by the party making the request and the authorisation of the current Owner is obtained.

9 Lay-up and re-commissioning

9.1 General principles

9.1.1 A ship put out of commission may be subject to specific requirements for maintenance of class, as specified below, provided that the Owner notifies the Society of the fact.

If the Owner does not notify the Society of the laying-up of the ship or does not implement the lay-up maintenance program, the ship's class will be suspended and/or withdrawn when the due surveys are not carried out by their limit dates in accordance with the applicable requirements given in Ch 2, Sec 3.

9.1.2 The lay-up maintenance program provides for a "laying-up survey" to be performed at the beginning of lay-up and subsequent "annual lay-up condition surveys" to be performed in lieu of the normal annual surveys which are no longer required to be carried out as long as the ship remains laid-up. The minimum content of the lay-up maintenance program as well as the scope of these surveys are given in Ch 3, App 1. The other periodical surveys which become overdue during the lay-up period may be postponed until the re-commissioning of the ship.

9.1.3 Where the ship has an approved lay-up maintenance program and its period of class expires, the period of class is extended until it is re-commissioned, subject to the satisfactory completion of the annual lay-up condition surveys as described in [9.1.2].

9.1.4 The periodical surveys carried out during the lay-up period may be credited, either wholly or in part, at the discretion of the Society, having particular regard to their extent and dates. These surveys will be taken into account for the determination of the extent of surveys required for the re-commissioning of the ship and/or the expiry dates of the next periodical surveys of the same type.

9.1.5 When a ship is re-commissioned, the Owner is to notify the Society and make provisions for the ship to be submitted to the following surveys:

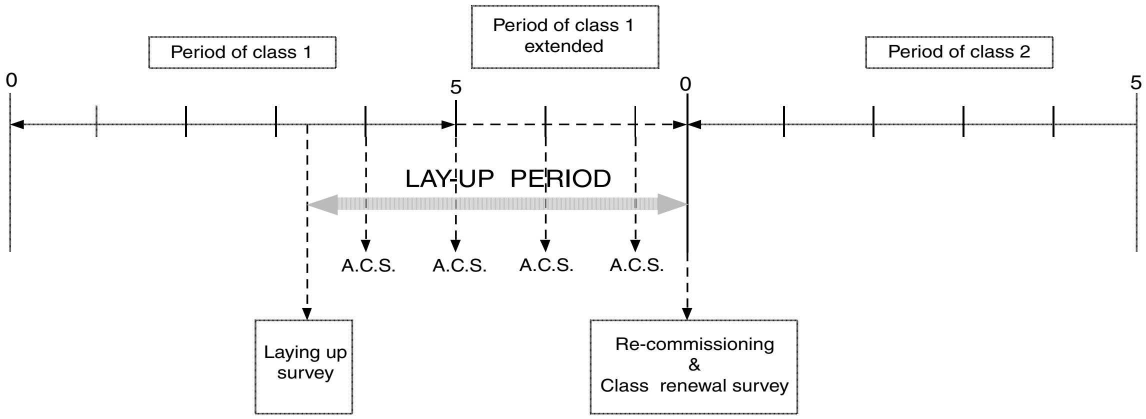
- an occasional survey prior to re-commissioning, the scope of which depends on the duration of the lay-up period
- all periodical surveys which have been postponed in accordance with [9.1.2], taking into account the provisions of [9.1.4].

9.1.6 Where the previous period of class expired before the re-commissioning and was extended as stated in [9.1.3], in addition to the provisions of [9.1.5] a complete class renewal survey is to be carried out prior to re-commissioning. Those items which have been surveyed in compliance with the class renewal survey requirements during the 15 months preceding the re-commissioning may be credited. A new period of class is assigned from the completion of this class renewal survey.

9.1.7 The principles of intervals or limit dates for surveys to be carried out during the lay-up period, as stated in [9.1.1] to [9.1.6], are summarized in Fig 3.

9.1.8 The scope of the laying-up survey and annual lay-up condition surveys are described in detail in Ch 3, App 1.

Figure 3 : Survey scheme of a case of a lay-up going beyond the expiry date of the period of class



Note 1: A.C.S. means annual lay-up condition survey.

Section 3 Suspension and Withdrawal of Class

1 General

1.1 Discontinuance of class

1.1.1 Terminology

The class may be discontinued either temporarily or permanently. In the former case it is referred to as “suspension” of class, in the latter case as “withdrawal” of class. In both these cases, the class is invalidated in all respects. In the case of withdrawal, a specific notation is entered in the supplement to the Register of Ships, until the ship is deleted from the Register.

1.2 Suspension of class

1.2.1 Military operations

When a ship is engaged in a particular operation, such as for example an operation considered with combat risks, the normal requirements for surveys are no more applicable, within the condition that the Owner notified this fact to the Society. During the notified period, the class is suspended.

At the end of the notified period the class is reinstated once the due, during the suspension period, items and/or surveys have been dealt with. The endorsement on the Certificate of Classification has to confirm that all concerned surveys have been performed and mention the period of the suspension of class.

Information given in the Certificate of Classification, associated endorsements, Rules and specific documents enables the Owner to identify the status of surveys and recommendations.

It is the Owner responsibility to verify that the ship parts not covered by the classification are in a satisfactory working state.

1.2.2 The class may be suspended either automatically or following the decision of the Society, or on the Owner request (see [1.2.1]). In any event, the ship will be considered as not retaining its class from the date of suspension until the date when class is reinstated.

1.2.3 The class may be automatically suspended when one or more of the following circumstances occur:

- when a ship is not operated in compliance with the rule requirements, such as in cases of services or conditions not covered by the service notation, or trade outside the navigation restrictions for which the class was assigned
- when a ship has the draught marks placed on the sides in a position higher than that assigned, or, in cases of ships where draught marks are not assigned, the draught is greater than that assigned
- when the Owner fails to inform the Society in order to submit the ship to a survey after defects or damages affecting the class have been detected
- when repairs, alterations or conversions affecting the class are carried out either without requesting the attendance of the Society or not to the satisfaction of the Surveyor. For voyage repairs, reference is to be made to Ch 2, Sec 2, [3.9]
- in case a freeboard has been assigned to the ship, when a ships proceeds to sea with less freeboard than that assigned.

Suspension of class with respect to the above cases will remain in effect until such time as the cause giving rise to suspension has been removed. Moreover, the Society may require any additional surveys deemed necessary taking into account the condition of the ship and the cause of the suspension.

1.2.4 In addition, the class is automatically suspended:

- when the class renewal survey has not been completed by its limit date or within the time granted for the completion of the survey, unless the ship is under attendance by the Society’s Surveyors with a view to completion prior to resuming trading, and unless a specific action plan has been agreed for completion of the survey
- when the annual or intermediate surveys have not been completed by the end of the corresponding survey time window (see Ch 2, Sec 2, [3.1.3]) unless a specific action plan has been agreed for completion of the survey. Continuous survey item(s) due or overdue at the time of the annual surveys is (are) to be dealt with unless a postponement is granted by agreement with the Society, and unless a specific action plan has been agreed for completion of the survey.

Suspension of class with respect to the above cases will remain in effect until such time as the class is reinstated once the due items and/or surveys have been dealt with.

1.2.5 In addition to the circumstances for which automatic suspension may apply, the class of a ship may also be suspended following the decision of the Society:

- when a recommendation is not dealt with within the time limit specified, unless it is postponed before the limit date by agreement with the Society
- when one or more surveys are not held by their limit dates (see Ch 2, Sec 2, [3.1.4]) or the dates stipulated by the Society also taking into account any extensions granted in accordance with the provisions of Part A
- when, due to reported defects, the Society considers that a ship is not entitled to retain its class even on a temporary basis (pending necessary repairs or renewals, etc.)
- when the ship has not been maintained in proper condition, as set forth in Ch 1, Sec 1, [3.3.1]
- in other circumstances which the Society will consider on their merits (e.g. in the event of non-payment of fees or where the Owner fails to subject the ship to the occasional survey as per the requirement in Ch 2, Sec 2, [7.2.1]).

Suspension of class decided by the Society takes effect from the date when the conditions for suspension of class are met and will remain in effect until such time as the class is reinstated once the due items and/or surveys have been dealt with.

1.3 Withdrawal of class

1.3.1 The Society will withdraw the class of a ship after consultation of the Classification Committee in the following cases:

- at the request of the Owner
- when the causes that have given rise to a suspension currently in effect have not been removed after due notification of suspension to the Owner
- when the ship is reported as a constructive total loss
- when the ship is lost
- when the ship is reported scrapped.

Withdrawal of class takes effect from the date on which the circumstances causing such withdrawal occur.

1.3.2 When the withdrawal of class of a ship comes into effect, the Society will:

- forward the Owner written notice
- delete the ship from the Register of Ships
- notify the Naval Authority.

1.4 Suspension/withdrawal of additional class notations

1.4.1 If the survey requirements related to maintenance of additional class notations are not complied with, the suspension or withdrawal may be limited to the notations concerned.

The same procedure may apply to service notations of ships which are assigned with more than one service notation.

1.4.2 The suspension or withdrawal of an additional class notation or a service notation (where a ship is assigned with more than one service notation) generally does not affect the class.

Appendix 1 Planned Maintenance Scheme

1 General

1.1

1.1.1 A Planned Maintenance Scheme (hereafter referred to as PMS) is a survey system for machinery items which may be considered as an alternative to the Continuous Machinery Survey system (hereafter referred to as CMS), as described in Ch 2, Sec 2, [5.3].

1.1.2 This survey scheme is to be approved by the Society before being implemented. When the PMS system is applied, the scope and periodicity of the class renewal survey are tailored for each individual item of machinery and determined on the basis of recommended overhauls stipulated by the manufacturers, documented experience of the operators and, where applicable and fitted, condition monitoring. For instance, within the scope of a PMS system the following cases may occur:

- switchboard A is surveyed based on the regular expiry date of the class renewal survey
- lubricating oil pump B is surveyed based on CMS
- diesel engine C is surveyed based on running hours
- turbo pump D is surveyed based on condition monitoring.

1.1.3 However, the survey intervals for items surveyed under the PMS system should not exceed those specified for the CMS. For certain components or items of machinery, the survey intervals based on the CMS system need not be taken into consideration, provided that an approved condition monitoring system is in effect for these parts.

1.1.4 When the condition monitoring of machinery and components included in the approved PMS shows that their condition and performance are within the allowable limits, no overhaul is necessary, unless specified by the Manufacturer.

1.1.5 On board the ship there is to be a person responsible for the management of the PMS for the purpose of which he is to possess the appropriate professional qualifications. This person is usually the Chief Engineer; however, another person designated by the Owner may be accepted by the Society provided that his qualifications are considered equivalent to those of the Chief Engineer.

The surveys of machinery items and components covered by the PMS may be carried out by personnel on board who have been issued a statement of authorisation, under the conditions and limits given in Ch 2, App 2.

Items surveyed by the authorised person will be subject to the confirmatory survey as detailed in Ch 2, App 2.

1.1.6 The conditions and procedures for the approval of a PMS are indicated in Article [2].

2 Conditions and procedures for the approval of the system

2.1 General

2.1.1 The PMS is to be approved by the Society. To this end the Owner is to make a formal request to the Society and provide the documentation and information specified in [2.2], combined in a manual describing the proposed scheme and including sample copies of the different documents to be used during the implementation of the scheme.

2.1.2 When using computerised systems, access for the purpose of updating the maintenance documentation and the maintenance programmes is only granted to the person responsible for the PMS or another person authorised by him.

The computerised systems are to include a back-up procedure, which is to be activated at regular intervals.

The functional application of these systems is to be approved by the Society.

2.2 Documentation

2.2.1 The documentation to be submitted is the manual mentioned above, which is to include:

a) a description of the scheme and its application on board as well as the proposed organisation chart identifying the areas of responsibility and the people responsible for the PMS on board
b) the list of items of machinery and components to be considered for classification in the PMS, distinguishing for each the principle of survey periodicity used as indicated in [1.1.2]
c) the procedure for the identification of the items listed in b), which is to be compatible with the identification system adopted by the Society
d) the scope and time schedule of the maintenance procedures for each item listed in b), including acceptable limit conditions of the parameters to be monitored based on the manufacturers' recommendations or recognised standards and laid down in appropriate preventive maintenance sheets

e) the original reference data, monitored on board, for machinery undergoing maintenance based on condition monitoring

f) the list and specifications of the condition monitoring equipment, including the maintenance and condition monitoring methods to be used, the time intervals for maintenance and monitoring of each item and acceptable limit conditions

g) the document flow and pertinent filing procedure.

2.3 Information on board

2.3.1 The following information is to be available on board:

a) all the documentation listed in [2.2], duly updated

b) the maintenance instructions for each item of machinery, as applicable (supplied by the manufacturer or by the shipyard)

c) the condition monitoring data of the machinery, including all data since the last dismantling and the original reference data

d) reference documentation (trend investigation procedures etc.)

e) the records of maintenance performed, including conditions found, repairs carried out, spare parts fitted

f) the list of personnel on board in charge of the PMS management.

2.4 Annual report

2.4.1 An annual report covering the year's service is to be supplied to the Society. It is to include the following information:

- the list of items of machinery and components (item b) in [2.2.1]) and the procedure for their identification
- the preventive maintenance sheets
- the condition monitoring data, including all data since the last dismantling and the original reference data of the machinery checked through condition monitoring
- any changes to the other documentation in [2.2].

All the documentation is to be signed by the person responsible mentioned in [1.1.5].

3 Implementation of the system

3.1

3.1.1 When the documentation submitted has been approved and the PMS system has been implemented on board and used for a sufficient period (which is not to exceed one year) so that all personnel become familiar with it, a survey is to be carried out in order to start the system and make it officially operational. The scope of this survey, referred to as Implementation Survey, is given in [5.1.1].

3.1.2 Upon the successful outcome of the Implementation Survey, the PMS is considered approved. The relevant annex to the Certificate of Classification of the ship is updated and the survey notation PMS is entered in the Register of Ships.

4 Retention and withdrawal of the system

4.1

4.1.1 The PMS system is retained throughout the class period provided that:

- an annual report covering the year's service is supplied to the Society in accordance with [2.4]
- an annual audit in accordance with [5.2] is satisfactorily completed
- any change to the approved PMS is submitted to the Society for agreement and approval.

4.1.2 The survey arrangement for machinery according to the PMS may be withdrawn by the Society if the PMS is not satisfactorily operated on account of either the maintenance records or the general condition of the machinery or the failure to observe the agreed intervals between overhauls.

4.1.3 The Owner may discontinue the PMS at any time by informing the Society in writing. In this case, the items which have been inspected under the PMS since the last annual audit will be credited for class at the discretion of the attending Surveyor.

4.1.4 In the case of sale or change of management of the ship, the approval of the PMS will be reconsidered.

5 Surveys

5.1 Implementation survey

5.1.1 The implementation survey is to be carried out by a Surveyor of the Society, as stated in [3.1.1], within one year from the date of the documentation approval.

5.1.2 The scope of this survey is to verify that:

- the PMS is implemented in accordance with the approved documentation and is suitable for the type and complexity of the components and systems on board
- the documentation required for the annual audit is produced by the PMS
- the requirements of surveys and testing for retention of class are complied with
- the shipboard personnel are familiar with the PMS procedures.

Upon the successful outcome of the survey confirming the proper implementation of the PMS, the system is considered operational subject to the submission to the Society of a report describing the system.

5.2 Annual audit

5.2.1 Once the PMS system is implemented, the continued compliance with the requirements for checks, overhauls and repairs, where needed, indicated in [2] is to be verified by means of annual audits in order to confirm the validity of the approved survey scheme system.

5.2.2 The annual audit is to be carried out in conjunction with the annual class surveys.

5.2.3 The purpose of this audit is to verify that the scheme is being correctly operated, in particular that all items (to be surveyed in the relevant period) have actually been surveyed in due time. A general examination of the items concerned is carried out.

5.2.4 The maintenance files and functioning records are examined to verify that the machinery has been functioning satisfactorily since the previous survey or audit or, if necessary, that the necessary measures have been taken in response to machinery operating parameters exceeding acceptable tolerances, and that the overhaul intervals have been observed.

5.2.5 Written reports of breakdown or malfunction are to be made available.

5.2.6 The description of the repairs, if any, carried out is to be examined. Any machinery part or component which has been replaced by a spare due to damage is to be retained on board, where possible. On this occasion such replaced parts are to be submitted to the examination of the Surveyor.

5.2.7 Where condition monitoring equipment is in use, functions tests, confirmatory inspections and random check readings are to be carried out as far as practicable and reasonable at the discretion of the Surveyor.

5.2.8 The Surveyor also checks that the personnel on board in charge of the PMS have the appropriate authorisation (see Ch 2, App 2).

5.2.9 A report containing the description of the overhaul and repair activity carried out throughout the period since the preceding audit, and signed by the person responsible, is to be submitted to the attending Surveyor.

5.2.10 If the Surveyor is not satisfied with the results the PMS is achieving, i.e. with the degree of accuracy as regards the maintenance records and/or the general condition of the machinery, he forwards the Society a report recommending the changes to the survey scheme and explaining the reasons for his suggestions.

5.2.11 Upon the satisfactory outcome of this audit, the Surveyor confirms the validity of the PMS, endorses the Certificate of Classification in accordance with Ch 2, Sec 2, [4.3] and decides which items can be credited for class.

5.3 Damage and repairs

5.3.1 Damage to components or items of machinery covered by the PMS which may affect the class is to be reported to the Society. A Surveyor will attend on board, survey the damaged items and, on the basis of the survey results, decide whether recommendations are to be imposed.

5.3.2 All parts of machinery or components which need to undergo substantial repairs are to be surveyed before, during and after the repairs, as deemed appropriate by the Surveyor.

5.3.3 In the case of outstanding recommendations or records of unrepaired damage which may affect the PMS, the relevant items are to be taken out of the PMS until the recommendations have been fulfilled or the repairs carried out.

6 Machinery items surveyed on the basis of condition monitoring

6.1

6.1.1 The extent of condition-based maintenance and associated monitoring equipment to be included in the maintenance scheme is decided by the Owner. The minimum parameters to be checked in order to monitor the condition of the various machinery for which this type of maintenance is accepted are indicated in [6.1.2] to [6.1.5].

6.1.2 For the main diesel engine the parameters to be checked are the following:

- power output
- rotational speed
- indicator diagram (where possible)
- fuel oil temperature and/or viscosity
- charge air pressure
- exhaust gas temperature for each cylinder
- exhaust gas temperature before and after the turbochargers
- temperatures and pressure of engine cooling systems
- temperatures and pressure of engine lubricating oil system
- rotational speed of turbochargers
- vibrations of turbochargers
- results of lubricating oil analysis
- crankshaft deflection readings
- temperature of main bearings.

6.1.3 For the main and auxiliary steam turbines the parameters to be checked are the following:

- turbine bearing vibrations
- power output
- rotational speed
- plant performance data, i.e. steam conditions at the inlet and outlet of each turbine, saturated, superheated and desuperheated steam conditions at the outlet of boilers, condenser vacuum, sea temperature.

6.1.4 For the auxiliary diesel engines the parameters to be checked are the following:

- exhaust gas temperature before and after the turbochargers
- temperatures and pressure of engine cooling systems
- temperatures and pressure of engine lubricating oil system
- rotational speed of turbochargers
- crankshaft deflection readings.

6.1.5 For other auxiliary machinery the parameters to be checked are the following, as applicable:

- inlet and outlet temperatures of cooling systems
- inlet and outlet temperatures of heating systems
- vibrations and performance data of pumps and fans
- differential pressure at filters.

Appendix 2 CSM and PMS Systems: Surveys Carried out by the Chief Engineer

1 Conditions

1.1

1.1.1 The basic conditions for the acknowledgment of surveys carried out by Chief Engineers are specified hereafter. Consideration may be given to other conditions on a case by case basis.

1.1.2 An Owner's attestation, confirming that the Chief Engineer is duly qualified to carry out the inspection of the machinery items when the CSM system or PMS system, as applicable, is implemented on-board ships in accordance with the requirements in [2.1.1] and [2.1.2], is to be made available to the Surveyor on-board.

2 Limits of the interventions

2.1

2.1.1 For ships where the CSM system is implemented, the following items of the class renewal survey for machinery cannot be inspected by the Chief Engineer:

- pressure vessels
- main and auxiliary turbines
- main reduction gears
- crankshafts, with associated main bearings and bottom end connecting rod bearings, of main propulsion internal combustion engines. However, bottom end connecting rod bearings of diesel engines having trunk pistons may be inspected by the Chief Engineer when the complete associated cylinder is inspected in the course of the engine maintenance program
- turbochargers of main propulsion internal combustion engines
- intermediate shafting and associated bearings.

Generally, within a 10-year cycle comprising two consecutive class cycles, all the items surveyed under CSM are to be inspected once by the Society’s Surveyors.

2.1.2 For ships where the PMS system is implemented, all items covered by the system can be surveyed by the Chief Engineer, with the exception of pressure vessels.

2.1.3 In no case may the surveys of tailshafts and boilers, which are items not included in the scope of the class renewal survey, be carried out by the Chief Engineer.

3 Procedure for carrying out surveys

3.1 General

3.1.1 As regards the procedure for carrying out surveys, the Owner is to inform the Chief Engineer that surveys are to be conducted in accordance with the Rules of the Society and, specifically, the requirements for class renewal surveys related to machinery and systems contained in Ch 3, Sec 3, [4].

It is the responsibility of the ship’s Captain and Chief Engineer to decide the date and place for the survey of each component in order to avoid possible accidents (fire included) in the event of damage to the unit(s) remaining in service.

Some guidelines for the Chief Engineer relevant to the dismantling and inspections of main components of the machinery installation are given below.

The items and/or machinery which, as a result of the surveys, are replaced due to wear, damage or defects, are to be kept on board until they are inspected by a Surveyor of the Society.

3.2 Main diesel engines

3.2.1 The following items are to be surveyed as indicated:

- the top and bottom halves of the main bearings are to be removed and inspected, and the clearances are to be taken, recorded and compared with the limits recommended by the engine builder
- the top and bottom halves of crankpin bearings are to be examined, and the clearances are to be taken, recorded and compared with the limits recommended by the engine builder
- crankpins, journals and webs are to be examined for crack detection, mainly at the fillets and in the vicinity of the lubricating oil holes
- crankshaft deflections are to be taken and recorded at regulars intervals, enabling verification of the trend when they are taken in the presence of the Society's Surveyor. This operation is to be effected bearing in mind that during the readings the journals are to be steady on their bearings
- other parts exposed to wear or operating incidents are to be carefully examined and the results recorded. In particular, the wear of liners is to be measured and recorded.

3.3 Auxiliary diesel engines

3.3.1 The survey generally consists of the complete dismantling of the engine and a careful examination of those items most liable to be exposed to wear or operating incidents. In particular:

- crankshaft deflections and wear of cylinder liners are to be measured
- the crankshaft is to be checked by means of dye penetrant in way of fillets and lubricating oil holes
- all top halves of the main bearings together with at least two bottom halves are to be dismantled
- crankcase explosion relief valves, if fitted, are to be checked.

3.4 Reciprocating compressors

3.4.1 The survey is to include:

- the dismantling of pistons and valves for inspection
- the examination and testing of the nest of cooler tubes
- the verification of safety relief valves after reassembling.

3.5 Coolers, condensers, heaters

3.5.1 The survey is to include:

- the dismantling of the covers
- the examination of the nest of tubes
- the testing of the nest of tubes, if necessary.

3.6 Electrical switchboard

3.6.1 The survey is to include:

- the cleaning of the switchboard
- the verification of the connection assemblies, locking device tightening and busbar tightening
- the examination of the condition of the circuit-breakers, switches and fuses
- the verification of the contacts and screens
- the checking of the measuring instruments, which are to be re-calibrated or replaced, if inaccurate
- the insulation resistance test.

3.7 a.c. and d.c. generators

3.7.1 The survey is to include:

- the removal of protection plates and brush carriers
- the cleaning of field coils and armature windings
- the verification of proper contact of brushes, which are to be renewed if excessively worn
- the verification of commutators and sliprings
- the measurement of air gap clearances
- the checking of journals and bearings
- the insulation resistance test.

3.8 Other items (pumps, electric motors, etc.)

3.8.1 The survey is generally to include the complete dismantling for inspection of the main parts exposed to wear or operating incidents, such as bearings, casings, impellers and rotors.

4 Records of surveys carried out

4.1

4.1.1 The surveys carried out by the Chief Engineer are to be recorded in the engine/machinery log-book and a survey report is to be prepared for each item surveyed.

The report is generally to be drawn up in English; however, for ships trading in specific restricted areas the use of the language of the country concerned will be accepted.

The report may be provided in hard copy or using a computerised recording system.

4.1.2 The report is to indicate the following information:

- identification data:
  - name of ship and register number
  - name of Chief Engineer and Owner's attestation
  - date and place (port or voyage leg) of the survey
  - reference of the item in the CSM or PMS list, and description of the item
- inspection conducted:
  - the type of inspection carried out: visual external examination, internal examination after dismantling, overhaul
  - readings performed, when applicable: clearances, measurements, working pressure, or other working parameters of the equipment
  - inspection findings: corrosion, fractures, pieces of equipment worn out, broken or missing
- maintenance and repairs carried out and parts replaced
- results of tests performed after the inspection, such as working test, pressure test.

For sake of completeness, other documentation such as sketches, photos, measurement reports may be attached to the report.

The report is to be signed by the Chief Engineer.

5 Confirmatory survey

5.1

5.1.1 A confirmatory survey, to be carried out by a Surveyor of the Society, is to be requested according to the following principle:

- for ships under the CSM system, within a reasonably short time from the date of the surveys carried out by the Chief Engineer, and, in any case, in the first port which is under the jurisdiction of an Office of the Society
- for ships under the PMS system, at the next annual audit (see Ch 2, App 1, [5.2]).

5.1.2 The Surveyor is to be supplied with a copy of this survey report and also shown the engine log-book.

5.1.3 The Surveyor carries out an external examination of the relevant items and parts replaced and, if applicable, attends running tests. If doubts arise, the Surveyor may request dismantling as deemed necessary.

5.1.4 If the persons on board are authorized to survey the main engine crankshaft and bearings (see [2.1.2]), the Surveyor performs the following:

- check of condition monitoring records (see Ch 2, App 1, [6.1.2])
- check of crankshaft deflection readings
- check of bearing clearances (where possible)
- checks for signs of wiped or broken white metal in the crankcase or filters
- check of the witness marks of shrink fits of crankshafts
- check of the bedplate structure (inside and outside)
- check that the condition of crankpins, journals and associated bearings is duly recorded.

5.1.5 Where the confirmatory survey is performed with an abnormal delay, the inspection is to be more extensive and, if necessary, the due surveys are to be completely repeated.

5.1.6 The date of the execution of the surveys will be assumed to be the date of the confirmatory survey.

6 Suspension of the Chief Engineer's authorization

6.1

6.1.1 Where the condition of the items surveyed by the Chief Engineer as specified in his or her reports does not correspond to the findings of the attending Surveyor, the Society may suspend the Chief Engineer's authorization.

6.1.2 The Society may also suspend the Chief Engineer's authorization in case of doubt on the general maintenance of the machinery installation.

Appendix 3 Thickness Measurements: Extent, Determination of Locations, Acceptance Criteria

1 General

1.1 Aim of the Appendix

1.1.1 Thickness measurements are a major part of surveys to be carried out for the maintenance of class, and the analysis of these measurements is a prominent factor in the determination and extent of the repairs and renewals of the ship's structure.

1.1.2 The Appendix is intended to provide Owners, companies performing thickness measurements and the Society's Surveyors with a uniform means with a view to fulfilling Rule requirements for thickness measurements. In particular, it will enable all the above-mentioned parties to carry out:

- the planning and preparation
- the determination of extent and location, and
- the analysis

of the thickness measurements in cooperation.

1.1.3 This Appendix is also to be used for the thickness measurements of ships assigned the notation **STAR-HULL** (see Ch 5, Sec 3 and Part E, Chapter 2). However, the acceptance criteria for thickness measurements specific to this notation are given in Pt E, Ch 9, Sec 3.

1.2 Scope of the Appendix

1.2.1 Separate Articles below provide the following information:

- references to rule requirements and some additional information on the extent of the thickness measurements to be performed during surveys according to types of ships and related surveys (see Article [2])
- locations of the measurements for the main parts of the ship (see Article [3])
- how to analyse the results of thickness measurements (see Article [4]).

Tables and sketches are also given to detail the above points according to the types of ships.

2 Rule requirements for the extent of measurements

2.1 General

2.1.1 For the maintenance of class, thickness measurements may be required during annual, intermediate and class renewal surveys.

Tab 1 gives the references to the requirements for minimum thickness measurements indicated in Part A, Chapter 3 and Part A, Chapter 4 for each service notation and related to the different types of surveys.

Some additional explanations are also given about the wording used in the Rules as well as the general principles of the required thickness measurements during class renewal surveys.

Table 1 : References to rule requirements related to thickness measurements

SERVICE NOTATION	TYPE OF SURVEY		
	CLASS RENEWAL	INTERMEDIATE	ANNUAL
All service notations	Ch 3, Sec 3, [3.5] and Ch 3, Sec 3, Tab 2: systematic measurements and suspect areas Where substantial corrosion is found, the extent of thickness measurements may be increased to the Surveyor's satisfaction, using Ch 3, Sec 3, Tab 3 as guidance	Ch 3, Sec 2, Tab 1: thickness measurements to be taken if deemed necessary by the Surveyor Where substantial corrosion is found, the extent of thickness measurements may be increased to the Surveyor's satisfaction, using Ch 3, Sec 3, Tab 3 as guidance	Ch 3, Sec 1, [2.1.2]: areas of substantial corrosion identified at previous surveys Where substantial corrosion is found, the extent of thickness measurements may be increased to the Surveyor's satisfaction, using Ch 3, Sec 3, Tab 3 as guidance

2.2 Class renewal survey

2.2.1 The thickness measurements required by the Rules consist of:

- systematic thickness measurements, i.e. measurements of different parts of the structure in order to assess the overall and local strength of the ship
- measurements of suspect areas as defined in Ch 2, Sec 2, [3.2.8]
- additional measurements on areas determined as affected by substantial corrosion as defined in Ch 2, Sec 2, [3.2.7].

3 Number and locations of measurements

3.1 General

3.1.1 Considering the extent of thickness measurements as required by the Rules and indicated in [2], the locations of the points to be measured are given here for the most important items of the structure. Thus the number of points can be estimated.

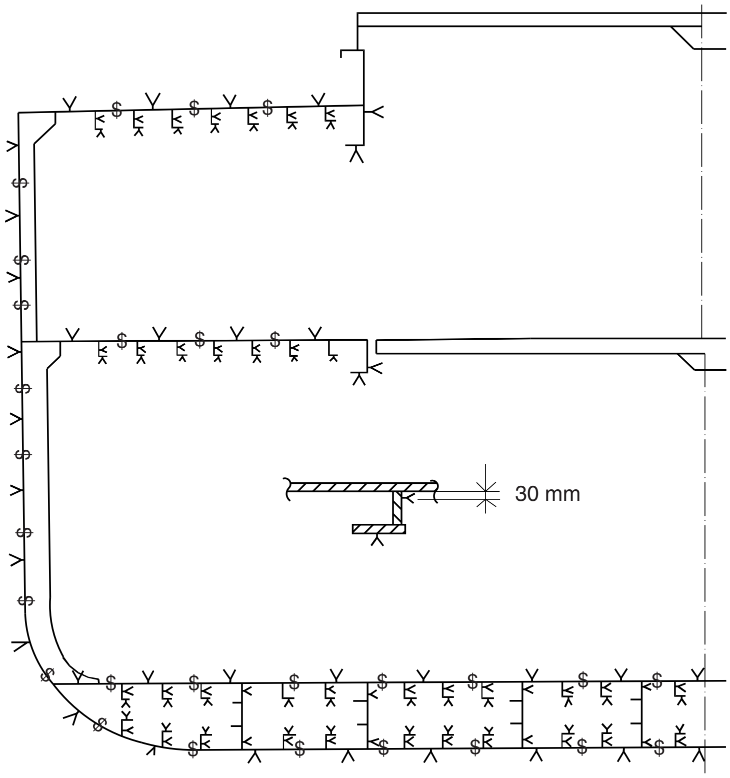
3.2 Locations of points

3.2.1 Tab 2 provides explanations and/or interpretations for the application of those requirements indicated in the Rules which refer to both systematic thickness measurements related to the calculation of global hull girder strength.

Table 2 : Interpretations of rule requirements for the locations and number of points to be measured

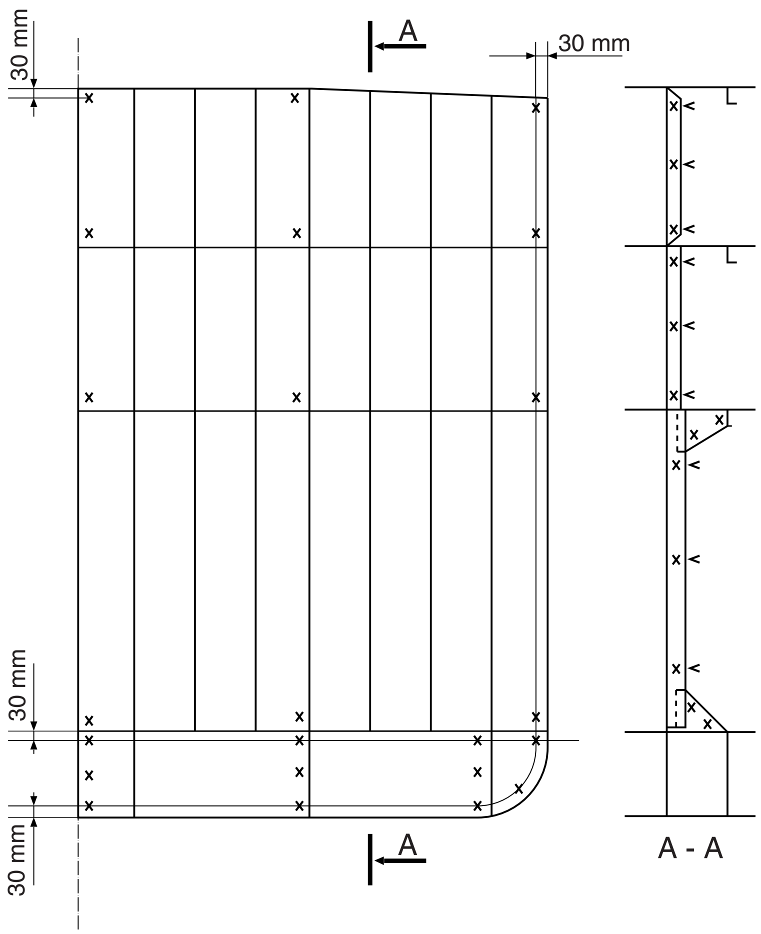
SYSTEMATIC MEASUREMENTS		
ITEM	INTERPRETATION	FIGURE
Selected plates on deck, tank top, bottom, double bottom and wind-and-water	"Selected" means at least a single point on one out of three plates, to be chosen on representative areas of average corrosion	No figure
All deck, tank top and bottom plates and wind-and-water strakes	At least two points on each plate to be taken either at each 1/4 extremity of plate or at representative areas of average corrosion	No figure
Transverse section	Refer to the definition given in Ch 2, Sec 2, [3.2.5]	Fig 1
Bulkheads	"Selected bulkheads" means at least 50% of the bulkheads	Fig 2
Selected internal structure such as floors and longitudinals, transverse frames, web frames, deck beams, 'tweendecks, girders	The internal structural items to be measured in each space internally surveyed are to be at least 10%	Fig 3

Figure 1 : Transverse section of a military ship



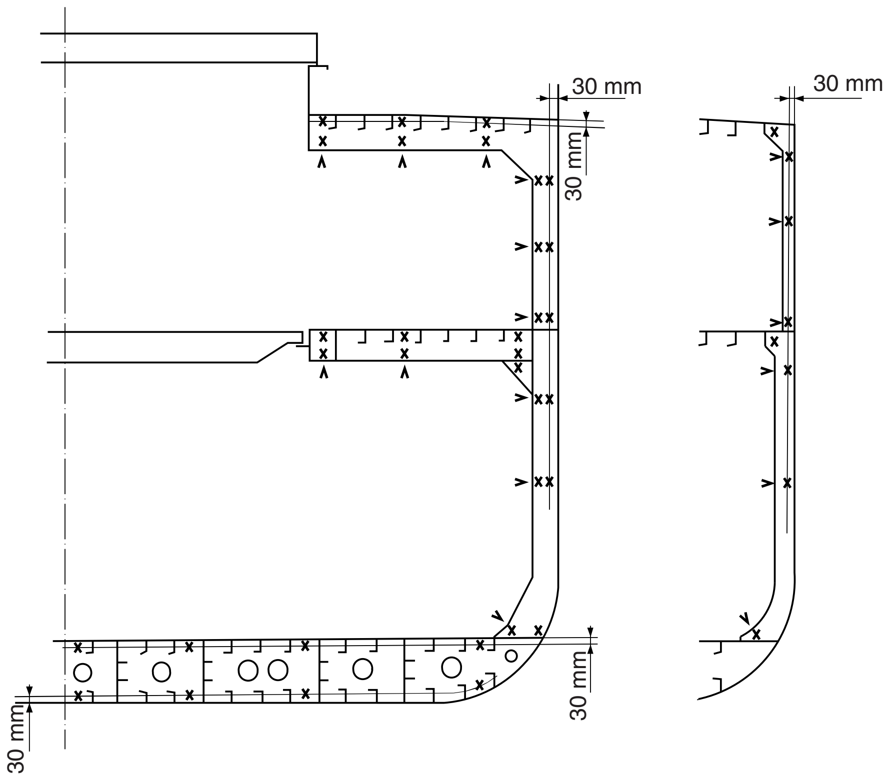
Measurements are to be taken on both port and starboard sides of the selected transverse section

Figure 2 : Locations of measurements on bulkheads of military ships



One stiffener out of three to be measured as per view A - A

Figure 3 : Locations of measurements on selected internal structural elements of military ships



4 Acceptance criteria for thickness measurements

4.1 General

4.1.1 Acceptance criteria stipulate limits of wastage which are to be taken into account for reinforcements, repairs or renewals of steel structure. These limits are generally expressed for each structural item as a maximum percentage of acceptable wastage (W). When the maximum percentage of wastage is indicated, the minimum acceptable thickness (t_{min}) is that resulting from applying this percentage to the rule thickness (t_{rule}), according to the following formula:

$$t_{min} = \left(1 - \frac{W}{100}\right) t_{rule}$$

However, when the rule thickness is not available, the as-built thickness can be used.

Only for criteria related to an item (see [4.3.4] b), the Society may establish a list of renewal thicknesses tailored to the different structural items. In such a case these thicknesses are used in lieu of the minimum thicknesses calculated from the percentage of wastage.

Note 1: In any case, at the request of the Owner, the Society may perform a direct calculation based on the current measurements.

4.1.2 In cases where the ship has some structural elements with reduced wear margins (e.g. due to ship conversion, increase of draught), the minimum acceptable thickness for these elements is to be calculated with reference to the rule scantlings without taking account of any reduction originally agreed.

4.1.3 Decisions on steel renewals are taken by the attending Surveyor applying the criteria given in this Article and based on his judgement and the actual condition of the ship. Should advice be needed to support his decision, the Surveyor may refer to the relevant technical office of the Society.

4.2 Criteria

4.2.1 The acceptance criteria for the minimum thicknesses are divided into:

- criteria on local and global strength, given in [4.3]
- criteria on buckling strength, given in [4.4]
- criteria on pitting, given in [4.5].

4.2.2 Each measured structural item is to be checked against these four criteria, as far as applicable. When the criteria are not met, reinforcements, repairs and renewals are to be carried out as appropriate.

4.3 Local and global strength criteria

4.3.1 Local and global strength criteria are given for the following ship types:

- **military ship**
- **oil replenishment ship**.

These criteria may also be used for other ship types taking into consideration the equivalence or similarity of structural elements and their contribution to local and/or global strength.

4.3.2 For the evaluation of the ship longitudinal strength, it is a prerequisite that fillet welding between longitudinal members and deck, side and bottom plating is maintained effective so as to keep continuity of hull structures.

4.3.3 Each structural item to be assessed is illustrated in a typical transverse section (see Fig 5).

These structural items are also listed in Tab 5 and grouped according to their position and contribution to the local or global strength of the ship.

4.3.4 Each structural item is to be assessed according to four different criteria which vary with regard to the domain under which it is considered, namely:

a) an isolated area, which is meant as a part of a single structural item. This criterion takes into consideration very local aspects such as grooving of a plate or web, or local severe corrosion; however, it is not to be used for pitting for which separate criteria are considered (see [4.5])

b) an item, which is meant as an individual element such as a plate, a stiffener, a web, etc. This criterion takes into consideration the average condition of the item, which is assessed by determining its average thickness using the various measurements taken on the same item

c) a group of items, which is meant as a set of elements of the same nature (plates, longitudinals, girders) contributing either to the longitudinal global strength of the ship in a given zone or to the global strength of other primary transverse elements not contributing to the ship longitudinal strength, e. g. bulkheads, hatch covers, web frames

d) a zone, which is meant as all and only longitudinal elements contributing to the longitudinal strength of the ship; in this regard, the three main zones are defined as deck zone, neutral axis zone and bottom zone. This criterion takes into consideration the average condition of all groups of items belonging to the same zone.

4.3.5 The assessment of the thickness measurements is to be performed using the values given in Tab 5, for each structural element with regard to the four criteria defined above, in the following order:

a) assessment of isolated areas (column 1 in the tables). If the criterion is not met, the wasted part of the item is to be dealt with as necessary.

b) assessment of items (column 2 in the tables). If the criterion is not met, the item is to be dealt with as necessary in the measured areas as far as the average condition of the item concerned is satisfactory. In cases where some items are renewed, the average thicknesses of these items to be considered in the next step are the new thicknesses.

c) assessment of groups of items (column 3 in the tables). If the criterion is not met, a sufficient number of elements are to be renewed in order to obtain an increased average thickness satisfying the considered criterion of the group (generally the elements to be renewed are those most wasted). As an example, for the assessment of the group "deck plates" all deck plates are measured and an average thickness of each of them is estimated. Then the average of all these values is to satisfy the criteria given for this group.

d) assessment of zones (column 4 in the tables). In principle, the criterion of the zone is met when all groups of items belonging to the zone meet their own criteria (see c) above). However, a greater diminution than those given in column 3 may be accepted for one group of items if, considering the other groups of items belonging to the same zone, the overall diminution of the zone does not exceed the criterion given for it in column 4.

   Example: The deck zone consists of two groups of items:

   - deck plating, which has an average diminution of 12% (criterion 10%)
   - deck longitudinals, which has an average diminution of 4% (criterion 10%).

   Even though the deck plating group exceeds its acceptance criterion, the average diminution of the zone, which can be very roughly estimated at 8%, is acceptable and thus the deck plating group can be accepted as it is.

Note 1: This criterion applicable to the zones is based on the general rule that the current hull girder section modulus is not to be less than 90% of the rule section modulus within 0,4L amidships. When the zone criterion is used, the assessment is made on the basis of the original modulus instead of the rule modulus. At the request of the Owner, a direct calculation using the ship's current thicknesses may be performed by the Society in order to accept greater diminutions than those given for this criterion.

4.3.6 These criteria take into consideration two main aspects:

- the overall strength of the hull girder
- the local strength and integrity of the hull structure, such as hatch covers, bulkheads, etc.

4.4 Buckling strength criterion

4.4.1 This criterion is applicable to ships having a length greater than 120 metres.

In addition to the evaluation of structural elements according to [4.3], the structural items contributing to the longitudinal strength of the ship, such as deck and bottom plating, deck and bottom girders, etc., are also to be assessed with regard to their buckling strength. The values shown in Tab 3 are not to be exceeded.

Note 1: The minimum thickness will be specially considered for ships built with excess hull girder section modulus.

4.5 Pitting

4.5.1 The maximum acceptable depth for isolated pits is 35% of the as-built thickness.

4.5.2 For areas with different pitting intensity, the intensity diagrams shown in Fig 4 are to be used to identify the percentage of affected areas.

For areas having a pitting intensity of 50% or more, the maximum average depth of pits is 20% of the as-built thickness. For intermediate values between isolated pits and 50% of affected area, the interpolation between 35% and 20% is made according to Tab 4.

Table 3 : Buckling strength criterion

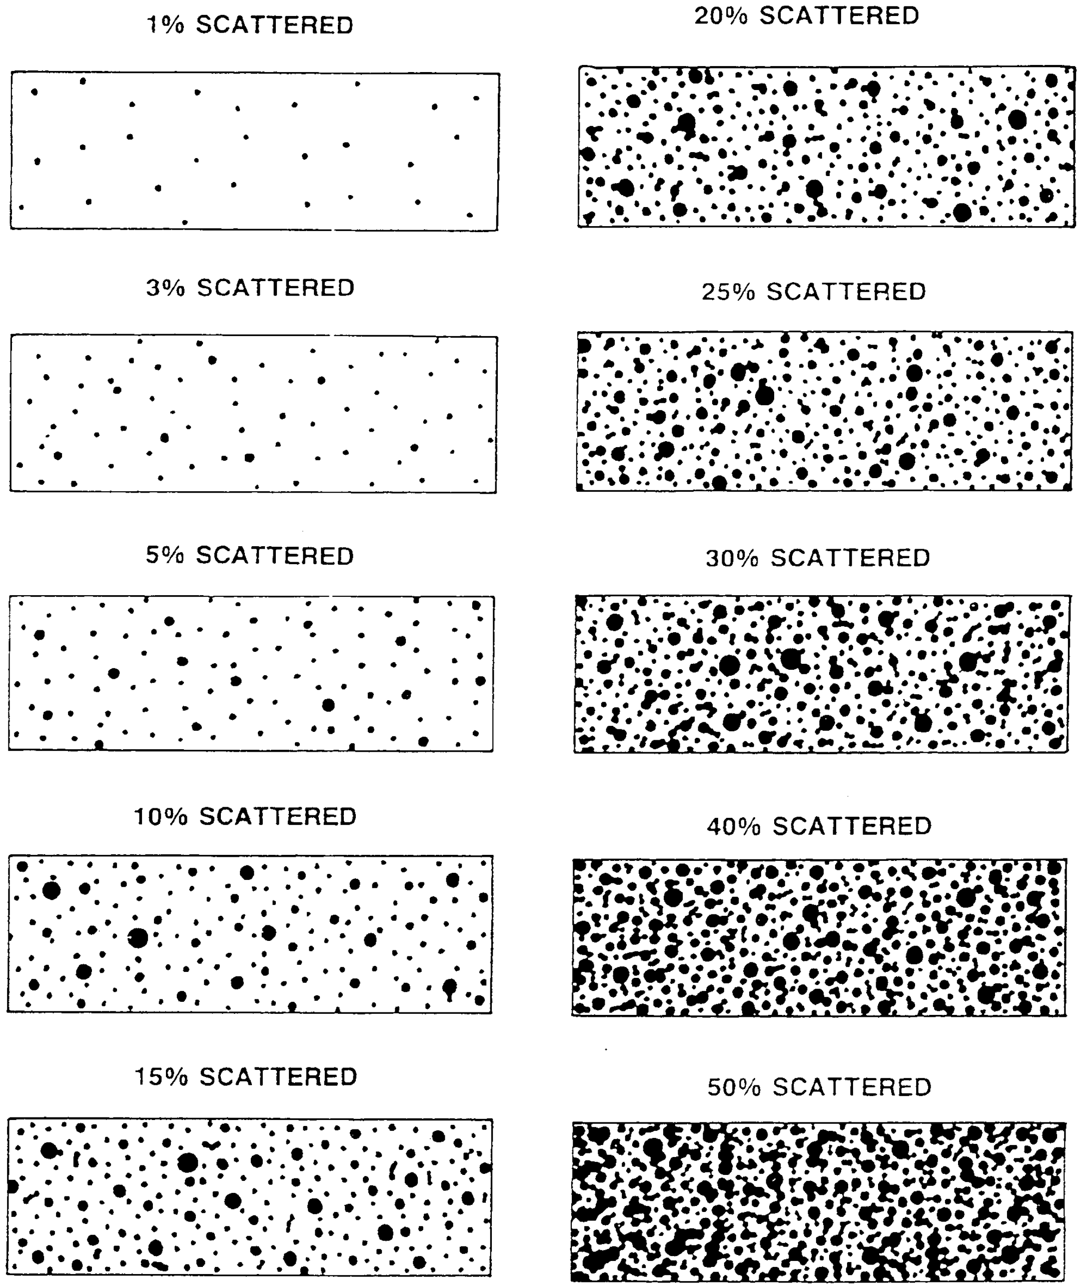
ITEMS		RATIO	MATERIAL (R_{eH})		
			235	315	355 and 390
Bottom and deck plates		s / t	56,0	51,0	49,0
Longitudinals	flat bar web	h_w / t_w	20,0	18,0	17,5
Flanged longitudinals / girders	web	h_w / t_w	56,0	51,0	49,0
Flanged longitudinals / girders	symmetrical flange	b_f / t_f	34,0	30,0	29,0
Flanged longitudinals / girders	asymmetrical flange	b_f / t_f	17,0	15,0	14,5

Symbols:
R_{eH} : Minimum yield stress of the material, in N/mm²;
s : Longitudinal spacing, in mm;
t : Actual plate thickness, in mm;
h_w : Web height, in mm;
t_w : Web thickness, in mm;
b_f : Flange breadth, in mm;
t_f : Flange thickness, in mm;

Table 4 : Pitting intensity and corresponding maximum average depth of pitting

PITTING INTENSITY (%)	MAXIMUM AVERAGE PITTING DEPTH (% of the as-built thickness)
Isolated	35,0
5	33,5
10	32,0
15	30,5
20	29,0
25	27,5
30	26,0
40	23,0
50	20,0

Figure 4 : Pitting intensity diagrams (from 1% to 50% intensity)



4.5.3 In addition, the thickness outside the pits in the area considered is to be assessed according to [4.3] and [4.4].

Note 1: Application of filler material (plastic or epoxy compounds) is recommended as a means to stop or reduce the corrosion process, but it is not considered an acceptable repair for pitting exceeding the maximum allowable wastage limits. Welding repairs may be accepted when performed in accordance with procedures agreed with the Society.

Figure 5 : Military ship: layout of items to be assessed

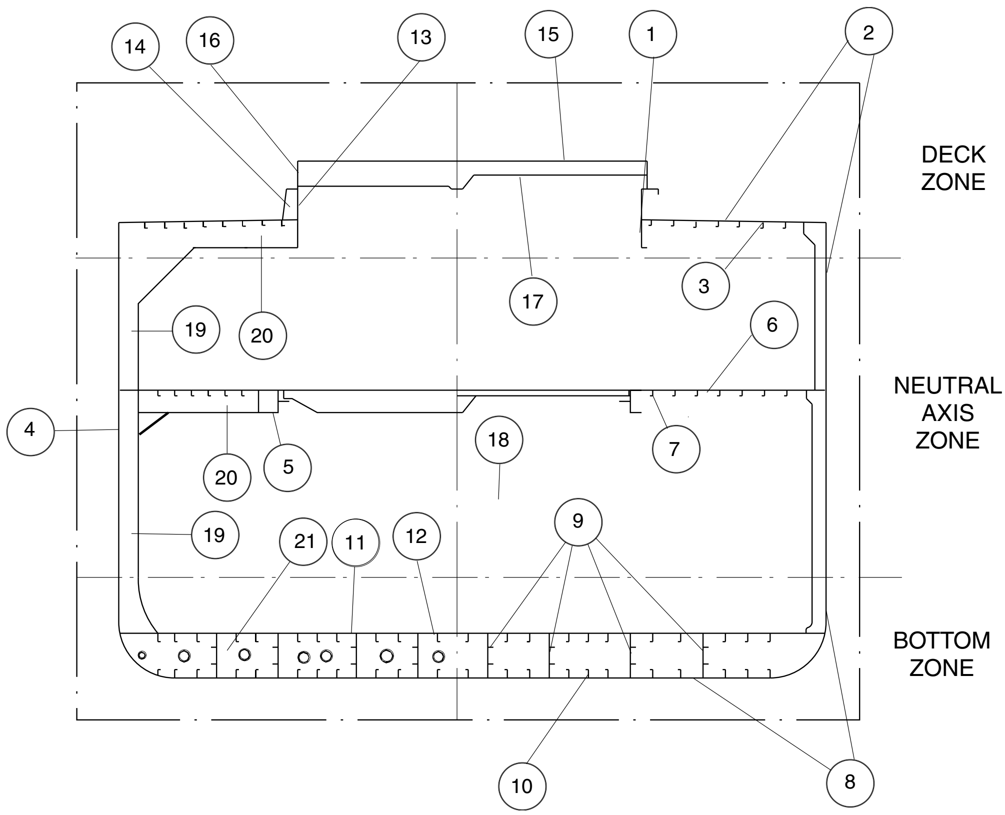


Table 5 : Local and global acceptance criteria for military ships (given in % of wastage)

Group of items	Description of items	1 Isolated area	2 Item	3 Group	4 Zone
ITEMS CONTRIBUTING TO THE LONGITUDINAL STRENGTH (TRANSVERSE SECTION)					
	DECK ZONE **(1)**	–	–	–	10

Part A
Classification and Surveys

CHAPTER 3
SCOPE OF SURVEYS (ALL SHIPS)

Section 1	Annual Survey
Section 2	Intermediate Survey
Section 3	Class Renewal Survey
Section 4	Bottom Survey
Section 5	Tailshaft Survey
Section 6	Boiler Survey
Appendix 1	Class Requirements and Surveys of Laid-up Ships

Section 1 Annual Survey

1 General

1.1

1.1.1 The requirements of this Section apply to annual surveys of all ships. The specific requirements for annual surveys related to service notations and additional class notations assigned to ships are addressed in Part A, Chapter 4 and Part A, Chapter 5, respectively.

1.1.2 At the time of annual surveys, the ship is to be generally examined. The survey is to include a visual inspection of the hull, equipment and machinery of the ship and some operational tests thereof, so far as necessary and practicable in order to verify that the ship is in a acceptable general condition and is properly maintained. This survey is carried out alongside without dismantling.

1.1.3 Owners are reminded that, in compliance with the requirements in Ch 2, Sec 2, [7.3], any modification to the ship's hull, equipment and machinery affecting its classification is to be made known to the Society.

2 Hull

2.1 Hull and hull equipment

2.1.1 The survey is to include a general external examination and testing, where appropriate, of the following items, as applicable:

- outer shell plating above the waterline, relevant shell doors and accessible parts of the rudder(s)
- plating of main deck and exposed decks, superstructures, with their openings and means of closure
- hatchways and other openings on exposed decks, with their coamings and their means of closure and securing arrangements (for details see [2.2])
- sidescuttles and deadlights, chutes and other openings with their means of closure
- bulwarks, guard rails, freeing ports, gangways and lifelines, ladders
- scuppers and sanitary discharges, valves on discharge lines and their controls
- ventilators, air pipes, overflow pipes and gas vent pipes, with their means of closure and flame screens, where required
- when a freeboard has been assigned to the ship, freeboard marks on the ship's sides
- deck equipment such as lifeboat davit foundations, bollards, fairleads, hawse pipes, etc., masts and associated rigging, including lightning conductors
- windlass and equipment of chain cables or wire ropes for anchors
- watertight bulkheads, their watertight doors and associated local and remote controls, and their watertight penetrations
- main and auxiliary steering arrangements, including their associated equipment and control systems, and manoeuvring gear
- fire divisions and fire doors, dampers in ventilation ducts, means of closure of skylights and other openings
- confirmation that emergency escape routes from accommodation and service spaces are satisfactory
- engine room
- where fitted, helicopter deck and its supporting structure, safety net and arrangements for the prevention of sliding
- availability of loading manual or, where required, electronic loading instrument, including standard test
- availability of approved stability documentation.

Note 1: Due attention is also to be given to fuel oil piping passing through ballast tanks, which is to be pressure tested at working nominal pressure where doubts arise.

2.1.2 Suspect areas identified at previous class renewal surveys are to be examined. Areas of substantial corrosion identified at previous class renewal or intermediate surveys are to be subjected to thickness measurements.

2.1.3 Ballast tanks are to be internally examined when required as a consequence of the results of the class renewal survey, see Ch 3, Sec 3, [3.4.2], or the intermediate survey, see Ch 3, Sec 2, Tab 1.

Thickness measurements are to be carried out as considered necessary by the Surveyor.

2.2 Hatch covers and coamings

2.2.1 The Owner or his representative is to declare to the attending Surveyor that no significant changes have been made to the hatch covers, hatch coamings and their securing and sealing devices without prior approval of the Society.

The survey of hatch covers and coamings is to include:

a) when fitted with portable covers, or wooden or steel pontoons, checking of the satisfactory condition of:
   - wooden covers and portable beams, carriers or sockets for the portable beams, and their securing devices
   - steel pontoons
   - tarpaulins
   - cleats, battens and wedges
   - hatch securing bars and their securing devices
   - loading pads/bars and the side plate edge
   - guide plates and chocks
   - compression bars, drainage channels and drain pipes (if any)

b) when fitted with mechanically operated steel covers, checking of the satisfactory condition of:
   - hatch covers
   - tightness devices of longitudinal, transverse and intermediate cross junctions (gaskets, gasket lips, compression bars, drainage channels and, if any, drain pipes)
   - clamping devices, retaining bars, cleating
   - chain or rope pulleys
   - guides
   - guide rails and track wheels
   - stoppers, etc.
   - wires, chains, gypsies, tensioning devices
   - hydraulic system essential to closing and securing
   - safety locks and retaining devices
   - the operation of hatch covers, by means of random examination: stowage and securing in open condition, proper fit, locking and efficiency of sealing in closed position, operational testing of hydraulic and power components, wires, chains and link drives

c) checking of the satisfactory condition of hatch coaming plating and its stiffeners.

3 Machinery and systems

3.1 General machinery installations

3.1.1 The survey of general machinery installations is to cover the following items:

- general examination of machinery and boiler spaces with particular attention to the fire and explosion hazards; confirmation that emergency escape routes are practicable and not blocked
- general examination of the machinery, steam, hydraulic, pneumatic and other systems and their associated fittings, for confirmation of their proper maintenance
- testing of the means of communication and order transmission between the navigating bridge and the machinery control positions and other control stations
- confirmation that the rudder angle indicator on the bridge is in working order
- examination, as far as practicable, of the bilge pumping systems and bilge wells, including operation of the pumps, remote reach rods and level alarms, where fitted
- visual examination of the condition of any expansion joints in sea water systems
- external examination of pressure vessels other than boilers and their appurtenances, including safety devices, foundations, controls, relieving gear, high pressure piping, insulation and gauges.

3.1.2 When the ship is equipped with a refrigerating plant (whether or not covered by an additional class notation), the annual survey is to include the external examination of:

- pressure vessels of the installation to the same extent as indicated in [3.1.1]
- refrigerant piping, as far as practicable
- for refrigerating machinery spaces using ammonia as refrigerant:
  - ventilation system including functional test
  - water-spraying fire-extinguishing system; see [3.4.2] item d)
  - bilge system including functional test
  - electrical equipment, confirming its proper maintenance
  - gas detection system
  - breathing apparatus and protective clothing.

3.1.3 When the ship is equipped with thruster installations, the annual survey is to include:

- an external examination of the machinery installation
- an operating test of the complete installation.

3.2 Boilers

3.2.1 For main and auxiliary boilers, the annual survey consists of an external examination of boilers and their appurtenances, including safety devices, foundations, controls, relieving, high pressure and steam escape piping, insulation and gauges.

3.2.2 For thermal oil heaters, a functional test while in operation is to be carried out, during which the following items are checked:

- the heater for detection of leakages
- the condition of the insulation
- the operation of indication, control and safety devices
- the condition of remote controls for shut-off and discharge valves

A satisfactory analysis of the quality of oil is to be made available to the Surveyor.

3.2.3 For exhaust gas thermal oil heaters, in addition to the requirements of [3.2.2], a visual examination and a tightness testing to the working pressure of the heater tubes are to be carried out.

3.3 Electrical machinery and equipment

3.3.1 The survey of electrical machinery and equipment is to cover the following items:

- general examination, visually and in operation, as feasible, of the electrical installations for power and lighting, in particular main and emergency generators, electric motors, switchboards, switchgears, cables and circuit protective devices, indicators of electrical insulation and automatic starting, where provided, of emergency sources of power
- checking, as far as practicable, the operation of emergency sources of power and, where they are automatic, also including the automatic mode.

3.3.2 The survey is also to cover the bridge control of propulsion machinery, and related arrangements (alarms and safety devices), when fitted.

The survey of an automated installation covered by an additional class notation is detailed in Part A, Chapter 5.

3.3.3 The survey is also to cover the computerized systems through the control of the Software Registry as mentioned in Pt C, Ch 3, Sec 3.This survey shall include:

- checking of modification of software rgistry, in particular the reporting of security checks during software modification inside the Software Registry
- checking that revision of software mentioned in Software Registry corresponds with revision effectively used for at least one computerized system chosen at the satisfaction of the surveyor.
- checking that Software Registry has been updated according to the last ship relevant modifications

3.3.4 For ships where the electrical distribution system includes harmonic filters, the survey is to include:

- Annual measurement, as a minimum, of the harmonic distortion levels of main busbars under seagoing conditions as close to the periodical machinery survey as possible so as to give a clear representation of the condition of the entire plant to the Surveyor. Harmonic distortion readings are to be carried out when the greatest amount of distortion is indicated by the measuring equipment. An entry showing which equipment was running and/or filters in service is to be recorded in the log so this can be replicated for the next periodical survey. Harmonic distortion levels are also to be measured following any modification to the ship's electrical distribution system or associated consumers by suitably trained ship's personnel or by a qualified outside source.
- Verification that records of all above measurements are made available to the Surveyor at each periodical survey.

Note 1: Those requirements apply at any scheduled machinery periodical survey having a due date on or after 1st July 2017 for ships contracted for construction before 1st July 2017.

- For ships contracted for construction on or after 1st July 2017, verification that the facilities used for continuous monitoring of the levels of harmonic distortion experienced on the main busbars as well as alerting the crew when the level of harmonic distortion exceeds the acceptable limits are working properly and review of corresponding records.

3.4 Fire protection, detection and extinction

3.4.1 The survey of fire prevention and other general arrangements is to cover the following items:

- checking that fire control plans are properly posted
- examination and testing, as feasible, of the operation of manual and/or automatic fire doors, where fitted
- checking, as far as practicable, that the remote controls for stopping fans and machinery and shutting off fuel supplies in machinery spaces and, where fitted, the remote controls for stopping fans in accommodation spaces and the means of cutting off power to the galley are in working order
- examination of the closing arrangements of ventilators, funnel annular spaces, skylights, doorways and tunnel, where applicable
- examination, as far as practicable, and testing, as feasible and at random, of the fire and/or smoke detection systems.

3.4.2 The survey requirements for all types of fire-fighting systems that are usually found on board ships related either to machinery spaces or to cargo areas and/or spaces or to accommodation spaces, irrespective of the service notation assigned, are the following:

a) water fire system
   - examination of the fire main system and confirmation that each fire pump including the emergency fire pump can be operated separately so that the two required powerful jets of water can be produced simultaneously from different hydrants, at any part of the ship whilst the required pressure is maintained in the fire main
   - checking that fire hoses, nozzles, applicators, spanners and international shore connection (where fitted) are in satisfactory working condition and situated at their respective locations

b) fixed gas fire-extinguishing system (CO_2 , Halon or other gas)
   - external examination of gas receivers of the fixed fire-extinguishing systems and their accessories, including the removal of insulation for insulated low pressure gas containers
   - examination of fixed fire-fighting system controls, piping, instructions and marking; checking for evidence of proper maintenance and servicing, including date of last system tests
   - test of the alarm triggered before the gas is released

c) sprinkler system
   - examination of the system, including piping, valves, sprinklers and header tank
   - test of the automatic starting of the pump activated by a pressure drop
   - check of the alarm system while the above test is carried out

d) water-spraying system
   - examination of the system, including piping, nozzles, distribution valves and header tank
   - test of the starting of the pump activated by a pressure drop (applicable only for machinery spaces)

e) fixed foam systems (low or high expansion)
   - examination of the foam system
   - test to confirm that the minimum number of jets of water at the required pressure in the fire main is obtained when the system is in operation
   - checking the supplies of foam concentrate and receiving confirmation that it is periodically tested (not later than three years after manufacture and annually thereafter) by the manufacturer or an agent

f) dry powder system
   - examination of the dry powder system, including the powder release control devices
   - checking the supplies of powder contained in the receivers and that it has maintained its original smoothness
   - checking that the pressure of propelling inert gas contained in the relevant bottles is satisfactory.

3.4.3 As far as other fire-fighting equipment is concerned, it is to be checked that:

- semi-portable and portable fire extinguishers and foam applicators are in their stowed positions, with evidence of proper maintenance and servicing, and detection of any discharged containers
- firemen's outfits are complete and in satisfactory condition.

3.4.4 Where a helideck is fitted, the following is to be checked, as far as appropriate:

- drainage arrangements around the landing area
- fire fighting appliances and arrangements (to be surveyed as per [3.4.2], according to the equipment installed
- overall examination of refuelling systems and hangar facilities for cleanliness and absence of leaks, condition of gutters and drainage arrangement.

Section 2 Intermediate Survey

1 General

1.1 Application

1.1.1 The requirements of this Section apply to intermediate surveys of all ships. The specific requirements for intermediate surveys related to service notations and additional class notations assigned to ships are addressed in Part A, Chapter 4 and Part A, Chapter 5, respectively.

1.1.2 The intermediate survey is to include examination and checks on a sufficiently extensive part of the structure to show that the structures of the ship are in satisfactory condition so that the ship is expected to operate until the end of the current period of class, provided that the ship is properly maintained and other surveys for maintenance of class are duly carried out during this period.

2 Hull

2.1 Surveys and testings

2.1.1 The requirements given in Tab 1 for the survey and testing of salt water ballast tanks are to be complied with.

Table 1 : Intermediate survey of hull (all ships)

ITEM	Age of ship (in years at time of intermediate survey)	
	5 < age ≤ 10	10 > age
SALT WATER BALLAST SPACES	Representative spaces internally examined Thickness measurements, if considered necessary by the Surveyor See **(1) (2) (3)**	All spaces internally examined Thickness measurements, if considered necessary by the Surveyor Tightness of inner bottom plating of cargo holds in way of double bottom salt water ballast tanks checked See **(1) (3)**

(1) If no visible structural defects are present, the examination is limited to verifying that the protective coating remains efficient.
(2) Where the protective coating is found to be in poor condition, as defined in Ch 2, Sec 2, [3.2.10], where a soft coating has been applied or where a protective coating has never been applied, i.e.neither at the time of construction nor thereafter, the examination is to be extended to other ballast spaces of the same type.
(3) For salt water ballast spaces other than double bottom tanks, where a protective coating is found to be in poor condition, as defined in Ch 2, Sec 2, [3.2.10], and is not renewed, where soft coating has been applied or where a protective coating has never been applied, i.e.neither at the time of construction nor thereafter, maintenance of class is to be subject to the spaces in question being internally examined at annual surveys. The Society may consider waiving such internal examination at annual surveys of tanks protected with soft coating, whose size is 12 m^3 or less.
For salt water ballast double bottom tanks, where such breakdown of coating is found and is not renewed, where soft coating has been applied or where a protective coating has never been applied, i.e. neither at the time of construction nor thereafter, maintenance of class may be subject to the tanks in question being internally examined at annual intervals.
Note 1: Due attention is also to be given to fuel oil piping passing through ballast tanks, which is to be pressure tested should doubts arise.

Section 3 Class Renewal Survey

1 General

1.1

1.1.1 The requirements of this Section apply to class renewal surveys of all ships. The specific requirements for class renewal surveys related to service notations and additional class notations assigned to ships are addressed in Part A, Chapter 4 and Part A, Chapter 5, respectively.

1.1.2 The class renewal survey is to include sufficiently extensive examination and checks to show that the structures, main and auxiliary machinery, systems, equipment and various arrangements of the ship are in satisfactory condition or restored to such condition as to allow the ship to operate for the new period of class to be assigned, provided that the ship is properly maintained and other surveys for maintenance of class are duly carried out during this period.

The examinations of the hull are to be supplemented by thickness measurements and testing as deemed necessary, to ensure that the structural integrity remains effective and sufficient to discover substantial corrosion, significant deformation, fractures, damages or other structural deterioration.

1.1.3 The Owner is to provide the necessary facilities to enable this class renewal survey. The conditions for survey as detailed in Ch 2, Sec 2, [3.5] to Ch 2, Sec 2, [3.7] are to be met.

1.1.4 When the ship is under the continuous survey system for hull or machinery, the scope of the class renewal survey as described in this Section is carried out on a continuous basis over the period of class according to the procedure laid down in Ch 2, Sec 2, [5.3].

When the machinery installation is surveyed under the Planned Maintenance System, a specific program of survey replaces the scope of the class renewal survey of machinery and systems as laid down in [4], according to the procedure laid down in Ch 2, Sec 2, [5.4].

When the additional class notation **STAR-MACH** is assigned, a specific program of survey replaces the scope of the class renewal survey of the installations covered by the notation, as specified in Pt E, Ch 2, Sec 2.

1.1.5 Upon completion of the class renewal survey, or at the end of the period of class (if the relevant part of the ship is surveyed under the continuous survey system), a general examination of the ship having the same scope as that of an annual survey, as detailed in Ch 3, Sec 1, is to be carried out.

2 Stability and ship lightweight

2.1 Ship lightweight check

2.1.1 A light ship mass check has to be performed as indicated in Ch 2, Sec 2, [6.4.2].

2.2 Hull girder deflection

2.2.1 A measurement of the hull girder vertical deformation has to be performed, at each visit, as indicated in Ch 2, Sec 2, [6.4.3].

2.3 Stability check

2.3.1 A ship stability check may be required as indicated in Ch 2, Sec 2, [6.4.4] when the results of the lightship check shows a significant difference with the previous one.

3 Hull and hull equipment

3.1 Bottom survey in dry condition

3.1.1 A bottom survey in dry condition is to be carried out, as detailed in Ch 3, Sec 4, [2], and in addition the requirements given in [3.1.3] to [3.1.5] are to be complied with.

3.1.2 For ships of unusual characteristics or engaged on special services, means of underwater inspection equivalent to the bottom survey in dry condition may be considered as an alternative by the Society, particularly when a suitable high resistance paint is applied to the underwater portion of the hull or an approved system of impressed current for external cathodic protection is fitted.

3.1.3 Anchors, windlass(es) and chain cables are to be ranged and examined, and the required complement and condition are to be checked. When the ship is more than 5 years old, chain cables are to be gauged.

Any length of chain cable which is found to be damaged or excessively worn is to be renewed.

3.1.4 Sea valves and cocks are to be opened up for internal examination.

3.1.5 Thickness measurements of the outer shell plating, as and if required within the scope of the related class renewal survey, are to be carried out (refer to [3.5]).

3.2 Decks, hatch covers and equipment

3.2.1 Decks are to be examined, particular attention being given to the areas where stress concentration or increased corrosion are likely to develop, such as hatch corners and other discontinuities of structure.

Deck erections such as hatch coamings, deckhouses and superstructures are to be examined.

The sheathing of wood-sheathed steel decks may be removed, at the Surveyor's discretion, in the case of doubt as to the condition of plating underneath.

Due attention is to be given to the examination in way of end and side openings and related shell and inner doors.

3.2.2 The survey of hatch covers and coamings is to include:

- checking of the satisfactory operation of all mechanically operated hatch covers: stowage and securing in open condition, proper fit, locking and efficiency of sealing in closed position, operational testing of hydraulic and power components, wires, chains and link drives
- checking of the effectiveness of sealing arrangements of all hatch covers by means of hose testing or equivalent
- thickness measurements of coaming and attached stiffeners, hatch cover plating and stiffeners (see Tab 2).

3.2.3 The survey of hull equipment is to cover the following points:

- windlass and chain stoppers, with disassembly as deemed necessary to verify the condition of the equipment and control and safety devices, hawse pipes
- steering arrangements, including steering gear, control and indication devices, operational tests and disassembly as deemed necessary; in the case of chain and rod gears, chains, rods, sheaves, pins and rollers are to be examined for wear
- connection of masts and standing rigging to the hull structure as well as condition of structure underneath.

3.2.4 Piping systems outside tanks and compartments are to be visually examined and pressure tested as necessary, as per the requirements laid down for the class renewal survey of machinery and systems; see [4.5].

3.3 Dry compartments

3.3.1 'Tweendecks, cofferdams, pipe tunnels and duct keels, void spaces and other dry compartments which are integral to the hull structure are to be internally examined, ascertaining the condition of the structure, bilges and drain wells, sounding, venting, pumping and drainage arrangements.

The number of compartments to be examined is fixed at 5% of the total, with a minimum of five. They are to be selected on a rotational basis from one class renewal survey to the other.

3.3.2 Machinery and boiler spaces, pump rooms and other spaces containing machinery are to be internally examined, ascertaining the condition of the structure. Particular attention is to be given to tank tops, shell plating in way of tank tops, brackets connecting side shell frames and tank tops, and bulkheads in way of tank tops and bilge wells. Where wastage is evident or suspected, thickness measurements are to be carried out, and renewals or repairs effected when wastage exceeds allowable limits.

Piping systems inside these spaces are to be dealt with according to [4.5].

3.3.3 Chain lockers are to be internally examined, while the anchor chains are ranged as required for the bottom survey in dry condition (see [3.1.3]). The pumping arrangement of the chain lockers is to be tested.

3.4 Tanks

3.4.1 The type and number of tanks to be internally examined at each class renewal survey are detailed in Tab 1, according to the age of the ship.

This internal examination is to ascertain the condition of the structure, bilges and drain wells, sounding, venting, pumping and drainage arrangements, including piping systems and their fittings. Due attention is to be given to plating or double plates below the lower end of sounding and suction pipes.

Where the inner surface of the tanks is covered with cement or other compositions, the removal of coverings may be waived provided they are examined, found sound and adhering satisfactorily to the steel structures.

Note 1: For examination of independent (non-structural) tanks, refer to [4.5.9].

Note 2: Due attention is also to be given to fuel oil piping passing through ballast tanks, which is to be pressure tested when the ship is more than 12 years old.

3.4.2 For salt water ballast spaces other than double bottom tanks, where a protective coating is found to be in poor condition, as defined in Ch 2, Sec 2, [3.2.10] and is not renewed, where soft coating has been applied or where a protective coating has never been applied, i.e. neither at the time of construction nor thereafter, maintenance of class is to be subject to the spaces in question being internally examined at annual surveys. The Society may consider waiving such internal examination at annual surveys of tanks protected with soft coating, whose size is 12 m^3 or less.

For salt water ballast double bottom tanks, where such breakdown of coating is found and is not renewed, where soft coating has been applied or where a protective coating has never been applied, i.e.neither at the time of construction nor thereafter, maintenance of class may be subject to the tanks in question being internally examined at annual intervals.

3.4.3 Double bottom tanks, peak tanks, wing tanks, deep tanks and other integral or independent tanks which are intended to contain sea water or fresh water are to be filled to overflow level, for testing.

Table 1 : Requirements for internal examination of structural tanks at class renewal survey

Type and use of structural tanks	Age of ship (in years at time of class renewal survey)			
	age ≤ 5	5 < age ≤ 10	10 < age ≤15	age > 15
Peaks (all use)	all	all	all	all
Salt water ballast tanks (all types)	all	all	all	all
Fresh water tanks	none	one	half	all
Fuel oil - diesel oil tanks	none	one	two	half **(1)**
Lubricating oil tanks	none	none	one	half **(1)**

(1) Half of the tanks considered are to be internally examined every 5 years (tanks not internally examined may be examined externally from accessible boundaries); at the next class renewal survey the tanks not inspected at the previous survey are to be internally examined, and so on alternatively, so that each tank is internally examined every second class renewal survey.
Note 1: Independent non-structural tanks are to be surveyed according to [4.5.9].
Note 2: The extent of the survey of tanks dedicated to liquids other than those indicated in this table will be considered by the Society on a case-by-case basis according to the nature of the liquids.

Table 2 : Requirements for thickness measurements at class renewal survey

<table>
<tr><th colspan="4">Age of ship (in years at time of class renewal survey)</th></tr>
<tr><th>age ≤ 5</th><th>5 < age ≤ 10</th><th>10 < age ≤15</th><th>age > 15</th></tr>
<tr><td>Suspect areas</td><td>Suspect areas</td><td>Suspect areas</td><td>Suspect areas</td></tr>
<tr><td></td><td>Within the cargo length area or 0,5 L amidships:
- selected deck plates
- 1 transverse section
- selected bottom plates
- selected wind and water strakes</td><td>Within the 0,5 L amidships:
- each deck plate
- 2 transverse sections
- selected tank top plates
- selected bottom plates
- all wind and water strakes</td><td>Within 0,5 L amidships:
- each deck plate
- 3 transverse sections (3)
- each tank top plate
- each bottom plate
- all wind and water strakes</td></tr>
<tr><td></td><td></td><td colspan="2">Outside the cargo length area or 0,5 L amidships:

- sea chests
- sea water manifold</td></tr>
<tr><td></td><td></td><td>Selected cargo hold bulkheads (transverse and longitudinal) (1)</td><td>All cargo hold bulkheads (transverse and longitudinal) (1)</td></tr>
<tr><td></td><td></td><td colspan="2">Selected internal structure such as floors and longitudinals, transverse frames, web frames, deck beams, tweendecks, girders, etc.
Measurements may be increased if the Surveyor deems it necessary</td></tr>
</table>

(1) Including plates and stiffeners.
(2) Measurements may be waived or reduced after satisfactory visual examination, when such bulkheads form the boundaries of dry (void) spaces.
(3) The number of transverse sections may be reduced at the Surveyor's discretion for ships of length under 90 m.

3.4.4 Tanks which are intended to contain liquids other than water such as fuel oil tanks are to be filled to the top of the tank, for testing.

3.4.5 Other testing procedures, in particular those specified in Pt B, Ch 11, Sec 3, [2] for the initial survey during construction, may be accepted.

For integral tanks which are intended to contain liquid cargoes such as edible oil, the Surveyor may waive the requirement specified in [3.4.4] subject to a satisfactory internal examination.

3.5 Thickness measurements

3.5.1 Thickness measurements are to be carried out according to the procedure detailed in Ch 2, Sec 2, [3.3].

The extent of thickness measurements is detailed in Tab 2, according to the age of the ship.

3.5.2 When the structure is coated and the coating is found to be in good condition, as defined in Ch 2, Sec 2, [3.2.10], the Surveyor may, at his discretion, accept a reduced program of thickness measurements in the corresponding areas. Other effective protective arrangements may also be considered.

3.5.3 When thickness measurements indicate substantial corrosion, the number of thickness measurements is to be increased to determine the extent of substantial corrosion. Tab 3 may be used as guidance for additional thickness measurements.

Table 3 : Guidance for additional thickness measurements in way of substantial corrosion areas

Structural member	Extent of measurements	Pattern of measurements
Plating	Suspect area and adjacent plates	5 point pattern over 1 square metre
Stiffeners	Suspect area	3 measurements each in line across web and flange

4 Machinery and systems

4.1 General

4.1.1 The survey items listed below are to be covered to the satisfaction of the Surveyor. However, other survey alternatives deemed equivalent by the Surveyor in relation to the characteristics and general condition of the ship concerned may also be accepted.

Note 1: Attention is drawn to the requirement Ch 2, Sec 2, [3.5.1] regarding safe execution of surveys, in particular as regards health hazards related to asbestos.

4.2 Main and auxiliary engines and turbines

4.2.1 General

Depending on the type of machinery, the following parts are to be opened up as necessary for inspection. Parts and components are to be pressure tested as appropriate or as deemed necessary by the Surveyor. A working test is also to be carried out, including testing of alarms and safety devices.

4.2.2 Internal combustion engines

a) Columns and entablature
b) Cylinders with their liners, cylinder covers (together with valves and valve gear), pistons with their rods, crossheads, slippers and guides (or gudgeon pins), connecting rods (with their top and bottom end bearings), control gear, driven scavenge pumps, driven air compressors, driven fuel pumps, supercharging blowers, fuel injection pumps, turning gear, etc.
c) Crankshafts (together with their main bearings)
d) Reverse gear, reduction gear and clutches, if fitted.

4.2.3 Steam turbines

a) Condensers and their cooling water and condensate extraction pumps
b) Casings and rotors (including their blading), impulse wheels (including guide blading and diaphragms), nozzles and nozzle boxes, journals and bearings, dummy pistons, labyrinths, external glands, etc.
c) Shafts, including their flexible couplings.

Where the propulsion steam turbines are of a well-known type, and fitted with rotor position indicators and vibration indicators of an approved type, as well as measuring equipment of steam pressure at proper locations along the steam flow, and the arrangements for change-over in the event of emergency operation of the plant are readily operable, the first class renewal survey may be limited to the examination of rotor bearings, thrust bearings and flexible couplings, provided the Surveyor is satisfied from operation service records and power trials subsequent to the survey, that the turbine plant is in good working condition.

4.2.4 Gas turbines

a) Casings, rotors and disks, impellers and blading of all turbines and compressors, combustion chambers, burners, heat exchangers, gas piping, compressed air piping with fittings, starting and reverse arrangements

b) Shafts and their flexible couplings.

4.2.5 Electric propulsion

Where the propulsion machinery consists of an electrical system, the propulsion motors, generators, cables and all ancillary electrical gear, exciters and ventilating plant (including coolers) associated therewith are to be examined and the insulation resistance to earth tested. Due attention is to be given to windings, commutations and sliprings. The operation of protective gear and alarm devices is to be checked, as far as practicable. Interlocks intended to prevent unsafe operations or unauthorised access are to be checked to verify that they are functioning correctly.

4.2.6 Thruster installations

When the ship is equipped with thruster installations, the class renewal survey is also to include:

- an examination of the machinery and electrical installation, as applicable
- an external examination of the propulsive part of the installation to be carried out at the dry dock survey due as part of the class renewal survey. During this examination other checks such as clearance readings, tightness of hub and blade sealing for controllable pitch propellers are to be verified. Locking arrangements for bolts, if fitted, are to be checked. Results of lubricating oil analysis to detect possible deterioration of internal gears and bearings or the presence of water are to be confirmed as acceptable. The Manufacturer's requirements may be taken into account. Dismantling of the assembly for the examination of internal parts may be required if the foregoing checks are not satisfactory
- a running test of the system under operating conditions.

4.3 Reduction gears, main thrust and intermediate shaft(s)

4.3.1 Reduction gears complete with all wheels, pinions, shafts, couplings, bearings and gear teeth, including incorporated clutch arrangements, are to be opened up, as deemed necessary by the Surveyor, for visual inspection. For complicated assemblies, gears and roller bearings may be inspected without dismantling.

4.3.2 All shafts, thrust blocks and bearings are to be examined.

4.4 Pumps and other machinery items

4.4.1 General

The items listed in [4.4.2] are to be opened up, as deemed necessary by the Surveyor, for visual inspection. Their parts and components are to be pressure tested as appropriate and considered necessary by the Surveyor. A working test is also to be carried out, including testing of alarms and safety devices if deemed necessary by the Surveyor.

4.4.2 Items to be surveyed

a) Air compressors with their intercoolers, filters and/or oil separators and safety devices

b) Heat exchangers, ventilation fans for boilers and other equipment used for essential services

c) Piston pumps and centrifugal pumps for sea water, bilge and salt water ballast

d) Screw pumps, gear pumps and centrifugal pumps other than those listed in item c) above (opening up is not required).

4.5 Systems in machinery spaces

4.5.1 Valves, cocks and strainers of the bilge and ballast systems are to be opened up, as deemed necessary by the Surveyor, for visual inspection, and, together with the piping and safety devices, examined and tested under working conditions.

4.5.2 The fuel oil, lubricating oil, hydraulic oil, thermal oil, and feed and cooling water systems, together with pressure filters, heaters and coolers used for essential services, are to be opened up and examined or tested, as considered necessary by the Surveyor. Safety devices for the foregoing items are to be examined.

4.5.3 The compressed air system together with its valves, fittings and safety devices is to be examined, as considered necessary by the Surveyor.

4.5.4 Compressed air receivers and other pressure vessels for essential services are to be cleaned internally and examined internally and externally. Their fittings, valves and safety devices are to be opened up, as deemed necessary by the Surveyor, for visual inspection and pressure tested as appropriate.

4.5.5 Steel pipes for superheated steam having a temperature of the steam at the superheater outlet exceeding 450°C are to be examined and tested in accordance with [4.5.7] to [4.5.8] at each class renewal survey.

4.5.6 Steel pipes for saturated steam or superheated steam having a temperature of the steam at the superheater outlet not exceeding 450°C are to be examined and tested in accordance with [4.5.7] to [4.5.8] at each class renewal survey for ships over 5 years of age. When the ship is 5 years of age or less, the inspection may be limited to a check of the satisfactory general condition of pipes.

4.5.7 The examination and hydrostatic test of steel pipes for main steam machinery, and steel pipes for auxiliary steam machinery having internal diameter 75 mm and over, are to be carried out on a number of pipes selected by the Surveyor after the lagging in way is removed.

4.5.8 Representative pipe lengths connected with bolted flanges are to be internally and externally examined, and hydrostatically tested to 1,1 times the working pressure at ambient temperature. Bolts and butt-welded joints between flanges and pipes are to be submitted to a non-destructive test for crack detection.

4.5.9 Non-structural tanks located in machinery spaces are to be externally examined; the relevant fittings, with particular regard to the remote control shut-off valves under hydrostatic head, are to be externally examined to check the efficiency of manoeuvres and the absence of cracks or leakage.

4.5.10 When the ship is equipped with a refrigerating plant (whether or not covered by an additional class notation), the class renewal survey is to include:

- examination and test at the design pressure of the parts of the plant under pressure
- for refrigerating machinery spaces using ammonia as refrigerant:
  - examination and test of the water-spraying fire-extinguishing system to the same extent as indicated in [4.8.3] item d)
  - examination of valves and pumps of the bilge system to the same extent as indicated in [4.4]
  - examination and test of the electrical equipment to the same extent as indicated in [4.6.11]
  - test of the gas detection system.

4.6 Electrical equipment and installations

4.6.1 An electrical insulation resistance test is to be performed on the electrical equipment and cables. If needed, for the purpose of this test, the installation may be subdivided or equipment which may be damaged disconnected.

4.6.2 The following minimum values, when performing the insulation test, are to be considered:

- for main and emergency switchboards, feeder circuit breakers being open, busbar circuit closed, measuring and monitoring instruments disconnected, the resistance of insulation measured across each insulated busbar and the hull, and across insulated busbars, should not be less than 1 megohm
- for generators, the equipment and circuits normally connected between the generator and the first circuit breaker being connected, the resistance of insulation (preferably at working temperature whenever possible), in ohms, is to be greater than 1 000 times the rated voltage, in volts. If appropriate, the Surveyor checks also that the insulation resistance of generators separate exciter gear is not less than 250 000 ohms
- the insulation resistance of the entire electrical system is to be checked with all circuit breakers and protective devices closed, except for generators; in general, the resistance should not be less than 100 000 ohms. However, the variation of the resistance with time is to be checked, comparing the current figure with previous readings. If the insulation resistance was to drop suddenly or be insufficient, the defective circuits are to be traced, disconnecting the circuits as much as necessary.

4.6.3 The prime movers of generators are to be surveyed in accordance with [4.2] and their governors tested. All generators are to be presented for inspection, clean and with covers opened and examined under working conditions.

4.6.4 Main and emergency switchboards, section boards and distribution boards are to be cleaned and doors or covers opened for examination of their fittings. The condition of overcurrent protective devices and fuses is to be checked. Circuit-breakers of generators are to be tested, as far as practicable, to verify that protective devices including preference tripping relays, if fitted, operate satisfactorily. The tightening of busbar connections is to be checked.

4.6.5 Electrical cables and cable runs are to be examined at random, in particular in places where deterioration is likely to occur; terminal boxes of essential services are also to be subjected to a random check.

4.6.6 The motors and starters concerning essential services together with associated control and switchgear are to be examined and, if considered necessary by the Surveyor, checked, as far as practicable, under working conditions.

4.6.7 Navigation light indicators are to be tested under working conditions, and correct operation on the failure of supply or failure of navigation lights verified.

4.6.8 The emergency sources of electrical power, their automatic arrangements and associated circuits are to be tested.

4.6.9 Emergency lighting, transitional emergency lighting, supplementary emergency lighting, general emergency alarm and public address systems are to be tested as far as practicable.

4.6.10 The visible condition of electrical equipment and installations is also to be checked as regards precautions against shock, fire and other hazards of electrical origin.

4.6.11 A general examination of the electrical equipment in areas where there may be flammable gas or vapour and/or combustible dust is to be carried out to ensure that the integrity of the electrical equipment of a safety type has not been impaired owing to corrosion, missing bolts, etc., and that there is not an excessive build-up of dust on or in dust-protected electrical equipment. Cable runs are to be examined for sheath and armouring defects, where practicable, and to ensure that the means of supporting the cables are in satisfactory condition. The proper condition of bonding straps for the control of static electricity is to be checked. Alarms and interlocks associated with pressurised equipment or spaces are to be tested for correct operation.

Note 1: Owners are reminded that maintenance, repairs or renewal of certified electrical equipment of a safe type remains their responsibility or that of their representatives.

4.6.12 The survey is also to cover the computerized systems through the control of the Software Registry as mentioned in Pt C, Ch 3, Sec 3. This survey shall include :

- checking of modification of software registry, in particular the reporting of security checks during software modification inside the Software Registry
- checking that revision of each piece of software mentioned in Software Registry corresponds with revision effectively used for any listed computerized system.
- checking that Software Registry has been updated according to the last ship relevant modifications.

4.6.13 For ships where the electrical distribution system includes harmonic filters, the survey is to include:

- annual measurement, as a minimum, of the harmonic distortion levels of main busbars under seagoing conditions as close to the periodical machinery survey as possible so as to give a clear representation of the condition of the entire plant to the surveyor. Harmonic distortion readings are to be carried out when the greatest amount of distortion is indicated by the measuring equipment. An entry showing which equipment was running and/or filters in service is to be recorded in the log so this can be replicated for the next periodical survey. Harmonic distortion levels are also to be measured following any modification to the ship's electrical distribution system or associated consumers by suitably trained ship's personnel or by a qualified outside source.
- verification that records of all above measurements are made available to the surveyor at each periodical survey.

Note 1: Those requirements apply at any scheduled machinery periodical survey having a due date on or after 1st July 2017 for ships contracted for construction before 1st July 2017.

- for ships contracted for construction on or after 1st July 2017, verification that the facilities used for continuous monitoring of the levels of harmonic distortion experienced on the main busbars as well as alerting the crew when the level of harmonic distortion exceeds the acceptable limits are working properly and review of corresponding records.

4.7 Controls, commands

4.7.1 Where remote and/or automatic controls-commands, not covered by an additional class notation related to automated installation, are fitted for essential machinery, they are to be tested to demonstrate that they are in satisfactory condition.

4.8 Fire protection, detection and extinction

4.8.1 The Owner or his representative is to declare to the attending Surveyor that no significant changes have been made to the arrangement of structural fire protection.

Note 1: Attention is drawn to the provisions of Ch 1, Sec 1, [3.1.1] regarding compliance with any additional and/or more stringent requirements issued by the Naval Authority.

4.8.2 The class renewal survey of fire prevention arrangements is to cover the following items.

a) Visible parts of items forming part of structural fire protection arrangements in accommodation spaces and in machinery spaces such as bulkheads, decks, doors, stairways, crew and service lift trunks, and light and air trunks are to be examined, due attention being given to their integrity and that of the insulating material.
b) The operation of manual/automatic fire doors, where fitted, is to be checked.
c) Remote controls for stopping fans and machinery and shutting off fuel supplies in machinery spaces and, where fitted, remote controls for stopping fans in accommodation spaces and means of cutting off power to the galley are to be tested.
d) Closing arrangements of ventilators, funnel annular spaces, skylights, doorways and tunnels, where applicable, are to be tested.
e) Fire and/or smoke detection and alarm systems are to be tested.

4.8.3 The survey requirements for all types of fire-fighting systems that are usually found on board ships related either to machinery spaces or to cargo areas and/or spaces or to accommodation spaces, irrespective of the service notation assigned, are the following:

a) water fire system
    - the associated pumps are to be opened up and examined at the Surveyor’s discretion
    - the fire main is to be hydrostatically tested to the working pressure at the Surveyor’s discretion

b) fixed gas fire-extinguishing system (CO_2 , Halon or other gas)

Receivers of gas of the fixed fire-extinguishing systems are to be externally examined together with all stationary fittings and devices. In addition, the following applies:

- the total loss of CO_2 is not to exceed 10% of the installed quantity, 5% for Halon
- after being repaired or discharged, containers are to be subjected to a hydrostatic test
- hydrostatic testing of high pressure CO_2 containers is to be carried out at intervals not exceeding 10 years; the number of the tested containers is to be not less than 10% of the total number
- low pressure gas containers are to be internally inspected if the content has been released and the container is older than five years; depending upon the result of the internal examination, the Surveyor may require the container to be hydrostatically tested.

It is to be checked that the distribution pipework is proved clear

c) sprinkler system

- the associated pumps are to be opened up and examined at the Surveyor's discretion

d) water spraying system

- the associated pumps are to be opened up and examined at the Surveyor's discretion
- a working test is to be carried out as far as reasonable and appropriate

e) fixed foam systems (low or high expansion)

- the associated pumps are to be opened up and examined at the Surveyor's discretion

f) dry powder system

- it is to be verified that the propelling inert gas bottles have been hydrostatically tested. The same applies to bottles disembarked for refilling or embarked for replacement.

4.8.4 As far as other fire-fighting equipment is concerned, the following items are to be hydrostatically tested:

- any CO_2 bottles of extinguishers
- shells of foam extinguishers
- shells of powder extinguishers
- air or gas bottles associated with fire extinguishers whose shells are not kept under pressure (if internally examined, the test need not be performed).

4.8.5 Where a helideck is fitted, the following is to be checked, as far as appropriate:

- drainage arrangements around the landing area
- fire fighting appliances and arrangements (to be surveyed as per [4.8.3] and [4.8.4], according to the equipment installed)
- other arrangements for helicopter refuelling and hangar facilities (fuel system, ventilation, fire protection and detection).

Section 4 Bottom Survey

1 General

1.1 Conditions

1.1.1 The bottom survey may be carried out in dry condition, such as in dry dock or on a slipway, or through an in-water survey.

The conditions for acceptance of a bottom in-water survey in lieu of a bottom survey in dry condition are laid down in Ch 2, Sec 2, [6.5].

2 Bottom survey in dry condition

2.1 General requirements

2.1.1 When a ship is in dry condition, it is to be placed on blocks of sufficient height to permit the examination of the bottom of the ship.

2.1.2 The outer shell plating is to be visually examined for excessive corrosion, or deterioration due to chafing or contact with the ground or for any undue deformation or buckling. Due attention is to be given to the plating of end structures (stem and sternframe), and to the bilge keel connection to the shell plating.

2.1.3 Sea chests and their gratings, sea connections and overboard discharge valves and cocks and their fastenings to the hull or sea chests are to be examined.

2.1.4 Visible parts of the propeller(s), stern bush(es), propeller shaft boss, brackets and tightness system(s) are to be examined. The clearances of the propeller shaft(s) (or wear down gauge) are to be checked and recorded. For controllable pitch propellers, the Surveyor is to be satisfied with the fastenings and tightness of hub and blade sealing.

Visible parts of other propulsion systems and propellers for steering purposes are also to be examined.

Dismantling is to be carried out, if considered necessary, notably where leakages are detected.

2.1.5 Visible parts of the rudder(s), rudder pintles, rudder stock and couplings as well as the sternframe are to be examined. If considered necessary by the Surveyor, the rudder(s) is (are) to be lifted or the inspection plates removed for the examination of pintles.

The clearances in the rudder bearings and the rudder lowering are to be checked and recorded.

2.2 Bottom survey held within the scope of class renewal survey

2.2.1 The examination and checks detailed in Ch 3, Sec 3, [3.1] are to be carried out as part of the class renewal survey. They are usually carried out during the bottom survey held concurrently with the class renewal survey.

3 Bottom in-water survey

3.1 General

3.1.1 An in-water survey may normally be carried out if the ship has been granted the additional class notation **INWATERSURVEY** as defined in Ch 1, Sec 2, [6.15.1]. Upon application by the Owner and in special circumstances, the Society may also authorise such bottom in-water survey for ships not assigned with the additional class notation **INWATERSURVEY**.

3.1.2 In principle, no outstanding recommendations are to exist requiring repair work to be carried out to the underwater part of the shell plating, the rudder, the propeller or the propeller shaft, unless the Society is satisfied that such repairs may be carried out while the ship is afloat.

3.1.3 The in-water survey is to be carried out with the ship at a suitable draught in sheltered water; the in-water visibility is to be good and the hull below the waterline is to be sufficiently clean to permit proper examination.

3.1.4 The in-water survey is to be carried out under the surveillance of a Surveyor by an in-water survey firm approved as a service supplier by the Society according to Ch 2, Sec 2, [3.4].

The Surveyor is to be satisfied with the methods of orientation of the diver(s) or remotely operated vehicle (ROV) on the plating, which should make use where necessary of permanent markings on the plating at selected points and with the method of pictorial representation. An efficient two-way communication between the Surveyor and the diver(s) is to be provided.

3.1.5 The bottom in-water survey is to provide the information normally obtained from a bottom survey carried out in dry condition, and the scope of the in-water survey is the same as detailed in [2.1], so far as practicable.

3.1.6 If the in-water survey reveals damage or deterioration that requires immediate attention, the Surveyor may require the ship to be drydocked in order for a detailed survey to be undertaken and the necessary repairs carried out.

Section 5 Tailshaft Survey

1 Survey of tailshafts

1.1 General

1.1.1 The different types of surveys to which tailshafts may be subjected and the intervals at which they are to be carried out are given in Ch 2, Sec 2, [6.6]. These surveys are:

- complete survey
- modified survey.

The requirements to be complied with at each survey are listed below.

1.2 Complete survey

1.2.1 The complete survey of tailshafts consists of the following, as applicable:

a) removal of propeller and key, where fitted, and their examination
b) complete withdrawal of shaft to permit the examination of sterntube bearings (outboard or inboard depending on the type of shaft)
c) examination by an appropriate crack detection method of the after end of the cylindrical part of the shaft and forward one third of shaft cone, or the fillet of the flange in the case of a flanged coupling
d) examination of shaft bearing surfaces, liners, joints, threaded end and nut
e) examination of oil sealing glands, if relevant, with the necessary dismantling
f) measurements of clearances and/or weardown (prior to and after the survey) and their recording
g) opening-up of controllable pitch propellers and examination of their working parts and control gear.

1.2.2 Where the notation **MON-SHAFT** has been assigned as specified in Ch 2, Sec 2, [6.6.4], the tailshaft need not be withdrawn at the complete survey and items b) and d) of [1.2.1] need not be covered provided that all condition monitoring data (bearings temperature, consumption and analysis of lubricating oil or water flow, bearings weardown, failure alarms) is found to be within permissible limits and the remaining requirements for the complete survey are complied with.

Where the Surveyor considers that the data presented is not entirely to his satisfaction, the shaft is to be withdrawn.

1.3 Modified survey

1.3.1 A modified survey may be carried out for those tailshafts which fulfil the conditions described in Ch 2, Sec 2, [6.6.3], where the periodicity of this type of survey is also shown.

1.3.2 The modified survey for all types of shafts consists of the following:

a) for oil lubricated tailshaft bearings
    - check of oil sealing glands in place
    - measurements of weardown and their recording
    - examination of the results of sterntube lubricating oil analyses, if relevant, to confirm they have been regularly performed and the recorded parameters are within acceptable limits
    - check of the records of lubricating oil consumption, if relevant, to confirm it is within permissible limits.
b) For sea water lubricated tailshaft bearings:
    - measurements of bearings weardown and clearance
    - external examination of the water pumping and filtering system and confirmation that such equipment operate satisfactorily
    - check of water flow measurements
    - verification of alarms (flow etc.) and interlock system.

1.3.3 In addition, for the different types of shafts, the following is required:

a) for shafts with keyed propeller coupling:
    - removal of propeller and key, and their examination in way of the connection area
    - examination by an appropriate crack detection method of the after end of the cylindrical part of shaft and forward one third of shaft cone

b) for shafts with keyless type propeller coupling:
   - check of the tightness of the propeller hub (propeller hood, fore gland)

c) for shafts with a solid flange coupling at the aft end and variable pitch propeller:
   - check of tightness in way of blade glands and distribution box
   - check of analysis of hydraulic oil
   - working test, as far as practicable, of the blade manoeuvring.

1.3.4 Where the Surveyor considers that the data presented is not entirely to his satisfaction, further dismantling may be required, including withdrawal of the tailshaft.

2 Periodical survey of other propulsion systems

2.1 Rotating and azimuth thrusters

2.1.1 The periodical survey of rotating and azimuth thrusters consists of:

a) removing the propeller(s) in order to examine the following items, as applicable:
   - exposed parts
   - cone and keyway to be checked by an appropriate crack detection method
   - sealing glands
   - threaded end and nut

b) examining the results of a lubricating oil analysis (water content and presence of material particles) to detect possible deterioration of internal gears and bearings

c) examining the orientation device.

If the foregoing checks are not satisfactory, dismantling of the internal parts may be required.

2.2 Vertical axis propellers

2.2.1 The periodical survey of vertical axis propeller systems consists of:

- checking the tightness of the oil glands and the backlash of the gears from outside by action on the blades
- checking the condition of gears and couplings from inside the ship
- examining the results of a lubricating oil analysis (water content and presence of material particles) to detect possible deterioration of internal gears and bearings.

If the foregoing checks are not satisfactory, dismantling of the internal parts may be required.

2.3 Ventilated propellers

2.3.1 When the ship is fitted with ventilated propellers, the survey includes, in addition with the requirements defined in [1.2] and [1.3], the following examinations:

- internal state of the air conducts with respect to free circulation of the air, corrosion and cracks
- air conducts tightness
- tightness of the mechanisms which may commit, in case of leakage, the safety of the tail shaft and of the propeller.

2.4 Pump jet systems

2.4.1 The periodical survey of pump jet systems consists of examining the following parts:

- impeller, shaft and clearances of bearings
- tightness of gland
- water duct
- steering nozzle
- reversing arrangements and control gear.

If the foregoing checks are not satisfactory, further dismantling may be required.

Section 6 Boiler Survey

1 Steam boilers

1.1

1.1.1 Steam boilers, superheaters and economisers are to be examined internally and externally with the periodicity given in Ch 2, Sec 2, [6.7]. To this end, boilers are to be emptied and suitably prepared for the examination, and the water-steam side and fire side are to be cleaned and cleared of soot. Where necessary, the external surfaces are to be made accessible for inspection by removal of insulation and lining.

1.1.2 Subject to the results of this visual examination, the Surveyor may require:

- non-destructive tests for detection of possible defects in critical areas of plating and shells, pipes and stays
- thickness measurements of plating and shells, furnaces, pipes and stays.

If appropriate, a new working pressure may be fixed by the Society.

When situated inside boiler combustion chambers, steam pipes of cylindrical boilers are to be examined at their ends, and if deemed necessary by the Surveyor, a sample pipe is to be removed for examination.

1.1.3 If the internal examination is not carried out for practicable reasons, the parts subject to pressure are to be submitted to a hydraulic test.

The testing pressure is fixed by the Surveyor versus the boiler working pressure and age.

1.1.4 Boiler supports and securing arrangements (fixed and sliding seating, chocks, rolling stays, if any, etc.) are to be examined.

Boiler accessories and mountings (such as valves and studs, water level indicators, safety valves) are to be externally and (as needed) internally examined.

Forced circulation pumps of fired steam generators are, wherever possible, to be opened up.

Fuel supply pipes between pumps and burners, fuel tank valves, pipes and deck control gear are to be examined.

1.1.5 Upon completion of the internal survey, the boiler is to be examined under steam and fuel oil burners and safety devices checked under working conditions.

Safety valves are to be checked for their setting. For auxiliary exhaust gas boilers, if steam cannot be raised at port, it is the Chief Engineer’s responsibility to set the safety valves at sea and record the setting pressure in the log-book.

2 Thermal oil heaters

2.1

2.1.1 Thermal oil heaters are to be internally and externally examined. The heater tubes are to be visually examined, and the tightness of the installation (including flange connections, valves and pumps) is to be checked through a test at the working pressure.

2.1.2 Thermal oil heater supports and securing arrangements are to be examined.

Heater accessories and mountings are to be externally and (as needed) internally examined.

Forced circulation pumps are, wherever possible, to be opened up.

Fuel supply pipes between pumps and burners, fuel tank valves, pipes and deck control gear are to be examined.

2.1.3 The following safety devices and instrumentation are to be examined and tested:

- thermal fluid temperature safety device and control
- thermal fluid flow meter
- device for low thermal fluid level in the expansion tank
- other regulation and safety systems.

2.1.4 Where repairs and/or renewal of components exposed to pressure are performed, a pressure test is to be carried out to 1,5 times the working pressure.

2.1.5 Upon completion of the survey, the thermal oil heater is to be examined under working conditions, with particular attention to safety devices and controls of the plant.

Appendix 1 Class Requirements and Surveys of Laid-up Ships

1 General

1.1

1.1.1 In order to maintain its class during a normal operation period, a ship is to be submitted to the surveys described in Ch 2, Sec 2 at their due dates and to the satisfaction of the Society, and is to be free of overdue surveys and conditions of class during the considered period.

1.1.2 When a ship stops trading and is put out of commission for a certain period, i.e. is laid-up, the normal survey requirements may no longer apply provided that the Owner notifies the Society of this fact. The Owner is also to submit a lay-up maintenance program to the Society for approval.

1.1.3 The lay-up maintenance program includes:

- the safety conditions to be kept throughout the lay-up period
- the measures taken to preserve the maintenance of the ship throughout the lay-up period
- the survey requirements to be complied with for lay-up, maintenance of class in lay-up and re-commissioning.

2 Safety conditions

2.1

2.1.1 Power supply

Adequate power supply is to be supplied, or readily available, all around the clock, either from independent means on board the ship or from shore.

The following safety conditions are to be kept throughout the lay-up period.

2.1.2 Manning

Watch personnel are to be provided. The number of the watch personnel will depend on the size of the ship, the lay-up site and mooring arrangements, the shore assistance available in case of fire, leakage or flooding, the maintenance required to provide adequate preservation. A permanent shore communication installation (radio, telephone) is also to be available.

2.1.3 Fire protection and fire fighting

The following is to be complied with:

- automatic fire alarm systems, where provided, are to be in working order and in operation
- fire-fighting installations are to be tested regularly and readily available
- the fire main is to be readily available and periodically tested under pressure
- ventilation trunks, air inlets and watertight doors are to be kept closed.

2.1.4 Protection against explosion

Cargo spaces and piping systems are to be cleaned and ventilated to prevent gas from forming any pockets.

An inert gas system in operation is recommended for the cargo spaces of oil and chemical tankers.

All flammable materials, sludge, etc. are to be removed from the ship's bilge, tank tops, double bottom tanks, engine room, pump rooms and similar spaces.

Hot work is not be carried out during lay-up, unless special precautionary measures are taken.

2.1.5 Safety equipment

All the equipment usually recommended for the safety of the watch personnel is to be provided, kept in working order and tested regularly.

The usual life-saving equipment such as liferafts, life-buoys, breathing apparatus, oxygen masks and distress signals is to be provided and made accessible.

The requirements of the flag Administration and of the local port authorities of the lay-up site are usually to be applied.

2.1.6 Emergency power

The emergency source of power, emergency generator and/or emergency air compressor are to be kept in working order and tested weekly.

3 Preservation measures for lay-up and maintenance

3.1 General

3.1.1 A lay-up log-book is to be kept on board, in which the maintenance work and tests carried out during the lay-up period are to be entered with the corresponding dates. The nature and frequency of the maintenance, inspections and tests are also to be defined in the lay-up log book.

3.1.2 The following measures for preservation and maintenance during the lay-up period are to be taken by Owners according to the type of ship, hull equipment, machinery installations and the specific cases of lay-up conditions.

3.2 Exposed parts of the hull

3.2.1 Underwater parts of the hull are to be protected against corrosion. It is advisable to provide an impressed current cathodic protection system where the quantity of corrosive waste discharge is particularly high. When such systems are provided they are to be serviced and checked at regular intervals. The condition of sacrificial anodes is to be evaluated at the annual lay-up condition surveys.

3.2.2 The coating of the hull above the waterline, exposed decks, access doors or covers on exposed decks, and hatch covers is to be maintained in satisfactory condition.

All accesses leading to internal spaces are to be kept closed.

All vent pipes and ventilation trunks are to be kept closed.

3.3 Internal spaces

3.3.1 Cargo tanks and cargo holds are to be emptied, cleaned and kept dry.

Ballast tanks are to be kept either full or empty. When ballast spaces are kept filled with sea water, special care is to be taken to keep such spaces topped up and protected against corrosion. When provided, sacrificial anodes are to be renewed when deemed necessary. The topping up is to be regularly verified.

3.3.2 Chain lockers are to be drained, cleaned and kept dry. Coating with bituminous paint is recommended.

3.3.3 Fuel oil and lubricating oil tanks are to be drained regularly.

Lubricating oil analysis is to be performed regularly and the oil renewed when the result is not satisfactory. Prior to being refilled, tanks are to be cleaned.

Empty lubricating oil tanks are to be cleaned and kept dry.

Fresh water or distilled water tanks are to be kept full or empty. Empty tanks are to be cleaned and kept dry. Where cement wash is used as a coating, this is to be examined and repaired prior to filling.

3.3.4 The bilge and tank top in engine rooms are to be cleaned and kept dry.

Hull sea inlet and outlet valves not in use are to be kept closed.

3.4 Deck fittings

3.4.1 The windlass, capstans and winches are to be regularly greased and turned once a week.

All wire cables are to be kept greased.

Visible parts of chains are to be coal-tarred and examined regularly.

Chocks and hawse pipes are to be coated with bituminous paint or equivalent if deemed necessary.

Cargo piping on deck is to be drained, blown through if deemed necessary and kept dry by opening up drains.

Electrical machinery and navigational equipment are to be protected by watertight covers.

3.5 Machinery

3.5.1 Machinery spaces

The air temperature inside the machinery spaces is normally to be kept above 0°C.

Humidity is to be kept as low as possible and within acceptable limits.

3.5.2 Machinery - General

Exposed mechanical parts of machinery are to be greased.

All rotating machinery such as diesel engines, reciprocating engines, pumps, turbines, electric motors and generators are to be turned at regular intervals with a limited number of revolutions (the lubricating oil system should be put in operation or proper priming applied). Units are not to be stopped in the same position as the previous one.

Bearing boxes are to be emptied, cleaned and refilled with new oil.

3.5.3 Main turbines

Turbines are to be kept dry.

All steam inlets are to be sealed.

Expansion arrangements (sliding feet) are to be suitably greased.

Electric heaters are to be put inside the turbines. Heat drying is to be made in open circuit, all valves shut and gland closing devices withdrawn.

Turbines are to be turned weekly, the lubricating oil system being put in service. The shaft line is to be stopped after turning an integer number of revolutions plus one quarter of a revolution.

3.5.4 Reduction gears

For large reduction gears, a fan activating the circulation of hot air in closed circuit with air hoses is to be fitted (intake at lower part of casing and discharge at upper part).

3.5.5 Auxiliary turbine-driven machinery

Stators are to be drained and kept dry.

Shaft sealing glands are to be lubricated.

Lubricating oil is to be analysed and renewed when deemed necessary. Prior to oil renewal, the oil casings are to be cleaned.

Exhaust steam pipes are to be kept dry.

Stuffing boxes are to be dismantled.

Turbines are to be turned weekly an integer number of revolutions plus one quarter of a revolution.

3.5.6 Condensers and heat exchangers

Condensers and heat exchangers are to be drained and kept dry.

Desiccant is to be placed in steam spaces.

Water sides are to be washed with fresh water.

The condition of the zinc anodes is to be periodically checked.

When tubes are fitted with plastic or fibre packing, water sides are to be filled with alkaline distilled water.

When tubes are expanded or fitted with metal packing, water sides are to be provided with desiccants and kept dry.

3.5.7 Auxiliary machinery

Air receivers are to be drained, opened up and cleaned. Pressure relief valves are to be cleaned and slightly lubricated.

Air compressor crankcases are to be drained, cleaned and refilled with clean oil. Cylinders and valves are to be lubricated. Coolers are to be drained and dried. Air drains are to be opened and the system dried.

Air start lines are to be drained and dried.

Hot-wells/return tanks are to be drained and dried.

De-aerators are to be drained and dried.

Feed pumps and extraction pumps are to be drained and dried.

Air ejectors are to be drained and dried.

Main circulation pumps are to be drained and dried.

Evaporators are to be drained, cleaned and dried.

3.5.8 Piping

Pipes not in use are to be drained and kept dry.

3.5.9 Diesel engines

Daily tank fuel oil outlet pipes and all injection equipment are to be filled with filtered gas oil.

Fresh water circuits are to be filled with water mixed with rust inhibitors. Fresh water pH is to be checked monthly.

Oil of hydraulic regulators is to be replaced.

Sea water cooling pipes are to be drained.

Crankcases are to be provided with desiccant.

Starting valves are to be lubricated (internally and externally).

Motor oil is to be sprayed in cylinders and on all external parts liable to corrosion.

Cams and cylinders are to be motor oil sprayed monthly.

Turbo-compressor/charger ball bearings are to be oil sprayed and rotated for an integer number of revolutions plus one quarter of a revolution.

Engine air inlets and exhaust gas pipes are to be sealed.

Scavenge spaces are to be cleaned.

Engines are to be turned weekly.

3.5.10 Shaft lines

Shaft lines are to be coated with grease.

Shaft bearing cooling pipes are to be drained.

For sea water lubricated propeller shafts, the packing gland of the engine room stuffing box is to be tightened.

For oil lubricated sterntubes, lubricating oil is to be analysed and renewed if not satisfactory. The oil level in the tank is to be verified regularly.

Propeller shaft lines are to be rotated an integer number of revolutions plus one quarter of a revolution.

3.6 Electrical installations

3.6.1 Main and secondary switchboards, sub-feeder panels, fuse panels and starters are to be made tight. Desiccant is to be provided.

Contacts of relays, breakers and switch-breakers are to be coated with neutral vaseline.

Bearings of generators are to be cleaned of old grease and protected with new oil or grease.

Carbon brushes are to be lifted off their commutations.

3.6.2 Electrical insulation of each item is to be kept at a minimum 200,000 Ohms and general insulation is to be not less than 50,000 Ohms. Local electric heating may be necessary to improve the level of insulation, particularly in the generators/alternators and large motors.

A insulation resistance test is to be performed regularly.

3.7 Steering gear

3.7.1 Exposed mechanical parts are to be greased or oil sprayed.

For electrical parts the same preservation measures given in [3.6] are to be taken.

It is recommended that the steering gear should be operated monthly.

3.8 Boilers

3.8.1 Smoke sides of boilers are to be swept, washed clean with basic hot water and hot air dried.

3.8.2 Water and steam sides should preferably be preserved using the dry method, keeping the moisture at the lowest possible level, the ideal level being between 30% and 35%. It is advisable to ensure that no residual water remains to cause rapid corrosion. Drum doors are to be kept closed.

In other cases, it is advisable to keep the boilers, superheaters and economisers filled with water having a pH around 10,5. Hydrazine hydrate treatment of the water is preferable to reduce risks of corrosion caused by dissolved oxygen. The water is to be regularly analysed.

3.8.3 Air heaters are to be cleaned and kept dry.

Uptake, shell and fan outlets are to be cleaned and kept closed with watertight hoods.

Burners are to be dismantled, and atomisers greased.

Desiccant is to be provided in furnaces where deemed necessary.

Expansion arrangements (sliding feet) are to be suitably greased.

The internal condition of boilers is to be checked every three months.

3.8.4 Boilers may also be preserved sealed with inert gas (nitrogen), provided that cocks and valves are tight and the installation allows an internal pressure of at least 0,05 bar to be maintained to prevent air penetration. Regular checks of the overpressure are to be carried out and results recorded in the log-book.

3.9 Automated installation

3.9.1 Recommendations for electronic components are the same as those given for electrical installations.

For pneumatic parts the manufacturers' recommendations are to be followed and the system is to be checked regularly.

Pressure, temperature or level sensors are generally not affected by damage when not used. However, when available, the manufacturers' recommendations are to be followed.

4 Lay-up site and mooring arrangements

4.1 General

4.1.1 The choice and suitability of the lay-up site, as well as the type of mooring conditions, the mooring arrangements and their efficiency during the lay-up period remain the responsibility of the Owner.

However, at the Owner's request, the mooring arrangement may be reviewed by the Society.

4.2 Recommendations for the lay-up site

4.2.1 The following recommendations are to be considered by Owners regarding the choice and suitability of the lay-up site.

The site should be:

- sheltered from open sea, strong currents and waves
- not exposed to whirling winds or turbulent tidal waves
- not exposed to moving ice
- clear of corrosive waste waters
- provided with adequate ship/shore communications.

4.3 Recommendations for the mooring arrangements

4.3.1 The following recommendations are to be considered by Owners with respect to the mooring arrangements:

- ground holding should be adequate
- vessels laid-up to buoys or anchored should be moored in such a way as to be prevented from swinging with normal wind and tidal changes
- chain cables should not be subject to cross-contact or twisting and stern anchorage should generally be provided
- laid-up ships should be in ballast condition in order to reduce the effects of wind. Due consideration should be given to the still water bending moment. For guidance, normal ballast draft should be roughly between 30% and 50% of the maximum draft.

4.3.2 Ships should normally be moored singly. However, when several ships are moored together, the following provisions are to be made:

- ships are to be moored bow to stern
- ships are to be of approximately the same size
- the number of ships moored together is, in principle, not to exceed six
- breast-lines are to be of similar elasticity
- fenders are to be provided.

4.4 Review of the mooring arrangements

4.4.1 As indicated in [4.1.1], at the Owners' request, the mooring arrangements may be reviewed by the Society.

4.4.2 The proposal for the mooring arrangements is in such case to be submitted by the Owner and is to include the following information.

a) Mooring site:
   - geographical area (to be specified on a map)
   - characteristics of the sea bottom
   - water depth
   - preferential angular sectors (effects of wind / tide / current) indicated according to statistical studies
   - wave characteristics (amplitude, periods)

b) Geometry of mooring arrangements:
   - ship's position and direction
   - shore anchorage
   - diagram showing mooring equipment (fore and aft)
   - angle between chain cables and ship's centreline

c) Characteristics of mooring equipment:
- maximum holding strength of each anchor
- type of mooring lines (chains, cables, sinkers, etc.)
- length of each section
- weight of each section
- mechanical characteristics of each section (breaking load)
- weight of sinkers.

4.4.3 On completion of the installation, the mooring arrangements are to be surveyed by the Society. When the ship is anchored, the underwater installation is to be inspected by a diver whose report is to be presented to the Society.

4.4.4 It is the responsibility of the Owners to ascertain the efficiency of the mooring arrangements during the lay-up period. The mooring arrangements are to be re-examined at regular intervals (at least each year when the ship is anchored) and when abnormal weather conditions occur at the lay-up site.

5 Surveys

5.1 Laying-up survey

5.1.1 At the beginning of the lay-up period a laying-up survey is to be carried out whose scope is to verify that the safety conditions, preservation measures, lay-up site and mooring arrangements are in accordance with the program agreed by the Society.

5.1.2 Upon satisfactory completion of this survey, an endorsement to confirm that the ship has been placed in lay-up is entered on the Certificate of Classification, which is subsequently to be kept on board.

5.2 Annual lay-up condition survey

5.2.1 As described in Ch 2, Sec 2, [9], an annual lay-up condition survey is to be performed in lieu of the normal annual class surveys. The purpose of this survey is to ascertain that the lay-up maintenance program implemented is continuously complied with.

5.2.2 It is to be checked that the arrangements made for the lay-up are unchanged and that the maintenance work and tests are carried out in accordance with the maintenance manual and recorded in the lay-up log-book.

5.2.3 Upon satisfactory completion of the survey, the Certificate of Classification is endorsed.

5.3 Re-commissioning survey

5.3.1 Owners are to make the necessary arrangements to remove the temporary lay-up installations provided for preservation measures and the protective materials and coatings (oil, grease, inhibitors, desiccants), before the survey is commenced.

It is the Owners' responsibility to verify that the ship parts that are not covered by class are reactivated in satisfactory operational condition.

5.3.2 The scope of the re-commissioning survey is to include:
- a general examination of the hull, deck fittings, safety systems, machinery installations (including boilers whose survey is not due) and steering gear
- all periodical surveys due at the date of re-commissioning or which became overdue during the lay-up period
- dealing with the recommendations due at the date of re-commissioning or which became due during the lay-up period.

5.3.3 For the hull the following is to be carried out:
- examination of shell plating above the waterline, deck plating, hatch covers and coamings
- examination of load line items
- overall survey of all cargo tanks/holds
- overall survey of representative ballast tanks when the lay-up period does not exceed two years
- overall survey of all ballast tanks when the lay-up period is two years and over
- function tests of bilge and ballast systems.

5.3.4 For the deck fittings the following is to be carried out:
- examination of the fire main under working pressure
- where possible, examination of deck piping under working pressure
- function tests of class items
- checking inert gas installation under working condition after inspection of water seal and function test of deck non-return valve and pressure/vacuum valves.

5.3.5 For machinery installations the following is to be checked:

- the analysis of lubricating oil of main engines, auxiliary engines, reduction gears, main thrust bearings and sterntube
- the general condition of crankcase, crankshaft, piston rods and connecting rods of diesel engines
- the crankshaft deflections of diesel engines. In addition when engines have been laid-up for more than two years, one piston is to be disconnected and one liner is to be removed for examination. Dismantling is to be extended if deemed necessary
- the condition of blades of turbines through the inspection doors
- the condition of the water side of condensers and heat exchangers
- the condition of expansion arrangements
- the condition of reduction gears through the inspection doors
- the condition after overhauling of pressure relief devices
- the test of bilge level alarms, when fitted.

5.3.6 The main and emergency electrical installations are to be tested. The parallel shedding of main generators and main switchboard safety devices are to be checked. An insulation resistance test of the electrical installation is to be performed.

5.3.7 For the fire prevention, detection and fire-fighting systems, the following is to be examined and/or tested:

- remote control for quick closing of fuel oil valves, stopping of fuel oil pumps and ventilation systems, closing of fire doors and watertight doors
- fire detectors and alarms
- fire-fighting equipment.

5.3.8 The automated installation is to be checked for proper operation.

5.3.9 When classed, the installations for refrigerated cargo are to be examined under working conditions. Where the lay-up period exceeds two years, representative components of the installation are to be dismantled.

5.3.10 For cargo installations on liquefied gas carriers, the following is to be carried out:

- inspection of the primary barrier in tanks
- for membrane tanks, a global gas test of tanks whose results are to be compared with those obtained at ship's delivery
- testing of gas piping at working pressure using inert gas.

A Surveyor of the Society is to attend the first cooling down and loading of the ship.

5.3.11 For other specific classed installations, the Owners are to submit a survey program to the Society.

5.3.12 On completion of the above surveys, sea trials are to be performed in the presence of a Surveyor of the Society.

The sea trials are to include:

- verification of the satisfactory performance of the deck installations, main propulsion system and essential auxiliaries, including a test of the safety devices
- an anchoring test
- complete tests of steering gear
- full head and full astern tests
- tests of automated machinery systems, where applicable.

5.3.13 Upon satisfactory completion of the surveys, an endorsement to confirm the carrying out of all relevant surveys and the re-commissioning of the ship is entered on the Certificate of Classification.

CHAPTER 4
SCOPE OF SURVEYS IN RESPECT OF THE DIFFERENT SERVICES OF SHIPS

Section 1 General

Section 2 Frigate, Corvette and Military OPV

Section 3 Aircraft Carrier

Section 4 Auxiliary Naval Vessel

Section 5 Amphibious Vessel

Section 1 General

1 General

1.1

1.1.1 The purpose of this Chapter is to give details on the scope of surveys of certain ships which, due to the service notation assigned and related equipment, need specific requirements to be verified for the maintenance of their class.

1.1.2 These specific requirements either are additional to or supersede those stipulated in Part A, Chapter 3, which gives general requirements for surveys applicable to all types of ships: this is indicated in each Section of this Chapter. These surveys are to be carried out at intervals as described in Ch 2, Sec 2, concurrently with the surveys of the same type, i.e. annual, intermediate or class renewal surveys, detailed in Part A, Chapter 3.

1.1.3 Owners are reminded that a general examination of the ship having the same scope of an annual survey is to be carried out at the completion of the class renewal survey, see Ch 3, Sec 3, [1.1.5]. Where specific requirements are given in this Chapter for the class renewal survey, they are additional to the applicable requirements for the annual survey.

2 Service notations subject to additional surveys

2.1

2.1.1 The specific requirements detailed in this Chapter are linked to the service notation(s) assigned to the ship at the request of the Owner. Where a ship has more than one service notation, the specific requirements linked to each one are applicable, insofar as they are not contradictory (in such case, the most stringent requirement will be applied).

2.1.2 Tab 1 indicates which service notations are subject to specific requirements, and in which Section they are specified.

Table 1 : Service notations for which specific requirements are applicable

Service notation assigned	Section applicable	Type of surveys affected by these specific requirements
frigate **corvette** **military OPV**	Ch 4, Sec 2	annual survey class renewal survey
aircraft carrier	Ch 4, Sec 3	annual survey class renewal survey
auxiliary naval vessel	Ch 4, Sec 4	annual survey class renewal survey
amphibious vessel	Ch 4, Sec 5	annual survey class renewal survey

Section 2 Frigate, Corvette and Military OPV

1 General

1.1

1.1.1 The requirements of this Section are applicable after construction to all self-propelled ships which have been assigned one of the following service notations:

- **frigate** as defined in Part D, Chapter 1
- **corvette** as defined in Part D, Chapter 3
- **military OPV** as defined in Part D, Chapter 6.

1.1.2 These requirements are additional to those laid down in Part A, Chapter 3, according to the relevant surveys.

2 Annual survey

2.1 Watertight bulkheads

2.1.1 The survey of watertight bulkheads and arrangements consists of:

- examination, as far as practicable, of collision and watertight bulkheads, and confirmation that their watertight integrity has not been impaired
- checking the diagram provided on the navigation bridge showing the location of the watertight doors and related indicators for their open/closed position
- testing operation of local and remote control (from the navigation bridge) of the watertight doors, and in particular, operation from each side of the bulkhead of audible alarms or visual signals and control handles, as required or fitted
- confirmation of operation of watertight doors in the event of failure of main and emergency sources of power
- confirmation that notices are affixed at appropriate locations.

2.2 Openings in shell plating

2.2.1 The survey consists of:

- examination of the arrangements for closing sidescuttles and their deadlights, as well as scuppers, sanitary discharges and similar openings and other inlets and discharges in the shell plating below the margin line
- confirmation that valves for closing the main and auxiliary sea inlets and discharges in the machinery spaces are readily accessible, and that indicators showing the status of the valves are provided, as required or fitted
- confirmation that gangway access and cargo ports fitted below the margin line may be effectively closed and that the inboard ends of any ash or rubbish chutes are fitted with an effective cover.

2.3 Shell and inner doors

2.3.1 The requirements of this item apply to all shell and inner doors fitted on these ships.

2.3.2 For the scope of survey of shell and inner doors, the following definitions are applicable:

- Securing device:

  a device used to keep the door closed by preventing it from rotating about its hinges
- Supporting device:

  a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship's structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, that transmits loads from the door to the ship's structure
- Locking device:

  a device that locks a securing device in the closed position.

2.3.3 It is to be checked that the operating procedures for closing the shell and inner doors are kept on board and posted at appropriate places.

When required, the Operating and Maintenance Manual is also to be checked for the verification of its approval and of any modification, reported repairs and proper endorsement by operating personnel.

2.3.4 The structural arrangements as well as welding are to be examined, including:

- plating, primary structure and secondary stiffeners
- hinging arms, hinges and bearings, thrust bearings
- hull and door side supports of securing, supporting and locking devices
- shell plating surrounding the openings and the securing, supporting and locking devices.

Hinge, bearing and thrust bearing clearances are to be measured when no dismantling is necessary for the measurement, or when the function tests detailed below are not satisfactory.

2.3.5 A close visual inspection of securing, supporting and locking devices, including their weld connections, is to be carried out and clearances are to be measured as required.

Non-destructive tests and/or thickness measurements may be required by the Surveyor after visual examination or in cases where cracks or deformations have been found.

2.3.6 A close visual inspection of sealing arrangements (packing material, rubber gaskets, packing retaining bars or channels) is to be carried out. For the tightness hose test, refer to [2.3.8].

2.3.7 The drainage arrangements including bilge wells, drain pipes and non-return valves are to be visually examined. A test of the bilge system between the inner and outer doors and that of the vehicle deck is to be carried out.

2.3.8 Function tests are to be carried out as follows, according to the required and/or existing equipment on board:

a) Doors are to be examined during a complete opening and closing operation; during this operation, the proper working of hinging arms and hinges, proper engagement of the thrust bearings and proper working of devices for locking the door in open position are to be checked

b) Securing, supporting and locking devices are to be examined during a complete opening and closing operation; the following items are to be checked:
   - opening/closing system and securing/locking devices are interlocked in such a way that they can only operate in proper sequence
   - mechanical lock of the securing devices
   - the securing devices remain locked in the event of loss of hydraulic fluid, if they are of hydraulic type

c) Indicators of open/closed position of doors and of securing/locking devices at remote control stations are to be checked; other safety devices such as isolation of securing/locking hydraulic system from other hydraulic systems, access to operating panels, notice plates and warning indicator lights are to be checked

d) A tightness hose test or equivalent of sealing arrangements is to be carried out

e) A working test of the indicator system is to be carried out, including checking of:
   - visual indicators and audible alarms on the navigation bridge and operating panel
   - lamp test function, fail safe performance, power supply for indicator system
   - proper condition of sensors and their protection from water, ice formation and mechanical damage

f) A working test of the water leakage detection system for inner doors and for the area between the bow door and the inner door (as applicable) is to be carried out and the proper function of audible alarms on the navigation bridge and the engine control room panel (as applicable) is to be ascertained

g) The television surveillance system is to be verified with proper indication on the navigation bridge and engine control room monitors

h) Electrical equipment for opening, closing and securing the doors is to be examined.

2.4 Fire protection, detection and extinction

2.4.1 Within the scope of survey of fire protection, detection and extinction arrangements as required for the annual survey of all ships in Ch 3, Sec 1, [3.4], attention is to be given to the particular arrangements related to ro-ro cargo spaces, such as:

- fire detection systems and alarms
- fixed fire-extinguishing arrangements (gas, water-spraying or foam systems)
- portable fire extinguishers in spaces and at entrances
- ventilation and related safety devices (including remote control on the bridge or on the central safety control room), and
- electrical equipment of a safe type.

2.5 Emergency escapes

2.5.1 It is to be verified that the emergency escape routes including related stairways and ladders, are kept clear.

2.6 Ballast equipment and installation

2.6.1 Piping

The visit includes:

- the examination of the state of the whole ballast piping system
- the examination of seals and space boundary penetrations with respect to cracks and leakages.

2.6.2 Control systems

The visit shall include the following points, as far as the elements exist:

- the examination of the filling measurement systems of the ballast capacities, upper level alarm and associated safety valves to control the overflows
- the confirmation that the pressure gauges installed on the ballast piping are correctly operational.

2.6.3 Ballasting system

The visit includes:

- the examination of all equipment of the ballasting system (pumps, valves and other components)
- the general examination of the ballast system equipment foundations and fixations
- the good working verification of the system, including the local manual means.

3 Class renewal survey

3.1 Stability

3.1.1 A lightweight survey is to be carried out to verify any changes in lightship displacement and in the longitudinal position of the centre of gravity. Where, in comparison with the approved stability information, a deviation exceeding 2% in the lightship displacement or 1% in the position of the longitudinal centre of gravity is found or anticipated, the ship is to be submitted to a new inclining test.

3.2 Lighting

3.2.1 The condition of the Low Location Lighting (LLL) system, where fitted, and its power source(s) is to be verified.

3.3 Shell and inner doors

3.3.1 A close visual inspection of structural arrangements is to be carried out, supplemented by non-destructive tests and/or thickness measurements, as deemed necessary by the Surveyor.

3.3.2 The close visual inspection of securing, supporting and locking devices, as required for the annual survey, is to be supplemented by non-destructive tests and/or thickness measurements.

3.3.3 Clearances of hinges, bearings and thrust bearings are to be measured. Dismantling may be required as deemed necessary by the Surveyor.

3.3.4 Non-return valves of drainage arrangements are to be checked after dismantling.

3.4 Fire protection, detection and extinction

3.4.1 Within the scope of survey of fire protection, detection and extinction arrangements as required for the class renewal survey of all ships in Ch 3, Sec 3, [4.8], attention is to be given to the particular arrangements related to ro-ro cargo spaces, such as those indicated in [2.4.1].

Section 3 Aircraft Carrier

1 General

1.1

1.1.1 The requirements of this Section are applicable after construction to all self-propelled ships which have been assigned the following service notation:

aircraft carrier

as defined in Part D, Chapter 2.

1.1.2 These requirements are additional to those laid down in Part A, Chapter 3, according to the relevant surveys.

2 Annual survey

2.1 Inner doors

2.1.1 The requirements of this sub-article apply to all inner doors fitted on these ships.

In particular, they apply to hangar doors and aircraft lift doors.

2.1.2 For the scope of survey of inner doors, the following definitions are applicable:

- Securing device:

  a device used to keep the door closed by preventing it from rotating about its hinges
- Supporting device:

  a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship's structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, that transmits loads from the door to the ship's structure
- Locking device:

  a device that locks a securing device in the closed position.

2.1.3 It is to be checked that the operating procedures for closing the inner doors are kept on board and posted at appropriate places.

When required, the Operating and Maintenance Manual is also to be checked for the verification of its approval and of any modification, reported repairs and proper endorsement by operating personnel.

2.1.4 The structural arrangements as well as welding are to be examined, including:

- plating, primary structure and secondary stiffeners
- hinging arms, hinges and bearings, thrust bearings
- hull and door side supports of securing, supporting and locking devices.

Hinge, bearing and thrust bearing clearances are to be measured when no dismantling is necessary for the measurement, or when the function tests detailed below are not satisfactory.

2.1.5 A close visual inspection of securing, supporting and locking devices, including their weld connections, is to be carried out and clearances are to be measured as required.

Non-destructive tests and/or thickness measurements may be required by the Surveyor after visual examination or in cases where cracks or deformations have been found.

2.1.6 A close visual inspection of sealing arrangements (packing material, rubber gaskets, packing retaining bars or channels) is to be carried out. For the tightness hose test, refer to [2.1.8].

2.1.7 The drainage arrangements including bilge wells, drain pipes and non-return valves are to be visually examined. A test of the bilge system between the inner and outer doors and that of the garage deck is to be carried out.

2.1.8 Function tests are to be carried out as follows, according to the required and/or existing equipment on board:

a) Doors are to be examined during a complete opening and closing operation; during this operation, the proper working of hinging arms and hinges, proper engagement of the thrust bearings and proper working of devices for locking the door in open position are to be checked

b) Securing, supporting and locking devices are to be examined during a complete opening and closing operation; the following items are to be checked:
   - opening/closing system and securing/locking devices are interlocked in such a way that they can only operate in proper sequence
   - mechanical lock of the securing devices
   - the securing devices remain locked in the event of loss of hydraulic fluid, if they are of hydraulic type

c) Indicators of open/closed position of doors and of securing/locking devices at remote control stations are to be checked; other safety devices such as isolation of securing/locking hydraulic system from other hydraulic systems, access to operating panels, notice plates and warning indicator lights are to be checked

d) A tightness hose test or equivalent of sealing arrangements is to be carried out

e) A working test of the indicator system is to be carried out, including checking of:
   - visual indicators and audible alarms on the navigation bridge and operating panel
   - lamp test function, fail safe performance, power supply for indicator system
   - proper condition of sensors and their protection from water, ice formation and mechanical damage

f) A working test of the water leakage detection system for inner doors and for the area between the bow door and the inner door (as applicable) is to be carried out and the proper function of audible alarms on the navigation bridge and the engine control room panel (as applicable) is to be ascertained

g) The television surveillance system is to be verified with proper indication on the navigation bridge and engine control room monitors

h) Electrical equipment for opening, closing and securing the doors is to be examined.

2.2 Internal platforms and ramps

2.2.1 The annual survey of internal movable platforms and ramps (excluding those considered as inner doors and covered in [2.1]) and related equipment consists of:

- a general examination of the installation, particular attention being paid to the condition of steel cables
- confirmation of the proper operation of platforms/ramps and of mechanical stops and locks
- checking, as far as practicable, of the alarms and safety devices.

2.3 Fire protection, detection and extinction

2.3.1 Within the scope of survey of fire protection, detection and extinction arrangements as required for the annual survey of all ships in Ch 3, Sec 1, [3.4], attention is to be given to the particular arrangements related to landing and garage spaces, such as:

- fire detection systems and alarms
- fixed fire-extinguishing arrangements (gas, water-spraying or foam systems)
- portable fire extinguishers in spaces and at entrances
- ventilation and related safety devices (including remote control on the bridge or on the central safety control room), and
- electrical equipment of a safe type.

2.4 Emergency escapes

2.4.1 It is to be verified that the emergency escape routes from passenger and crew spaces, including related stairways and ladders, are kept clear.

3 Class renewal survey

3.1 Stability

3.1.1 A lightweight survey is to be carried out to verify any changes in lightship displacement and in the longitudinal position of the centre of gravity. Where, in comparison with the approved stability information, a deviation exceeding 2% in the lightship displacement or 1% in the position of the longitudinal centre of gravity is found or anticipated, the ship is to be submitted to a new inclining test.

3.2 Lighting

3.2.1 The condition of the Low Location Lighting (LLL) system, where fitted, and its power source(s) is to be verified.

3.3 Inner doors

3.3.1 A close visual inspection of structural arrangements is to be carried out, supplemented by non-destructive tests and/or thickness measurements, as deemed necessary by the Surveyor.

3.3.2 The close visual inspection of securing, supporting and locking devices, as required for the annual survey, is to be supplemented by non-destructive tests and/or thickness measurements.

3.3.3 Clearances of hinges, bearings and thrust bearings are to be measured. Dismantling may be required as deemed necessary by the Surveyor.

3.3.4 Non-return valves of drainage arrangements are to be checked after dismantling.

3.4 Internal platforms and ramps

3.4.1 The condition of pulleys, axles, cables and structure of the platforms and ramps is to be checked.

Electric motors and/or hydraulically operated equipment are to be surveyed according to the scope detailed in Ch 3, Sec 3, [4] for the class renewal survey of machinery installations.

3.5 Fire protection, detection and extinction

3.5.1 Within the scope of survey of fire protection, detection and extinction arrangements as required for the class renewal survey of all ships in Ch 3, Sec 3, [4.8], attention is to be given to the particular arrangements related to landing and garage spaces, such as those indicated in [2.3.1].

Section 4 Auxiliary Naval Vessel

1 General

1.1 Application

1.1.1 The requirements of this Section apply to self-propelled ships which have been assigned the following service notation:

auxiliary naval vessel

as defined in Part D, Chapter 4.

1.1.2 The requirements for hull surveys apply to the surveys of the hull structure and piping systems in way of cargo tanks, pump rooms, cofferdams, pipe tunnels and void spaces within the cargo area and all ballast tanks. They are additional to the requirements applicable to the remainder of the ship, given in Part A, Chapter 3 according to the relevant surveys.

1.1.3 The requirements contain the minimum extent of examination, thickness measurements and tank testing. When substantial corrosion, as defined in Ch 2, Sec 2, [3.2.7], and/or structural defects are found, the survey is to be extended and is to include additional close-up surveys when necessary.

1.1.4 In all cases the extent of thickness measurements is to be sufficient as to represent the actual average condition.

1.1.5 When, in any survey, thickness measurements are required:

- the procedure detailed in Ch 2, Sec 2, [3.3] is to be applied
- the thickness measurement operator is to attend the survey planning meeting held prior to commencing the survey.

1.1.6 The requirements for machinery surveys apply to surveys of the machinery and equipment in the cargo area or dedicated to cargo service systems and are additional to those given in Part A, Chapter 3 for all ships.

1.2 Documentation on board

1.2.1 The Owner is to obtain, supply and maintain documentation on board as specified in [1.2.2] and [1.2.3], which is to be readily available for examination by the Surveyor. The documentation is to be kept on board for the lifetime of the ship.

1.2.2 A survey report file is to be a part of the documentation on board consisting of:

- reports of structural surveys
- thickness measurement reports.

The survey report file is also to be available in the Owner's management office.

1.2.3 The following additional supporting documentation is to be available on board:

- main structural plans of cargo tanks and ballast tanks
- previous repair history
- cargo and ballast history
- extent of use of inert gas system and tank cleaning procedures
- ship’s personnel reports on:
  - structural deterioration/defects in general
  - leakage in bulkheads and piping systems
  - condition of coatings or corrosion prevention systems, if any
- any other information that may help to identify critical structural areas and/or suspect areas requiring inspection.

1.2.4 Prior to survey, the Surveyor examines the documentation on board and its contents, which are used as a basis for the survey.

1.3 Reporting and evaluation of surveys

1.3.1 The data and information on the structural condition of the ship collected during survey are evaluated for acceptability and structural integrity of the ship's cargo area.

1.3.2 When a survey is split between different survey stations, a report is to be made for each portion of the survey. A list of items examined and/or tested (pressure testing, thickness measurements etc.) and an indication of whether the item has been credited, are to be made available to the next attending Surveyor(s), prior to continuing or completing the survey.

1.3.3 A hull condition evaluation report (summarizing the results of class renewal surveys) is issued by the Society to the Owner, who is to place it on board the ship for reference at future surveys. The hull condition evaluation report is endorsed by the Society.

1.4 Conditions for survey

1.4.1 In order to enable the attending Surveyor(s) to carry out the survey, provisions for proper and safe access are to be agreed between the Owner and the Society.

Details of the means of access are to be provided in the survey planning questionnaire.

In cases where the provisions of safety and required access are judged by the attending Surveyor(s) not to be adequate, the survey of the spaces involved is not to proceed.

1.4.2 The Surveyor(s) are to always be accompanied by at least one responsible person, assigned by the Owner, experienced in tank and enclosed spaces inspection. In addition a back-up team of at least two experienced persons is to be stationed at the hatch opening of the tank or space that is being surveyed. The back-up team is to continuously observe the work in the tank or space and is to keep lifesaving and evacuation equipment ready for use.

1.5 Access to structures

1.5.1 For overall survey, means are to be provided to enable the Surveyor(s) to examine the hull structure in a safe and practical way.

2 Annual survey - Hull items - Liquid cargo area

2.1 Weather decks

2.1.1 The survey is to include:

- examination of cargo tank openings, including gaskets, covers, coamings and screens
- examination of cargo tank pressure/vacuum valves and flame screens
- examination of flame screens on vents to all bunker, oily-ballast and oily slop tanks and void spaces
- examination of cargo, crude oil washing, bunker, ballast and vent piping systems, including remote control valves, safety valves and various safety devices, as well as vent masts and headers
- confirmation that wheelhouse doors and windows, sidescuttles and windows in superstructure and deckhouse ends facing the cargo area are in satisfactory condition.

2.2 Cargo pump rooms and pipe tunnels

2.2.1 The survey is to include:

- examination of all pump room bulkheads and pipe tunnels (if any) for signs of oil leakage or fractures and, in particular, the sealing arrangements of penetrations in these bulkheads
- examination of the condition of all piping systems, in cargo pump rooms and pipe tunnels (if any)
- examination of the bilge and ballast arrangements.

2.3 Ballast tanks

2.3.1 Ballast tanks are to be internally examined when required as a consequence of the results of the class renewal survey or the intermediate survey.

2.3.2 When considered necessary by the Surveyor, or when extensive corrosion exists, thickness measurements are to be carried out and if the results of these thickness measurements indicate that substantial corrosion is found, the extent of thickness measurements is to be increased in accordance with Tab 2 or Tab 3. These extended thickness measurements are to be carried out before the survey is credited as completed. Suspect areas identified at previous surveys are to be examined. Areas of substantial corrosion identified at previous surveys are to have thickness measurements taken.

2.4 Safe access to tanker bows

2.4.1 The access to bow arrangement is to be examined, as applicable.

3 Annual survey - Hull items - Dry cargo area

3.1 Watertight bulkheads

3.1.1 The survey of watertight bulkheads and arrangements consists of:

- examination, as far as practicable, of collision and watertight bulkheads, and confirmation that their watertight integrity has not been impaired
- checking the diagram provided on the navigation bridge showing the location of the watertight doors and related indicators for their open/closed position
- testing operation of local and remote control (from the navigation bridge) of the watertight doors, and in particular, operation from each side of the bulkhead of audible alarms or visual signals and control handles, as required or fitted
- confirmation of operation of watertight doors in the event of failure of main and emergency sources of power
- confirmation that notices are affixed at appropriate locations.

3.2 Openings in shell plating

3.2.1 The survey consists of:

- examination of the arrangements for closing sidescuttles and their deadlights, as well as scuppers, sanitary discharges and similar openings and other inlets and discharges in the shell plating below the margin line
- confirmation that valves for closing the main and auxiliary sea inlets and discharges in the machinery spaces are readily accessible, and that indicators showing the status of the valves are provided, as required or fitted
- confirmation that gangway access and cargo ports fitted below the margin line may be effectively closed and that the inboard ends of any ash or rubbish chutes are fitted with an effective cover.

3.3 Shell and inner doors

3.3.1 The requirements of this sub-article apply to all shell and inner doors fitted on these ships.

3.3.2 For the scope of survey of shell and inner doors, the following definitions are applicable:

- Securing device:

  a device used to keep the door closed by preventing it from rotating about its hinges
- Supporting device:

  a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship’s structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, that transmits loads from the door to the ship’s structure
- Locking device:

  a device that locks a securing device in the closed position.

3.3.3 It is to be checked that the operating procedures for closing the shell and inner doors are kept on board and posted at appropriate places.

When required, the Operating and Maintenance Manual is also to be checked for the verification of its approval and of any modification, reported repairs and proper endorsement by operating personnel.

3.3.4 The structural arrangements as well as welding are to be examined, including:

- plating, primary structure and secondary stiffeners
- hinging arms, hinges and bearings, thrust bearings
- hull and door side supports of securing, supporting and locking devices
- shell plating surrounding the openings and the securing, supporting and locking devices.

Hinge, bearing and thrust bearing clearances are to be measured when no dismantling is necessary for the measurement, or when the function tests detailed below are not satisfactory.

3.3.5 A close visual inspection of securing, supporting and locking devices, including their weld connections, is to be carried out and clearances are to be measured as required.

Non-destructive tests and/or thickness measurements may be required by the Surveyor after visual examination or in cases where cracks or deformations have been found.

3.3.6 A close visual inspection of sealing arrangements (packing material, rubber gaskets, packing retaining bars or channels) is to be carried out. For the tightness hose test, refer to Ch 4, Sec 2, [2.3.8].

3.3.7 The drainage arrangements including bilge wells, drain pipes and non-return valves are to be visually examined. A test of the bilge system between the inner and outer doors and that of the vehicle deck is to be carried out.

3.3.8 Function tests are to be carried out as follows, according to the required and/or existing equipment on board:

a) Doors are to be examined during a complete opening and closing operation; during this operation, the proper working of hinging arms and hinges, proper engagement of the thrust bearings and proper working of devices for locking the door in open position are to be checked

b) Securing, supporting and locking devices are to be examined during a complete opening and closing operation; the following items are to be checked:
   - opening/closing system and securing/locking devices are interlocked in such a way that they can only operate in proper sequence
   - mechanical lock of the securing devices
   - the securing devices remain locked in the event of loss of hydraulic fluid, if they are of hydraulic type

c) Indicators of open/closed position of doors and of securing/locking devices at remote control stations are to be checked; other safety devices such as isolation of securing/locking hydraulic system from other hydraulic systems, access to operating panels, notice plates and warning indicator lights are to be checked

d) A tightness hose test or equivalent of sealing arrangements is to be carried out

e) A working test of the indicator system is to be carried out, including checking of:
   - visual indicators and audible alarms on the navigation bridge and operating panel
   - lamp test function, fail safe performance, power supply for indicator system
   - proper condition of sensors and their protection from water, ice formation and mechanical damage

f) A working test of the water leakage detection system for inner doors and for the area between the bow door and the inner door (as applicable) is to be carried out and the proper function of audible alarms on the navigation bridge and the engine control room panel (as applicable) is to be ascertained

g) The television surveillance system is to be verified with proper indication on the navigation bridge and engine control room monitors

h) Electrical equipment for opening, closing and securing the doors is to be examined.

4 Annual survey - Machinery items - Liquid cargo area

4.1 Cargo area and cargo pump rooms

4.1.1 The Owner or his representative is to declare to the attending Surveyor that no modifications or alterations which might impair safety have been made to the various installations in dangerous zones without prior approval from the Society.

The survey is to include:

- check of the protection of cargo pump room, as applicable, and in particular, check of:
  - temperature sensing devices for bulkheads glands and alarms
  - interlock between lighting and ventilation
  - gas detection system
  - bilge level monitoring devices and alarms
- examination of the emergency lighting in cargo pump rooms
- confirmation that potential sources of ignition in or near the cargo pump rooms, such as loose gear, excessive product in bilge, excessive vapours, combustible materials, etc., are eliminated and that access ladders are in satisfactory condition
- examination, as far as practicable, of cargo, bilge, ballast and stripping pumps for excessive gland seal leakage, verification of proper operation of electrical and mechanical remote operating and shutdown devices and operation of the pump room bilge system, and checking that pump foundations are intact
- confirmation that the ventilation system, including portable equipment, if any, of all spaces in the cargo area (including cargo pump rooms) is operational, ducting is intact, dampers are operational and screens are clean
- confirmation that electrical equipment in dangerous zones, cargo pump rooms and other spaces is in satisfactory condition and has been properly maintained
- confirmation that the remote operation of the cargo pump room bilge system is satisfactory
- examination of the cargo heating system, as appropriate
- examination of the cargo-transfer arrangement and confirmation that the ship's cargo hoses are suitable for their intended purpose and in satisfactory condition
- confirmation that any special arrangement made for bow or stern loading/unloading is in satisfactory condition and test of the means of communication and remote shutdown of the cargo pumps.

4.2 Instrumentation and safety devices

4.2.1 The survey is to include:

- examination of cargo tank gauging devices, high level alarms and valves associated with overflow control
- verification that installed pressure gauges on cargo discharge lines are properly operational
- confirmation that the required gas detection instruments are on board and satisfactory arrangements have been made for the supply of any required vapour detection tubes
- confirmation that devices provided for measuring the temperature of the cargo, if any, operate satisfactorily.

4.3 Fire-fighting systems in cargo area

4.3.1 The survey is to include:

- external examination of piping and cut-out valves of fixed fire-fighting systems related to cargo tanks and cargo pump rooms
- confirmation, as far as practicable and when appropriate, that the remote means for closing the various openings are operable
- examination of the appropriate portable fire-extinguishing equipment for the cargoes to be carried in accordance with the relevant requirements given in Ch 3, Sec 1, [3.4.3]
- examination of fire-fighting systems of any type fitted on board such as deck foam, water-spraying, etc., as applicable in accordance with the relevant requirements given in Ch 3, Sec 1, [3.4].

4.4 Inert gas system

4.4.1 The survey is to include:

- external examination of the whole system, to check the condition of all piping, including vent piping above the upper deck in the cargo tank area and overboard discharges through the shell so far as practicable, and associated components to verify, in particular, the absence of signs of corrosion and leakage of gas, water or other liquid from inert gas and water piping systems or from the pressure/vacuum breaking device
- check of proper operation of both inert gas blowers
- check of proper operation of ventilation system required for scrubber room (if any)
- check of deck water seal for automatic water filling and draining
- check of absence of water carry over in the inert gas from the deck water seal and check of the condition of the non-return valve
- check of proper operation of all remotely operated or automatically controlled valves and, in particular, of the flue gas isolating valve located on the inert gas supply main after the blowers
- check of proper operation of the interlocking feature fitted to prevent soot blowers from operating when the inert gas system is working
- check that the gas pressure regulating valve automatically closes when gas blowers are stopped
- check, as far as practicable and using simulated conditions where necessary, of the following alarms and safety devices of the inert gas system:
  - high oxygen content of gas in the inert gas main
  - low gas pressure in the inert gas main
  - low pressure in the supply to the deck water seal
  - high temperature of gas in the inert gas main, including automatic shutdown devices
  - low water pressure to the scrubber, including automatic shutdown devices
  - accuracy of portable and fixed oxygen measuring equipment by means of calibration gases
  - high water level in the scrubber, including automatic shutdown devices
  - failure of the inert gas blowers
  - failure of the power supply to the automatic control system for the gas regulating valve and to the instrumentation for continuous indication and permanent recording of pressure and oxygen content in the inert gas main
  - high pressure of gas in the inert gas main
- check, when practicable, of the proper operation of the inert gas system on completion of the checks listed above.

5 Annual survey - Machinery items - Dry cargo area

5.1 Fire protection, detection and extinction

5.1.1 Within the scope of survey of fire protection, detection and extinction arrangements as required for the annual survey of all ships in Ch 3, Sec 1, [3.4], attention is to be given to the particular arrangements related to ro-ro cargo spaces, such as:

- fire detection systems and alarms
- fixed fire-extinguishing arrangements (gas, water-spraying or foam systems)
- portable fire extinguishers in spaces and at entrances
- ventilation and related safety devices (including remote control on the bridge or on the central safety control room), and
- electrical equipment of a safe type.

5.2 Emergency escapes

5.2.1 It is to be verified that the emergency escape routes including related stairways and ladders, are kept clear.

5.3 Ballast equipment and installation

5.3.1 Piping

The visit includes:

- the examination of the state of the whole ballast piping system
- the examination of seals and space boundary penetrations with respect to cracks and leakages.

5.3.2 Control systems

The visit shall include the following points, as far as the elements exist:

- the examination of the filling measurement systems of the ballast capacities, upper level alarm and associated safety valves to control the overflows
- the confirmation that the pressure gauges installed on the ballast piping are correctly operational.

5.3.3 Ballasting system

The visit includes:

- the examination of all equipment of the ballasting system (pumps, valves and other components)
- the general examination of the ballast system equipment foundations and fixations
- the good working verification of the system, including the local manual means.

6 Intermediate survey - Hull items

6.1 General

6.1.1 The survey of weather decks is to include:

- examination, as far as applicable, of cargo, crude oil washing, bunker, ballast, steam and vent piping systems as well as vent masts and headers. If upon examination there is any doubt as to the condition of the piping, the piping may be required to be pressure tested, thickness measured or both
- confirmation, if applicable, that cargo pipes are electrically bonded to the hull
- examination of vent line drainage arrangements.

6.2 Ships between 5 and 10 years of age

6.2.1 For single hull oil tankers, all ballast tanks are to be examined.

When considered necessary by the Surveyor, thickness measurements and testing are to be carried out to ensure that the structural integrity remains effective.

6.2.2 For double hull oil tankers, an overall survey of representative salt water ballast tanks selected by the Surveyor is to be carried out.

If such overall survey reveals no visible structural defects, the examination may be limited to a verification that the hard protective coating remains in good condition.

6.2.3 A ballast tank is to be examined at subsequent annual surveys where:

- a hard protective coating has not been applied from the time of construction, or
- a soft or semi-hard coating has been applied, or
- substantial corrosion is found within the tank, or
- the hard protective coating is found to be in less than good condition and the hard protective coating is not repaired to the satisfaction of the Surveyor.

Thickness measurement is to be carried out as deemed necessary by the Surveyor.

6.2.4 In addition to the requirements above, suspect areas identified at previous surveys are to be examined.

6.3 Ships between 10 and 15 years of age

6.3.1 The scope of intermediate survey of ships between 10 and 15 years of age is the scope of the preceding class renewal survey of hull, as detailed in [8] with bottom survey in dry condition or bottom in water survey as applicable. However, pressure testing of all cargo and ballast tanks and the requirements for longitudinal strength evaluation of hull girder as required in [8.4.5] are not required unless deemed necessary by the attending Surveyor.

6.4 Ships over 15 years of age

6.4.1 The scope of intermediate survey of ships over 15 years of age is the scope of the preceding class renewal survey of hull, as detailed in [8] with bottom survey in dry condition, except that pressure testing of ballast and cargo tanks and the requirements for longitudinal strength evaluation of hull girder as required in [8.4.5] is not required unless deemed necessary by the Surveyor.

The overall and close-up surveys and thickness measurements, as applicable, of the lower portions of the cargo tanks and water ballast tanks are to be carried out during the bottom survey in accordance with the applicable requirements for intermediate surveys, if not already performed.

Lower portions of the cargo and ballast tanks are considered to be the parts below light ballast waterline.

7 Intermediate survey - Machinery items - Liquid cargo area

7.1 Cargo area and cargo pump rooms

7.1.1 A general examination of the electrical equipment and cables in dangerous zones such as cargo pump rooms and areas adjacent to cargo tanks is to be carried out for defective and non-certified safe type electrical equipment and fixtures, non-approved lighting and fixtures, and improperly installed or defective or dead-end wiring.

7.1.2 The electrical insulation resistance of the electrical equipment and circuits terminating in or passing through the dangerous zones is to be tested; however, in cases where a proper record of testing is maintained, consideration may be given to accepting recent test readings effected by the ship’s personnel.

7.1.3 The satisfactory condition of the cargo heating system is to be verified.

7.2 Inert gas system

7.2.1 The following is to be carried out:

- main parts such as the scrubber, washing machines, blowers, deck water seal and non-return valve are to be opened out as considered necessary and examined
- gas distribution lines and shut-off valves, including soot blower interlocking devices, are to be examined as deemed necessary
- all automatic shutdown devices and alarms are to be examined and tested.

8 Class renewal survey - Hull items - Liquid cargo area

8.1 Survey planning meeting

8.1.1 The establishment of proper preparation and the close co-operation between the attending Surveyor(s) and the Owner's representatives onboard prior to and during the survey are an essential part in the safe and efficient conduct of the survey. During the survey on board, safety meetings are to be held regularly.

8.1.2 Prior to commencement of any part of the renewal and intermediate survey, a survey planning meeting is to be held between the attending Surveyor(s), the Owner's representative in attendance, the thickness measurement company representative, where involved, and the master of the ship or an appropriately qualified representative appointed by the master or Company for the purpose to ascertain that all the arrangements envisaged in the survey programme are in place, so as to ensure the safe and efficient conduct of the survey work to be carried out. See also [1.1.5].

8.1.3 The following is an indicative list of items that are to be addressed in the meeting:

a) schedule of the ship (i.e. the voyage, docking and undocking manoeuvres, periods alongside, cargo and ballast operations, etc.)

b) provisions and arrangements for thickness measurements (i.e. access, cleaning/de-scaling, illumination, ventilation, personal safety)

c) extent of the thickness measurements

d) acceptance criteria (refer to the list of minimum thicknesses)

e) thickness measurements considering the coating condition and suspect areas/areas of substantial corrosion

f) execution of thickness measurements

g) taking representative readings in general and where uneven corrosion/pitting is found

h) mapping of areas of substantial corrosion, and

i) communication between the attending Surveyor(s), the thickness measurement company operator(s) and the Owner's representative(s) concerning findings.

8.2 Scope of survey

8.2.1 In addition to the requirements of annual surveys, the class renewal survey is to include examination, tests and checks of sufficient extent to ensure that the hull and related piping are in satisfactory condition for the new period of class to be assigned, subject to proper maintenance and operation and to periodical surveys being carried out at the due dates.

8.2.2 All cargo tanks, ballast tanks, including double bottom tanks, pump rooms, pipe tunnels, cofferdams and void spaces bounding cargo tanks, decks and outer hull are to be examined, and this examination is to be supplemented by thickness measurement and testing as required in [8.4] and [8.5], to ensure that the structural integrity remains effective. The aim of the examination is to discover substantial corrosion, significant deformation, fractures, damages or other structural deterioration, that may be present.

8.2.3 As indicated in Ch 3, Sec 3, [2.1.1], a bottom survey in dry condition is to be a part of the class renewal survey. The overall and close-up surveys and thickness measurements, as applicable, of the lower portions of the cargo tanks and ballast tanks are to be carried out during this bottom survey in accordance with the applicable requirements for class renewal surveys, if not already performed.

Lower portions of the cargo and ballast tanks are considered to be the parts below light ballast waterline.

8.2.4 Where provided, the condition of the corrosion prevention system of cargo tanks is to be examined.

A ballast tank is to be examined at subsequent annual surveys where:

- a hard protective coating has not been applied from the time of construction, or
- a soft or semi-hard coating has been applied, or
- substantial corrosion is found within the tank, or
- the hard protective coating is found to be in less than good condition and the hard protective coating is not repaired to the satisfaction of the Surveyor.

Thickness measurement is to be carried out as deemed necessary by the Surveyor.

8.3 Overall surveys

8.3.1 Each class renewal survey is to include an overall survey of all tanks and spaces.

8.4 Thickness measurements

8.4.1 The minimum requirements for thickness measurements at class renewal survey are given in Tab 1.

8.4.2 Provisions for extended measurements for areas with substantial corrosion are given in Tab 2 for single hull oil tankers and combination carriers or Tab 3 for double hull oil tankers and as may be additionally specified in the survey program as required in [8.1]. These extended thickness measurements are to be carried out before the survey is credited as completed.

Suspect areas identified at previous surveys are to be examined.

Areas of substantial corrosion identified at previous surveys are to have thickness measurements taken.

The Surveyor may further extend the thickness measurements as deemed necessary.

Table 1 : Thickness measurements at class renewal survey - Auxiliary naval vessels

Age of ship (in years at time of class renewal survey)			
age ≤ 5	5 < age ≤ 10	10 < age ≤ 15	age > 15
Suspect areas	Suspect areas	Suspect areas	Suspect areas
One section of deck plating for the full beam of the ship within the cargo area (in way of a ballast tank, if any, or a cargo tank used primarily for water ballast)	Within the cargo area: • each deck plat • 1 transverse section**(1)**	Within the cargo area: • each deck plate • 2 transverse sections**(1)(2)** • all wind and water strakes	Within the cargo area: • each deck plate • 3 transverse sections**(1)(2)** • each bottom plate
Measurements, for general assessment and recording of corrosion pattern, of those structural members subject to close-up survey**(3)**	Measurements, for general assessment and recording of corrosion pattern, of those structural members subject to close-up survey**(3)**	Measurements, for general assessment and recording of corrosion pattern, of those structural members subject to close-up survey**(3)**	Measurements, for general assessment and recording of corrosion pattern, of those structural members subject to close-up survey**(3)**
	Selected wind and water strakes outside the cargo area	Selected wind and water strakes outside the cargo area	All wind and water strakes, full length

(1) Transverse sections are to be chosen where the largest reductions are likely to occur or as revealed by deck plating measurements.
(2) At least one section is to be within 0,5 L amidships and, where applicable, in way of a ballast tank.
(3) A close-up survey is a survey where the details of structural components are within the close visual inspection range of the Surveyor, i.e. normally within reach of hand.

Table 2 : Extended thickness measurements at those areas of substantial corrosion - Auxiliary naval vessels

BOTTOM STRUCTURE		
Structural member	Extent of measurement	Pattern of measurement
Bottom plating	Minimum of 3 bays across tank, including aft bay Measurements around and under all suction bell mouths	5-point pattern for each panel between longitudinals and webs
Bottom longitudinals	Minimum of 3 longitudinals in each bay where bottom plating measured	3 measurements in line across flange and 3 measurements on vertical web
Bottom girders and brackets	At fore and aft transverse bulkhead, bracket toes and in centre of tanks	Vertical line of single measurements on web plating with one measurement between each panel stiffener, or a minimum of 3 measurements. 2 measurements across face flat. 5-point pattern on girder/bulkhead brackets.
Bottom transverse webs	3 webs in bays where bottom plating measured, with measurements at both ends and middle	5-point pattern over 2 square metre area. Single measurements on face flat.
Panel stiffening	Where provided	Single measurements

DECK STRUCTURE		
Structural member	Extent of measurement	Pattern of measurement
Deck plating	2 bands across tank	Minimum of 3 measurements per plate per band
Deck longitudinals	Minimum of 3 longitudinals in each of 2 bays	3 measurements in line vertically on webs and 2 measurements on flange (if fitted)
Deck girders and brackets	At fore and aft transverse bulkhead, bracket toes and in centre of tanks	Vertical line of single measurements on web plating with one measurement between each panel stiffener, or a minimum of 3 measurements. 2 measurements across face flat. 5-point pattern on girder/bulkhead brackets.
Deck transverse webs	Minimum of 2 webs, with measurements at both ends and middle of span	5-point pattern over 2 square metre area. Single measurements on face flat.
Panel stiffening	Where provided	Single measurements

SIDE SHELL AND LONGITUDINAL BULKHEADS		
Structural member	Extent of measurement	Pattern of measurement
Deckhead and bottom strakes and strakes in way of stringer platforms	Plating between each pair of longitudinals in a minimum of 3 bays	Single measurement
All other strakes	Plating between every third pair of longitudinals in same 3 bays	Single measurement
Longitudinals on deckhead and bottom strakes	Each longitudinal in same 3 bays	3 measurements across web and 1 measurement on flange
All other longitudinals	Every third longitudinal in same 3 bays	3 measurements across web and 1 measurement on flange
Longitudinal brackets	Minimum of 3 at top, middle and bottom of tank in same 3 bays	5-point pattern over area of bracket
Web frames and cross ties	3 webs with minimum of 3 locations on each web, including in way of cross tie connections	5-point pattern over approximately 2 square metre area, plus single measurements on web frame and cross tie face flats

TRANSVERSE BULKHEADS AND SWASH BULKHEADS		
Structural member	Extent of measurement	Pattern of measurement
Deckhead and bottom strakes, and strakes in way of stringer platforms	Plating between pair of stiffeners at 3 locations: approximately 1/4, 1/2 and 3/4 width of tank	5-point pattern between stiffeners over 1 metre length
All other strakes	Plating between pair of stiffeners at middle location	Single measurement
Strakes in corrugated bulkheads	Plating for each change of scantling at centre of panel and at flange of fabricated connection	5-point pattern over about 1 square metre of plating
Stiffeners	Minimum of 3 typical stiffeners	For web, 5-point pattern over span between bracket connections (2 measurements across web at each bracket connection and one at centre of span). For flange, single measurements at each bracket toe and at centre of span
Brackets	Minimum of 3 at top, middle and bottom of tank	5-point pattern over area of bracket
Deep webs and girders	Measurements at toe of bracket and at centre of span	For web, 5-point pattern over about 1 square metre. 3 measurements across face flat.
Stringer platforms	All stringers with measurements at both ends and middle	5-point pattern over 1 square metre of area plus single measurements near bracket toes and on face flats

8.4.3 When pitting is found on bottom plating and its intensity is 20% or more, thickness measurements are to be extended in order to determine the actual plate thickness out of the pits and the depth of the pits. Where the wastage is in the substantial corrosion range or the average depth of pitting is 1/3 or more of the actual plate thickness, the pitted plate is to be considered as a substantially corroded area.

8.4.4 For areas in tanks where hard protective coatings are found to be in good condition as defined in Ch 2, Sec 2, [3.2.9], the extent of thickness measurements according to Tab 1 may be specially considered.

8.4.5 On oil tankers of 130 m in length and upwards (as defined in the International Convention on Load Lines in force) and more than 10 years of age, the longitudinal strength of the ship's hull girder is to be evaluated in compliance with the requirements of NR467, Pt A, Ch 4, App 1 on the basis of the thickness of the structures measured, renewed or reinforced, as appropriate, during the class renewal survey.

8.5 Tank testing

8.5.1 The requirements for tank testing at class renewal survey are given in Tab 4.

8.5.2 The Surveyor may extend the tank testing as deemed necessary.

8.5.3 Boundaries of ballast tanks are to be tested with a head of liquid to the top of air pipes.

Boundaries of cargo tanks are to be tested to the highest point that liquid will rise under service conditions

For double hull oil tankers, the testing of double bottom tanks and other spaces not designed for the carriage of liquid may be omitted, provided a satisfactory internal examination together with an examination of the tank top is carried out.

Table 3 : Extended thickness measurements at those areas of substantial corrosion - Auxiliary naval vessel with double hull

BOTTOM, INNER BOTTOM AND HOPPER STRUCTURE		
Structural member	Extent of measurement	Pattern of measurement
Bottom, inner bottom and hopper structure plating	Minimum of 3 bays across double bottom tank, including aft bay Measurements around and under all suction bell mouths	5-point pattern for each panel between longitudinals and floors
Bottom, inner bottom and hopper structure longitudinals	Minimum of 3 longitudinals in each bay where bottom plating measured	3 measurements in line across flange and 3 measurements on vertical web
Bottom girders, including the watertight ones	At fore and aft watertight floors and in centre of tanks	Vertical line of single measurements on girder plating with one measurement between each panel stiffener, or a minimum of 3 measurements
Bottom floors, including the watertight ones	3 floors in bays where bottom plating measured, with measurements at both ends and middle	5-point pattern over 2 square metre area
Hopper structure web frame ring	3 floors in bays where bottom plating measured	5-point pattern over about 1 square metre of plating. Single measurements on flange.
Hopper structure transverse watertight bulkhead or swash bulkhead	• lower 1/3 of bulkhead	5-point pattern over about 1 square metre of plating
	• upper 2/3 of bulkhead	5-point pattern over 2 square metre of plating
	• stiffeners (minimum of 3)	For web, 5-point pattern over span (2 measurements across web at each end and one at centre of span). For flange, single measurements at each end and centre of span.
Panel stiffening	Where provided	Single measurements

DECK STRUCTURE		
Structural member	Extent of measurement	Pattern of measurement
Deck plating	2 transverse bands across tank	Minimum of 3 measurements per plate per band
Deck longitudinals	Every third longitudinal in each of 2 bands with a minimum of one longitudinal	3 measurements in line vertically on webs and 2 measurements on flange (if fitted)
Deck girders and brackets (usually in cargo tanks only)	At fore and aft transverse bulkhead, bracket toes and in centre of tanks	Vertical line of single measurements on web plating with one measurement between each panel stiffener, or a minimum of 3 measurements. 2 measurements across flange. 5-point pattern on girder/bulkhead brackets.
Deck transverse webs	Minimum of 2 webs, with measurements at both ends and middle of span	5-point pattern over 1 square metre area. Single measurements on flange.
Vertical web and transverse bulkhead in wing ballast tank (2 metres from deck)	Minimum of 2 webs, and both transverse bulkheads	5-point pattern over 1 square metre area
Panel stiffening	Where provided	Single measurements

STRUCTURE IN WING BALLAST TANKS		
Structural member	Extent of measurement	Pattern of measurement
Side shell and longitudinal bulkhead plating:		
• upper strake and strakes in way of horizontal girders	Plating between each pair of longitudinals in a minimum of 3 bays (along the tank)	Single measurement
• all other strakes	Plating between every third pair of longitudinals in same 3 bays	Single measurement
Side shell and longitudinal bulkhead longitudinals on:		
• upper strake	Each longitudinal in same 3 bays	3 measurements across web and 1 measurement on flange
• all other strakes	Every third longitudinal in same 3 bays	3 measurements across web and 1 measurement on flange
Longitudinal brackets	Minimum of 3 at top, middle and bottom of tank in same 3 bays	5-point pattern over area of bracket
Vertical web and transverse bulkheads (excluding deckhead area):		
• strakes in way of horizontal girders	Minimum of 2 webs and both transverse bulkheads	5-point pattern over 2 square metre area
• other strakes	Minimum of 2 webs and both transverse bulkheads	2 measurements between each pair of vertical stiffeners
Horizontal girders	Plating on each girder in a minimum of 3 bays	2 measurements between each pair of longitudinal girder stiffeners
Panel stiffening	Where provided	Single measurements

LONGITUDINAL BULKHEADS IN CARGO TANKS		
Structural member	Extent of measurement	Pattern of measurement
Deckhead and bottom strakes and strakes in way of the horizontal stringers of transverse bulkheads	Plating between each pair of longitudinals in a minimum of 3 bays	Single measurement
All other strakes	Plating between every third pair of longitudinals in same 3 bays	Single measurement
Longitudinals on deckhead and bottom strakes	Each longitudinal in same 3 bays	3 measurements across web and 1 measurement on flange
All other longitudinals	Every third longitudinal in same 3 bays	3 measurements across web and 1 measurement on flange
Longitudinal brackets	Minimum of 3 at top, middle and bottom of tank in same 3 bays	5-point pattern over area of bracket
Web frames and cross ties	3 webs with minimum of 3 locations on each web, including in way of cross tie connections	5-point pattern over approximately 2 square metre area of webs, plus single measurements on flanges of web frame and cross ties
Lower end brackets (opposite side of web frame)	Minimum of 3 brackets	5-point pattern over approximately 2 square metre area of brackets, plus single measurements on bracket flanges

TRANSVERSE WATERTIGHT AND SWASH BULKHEADS IN CARGO TANKS		
Structural member	Extent of measurement	Pattern of measurement
Upper and lower stool, where fitted	• Transverse band within 25mm of welded connection to inner bottom/deck plating • Transverse band within 25mm of welded connection to shelf plate	5-point pattern between stiffeners over 1 metre length
Deckhead and bottom strakes, and strakes in way of horizontal stringers	Plating between pair of stiffeners at 3 locations: approximately 1/4, 1/2 and 3/4 width of tank	5-point pattern between stiffeners over 1 metre length
All other strakes	Plating between pair of stiffeners at middle location	Single measurement
Strakes in corrugated bulkheads	Plating for each change of scantling at centre of panel and at flange of fabricated connection	5-point pattern over about 1 square metre of plating
Stiffeners	Minimum of 3 typical stiffeners	For web, 5-point pattern over span between bracket connections (2 measurements across web at each bracket connection and one at centre of span). For flange, single measurements at each bracket toe and at centre of span.
Brackets	Minimum of 3 at top, middle and bottom of tank	5-point pattern over area of bracket
Horizontal stringers	All stringers with measurements at both ends and middle	5-point pattern over 1 square metre of area plus single measurements near bracket toes and on flange

Table 4 : Tank testing at class renewal survey - Auxiliary naval vessels

Age of ship (in years at time of class renewal survey)	
age ≤ 6	age > 6
All ballast tank boundaries	All ballast tank boundaries
Cargo tank boundaries facing ballast tanks, void spaces, pipe tunnels, pump rooms or cofferdams	All cargo tank bulkheads

8.6 Cargo piping, area and pump rooms

8.6.1 Cargo piping on deck and cargo and ballast piping systems within the cargo area are to be examined and operationally tested to working pressure to the attending Surveyor's satisfaction to ensure that their tightness and condition remain satisfactory. Special attention is to be given to any ballast piping in cargo tanks and cargo piping in ballast tanks and void spaces. Surveyors are to be advised on all occasions when this piping, including valves and fittings, is opened during repair periods and can be examined internally.

The Surveyor may require dismantling and/or thickness measurements of piping. A hydraulic test is to be carried out in the event of repair or dismantling or cargo, crude oil washing, or ballast piping, or where doubts arise.

8.6.2 All safety valves on cargo piping and of cargo tanks are to be dismantled for examination, adjusted and, as applicable, resealed.

8.6.3 All cargo pump room boundaries are to be generally examined. All gas-tight shaft sealing devices are to be examined. The bottom of cargo pump rooms is to be presented clean for the examination of stripping devices and gutters.

9 Class renewal survey - Hull items - Dry cargo area

9.1 Stability

9.1.1 A lightweight survey is to be carried out to verify any changes in lightship displacement and in the longitudinal position of the centre of gravity. Where, in comparison with the approved stability information, a deviation exceeding 2% in the lightship displacement or 1% in the position of the longitudinal centre of gravity is found or anticipated, the ship is to be submitted to a new inclining test.

9.2 Shell and inner doors

9.2.1 A close visual inspection of structural arrangements is to be carried out, supplemented by non-destructive tests and/or thickness measurements, as deemed necessary by the Surveyor.

9.2.2 The close visual inspection of securing, supporting and locking devices, as required for the annual survey, is to be supplemented by non-destructive tests and/or thickness measurements.

9.2.3 Clearances of hinges, bearings and thrust bearings are to be measured. Dismantling may be required as deemed necessary by the Surveyor.

9.2.4 Non-return valves of drainage arrangements are to be checked after dismantling.

10 Class renewal survey - Machinery items - Liquid cargo area

10.1 Cargo area and cargo pump rooms

10.1.1 Ballast and stripping pumps are to be internally examined and prime movers checked. A working test is to be carried out, as far as practicable.

Maintenance records of cargo pumps are to be made available to the Surveyor.

10.1.2 The satisfactory condition of the cargo heating system is to be verified and, if deemed necessary by the Surveyor, the system is to be pressure tested.

10.1.3 An operating test of the remote control of pumps and valves and of automatic closing valves is to be carried out.

10.1.4 A general examination of the electrical equipment and cables in dangerous zones such as cargo pump rooms and areas adjacent to cargo tanks is to be carried out for defective and non-certified safe type electrical equipment and fixtures, non-approved lighting and fixtures, and improperly installed or defective or dead-end wiring.

The electrical insulation resistance of the electrical equipment and circuits terminating in or passing through the dangerous zones is to be tested; however, in cases where a proper record of testing is maintained, consideration may be given to accepting recent test readings effected by the ship's personnel.

10.2 Fire-fighting systems in cargo area

10.2.1 The survey is to include the examination of fire-fighting systems of any type fitted on board for the protection of the cargo area, cargo pump room and other dangerous spaces, such as deck foam, water-spraying systems, etc., as applicable in accordance with the relevant requirements given in Ch 3, Sec 3, [4.8].

10.3 Inert gas system

10.3.1 In addition to the inspections required at the intermediate survey, the following is to be carried out:

a) An internal examination of:
   - the inert gas generator, where fitted
   - the scrubber
   - the deck water seal including the non-return valve
   - the pressure/vacuum breaking device
   - the cooling water systems including overboard discharge from the scrubber
   - all valves

b) A test to verify the proper operation of the system upon completion of all survey checks.

11 Class renewal survey - Machinery items - Dry cargo area

11.1 Lighting

11.1.1 The condition of the Low Location Lighting (LLL) system, where fitted, and its power source(s) is to be verified.

11.2 Fire protection, detection and extinction

11.2.1 Within the scope of survey of fire protection, detection and extinction arrangements as required for the class renewal survey of all ships in Ch 3, Sec 3, [4.8], attention is to be given to the particular arrangements related to ro-ro cargo spaces, such as those indicated in [5.1.1].

Section 5 Amphibious Vessel

1 General

1.1

1.1.1 The requirements of this Section are applicable after construction to all self-propelled ships which have been assigned the following service notation:

amphibious vessel

as defined in Part D, Chapter 5.

1.1.2 These requirements are additional to those laid down in Part A, Chapter 3, according to the relevant surveys.

2 Annual survey

2.1 Shell and inner doors

2.1.1 The requirements of this sub-article apply to all shell and inner doors fitted on these ships.

2.1.2 For the scope of survey of shell and inner doors, the following definitions are applicable:

- Securing device:
  a device used to keep the door closed by preventing it from rotating about its hinges
- Supporting device:
  a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship's structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, that transmits loads from the door to the ship's structure
- Locking device:
  a device that locks a securing device in the closed position.

2.1.3 It is to be checked that the operating procedures for closing the shell and inner doors are kept on board and posted at appropriate places.

When required, the Operating and Maintenance Manual is also to be checked for the verification of its approval and of any modification, reported repairs and proper endorsement by operating personnel.

Confirmation is to be obtained that no unapproved changes have been made to the bow, inner, side shell and stern doors since the last survey.

2.1.4 The structural arrangements as well as welding are to be examined, including:

- plating, primary structure and secondary stiffeners
- hinging arms, hinges and bearings, thrust bearings
- hull and door side supports of securing, supporting and locking devices
- shell plating surrounding the openings and the securing, supporting and locking devices.

Clearances of hinges, bearings and thrust bearings are to be taken, where no dismantling is required. Where the function test is not satisfactory, dismantling may be required to measure the clearances. If dismantling is carried out, a visual examination of hinge pins and bearings together with NDT of the hinge pin is to be carried out. Clearances of securing, supporting and locking devices are to be measured, where indicated in the Operation and Maintenance Manual (OMM).

2.1.5 A close-up survey of securing, supporting and locking devices as listed below, including welding, is to be carried out:

- cylinder securing pins, supporting brackets, back-up brackets (where fitted) and their welded connections
- hinge pins, supporting brackets, back-up brackets (where fitted) and their welded connections
- locking hooks, securing pins, supporting brackets, back-up brackets (where fitted) and their welded connections
- locking pins, supporting brackets, back-up brackets (where fitted) and their welded connections
- locating and stopper devices and their welded connections.

2.1.6 A close visual inspection of sealing arrangements (packing material, rubber gaskets, packing retaining bars or channels) is to be carried out. For the tightness hose test, refer to [2.1.8].

2.1.7 The drainage arrangements including bilge wells, drain pipes and non-return valves are to be visually examined. A test of the bilge system between the inner and outer doors and that of the vehicle deck is to be carried out.

2.1.8 Function tests are to be carried out as follows, according to the required and/or existing equipment on board:

a) Doors are to be examined during a complete opening and closing operation; during this operation, the proper working of hinging arms and hinges, proper engagement of the thrust bearings and proper working of devices for locking the door in open position are to be checked

b) Securing, supporting and locking devices are to be examined during a complete opening and closing operation; the following items are to be checked:
   - opening/closing system and securing/locking devices are interlocked in such a way that they can only operate in proper sequence
   - mechanical lock of the securing devices
   - the securing devices remain locked in the event of loss of hydraulic fluid, if they are of hydraulic type

c) Indicators of open/closed position of doors and of securing/locking devices at navigation bridge and other remote control stations are to be checked; other safety devices such as isolation of securing/locking hydraulic system from other hydraulic systems, access to operating panels, notice plates and warning indicator lights are to be checked

d) A tightness hose test or equivalent of sealing arrangements is to be carried out

e) A working test of the indicator system is to be carried out, including checking of:
   - visual indicators and audible alarms on the navigation bridge and operating panel
   - lamp test function, fail safe performance, power supply for indicator system
   - proper condition of sensors and their protection from water, ice formation and mechanical damage
   - confirmation that power supply for indicator system is supplied by the emergency source or other secure power supply and is independent of the power supply for operating the doors

f) A working test of the water leakage detection system for inner doors and for the area between the bow door and the inner door (as applicable) is to be carried out and the proper function of audible alarms on the navigation bridge and the engine control room panel (as applicable) is to be ascertained

g) The television surveillance system is to be verified with proper indication on the navigation bridge and engine control room monitors

h) Electrical equipment for opening, closing and securing the doors is to be examined.

2.1.9 Non-destructive tests and/or thickness measurements may be required by the Surveyor after visual examination and function test or in cases where cracks or deformations have been found.

2.2 Internal platforms and ramps

2.2.1 The annual survey of internal movable platforms and ramps (excluding those considered as inner doors and covered in [2.1]) and related equipment consists of:

- a general examination of the installation, particular attention being paid to the condition of steel cables
- confirmation of the proper operation of platforms/ramps and of mechanical stops and locks
- checking, as far as practicable, of the alarms and safety devices.

2.3 Watertight bulkheads

2.3.1 The survey of watertight bulkheads and arrangements consists of:

- examination, as far as practicable, of collision and watertight bulkheads, and confirmation that their watertight integrity has not been impaired
- checking the diagram provided on the navigation bridge showing the location of the watertight doors and related indicators for their open/closed position
- testing operation of local and remote control (from the navigation bridge) of the watertight doors, and in particular, operation from each side of the bulkhead of audible alarms or visual signals and control handles, as required or fitted
- confirmation of operation of watertight doors in the event of failure of main and emergency sources of power
- confirmation that notices are affixed at appropriate locations.

2.4 Openings in shell plating

2.4.1 The survey consists of:

- examination of the arrangements for closing sidescuttles and their deadlights, as well as scuppers, sanitary discharges and similar openings and other inlets and discharges in the shell plating below the margin line
- confirmation that valves for closing the main and auxiliary sea inlets and discharges in the machinery spaces are readily accessible, and that indicators showing the status of the valves are provided, as required or fitted
- confirmation that gangway access and cargo ports fitted below the margin line may be effectively closed and that the inboard ends of any ash or rubbish chutes are fitted with an effective cover.

2.5 Fire protection, detection and extinction

2.5.1 Within the scope of survey of fire protection, detection and extinction arrangements as required for the annual survey of all ships in Ch 3, Sec 1, [3.4], attention is to be given to the particular arrangements related to amphibious vessel spaces, such as:

- fire detection systems and alarms
- fixed fire-extinguishing arrangements (gas, water-spraying or foam systems)
- portable fire extinguishers in spaces and at entrances
- ventilation and related safety devices (including remote control on the bridge), and
- electrical equipment of a safe type.

2.6 Means of escape

2.6.1 The condition of means of escape as well as of fire protection, detection and extinction in special category spaces is to be checked.

2.6.2 It is to be verified that the emergency escape routes from passenger and crew spaces, including related stairways and ladders, are kept clear.

3 Class renewal survey

3.1 Lightweight survey

3.1.1 A lightweight survey is to be carried out to verify any changes in lightship displacement and in the longitudinal position of the centre of gravity. Where, in comparison with the approved stability information, a deviation exceeding 2% in the lightship displacement or a deviation of the longitudinal centre of gravity exceeding 1% of the length between perpendiculars is found or anticipated, the ship is to be submitted to a new inclining test.

3.2 Shell and inner doors

3.2.1 The class renewal survey is to include, in addition to the requirements of the annual survey as required in [2], examination, tests and checks of sufficient extent to verify that the bow, inner, side shell and stern doors are in satisfactory condition and considered able to remain in compliance with the applicable requirements, subject to proper maintenance and operation in accordance with the OMM or the manufacturer's recommendations and the periodical surveys being carried out at the due dates for the five-year period until the next class renewal survey.

3.2.2 The examinations of the doors are to be supplemented by thickness measurements and testing to verify compliance with the applicable requirements so that the structural and weathertight integrity remains effective. The aim of the examination is to identify corrosion, significant deformation, fractures, damages or other structural deterioration that may be present.

3.2.3 A close visual inspection of structural arrangements is to be carried out, supplemented by non-destructive tests and/or thickness measurements, as deemed necessary by the Surveyor.

3.2.4 A survey of the items listed in [2.1.4] and [2.1.5], including close-up survey of securing, supporting and locking devices, together with welding, is to be carried out.

Non-destructive testing and thickness measurements are to be carried out on securing, supporting and locking devices, including welding, to the extent considered necessary by the Surveyor. Whenever a crack is found, an examination with NDT is to be carried out in the surrounding area and for similar items, as considered necessary by the Surveyor.

3.2.5 Clearances of hinges, bearings and thrust bearings are to be taken. Unless otherwise specified in the OMM or by the manufacturer's recommendation, the measurement of clearances on amphibious vessels may be limited to representative bearings where dismantling is needed in order to measure the clearances.

If dismantling is carried out, a visual examination of hinge pins and bearings together with NDT of the hinge pins are to be carried out.

3.2.6 Non-return valves of drainage arrangements are to be checked after dismantling.

3.2.7 The maximum thickness diminution of hinging arms, securing, supporting and locking devices is to be treated according to the normal procedure for primary structures, but is not to be more than 15% of the as-built thickness or the maximum corrosion allowance of the Society, whichever is less. Certain designs may be subject to the Society's special consideration.

3.2.8 Checking the effectiveness of sealing arrangements by hose testing or equivalent is to be carried out.

3.3 Internal platforms and ramps

3.3.1 The condition of pulleys, axles, cables and structure of the platforms and ramps is to be checked.

Electric motors and/or hydraulically operated equipment are to be surveyed according to the scope detailed in Ch 3, Sec 3, [4] for the class renewal survey of machinery installations.

3.4 Fire protection, detection and extinction

3.4.1 Within the scope of survey of fire protection, detection and extinction arrangements as required for the class renewal survey of all ships in Ch 3, Sec 3, [4.8], attention is to be given to the particular arrangements related to amphibious vessel spaces, such as those indicated in [2.5.1].

3.5 Means of escape

3.5.1 The condition of means of escape as well as of fire protection, detection and extinction in special category spaces is to be checked.

3.5.2 The condition of the Low Location Lighting (LLL) system, where fitted, and its power source(s) is to be verified.

Part A
Classification and Surveys

CHAPTER 5
SCOPE OF SURVEYS RELATED TO ADDITIONAL CLASS NOTATIONS

Section	1	General
Section	2	Military environment
Section	3	VeriSTAR System
Section	4	Availability of Machinery
Section	5	Automated Machinery Systems
Section	6	Integrated Ship Systems
Section	7	Monitoring Equipment
Section	8	Refrigerating Installations
Section	9	Environmental Protection
Section	10	CBRN Protection
Section	11	Manoeuvrability
Section	12	Towing
Section	13	Helideck

Section 1 General

1 General

1.1

1.1.1 The purpose of this Chapter is to give details on the scope of surveys of specific equipment and systems fitted on board the ship, which are covered by an additional class notation. Unless otherwise specified in Ch 1, Sec 2, [6], the scope of these surveys provides the requirements to be complied with for the maintenance of the relevant additional class notation.

1.1.2 These specific requirements are additional to those laid down in Part A, Chapter 3 and Part A, Chapter 4. These surveys are to be carried out at intervals as described in Ch 2, Sec 2, as far as possible concurrently with the surveys of the same type, i.e. annual, intermediate or class renewal survey.

1.1.3 The equipment and systems are also to be submitted to occasional survey whenever one of the cases indicated in Ch 2, Sec 2, [7] occurs.

1.1.4 Where specific requirements are given for the class renewal survey, they are additional to the requirements for the annual survey, which, in accordance with Ch 3, Sec 3, [1.1.5], is to be carried out at the completion of the class renewal survey.

1.1.5 For the assignment of the additional class notations, ships are to be submitted to an admission to class survey as described in Ch 2, Sec 1, [2] and Ch 2, Sec 1, [3] for new and existing installations, respectively, as applicable.

2 Additional class notations subject to additional surveys

2.1

2.1.1 The specific requirements detailed in this Chapter are linked to the additional class notation(s) assigned to the ship. Where a ship has more than one additional class notation, the specific requirements linked to each additional class notation are applicable as long as they are not contradictory.

2.1.2 Tab 1 indicates which additional class notations are subject to specific requirements, and in which Section they are specified.

Table 1 : Additional class notations for which specific survey requirements are applicable

Additional class notation	Section applicable in this Chapter	Type of surveys affected by these specific requirements	Remarks
Military environment: **ARMOUR** **FFS**	Ch 5, Sec 2	See Remarks	As applicable in accordance with the related Articles in Ch 5, Sec 2
VeriSTAR system: **STAR-HULL** **STAR-MACH**	Ch 5, Sec 3	See Remarks	The scope and periodicity of surveys are stipulated by specific requirements given in Part E, Chapter 2
Availability of machinery: **AVM-APM**, **AVM-DPS**, **AVM-IPSx-(V)**	Ch 5, Sec 4	annual survey class renewal survey	
Automated machinery systems: **AUT-QAS**, **AUT-PORT**, **AUT-IAS**	Ch 5, Sec 5	annual survey class renewal survey	
Integrated ship systems: **SYS-NEQ**, **SYS-NEQ1**	Ch 5, Sec 6	annual survey class renewal survey	
Monitoring equipment: **MON-HULL**, **MON-SHAFT**	Ch 5, Sec 7	annual survey class renewal survey tailshaft survey	
Refrigerating installations: **REF-STORE**	Ch 5, Sec 8	annual survey class renewal survey	
Environmental Protection: **CLEANSHIP**, **CLEANSHIP SUPER** **AWT**, **BWE**, **BWT**, **GWT** **NDO-x days**, **NOX-x%** **OWS-x ppm**, **SOX-x%**	Ch 5, Sec 9	annual survey class renewal survey	

Additional class notation	Section applicable in this Chapter	Type of surveys affected by these specific requirements	Remarks
CBRN protection: **CBRN** **CBRN-AIR BLAST RESISTANCE**	Ch 5, Sec 10	annual surveys class renewal surveys	
Manoeuvrability: **MANOVR**	Ch 5, Sec 11	class renewal surveys	
Towing: **TOW**	Ch 5, Sec 12	annual surveys class renewal surveys	
Helideck: **HELICOPTER**	Ch 5, Sec 13	annual surveys class renewal surveys	

Section 2 Military environment

1 General

1.1 Application

1.1.1 The requirements of this Section apply to self-propelled ships granted with one or more of the following additional class notations:

ARMOUR

FFS

1.1.2 These requirements apply in addition to the requirements given in Part A, Chapter 3 and Part A, Chapter 4 versus the type of surveys.

2 ARMOUR

2.1 Class renewal surveys

2.1.1 Surveys

The survey shall include:

- an examination of the armour components as described in the armouring table
- the confirmation that the armour components are still in place, without external deficiency that can be detected by visual examination.

3 FFS

3.1 Annual survey

3.1.1 The annual survey is to include the following items:

- examination, as far as practicable, of the FFS pumping systems and suctions
- general examination of FFS piping, valves, indicators and remote controls.

3.2 Class renewal survey

3.2.1 The requirements given in [3.1] for annual survey are to be complied with.

3.2.2 In addition, the class renewal survey is to include a functional test of the flooding fighting system. If impractical to conduct, an exemption may be granted for actual pumping if agreed upon by the Naval Authority.

Section 3 VeriSTAR System

1 General

1.1 Application

1.1.1 The requirements of this Section apply to ships which have been assigned one of the following additional class notations related to the **VeriSTAR** system, as described in Ch 1, Sec 2, [6.3]:

STAR-HULL

STAR-MACH

2 STAR-HULL

2.1 Survey scope and periodicity

2.1.1 The scope and periodicity of surveys for the maintenance of the **STAR-HULL** notation are given in Pt E, Ch 2, Sec 1.

3 STAR-MACH

3.1 Survey scope and periodicity

3.1.1 The procedures for the maintenance of the **STAR-MACH** notation are given in Pt E, Ch 2, Sec 2.

Section 4 Availability of Machinery

1 General

1.1

1.1.1 The requirements of this Section apply to ships which have been assigned one of the following additional class notations related to availability of machinery, as described in Ch 1, Sec 2, [6.4]:

AVM-APM

AVM-DPS

AVM-IPSx-(V)

2 Annual survey

2.1

2.1.1 At each annual survey the Owner or his representative is to declare to the attending Surveyor that no modifications have been made to the systems affecting the notations without prior approval by the Society.

3 Class renewal survey

3.1

3.1.1 At each class renewal survey a test is to be conducted in order to ascertain that the systems affecting the notations operate satisfactorily. This test is usually to be carried out at sea.

Section 5 Automated Machinery Systems

1 General

1.1

1.1.1 The requirements of this Section apply to ships which have been assigned one of the following additional class notations related to automated machinery systems, as described in Ch 1, Sec 2, [6.5]:

AUT-QAS

AUT-PORT

AUT-IAS

2 Annual survey

2.1

2.1.1 The Owner or his representative is to declare to the attending Surveyor that no significant modifications have been made without prior approval by the Society.

2.1.2 The annual survey is to include:

- an examination of the engineers' log-book to verify the proper operation of automation systems in the period subsequent to the last survey and measures taken to avoid repetition of any malfunctions or failures which have occurred during the same period
- a general examination of the control systems covered by the notation, including a random check of the proper operation and calibration of main measuring, monitoring, alarm, and automatic shut-off devices
- a check of the fire detectors
- a check of the bilge flooding alarms
- a running test which may be also performed by a spot check method.

3 Class renewal survey

3.1

3.1.1 The requirements given in [2] for annual survey are to be complied with. An additional program of examinations, checks and tests is to be devised in agreement with the Owner and based on the operational data and experience of previous surveys. This program is to include verification of the calibration of instruments and testing of control and safety functions of the machinery. The Owner is to produce evidence that all these checks and tests have been carried out and this will be verified by the Surveyor at random. In addition, the proper operation of the control system of propulsion machinery is to be checked at sea.

Section 6 Integrated Ship Systems

1 General

1.1

1.1.1 The requirements of this Section apply to ships which have been assigned one of the following additional class notations related to integrated ship systems, as described in Ch 1, Sec 2, [6.6.1]:

SYS-NEQ

SYS-NEQ-1

2 Annual survey

2.1

2.1.1 The Owner or his representative is to declare to the attending Surveyor that no significant modifications have been made to the relevant installations without the prior approval by the Society.

An examination of the log-books is to be carried out to verify the proper operation of systems in the period subsequent to the last survey and measures taken to avoid repetition of any malfunctions or failures which have occurred during the same period

2.1.2 The annual survey is to include:

a) General:
   - general examination of the bridge layout, with regard to the field of vision, window wipe and wash system, wheelhouse lighting and heating/cooling systems, and arrangements for the safety of navigators

b) Propulsion and steering controls:
   - operational test of the steering gear to confirm the proper operation of the various remote controls from the wheelhouse
   - operational test, as far as practicable, of the propulsion control, including propeller pitch control, where fitted
   - check of the relevant indicators such as rudder angle, ahead/astern position, propeller rpm or pitch

c) Navigation aids:
   - operational test of the satisfactory operating condition of radars
   - operational test of the functions available at quay side of the ARPA and collision avoidance system
   - operational test of the position fixing system
   - operational test of the gyro compass system
   - operational test of the echo sounding device, using appropriate scale of depth
   - operational test of other available alarms (sounding equipment, self-checking device, etc.), as far as practicable

d) Communications:
   - operational test of the whistle control device from the relevant workstation
   - check of the different communication systems (internal communication, VHF radiotelephone installation, NAVTEX)

e) Bridge safety and alarm system (notation **SYS-NEQ-1**)
   - operational test, as far as practicable, of the vigilance system and related alarm/warning transfer system.

3 Class renewal survey

3.1

3.1.1 The requirements given in Article [2] for annual survey are to be complied with. An additional program of examinations, checks and operational tests is to be devised in agreement with the Owner and based on the operational data and experience of previous surveys. This program is to include verification of the calibration of instruments and testing of control and safety functions of the installation. An additional program of random tests of the systems is to be performed during sea trials.

The Owner is to confirm that any modification to the hardware and software is fully documented and properly recorded.

Section 7 Monitoring Equipment

1 General

1.1 Application

1.1.1 The requirements of this Section apply to ships which have been assigned one of the following additional class notations related to hull and tailshaft monitoring equipment, as described in Ch 1, Sec 2, [6.7]:

MON-HULL

MON-SHAFT

2 MON-HULL

2.1 Annual and class renewal survey

2.1.1 The Owner or his representative is to declare to the attending Surveyor that the hull monitoring equipment has been recently calibrated using a reference loading case.

3 MON-SHAFT

3.1 Tailshaft survey

3.1.1 When the records of the tailshaft bearing temperature readings are checked and doubts arise, the Surveyor may require the verification of the accuracy of the gauging devices.

Section 8 Refrigerating Installations

1 General

1.1

1.1.1 The requirements of this Section apply to ships which have been assigned the following additional class notation related to refrigerating installations, as described in Ch 1, Sec 2, [6.9]:

REF-STORE

2 Annual survey

2.1 General

2.1.1 The annual survey of refrigerating installations (plants and spaces) is to be carried out with the installation in running condition and, whenever possible, during unloading operations or without supplies in refrigerated spaces.

2.1.2 The refrigeration installation log-book (or other similar record) is to be made available to the Surveyor for examination of the records since the last survey, and checking any unusual consumption of refrigerant, breakdown or defective items.

2.1.3 Decks, bulkheads or ship sides adjacent to refrigerated spaces are to be checked as far as practicable in order to verify the absence of cold spots.

2.1.4 The Owner or his representative is to declare to the attending Surveyor that no significant modifications have been made to the installations that could affect the class notations without the prior approval by the Society.

2.2 Refrigerating plant

2.2.1 Refrigerating machines and related accessories, including compressors, condensers, pumps and piping are to be examined externally and in running condition. Insulation of insulated parts is to be checked for possible signs of humidity or wear. The tightness of the system is to be ascertained.

2.2.2 The electrical installation is to be generally examined, and the insulation resistance of the installation is to be checked as deemed necessary by the Surveyor.

2.2.3 If independent from the electrical installation of the ship, the generators supplying electrical power to the refrigerating installation are to be examined to the same extent as described in Ch 3, Sec 1, [3.3].

2.3 Refrigerated spaces

2.3.1 Refrigerated spaces are to be generally examined to ascertain the condition of:

- insulation lining; removable panels or covers may be dismantled for examination of insulation, as deemed necessary by the Surveyor
- hatch covers, doors, access panels (including gaskets and securing devices) and dampers of ventilation ducts
- air coils, coolers, fans, air ducts, coolant piping systems and associated equipment; cleanliness of grids
- bilge wells
- protection of fans and other rotating machinery, battens for air circulation within the space.

2.4 Instrumentation and safety devices

2.4.1 Thermometers used for measurement of temperature in refrigerated spaces, air ducts and other elements of the installation are to be examined and checked for their accuracy. The Surveyor may require the calibration of one or more thermometers and one or more automation devices to be checked in his presence or, failing this, a certificate of calibration is to be presented to him.

2.4.2 The following alarm and safety devices are also to be checked, as required or fitted:

- alarm and emergency shutdown devices
- CO_2 detectors, if any
- refrigerant leakage detectors
- access to spaces, with regard to possibilities of escape and prevention of personnel being trapped within spaces.

3 Class renewal survey

3.1 General

3.1.1 The installation is to be surveyed out of operation in order to enable examinations in opened condition of certain items.

3.1.2 After completion of these examinations, the installation is to be checked while cooling down from the ambient temperature to the lowest design temperature for the refrigerated spaces. The plant is to be examined for ability to maintain stable air temperatures and defrosting operation is to be checked.

3.2 Refrigerating plant

3.2.1 The equipment is to be dismantled to a sufficient extent to enable the following examinations:

- reciprocating compressors: examination of cylinders, valves, crankshaft, connecting rods, pistons, bearings and safety devices
- screw compressors, turbo compressors and pumps: parts subject to wear and tear; the equipment may not need to be opened up if log-book records and a running test show proper functioning.

3.2.2 Prime movers of pumps, compressors and fans are to be examined to the same extent as required in Ch 3, Sec 3, [4] for similar equipment for the class renewal survey of machinery.

3.2.3 Condensers and coolers are to be opened up for examination of tube plates, tubes and end covers.

Condensers are to be pressure tested to 1,2 times the rated working pressure.

3.2.4 Insulation of insulated parts (such as piping and pressure vessels) may need to be removed at random, to ascertain the condition of such parts and of the insulation itself.

3.2.5 The electrical installation of the plant is to be examined and insulation tests checked.

3.2.6 If independent from the electrical installation of the ship, the generators supplying electrical power to the refrigerating installation are to be examined to the same extent as described in Ch 3, Sec 3, [4.6].

3.2.7 Sea connections to condenser circulating pumps are to be opened up and piping examined.

3.2.8 Other equipment, such as oil separators on refrigerant systems, filters and dehydrators, are to be examined to the satisfaction of the Surveyor.

3.3 Refrigerated spaces

3.3.1 The lining and insulation in the refrigerated spaces may need to be partly removed for examination of its condition. The condition of the hull part under the insulation is then ascertained, as well as that of girders, meat rails, hooks and coil/cooler supports.

3.3.2 Air coolers and coils are to be examined and pressure tested at the rated working pressure and at 1,2 times such pressure in the case of hydraulic test after repairs.

3.3.3 Air cooler fans are to be examined and their prime movers are to be checked to the same extent as stated in [3.2.2].

3.3.4 The electrical installation in the refrigerated spaces is to be examined and insulation tests checked.

3.3.5 Defrosting and heating systems are to be examined to the satisfaction of the Surveyor.

3.4 Instrumentation and safety devices

3.4.1 Pressure relief valves and safety disks are to be checked. Discharge piping is to be examined with regard to integrity and non-obstructed flow.

Section 9 Environmental Protection

1 General

1.1 Application

1.1.1 The requirements of this Section apply to ships which have been assigned one of the following additional class notations related to pollution prevention systems, as described in Ch 1, Sec 2, [6.10]:

- **CLEANSHIP**
- **CLEANSHIP SUPER**
- **AWT**
- **BWE**
- **BWT**
- **GWT**
- **NDO-x days**
- **NOX-x%**
- **OWS-x ppm**
- **SOX-x%**

2 Prevention of sea pollution

2.1 First annual survey

2.1.1 Confirmation of no discharge period

During the first annual survey, the Surveyor collects the results of tests and measurements undertaken by the Shipowner according to Pt E, Ch 7, Sec 3. These results are used to confirm or modify the no discharge numeral appended to the notations **NDO-x days**.

2.1.2 Audit

An on-board audit of the procedures, as required in Part E, Chapter 7, is done by the Surveyor in order to ascertain that the Master and crew are familiar with the ship's on-board procedures for preventing pollution and in order to check that the discharge records mentioned in Part E, Chapter 7 are properly completed.

2.2 Annual survey

2.2.1 General

The survey is to include, as far as practicable:

- confirmation of the installation being in accordance with the plans. If modifications have been made, checking that these modifications are in accordance with approved documentation (for all additional class notations related to pollution prevention systems)
- confirmation that the IOPP certificate is valid (for **CLEANSHIP**, **CLEANSHIP SUPER** and **OWS-x ppm**)
- general examination of the most important components of the sewage treatment plant, the garbage treatment plant, the oil filtering equipment, the incinerators if fitted, the comminuters and grinders, the hazardous wastes recovery unit if fitted (for **CLEANSHIP** and **CLEANSHIP SUPER**)
- general examination of the holding tanks, including examination of a possible corrosion protection of the inside surfaces of the tanks which are to be in good condition (for **CLEANSHIP** and **CLEANSHIP SUPER**)
- verification of the satisfactory condition of the standard discharge connections for oil and wastewater (for **CLEANSHIP**, **CLEANSHIP SUPER**, **AWT** and **NDO-x days**)
- external examination and operating tests of the equipment and systems as required in Pt E, Ch 7, Sec 2 and Pt E, Ch 7, Sec 3 (for all additional class notations related to pollution prevention systems).
- confirmation that the hazardous wastes are properly stowed as specified in the garbage management plan (for **CLEANSHIP**, **CLEANSHIP SUPER** and **NDO-x days**).

For some pollution prevention system of [1.1.1], the survey is also to include, as far as practicable:

- ascertainment of the correct concentration of the disinfectant in the effluent (for **CLEANSHIP**, **CLEANSHIP SUPER**, **AWT** and **GWT**)
- ascertainment of possible concentration of other chemicals in the effluent (for **CLEANSHIP**, **CLEANSHIP SUPER**, **AWT** and **GWT**).

2.2.2 Review of records

The following records for the preceding 12 months are to be reviewed as necessary:

- oil record book (for **CLEANSHIP**, **CLEANSHIP SUPER** and **OWS-x ppm**)
- garbage record book (for **CLEANSHIP**, **CLEANSHIP SUPER** and **OWS-x ppm**)
- records of ballast exchanges after international voyages (for **BWE** and **BWT**)
- ballast water record book (for **BWE** and **BWT**)
- sewage and grey water discharge book (for **CLEANSHIP**, **CLEANSHIP SUPER**, **GWT** and **AWT**)
- emissions record (for **CLEANSHIP SUPER**, **NOX-x%** and **SOX-x%**)
- results of the tests on effluents done by the Shipowner according to Pt E, Ch 7, Sec 4, [2.3.1] for any pollution prevention system of Pt E, Ch 7, Sec 4, [1.1.1] (for **AWT**).

2.3 Class renewal survey

2.3.1 The requirements given in [2.2] for annual surveys are to be complied with. In addition, for all additional class notations related to pollution prevention systems, the following is to be carried out:

- demonstration, under working conditions, of the correct functions of the most important components of the sewage treatment plant or AWT plant if fitted, the garbage treatment plant, the oil filtering equipment, the incinerators if fitted, the comminuters and grinders, the hazardous waste recovery unit if fitted
- ascertainment of the correct function of the alarms.

3 Prevention of air pollution

3.1 Annual survey

3.1.1 Ozone depleting substances (CLEANSHIP, CLEANSHIP SUPER)

a) A procedure for annual verification of the system and equipment condition by an authorised organisation is to be settled. The interval of this verification may be extended in case of predictive maintenance scheme approved by the Society.

b) A procedure for weekly verification and maintenance is to be settled enabling to:

- check the tightness of the circuits by satisfactory means (such as weighing or vessel pressure monitoring)
- identify the location of possible leakage
- carry out necessary corrective actions.

Record books tracing all the operations carried out on board the ship according to the procedures mentioned in the NOx Technical Code are to be kept on-board and updated after each intervention. They are to include in particular the following records:

- presence of leak and corrective action
- volume of substance recovered and indication of the storage location
- volume of substance recharged
- volume of substance consumed
- volume of substance disposed.

The survey is to include the following items:

- verification that the above procedures for annual and weekly checking of systems with ozone depleting substances are available on-board
- confirmation that appropriate entries are being made in the record book for ozone depleting substances
- test of the proper operation of the leak detectors and related audible and visual alarms.

c) Review of ozone - depleting substance record book.

3.1.2 NOx emission (CLEANSHIP SUPER, NOX-x%)

- The procedures for demonstrating compliance with NOx emission limits on board are given in the NOx Technical Code.
- During the annual survey, it is to be confirmed that the NOx emission control procedure is available on-board.
- NOx emission records.

3.1.3 SOx emission (CLEANSHIP, CLEANSHIP SUPER, SOX-x%)

Procedures are to be established to detail the maximum sulphur content in the fuel oil purchase orders, and to check the actual content of sulphur at the delivery of bunker.

In the case the actual sulphur content is checked by sampling testing and analysis, procedures are to be carried out in accordance with a recognised standard acceptable to the Society.

The fuel management procedures are to be established and followed as part of the certified ship management system of the ship.

Records on purchase orders and on type of checking carried out, including results, are to be kept on-board.

The survey is to include the following items:

- verification that the above procedures for defining, ordering and checking fuel oils for control of SOx emission are available on-board
- confirmation that fuel oil sulphur content records are available on-board
- emission record (when exhaust gas cleaning is provided (EGC)).

3.1.4 Shipboard incineration (CLEANSHIP, CLEANSHIP SUPER)

The annual survey is to include the following items, when fitted:

- external examination of the incinerators and confirmation that such equipment operates satisfactorily
- test of the alarms, exhaust monitoring devices and emergency stop located outside the compartment.

3.2 Class renewal survey

3.2.1 The requirements given in [3.1] for annual surveys are to be complied with. In addition, the following is to be carried out:

- confirmation of the operation and calibration of the emissions analysers if fitted (for **CLEANSHIP SUPER**, **NOX-x%** and **SOX-x%**)
- external examination and operating tests of the equipment and systems, as required in Pt E, Ch 7, Sec 2 and Pt E, Ch 7, Sec 3 (for all additional class notations related to pollution prevention systems).

Section 10 CBRN Protection

1 General

1.1 Application

1.1.1 The requirements of this Article apply to ships which have been assigned the **CBRN** or **CBRN-AIR BLAST RESISTANCE** additional class notation as described in Ch 1, Sec 2, [6.11].

1.2 Significant modifications

1.2.1 At each survey, the Owner or his representative is to declare to the attending Surveyor that no significant modifications have been made to the installations that could affect the class notations without prior approval by the Society.

2 Annual survey

2.1 General

2.1.1 The CBRN operation manual is to be made available to the Surveyor and may be used as a basis for survey.

An examination of the log-books is to be carried out to verify the proper operation of the systems in the period subsequent to the last survey and measures taken to avoid repetition of any malfunctions and failures which have occurred during the same period.

2.1.2 The annual survey is to include:

- examination and testing, as feasible, of airlocks, cleansing station(s) and CBRN protection plant(s)
- examination of CBRN detection system, including checking of number and location of each detector
- verification that each opening in the citadel and shelter boundaries is provided with a closing appliance in working order and suitably marked
- verification of remote indication, alarm and control functions at the damage control station
- verification of ventilation non-return devices and dampers
- verification of water traps or equivalent devices against air entrance
- examination of CBRN ventilation system, including ducts, filters and dampers
- examination of pre-wetting and washdown system, including piping, valves and nozzles.

2.2 Air blast resistance

2.2.1 In addition, for ships assigned the additional class notation **CBRN-AIR BLAST RESISTANCE**, the annual survey is to include:

- examination of the air blast protective device
- checking that the remotely controlled means of closing ventilation openings are in working order.

3 Class renewal survey

3.1 General

3.1.1 The CBRN operation manual is to be made available to the Surveyor and may be used as a basis for survey.

An examination of the log-books is to be carried out to verify the proper operation of the systems in the period subsequent to the last survey and measures taken to avoid repetition of any malfunctions and failures which have occurred during the same period.

3.1.2 The class renewal survey is to include:

- Check of overpressure levels in the citadel with the collective protection ventilation system working. The required overpressure is to be held for at least 30 min. The test may be carried out with dummy filters in lieu of CBRN filters.

- Verification of gastightness of engine enclosure and associated supply and exhaust ducts, for engines with dedicated air supply.
- Verification of air conditioning capability under CBRN condition.
- Functioning test of the CBRN detection system. Each line is to be tested from the level of the detector, with means defined by the system supplier.
- Functioning test of the pre-wetting and washdown system, including verification that all external surfaces are properly covered, verification of water drainage and verification of section valve remote operation.
- Checking that the environmental conditions related to temperature remain inside the limits as defined in Pt C, Ch 1, Sec 1 with the propulsion machinery at maximum power setting during CBRN operations.

- Verification of gastightness of engine enclosure and associated supply and exhaust ducts, for engines with dedicated air supply.
- Verification of air conditioning capability under CBRN condition.
- Functioning test of the CBRN detection system. Each line is to be tested from the level of the detector, with means defined by the system supplier.
- Functioning test of the pre-wetting and washdown system, including verification that all external surfaces are properly covered, verification of water drainage and verification of section valve remote operation.
- Checking that the environmental conditions related to temperature remain inside the limits as defined in Pt C, Ch 1, Sec 1 with the propulsion machinery at maximum power setting during CBRN operations.

Section 11 Manoeuvrability

1 General

1.1 Application

1.1.1 The requirements of this Section apply to self-propelled ships granted with one or more of the following additional class notations:

MANOVR

1.1.2 These requirements apply in addition to the requirements given in Part A, Chapter 3 and Part A, Chapter 4 versus the type of surveys.

2 MANOVR

2.1 Annual survey

2.1.1 At each annual survey the Owner or his representative is to declare to the attending Surveyor that no repairs, alterations or modifications have been made, which may influence the vessel's manoeuvrability characteristics.

In the event of repairs, alterations or modifications, which, in the opinion of the Society, may influence the vessel's manoeuvrability characteristics, the continued compliance with the criteria as described in Pt E, Ch 9, Sec 1 is to be verified to the satisfaction of the Society.

2.2 Class renewal survey

2.2.1 The requirements given in Sub-article [2.1] for annual survey are to be complied with.

Section 12 Towing

1 General

1.1 Application

1.1.1 The requirements of this Section apply to self-propelled ships granted with one or more of the following additional class notations:

TOW

1.1.2 These requirements apply in addition to the requirements given in Part A, Chapter 3 and Part A, Chapter 4 versus the type of surveys.

2 TOW

2.1 Annual survey

2.1.1 The additional items and equipment to be surveyed together with the scope of the survey shall be defined, on a case by case basis, by an agreement between the Surveyor and the Owner representative.

2.1.2 The type and number of additional tests to be performed shall be defined, on a case by case basis, by an agreement between the Surveyor and the Owner representative.

2.1.3 The survey shall include:.

- an examination of the emergency towing installation
- the confirmation that the installation is instantaneously available including a pre-rigged aft towing arrangements and a forward chafing gear secured to the strong-point
- an examination of the pick-up gear, towing pennant and chafing gear over the full length for detection of possible deterioration. Where the pennant line is stored in a watertight condition and can be confirmed as being maintained, consideration may be given to waiving the requirement to examine the pennant line over the full length
- an examination of the strong-points, fairleads and pedestal roller together with their attachments to the hull structure.

2.2 Class renewal survey

2.2.1 The additional items and equipment to be surveyed together with the scope of the survey shall be defined, on a case by case basis, by an agreement between the Surveyor and the Owner representative.

2.2.2 The type and number of additional tests to be performed shall be defined, on a case by case basis, by an agreement between the Surveyor and the Owner representative.

Section 13 Helideck

1 General

1.1 Application

1.1.1 The requirements of this Section apply to self-propelled ships granted with one or more of the following additional class notations:

HELICOPTER

1.1.2 These requirements apply in addition to the requirements given in Part A, Chapter 3 and Part A, Chapter 4 versus the type of surveys.

2 HELICOPTER

2.1 Annual survey

2.1.1 The additional items and equipment to be surveyed together with the scope of the survey shall be defined, on a case by case basis, by an agreement between the Surveyor and the Owner representative.

2.1.2 The type and number of additional tests to be performed shall be defined, on a case by case basis, by an agreement between the Surveyor and the Owner representative.

2.2 Class renewal survey

2.2.1 The additional items and equipment to be surveyed together with the scope of the survey shall be defined, on a case by case basis, by an agreement between the Surveyor and the Owner representative.

2.2.2 The type and number of additional tests to be performed shall be defined, on a case by case basis, by an agreement between the Surveyor and the Owner representative.

Appendix 1 Inertial Pressure for Typical Tank Arrangement
1 Inertial ballast pressure 171
1.1 Introduction
1.2 Formulae for the inertial pressure calculation

Chapter 6 Hull Girder Strength

Section 1 Strength Characteristics of the Hull Girder Transverse Sections
1 Application 175
1.1 General
2 Calculation of the strength characteristics of hull girder transverse sections 175
2.1 Hull girder transverse sections
2.2 Strength deck
2.3 Section modulus
2.4 Moments of inertia
2.5 First moment
2.6 Structural models for the calculation of normal warping stresses and shear stresses

Section 2 Yielding Checks
1 Application 179
1.1 General
2 Hull girder stresses 179
2.1 Normal stresses induced by vertical bending moments
2.2 Normal stresses induced by vertical and horizontal bending moments
2.3 Shear stresses
2.4 Simplified calculation of shear stresses induced by vertical shear forces
3 Checking criteria 181
3.1 General
3.2 Normal stresses induced by vertical bending moments
3.3 Shear stresses

4 Section modulus and moment of inertia 182

4.1 General
4.2 Section modulus within 0,4L amidships
4.3 Section modulus outside 0,4L amidships
4.4 Midship section moment of inertia
4.5 Extent of higher strength steel

5 Permissible still water bending moment and shear force during navigation 184

5.1 Permissible still water bending moment
5.2 Permissible still water shear force

6 Permissible still water bending moment and shear force in harbour conditions 184

6.1 Permissible still water bending moment
6.2 Permissible shear force

Section 3 Ultimate Strength Check

1 Application 185

1.1

2 General 185

2.1 Net scantlings
2.2 Partial safety factors

3 Hull girder ultimate strength check 185

3.1 Hull girder loads
3.2 Hull girder ultimate bending moment capacities
3.3 Checking criteria

Appendix 1 Hull Girder Ultimate Strength

1 Hull girder ultimate strength check 187

1.1 Introduction
1.2 Criteria for the calculation of the curve M-χ
1.3 Load-end shortening curves σ-ε

Chapter 7 Hull Scantlings

Section 1 Plating

1 General 196

1.1 Net thicknesses
1.2 Partial safety factors
1.3 Elementary plate panel
1.4 Load point

2 General requirements 197

2.1 General
2.2 Minimum net thicknesses
2.3 Bilge plating
2.4 Sheerstrake
2.5 Stringer plate

3 Strength check of plating subjected to lateral pressure 198

3.1 General
3.2 Load model
3.3 Longitudinally framed plating contributing to the hull girder longitudinal strength
3.4 Transversely framed plating contributing to the hull girder longitudinal strength
3.5 Plating not contributing to the hull girder longitudinal strength

4 Strength check of plating subjected to wheeled loads 202

4.1 General
4.2 Load model
4.3 Plating

5 Buckling check 203

5.1 General
5.2 Load model
5.3 Critical stresses
5.4 Checking criteria

Section 2 Ordinary Stiffeners

1 General 211

1.1 Net scantlings
1.2 Partial safety factors
1.3 Load point
1.4 Net dimensions of ordinary stiffeners

2 General requirements 212

2.1 General
2.2 Struts of open floors

3 Yielding check 213

3.1 General
3.2 Structural model
3.3 Load model
3.4 Normal and shear stresses due to lateral pressure in intact conditions
3.5 Normal and shear stresses due to wheeled loads
3.6 Checking criteria
3.7 Net section modulus and net shear sectional area of ordinary stiffeners, complying with the checking criteria
3.8 Net section modulus and net shear sectional area of ordinary stiffeners subjected to lateral pressure in flooding conditions
3.9 Net section modulus and net shear sectional area of ordinary stiffeners subjected to lateral pressure in testing conditions

4 Buckling check 221

4.1 Width of attached plating
4.2 Load model
4.3 Critical stress
4.4 Checking criteria

5 Ultimate strength check of ordinary stiffeners contributing to the hull girder longitudinal strength 225

5.1 Application
5.2 Width of attached plating
5.3 Load model
5.4 Ultimate strength stress
5.5 Checking criteria

Section 3 Primary Supporting Members

1 General 228

1.1 Application
1.2 Net scantlings
1.3 Partial safety factors

2 Yielding check of primary supporting members analysed through an isolated beam structural model 230

2.1 General
2.2 Bracket arrangement
2.3 Load point
2.4 Load model
2.5 Normal and shear stresses due to lateral pressure in intact conditions
2.6 Checking criteria
2.7 Net section modulus and net sectional shear area complying with the checking criteria
2.8 Net section modulus and net shear sectional area of primary supporting members subjected to lateral pressure in flooding conditions

3 Yielding check of primary supporting members analysed through a three-dimensional structural model 236

3.1 General
3.2 Analysis criteria
3.3 Checking criteria

4 Yielding check of primary supporting members analysed through a complete ship structural model 237

4.1 General
4.2 Analysis criteria
4.3 Checking criteria

5 Buckling check 237

5.1 Local buckling of plate panels
5.2 Buckling of pillars subjected to compression axial load
5.3 Buckling of pillars subjected to compression axial load and bending moments

6 Dynamic analysis of main weapon mount supporting structure 241

6.1 Application
6.2 Dynamic analysis

Section 4 Fatigue Check of Structural Details

1 General 243

1.1 Net scantlings
1.2 Application
1.3 Definitions
1.4 Partial safety factors

2 Load model 244

2.1 General
2.2 Local lateral pressures
2.3 Nominal hull girder normal stresses

3 Fatigue damage ratio 247

3.1 General

4 Stress range 250

4.1 General
4.2 Hot spot stress range
4.3 Notch stress range

5 Checking criterion 252

5.1 Damage ratio

6 Structural details located at ends of ordinary stiffeners 252

6.1 General
6.2 Determination of elementary hot spot stress range

Table of Content

Appendix 1 Analyses Based on Three-Dimensional Models

1 General 254

1.1 Application
1.2 Information required

2 Analysis criteria 255

2.1 General
2.2 Finite element model analysis
2.3 Beam model analysis
2.4 Structural detail analysis

3 Structural modelling of primary supporting members 256

3.1 Model construction
3.2 Model extension
3.3 Finite element modelling criteria
3.4 Finite element models
3.5 Beam models
3.6 Boundary conditions of the whole three-dimensional model

4 Load models of primary supporting members 260

4.1 General
4.2 Local loads
4.3 Hull girder loads

5 Stress calculation 262

5.1 Analysis based on finite element models
5.2 Analysis based on beam models

6 Fatigue analysis 263

6.1 Elementary hot spot stress range calculation
6.2 Hot spot stresses directly obtained through finite element analysis
6.3 Hot spot stresses directly obtained through calculation of nominal stresses

Appendix 2 Analyses of Primary Supporting Members Subjected to Wheeled Loads

1 General 266

1.1 Scope
1.2 Application
1.3 Information required
1.4 Lashing of vehicles

2 Analysis criteria 267

2.1 Finite element model analysis
2.2 Beam model analysis

3 Structural modelling of primary supporting members 267

3.1 Model construction
3.2 Model extension
3.3 Boundary conditions of the three-dimensional model

4 Load model 268

4.1 General
4.2 Local loads
4.3 Hull girder loads

5 Stress calculation 269

5.1 Stresses induced by local and hull girder loads
5.2 Analysis based on finite element models
5.3 Analysis based on beam models

6 Grillage analysis of deck primary supporting members 270
6.1 Application
6.2 Analysis criteria
6.3 Boundary conditions
6.4 Load model
6.5 Stress calculation

Appendix 3 Analyses Based on Complete Ship Models

1 General 272
1.1 Application

2 Structural modelling 272
2.1 Model construction
2.2 Model extension
2.3 Finite element modelling criteria
2.4 Finite element models
2.5 Boundary conditions of the model

3 Load model 274
3.1 General
3.2 Procedure for the selection of design waves
3.3 Load cases

4 Stress calculation 278
4.1 Stress components

Chapter 8 Other Structures

Section 1 Fore Part

1 General 280
1.1 Application
1.2 Connections of the fore part with structures located aft of the collision bulkhead
1.3 Net scantlings

2 Fore peak 281
2.1 Partial safety factors
2.2 Load point
2.3 Load model
2.4 Longitudinally framed bottom
2.5 Transversely framed bottom
2.6 Longitudinally framed side
2.7 Transversely framed side
2.8 Decks
2.9 Platforms
2.10 Central longitudinal bulkhead
2.11 Bulbous bow

3 Reinforcements of the flat bottom forward area 288
3.1 Area to be reinforced
3.2 Bottom impact pressure
3.3 Partial safety factors
3.4 Scantlings
3.5 Arrangement of primary supporting members and ordinary stiffeners: longitudinally framed bottom
3.6 Arrangement of primary supporting members and ordinary stiffeners: transversely framed double bottom

Table of Content

4 Reinforcements of the bow flare area 290

4.1 Area to be reinforced
4.2 Bow impact pressure
4.3 Partial safety factors
4.4 Scantlings

5 Stems 291

5.1 General
5.2 Plate stems
5.3 Bar stems

6 Transverse thrusters 292

6.1 Scantlings of the thruster tunnel and connection with the hull

Section 2 Aft Part

1 General 293

1.1 Application
1.2 Connections of the aft part with structures located fore of the after peak bulkhead
1.3 Net scantlings

2 Aft peak 294

2.1 Partial safety factors
2.2 Load point
2.3 Load model

3 After peak 295

3.1 Arrangement
3.2 Scantlings

4 Reinforcements of the flat area of the bottom aft 297

4.1 General

5 Connection of hull structures with the rudder horn 297

5.1 Connection of after peak structures with the rudder horn
5.2 Structural arrangement above the after peak

6 Sternframes 298

6.1 General
6.2 Connections
6.3 Propeller posts
6.4 Integral rudder posts
6.5 Propeller shaft bossing
6.6 Rudder gudgeon
6.7 Sterntubes

Section 3 Machinery Space

1 General 301

1.1 Application
1.2 Scantlings
1.3 Connections of the machinery space with structures located aft and forward

2 Double bottom 301

2.1 Arrangement
2.2 Minimum thicknesses

3 Single bottom 303

3.1 Arrangement
3.2 Minimum thicknesses

4 Side 304

4.1 Arrangement

5 Platforms 304

5.1 Arrangement
5.2 Minimum thicknesses

6 Pillaring 304

6.1 Arrangement

7 Machinery casing 305

7.1 Arrangement
7.2 Openings
7.3 Scantlings

8 Main machinery seatings 305

8.1 Arrangement
8.2 Minimum scantlings

Section 4 Superstructures and Deckhouses

1 General 307

1.1 Application
1.2 Net scantlings
1.3 Definitions
1.4 Connections of superstructures and deckhouses with the hull structure
1.5 Structural arrangement of superstructures and deckhouses

2 Design loads 308

2.1 Sides contributing to the longitudinal strength
2.2 Front, side and aft bulkheads not contributing to the longitudinal strength
2.3 Decks

3 Plating 310

3.1 Front, side and aft bulkheads
3.2 Decks

4 Ordinary stiffeners 311

4.1 Front, side and aft bulkheads
4.2 Decks

5 Primary supporting members 312

5.1 Front, side and aft bulkheads
5.2 Decks

Section 5 Bow Doors and Inner Doors

1 General 313

1.1 Application
1.2 Gross scantlings
1.3 Arrangement
1.4 Definitions

2 Design loads 314

2.1 Bow doors
2.2 Inner doors

3 Scantlings of bow doors 316

3.1 General
3.2 Plating and ordinary stiffeners
3.3 Primary supporting members

4 Scantlings of inner doors 316

4.1 General

5 Securing and supporting of bow doors 317

5.1 General
5.2 Scantlings

1.1 General

Part B
Hull and Stability

CHAPTER 1
GENERAL

Section 1 Application

Section 2 Symbols and Definitions

Section 3 Documentation to be Submitted

Section 1 Application

1 General

1.1 Structural requirements

1.1.1 Part B of the Rules contains the requirements for determination of the minimum hull scantlings, applicable to all types of seagoing single hull displacement ships of normal form, speed and proportions, made in welded steel construction, with a length not less than 65m. These requirements are to be integrated with those specified in Part E, as applicable, depending on the additional class notations assigned to the ships.

1.1.2 The requirements of Part B and Part E apply also to those steel ships in which parts of the hull, e.g. superstructures or movable decks, are built in aluminium alloys.

1.1.3 Ships whose hull materials are different than those given in [1.1.2] and ships with novel features or unusual hull design are to be individually considered by the Society, on the basis of the principles and criteria adopted in the Rules.

1.1.4 The strength of ships constructed and maintained according to the Rules is sufficient for the draught corresponding to the loading conditions as defined in Ch 5, Sec 1, [2.4.3]. The scantling draught considered when applying the Rules is to be not less than that corresponding to the assigned intact ship deepest full load waterline.

1.1.5 Where scantlings are obtained from direct calculation procedures which are different from those specified in Part B, Chapter 7, adequate supporting documentation is to be submitted to the Society, as detailed in Ch 1, Sec 3.

1.2 Limits of application to lifting appliances and weapons

1.2.1 The fixed parts of lifting appliances, considered as an integral part of the hull, are the structures permanently connected by welding to the ship's hull (for instance crane pedestals, masts, king posts, derrick heel seatings, etc., excluding cranes, derrick booms, ropes, rigging accessories, and, generally, any dismountable parts). The shrouds of masts embedded in the ship's structure are considered as fixed parts.

1.2.2 The fixed parts of lifting appliances and weapons and their connections to the ship's structure are covered by the Rules.

1.2.3 As far as the weapons are concerned, the load effects of blast and recoil on the structures are covered by the Rules. The safety aspects regarding personnel and other systems are not covered by the Rules.

2 Rule application

2.1 Ship parts

2.1.1 General

For the purpose of application of the Rules, the ship is considered as divided into the following three parts:

- the fore part
- the central part
- the aft part.

2.1.2 Fore part

The fore part includes the structures located forward of the collision bulkhead, i.e.:

- the fore peak structures
- the stems.

In addition, it includes:

- the reinforcements of the flat bottom forward area
- the reinforcements of the bow flare area.

2.1.3 Central part

The central part includes the structures located between the collision bulkhead and the after peak bulkhead.

Where the flat bottom forward area or the bow flare area extend aft of the collision bulkhead, they are considered as belonging to the fore part.

2.1.4 Aft part

The aft part includes the structures located aft of the after peak bulkhead.

2.2 Rules applicable to various ship parts

2.2.1 The various Chapters and Sections of Part B are to be applied for the general arrangement and scantling of ship parts according to Tab 1.

Table 1 : Rule requirements of Part B applicable for the general arrangement and scantling of ship parts

Parts	Applicable Chapters and Sections	
	General	Specific
Fore part	Part B, Chapter 1 Part B, Chapter 2 Part B, Chapter 3 Part B, Chapter 4 Part B, Chapter 8 **(1)**, excluding: • Ch 8, Sec 1 • Ch 8, Sec 2 Part B, Chapter 10 Part B, Chapter 11	Ch 8, Sec 1
Central part		Part B, Chapter 5 Part B, Chapter 6 Part B, Chapter 7
Aft part		Ch 8, Sec 2
(1) See also [2.3].		

2.3 Rules applicable to other ship items

2.3.1 The various Chapters and Sections of Part B are to be applied for the general arrangement and scantling of other ship items according to Tab 2.

Table 2 : Rule requirements of Part B applicable for the general arrangement and scantling of other items

Items	Applicable Chapters and Sections
Machinery space	Ch 8, Sec 3
Superstructures and deckhouses	Ch 8, Sec 4
Bow doors and inner doors	Ch 8, Sec 5
Slide shell doors and stern doors	Ch 8, Sec 6
Hatch covers	Ch 8, Sec 7
Movable decks and inner ramps External ramps	Ch 8, Sec 8
Rudders	Ch 9, Sec 1
Hull outfitting and masts	Ch 9, Sec 2 Ch 9, Sec 3 Ch 9, Sec 4 Ch 9, Sec 5

3 Rounding off of scantlings

3.1

3.1.1 Plate thicknesses

The rounding off of plate thicknesses is to be obtained from the following procedure:

a) the net thickness (see Ch 4, Sec 2) is calculated in accordance with the rule requirements

b) corrosion addition t_C (see Ch 4, Sec 2) is added to the calculated net thickness, and this gross thickness is rounded off to the nearest half-millimetre

c) the rounded net thickness is taken equal to the rounded gross thickness, obtained in item b), minus the corrosion addition t_C.

3.1.2 Stiffener section moduli

Stiffener section moduli as calculated in accordance with the rule requirements are to be rounded off to the nearest standard value; however, no reduction may exceed 3%.

Section 2 Symbols and Definitions

1 Units

1.1

1.1.1 Unless otherwise specified, the units used in the Rules are those defined in Tab 1.

Table 1 : Units

Designation	Usual symbols	Units
Ship dimensions	See Article [2]	m
Hull girder section modulus	Z	m^3
Density	ρ	t/m^3

Sectional area of ordinary stiffeners and primary supporting members	A	cm^2

2 Definitions

2.1 Symbols

2.1.1

L : Rule length, in m, defined in [4.1]

L_1 : L, but to be taken not greater than 200 m

L_2 : L, but to be taken not greater than 120 m

B : Moulded breadth, in m, defined in [4.4]

B_{WS} : Breadth at full load waterline, in m, defined in [4.4]

D : Depth, in m, defined in [4.5]

T : Moulded draught, in m, defined in [4.6]

Δ : Moulded displacement, in tonnes, at draught, in sea water (density ρ = 1,025 t/m^3)

C_B : Total block coefficient:

$$C_B = \frac{\Delta}{1,025 L B_{WS} T}$$

3 Waterlines

3.1 Subdivision lines

3.1.1 Subdivision load line

Subdivision load line is a waterline used in determining the subdivision of the ship.

3.1.2 Deepest subdivision load line

Deepest subdivision load line is the waterline which corresponds to the greatest draught permitted by the subdivision requirements which are applicable.

3.2 Specific lines

3.2.1 Margin line

Margin line is an imaginary line drawn at side of the hull above which the presence of water is not allowable when the ship, after damage, is in condition of static equilibrium.

Such line divides the hull into two parts:

- the part below the margin line

  Such part when damaged may be floodable according to Ch 3, Sec 3.
- the part above the margin line

  Such part cannot be flooded according to Ch 3, Sec 3 because the buoyancy and stability requirements might result highly compromised (for example for progressive flooding).

Generally the margin line is positioned 76 mm (3") below the Watertight Deck (W.D.).

If, for the purpose of complying the damage stability requirements, some of the Main Transversal Watertight Bulkheads (M.T.W.B.) are extended to a higher deck, here called Bulkhead Deck (B.D.), by means of Auxiliary Transversal Watertight Bulkheads (A.T.W.B.), the margin line may be referred:

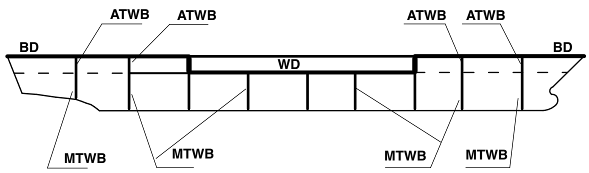
a) to the Bulkhead Deck (B.D.), where the Main Transversal Watertight Bulkheads (M.T.W.B.) are extended by Auxiliary Transversal Watertight Bulkheads (A.T.W.B.)

b) to the Watertight Deck (W.D.), in the other parts.

This represents really the upper limit of the floodable volumes supplied with watertight closure devices which stop the flooding of the undamaged neighbour volumes.

See Fig 1.

Figure 1 : Deck to which the margin line may be referred



3.2.2 Submersible areas

Some areas of the vessel on the Watertight Deck (W.D.) as mooring and quartering areas, in any case may result immersed provided that every access or openings to the buoyant compartments are watertight, so that progressive flooding will be avoided. The bounding bulkheads have to be considered as the hull.

To the purpose of considering an area submersible, the following requirements are to be complied:

- all the openings are to be closed before sailing by means of watertight closure such to face the hydrostatic head corresponding to the maximum draught. These openings are to be of reduced size, such as access hatches
- not to compromise, when immersed, the access to area essential for surviving.

In the submersible areas, the margin line is described as follows:

- in the fore part of the longitudinal extent of the submersible area of the ship, the margin line is limited to the aft main transverse watertight bulkhead bounding this submersible area
- in the aft part of the longitudinal extent of the submersible area of the ship, the margin line is limited to the fore main transverse watertight bulkhead bounding this submersible area.

3.2.3 "V" Lines

At each ship section, "V" Lines are the envelope of the damaged ship waterlines at final flooding stage and during intermediate stages of flooding (see Ch 3, App 4).

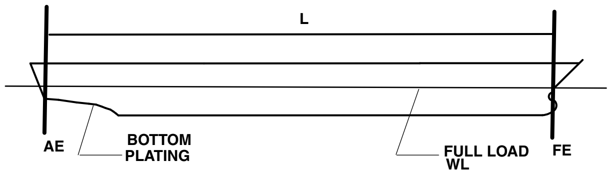
4 Dimensions

4.1 Rule length

4.1.1 The rule length L, see Fig 2, is the distance, in m, measured on the full load waterline between the aft end (AE) and the fore end (FE), as defined in [4.2].

4.1.2 In ships with unusual stem or stern arrangements, the rule length L is considered on a case-by-case basis.

Figure 2 : Rule length



4.2 Ends of rule length L and midship

4.2.1 Aft end

The aft end (AE) of the rule length L is the perpendicular to the deepest full load waterline at the lowest corner between the transom and the bottom plating.

4.2.2 Fore end

The fore end (FE) of the rule length L, is the perpendicular to the full load waterline at the forward side of the stem.

4.2.3 Midship

The midship is the perpendicular to the deepest full load waterline at the distance 0,5L aft of the fore end FE.

4.3 Length between perpendiculars

4.3.1 The length between perpendiculars L_{bp} is the length, in metres, at the waterline corresponding to the full load as defined in Tab 2.

4.4 Moulded breadths

4.4.1 The moulded breadth B is the greatest moulded breadth, in m, measured amidships below the uppermost continuous deck, excluding sponsons.

4.4.2 The breadth B_{WS} is the moulded breadth, in m, measured amidships at the full load waterline “end of life”.

4.5 Moulded depth

4.5.1 The moulded depth D is the distance, in m, measured vertically on the midship transverse section, from the moulded base line to the top of the deck at side on the uppermost continuous deck.

In the case of a ship with a solid bar keel, the moulded base line is to be taken at the intersection between the upper face of the bottom plating and the solid bar keel at the middle of length L.

4.6 Moulded draught

4.6.1 The moulded draught T is the distance, in m, measured vertically on the midship transverse section, from the moulded base line to the full load waterline “end of life”.

4.6.2 In the case of ships with a solid bar keel, the moulded base line is to be taken as defined in [4.5.1].

5 Ship weights

5.1 Lightship

5.1.1 The lightship is a ship complete in all respects, but without consumables, stores, and crew and effects, and without any liquids on board except for machinery and piping fluids, such as lubricant and hydraulic, which are at operating levels.

Considering the evolution of mass as described in Ch 3, Sec 2, [2.1.4], a lightship condition “at delivery” and a lightship condition “end of life” are to be considered for the assessment of the stability and strength effects.

5.2 Full load

5.2.1 The full load condition corresponds to the ship loaded departure as defined in Tab 2.

Considering the evolution of mass as described in Ch 3, Sec 2, [2.1.4], a full load condition “at delivery” and a full load condition “end of life” are to be considered for the assessment of the stability and strength effects.

Table 2 : Definition of loading cases (% of mass or specified maximum loads)

Components	Full load condition	Operational load condition	Minimum operational condition	Comments
Lightship	100%	100%	100%	See [5.1.1]
Crew with luggage	100%	100%	100%	
External personnel with equipment	100%	100%	100%	Personnel not belonging to the crew
Ship logistic material	100%	100%	100%	On board documents, equipment for repairs
Foods	100%	66,6%	33,3%	Otherwise specified uniformly distributed in storage spaces
Ammunition	100%	66,6%	33,3%	In storage spaces above the ship centre of gravity
Helicopters with their logistic	100%	100%	100%	At location as specified
Fuels (propulsion, auxiliaries, helicopters,...)	100%	66,6%	33,3%	Otherwise specified uniformly distributed in storage spaces The filling of the overflow fuel oil tanks is to be limited to 75% of the net volume of these tanks
		100%	100%	For capacity provided with an automatic continuous compensation system
Lubricant storage	100%	66,6%	33,3%	Otherwise specified uniformly distributed in storage spaces
Other consumable materials	100%	66,6%	33,3%	Otherwise specified uniformly distributed in storage spaces
Drinking water	100%	66,6%	66,6%	When produced on board
Drinking water	100%	66,6%	33,3%	When not produced on board
Industrial waters	100%	66,6%	66,6%	
Grey and black waters	0%	33,3%	33,3%	
Ballast waters	0%	0%	0%	For the minimum operation condition, ballast necessary to comply with the stability criteria may be accepted, subject that the total displacement including the ballast tanks does not exceed the displacement corresponding to the operational condition
Stabilizing tanks	op. level	op. level	op. level	At the operational level
Non consumables and pumping residues	100%	100%	100%	Corresponding to 2% of the net volume of the capacities; if a value lower than 2% is used, this value is to be justified
Miscellaneous	100%	100%	100%	Mobile liquid or solid ballast

5.3 Operational load

5.3.1 The operational load condition is defined in Tab 2.

Considering the evolution of mass as described in Ch 3, Sec 2, [2.1.4], an operational load condition “at delivery” and an operational load condition “end of life” are to be considered for the assessment of the stability and strength effects.

5.4 Minimum operational load

5.4.1 The minimum operational load is defined in Tab 2.

5.5 Deadweight

5.5.1 The deadweight is the difference, in t, between the displacement, at the full load draught in sea water of density ρ = 1,025 t/m^3, and the lightship.

6 Decks and bulkheads

6.1 General

6.1.1 From the point of view of subdivision and stability of surface vessels, two kinds of tightness are to be defined:

- watertight
- weathertight.

6.1.2 Watertight

The watertight elements assure the tightness even with a constant hydrostatic head.

6.1.3 Weathertight

The weathertight elements assure the tightness under the action of weather agents, hose or temporary phase during rolling periods.

6.2 Bulkhead deck (B.D.)

6.2.1 The bulkhead deck is the highest deck to which auxiliary watertight transversal bulkheads are raised. The watertight boundaries after damage are limited to the bulkhead deck.

6.3 Exposed decks - Upper decks (E.D.)

6.3.1 Above the volume limited by the bulkhead deck, weathertight volumes under exposed decks or part of them may exist.

The sum of such volumes plus those defined in [6.2] (compressive volume watertight and weathertight) constitute the intact stability reserve.

The enclosed superstructures as defined in [8.2.1] may be considered as intact stability reserve.

6.4 Watertight deck (W.D.)

6.4.1 The watertight deck is the first continuous watertight deck above the waterline, up to which the main transversal watertight bulkheads (M.T.W.B.) are to be extended.

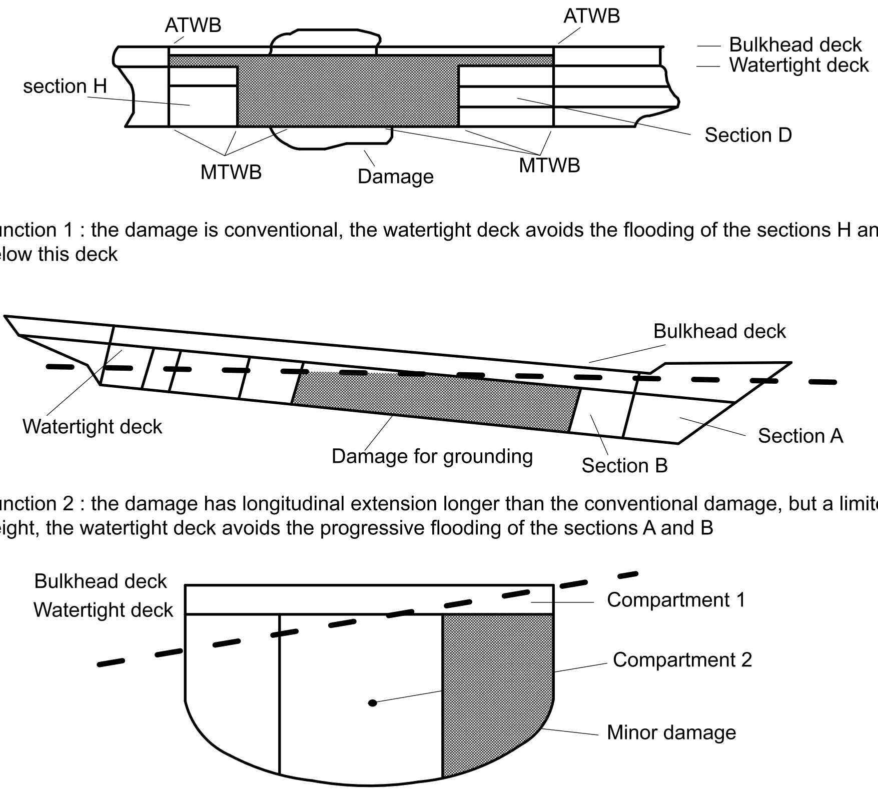
The watertight deck acts a vertical limit (see Fig 3, function 2) for flooding of the ship caused by damage to the sideshell below the waterline and thus prevents progressive flooding of undamaged compartments in a transverse direction (see Fig 3, function 3). Similarly it prevents progressive flooding in a longitudinal direction (see Fig 3, function 1) when the sideshell breach involves the entire height of the ship and when not all M.T.W.B. are extended up to the bulkhead deck.

The watertight deck is the deck below which all openings in the sideshell and all passages crossing main transversal bulkheads are forbidden or otherwise guided according to the requirements of Ch 2, Sec 1, Tab 2 “Requirements for openings and crossing in several water (weather)tight elements”.

The watertightness of elements crossing the watertight deck is to be ensured and openings in this deck are to be supplied with devices which make them watertight.

As a rule, the watertight deck generally serves as the “damage control deck”.

Figure 3 : Functions of the watertight deck (W.D.)



Function 1 : the damage is conventional, the watertight deck avoids the flooding of the sections H and D below this deck

Function 2 : the damage has longitudinal extension longer than the conventional damage, but a limited height, the watertight deck avoids the progressive flooding of the sections A and B

Function 3 : the damage is extended less than the conventional damage, the watertight deck avoids the flooding of the compartments 1 and 2, so timing the major effects of the damage

6.5 Damage control deck

6.5.1 The damage control deck is a deck above the waterline after damage that permits access along the length of the vessel, for the purpose of efficiently coordinating and conducting damage control. It is, in general, continuous and is typically the lowest deck upon which movement from forward to aft and vice versa is possible, via watertight openings in the transversal watertight bulkheads.

The damage control deck is to be positioned above point A shown in Ch 3, App 4, Fig 2, at each transverse watertight bulkhead. Where this is not possible, it is to be shown that alternate arrangements are able to permit the safe and effective conduct of damage control activities, including control of progressive flooding, to the satisfaction of the Society.

The deck structure constituting the damage control deck, along with all elements crossing this deck are to be watertight. Openings in the damage control deck are to be supplied with devices which make them watertight

6.6 Main transversal watertight bulkhead (M.T.W.B.)

6.6.1 The adequate subdivision of the internal volume by main transversal watertight bulkheads is essential to achieve an adequate buoyancy and stability in case of damage.

The main transversal watertight bulkheads extend up to the watertight deck from side to side.

Their essential task is to limit compartments and therefore to avoid the progressive flooding from a damaged to an intact compartment.

6.7 Main watertight compartment

6.7.1 A main watertight compartment is a volume bounded by two main transversal watertight bulkheads up to the watertight deck and by two auxiliary transversal watertight bulkheads between the watertight deck and the bulkhead deck and topped by the watertight deck (W.D.).

It has to be distinguished from the safety zone of fire protection.

The minimum distance between M.T.W.B., therefore the minimum length of a compartment, is provided by the formulae:

- 3 m + 3% L_{bp} , for ships of length between perpendiculars less than 250 m
- 10,5 m for ships of length between perpendiculars not less than 250 m.

6.8 Auxiliary transversal watertight bulkheads (A.T.W.B.)

6.8.1 The auxiliary transversal watertight bulkheads (A.T.W.B.) are the extension of main transversal watertight bulkheads (M.T.W.B.) above the watertight deck (W.D.) up to the bulkhead deck (B.D.).

They give the possibility to limit the longitudinal extension of flooding above the watertight deck (W.D.) and to add a further reserve of buoyancy/stability consequent to the volume bounded by such bulkheads, watertight deck and bulkhead deck.

7 Spaces definition

7.1 Machinery space

7.1.1 Machinery space is to be taken as extending from the moulded base line to the margin line and between the extreme main transverse watertight bulkheads, bounding the spaces containing the main and auxiliary propulsion machinery, boilers serving the needs of propulsion.

7.2 Ro-ro cargo spaces

7.2.1 Ro-ro cargo spaces are spaces not normally subdivided in any way and extending to either a substantial length or the entire length of the ship in which goods (packaged or in bulk, or in land vehicles, or in barges or crafts) can be loaded and unloaded normally in a horizontal direction.

7.3 Passenger spaces

7.3.1 Passengers

Passengers means every person other than:

- the captain and the members of the crew or other persons employed or engaged in any capacity on board a ship on the business of that ship, and
- a child under one year of age.

7.3.2 Passenger spaces

Passenger spaces are those spaces which are provided for the accommodation and use of passengers, excluding baggage, store, provisions and mail rooms.

In all cases volumes and areas are to be calculated to moulded lines.

7.4 Special personnel

7.4.1 Special personnel means all persons who are not passengers or members of the crew or children of under one year of age and who are carried on board in connection with the special purpose of that ship because of special work being carried out aboard that ship.

7.5 Special category spaces

7.5.1 Special category spaces are those enclosed spaces above or below the bulkhead deck intended for the carriage of motor vehicles, or barges or crafts, or helicopters with fuel in their tanks for their own propulsion, into and from which such vehicles can be driven and to which passengers have access.

7.6 Military special category spaces

7.6.1 Military special category spaces are special category spaces intended for the carriage of motor vehicles, or barges, crafts or helicopters with ammunition.

8 Superstructures

8.1 General

8.1.1 A superstructure is a decked structure, extending from side to side of the ship or with the side plating not being inboard of the shell plating more than 0,04 B.

8.2 Enclosed and open superstructures

8.2.1 A superstructure may be:

- enclosed, where:
  - it is enclosed by front, side and aft bulkheads complying with the requirements of Ch 8, Sec 4
  - all front, side and aft openings are fitted with efficient weathertight means of closure
- open, where it is not enclosed.

8.3 Raised quarterdeck

8.3.1 A raised quarterdeck is a partial superstructure of reduced height.

8.4 Deckhouse

8.4.1 A deckhouse is a decked structure other than a superstructure, located on the main deck or above.

8.5 Trunk

8.5.1 A trunk is a decked structure similar to a deckhouse, but not provided with a lower deck.

9 Deck positions

9.1 Definitions

9.1.1 Position 1

Position 1 includes:

- exposed main deck and raised quarter decks
- exposed superstructure decks situated forward of 0,25 L from the fore end FE.

9.1.2 Position 2

Position 2 includes exposed superstructure decks situated aft of 0,25 L from the fore end FE.

10 Reference co-ordinate system

10.1

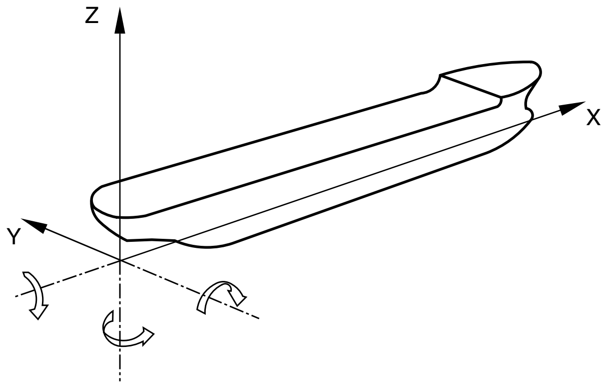
10.1.1 The ship's geometry, motions, accelerations and loads are defined with respect to the following right-hand co-ordinate system (see Fig 4):

- Origin: the intersection between the longitudinal plane of symmetry of ship, the aft end of L and the baseline
- X axis: the longitudinal axis, positive forwards
- Y axis: the transverse axis, positive towards portside
- Z axis: the vertical axis, positive upwards.

10.1.2 Positive rotations are oriented in anti-clockwise direction about the X, Y and Z axes.

10.1.3 A different co-ordinate system may be used subject that the description of the co-ordinate system is clearly indicated in the trim and stability booklet and the same co-ordinate system is used throughout the booklet.

Figure 4 : Reference co-ordinate system



Section 3 Documentation to be Submitted

1 Documentation to be submitted for all ships

1.1 Ships built under the Society supervision

1.1.1 Plans and documents to be submitted for approval

The plans and documents to be submitted to the Society for approval are listed in Tab 1.

The above plans and documents are to be supplemented by further documentation which depends on the service notation and, possibly, the additional class notation (see Pt A, Ch 1, Sec 2) assigned to the ship, as specified in Article [2].

Structural plans are to show details of connections of the various parts and, in general, are to specify the materials used, including their manufacturing processes, welded procedures and heat treatments. See also Ch 11, Sec 1, [1.6].

1.1.2 Plans and documents to be submitted for information

In addition to those in [1.1.1], the following plans and documents are to be submitted to the Society for information:

- general arrangement
- capacity plan, indicating the volume and position of the centre of gravity of all compartments and tanks, if this information is not already included in the general arrangement plan
- lines plan
- hydrostatic curves
- lightweight distribution
- design load plan, indicating all applicable design loads according to Ch 5, Sec 6.

In addition, when direct calculation analyses are carried out by the Designer according to the rule requirements, they are to be submitted to the Society.

Table 1 : Plans and documents to be submitted for approval for all ships

Plan or document	Containing also information on
Watertight subdivision decks Watertight subdivision bulkheads Watertight tunnels	Openings and their closing appliances, if any
Plan of watertight doors and scheme of relevant manoeuvring devices	Manoeuvring devices Electrical diagrams of power control and position indication circuits
Loading manual	See Ch 10, Sec 2, [3]
Calculations relevant to intact stability and damage stability	See Ch 3, Sec 3
Stability documentation	See Ch 3, Sec 1, [3.1]
Midship section Transverse sections Shell expansion Decks and profiles Double bottom Pillar arrangements Framing plan Deep tank and ballast tank bulkheads, wash bulkheads	Class characteristics Main dimensions Draught at minimum operational condition (at delivery) and associated displacement Draught at full load condition (end of life) and associated displacement Frame spacing Maximum ahead service speed Density of cargoes Design loads on decks and double bottom Steel grades Location and height of air vent outlets of various compartments Corrosion protection Openings in decks and shell and relevant compensations Boundaries of flat areas in bottom and sides Details of structural reinforcements and/or discontinuities Bilge keel with details of connections to hull structures
(1) Where other steering or propulsion systems are adopted (e.g. steering nozzles or azimuth propulsion systems), the plans showing the relevant arrangement and structural scantlings are to be submitted. For azimuth propulsion systems, see Ch 9, Sec 1, [11].	

Plan or document	Containing also information on
Fore part structure	Location and height of air vent outlets of various compartments
Machinery space structures Foundations of propulsion machinery and boilers	Type, power and r.p.m. of propulsion machinery Mass and centre of gravity of machinery and boilers
Aft part structure	Location and height of air vent outlets of various compartments
Sternframe or sternpost, sterntube Propeller shaft boss and brackets **(1)**	
Rudder and rudder horn **(1)**	Maximum ahead service speed
Transverse thruster, if any, general arrangement, tunnel structure, connections of thruster with tunnel and hull structures	
Superstructures and deckhouses Machinery space casing	Extension and mechanical properties of the aluminium alloy used (where applicable)
Helicopter landing decks	General arrangement Main structure Characteristics of helicopters: maximum mass, distance between axles of wheels or skids, print area of wheels or skids, rotor diameter
Plan of ventilation	Use of spaces
Scuppers and sanitary discharges	
Bulwarks and freeing ports	Arrangement and dimensions of bulwarks and freeing ports on the watertight deck and decks above the watertight deck
Hawse pipes	
Windows and side scuttles, arrangements and details	
Sea chests, stabilizer recesses, etc.	
Plan of manholes	
Plan of access to and escape from spaces	
Plan of outer doors and hatchways	
Bow doors, stern doors and inner doors, if any, side doors and other openings in the side shell	Closing appliances Electrical diagrams of power control and position indication circuits for bow doors, stern doors, side doors, inner doors, television system and alarm systems for ingress of water
Movable decks and ramps, if any	
Hatch covers, if any	Design loads on hatch covers Sealing and securing arrangements, type and position of locking bolts Distance of hatch covers from the full load waterline and from the fore end
Derricks and lifting appliances	Design loads (forces and moments) including weapon loads Connections to the hull structures
Plan of tank testing	Testing procedures for the various compartments Height of pipes for testing
Equipment number calculation	Geometrical elements for calculation List of equipment Construction and breaking load of steel wires Material, construction, breaking load and relevant elongation of synthetic ropes
Emergency towing arrangement	See Pt E, Ch 10, Sec 2
(1) Where other steering or propulsion systems are adopted (e.g. steering nozzles or azimuth propulsion systems), the plans showing the relevant arrangement and structural scantlings are to be submitted. For azimuth propulsion systems, see Ch 9, Sec 1, [11].	

2 Further documentation to be submitted for ships with certain additional class notations

2.1 General

2.1.1 Depending on the additional class notation (see Pt A, Ch 1, Sec 2) assigned to the ship, other plans or documents may be required to be submitted to the Society, in addition to those in [1.1]. They are listed in [2.2] for the additional class notations which require this additional documentation.

2.2 Additional class notations

2.2.1 The plans or documents to be submitted to the Society are listed in Tab 2.

Table 2 : Plans and documents to be submitted depending on additional class notations

Additional class notation	Plans and documents

CHAPTER 2
GENERAL ARRANGEMENT DESIGN

Section 1	Subdivision Arrangement
Section 2	Compartment Arrangement
Section 3	Access and Openings Arrangement

Section 1 Subdivision Arrangement

1 General

1.1 Definitions

1.1.1 Ship dimensions

The ship dimensions are defined in Ch 1, Sec 2, [6].

1.1.2 Watertight decks and bulkheads

The definitions of the watertight decks and bulkheads are given in Ch 1, Sec 2.

1.1.3 V-lines

V-lines are oblique lines as defined in Ch 3, App 4 corresponding to possible water level limits in a ship transversal section after damage.

2 Number and arrangement of transverse watertight bulkheads

2.1 Number of main watertight bulkheads

2.1.1 General

All ships, in addition to complying with the requirements of [2.1.2], are to have at least the following main transverse watertight bulkheads:

- one collision bulkhead
- one aft bulkhead
- two bulkheads forming the boundaries of the machinery space in ships with machinery amidships, and a bulkhead forward of the machinery space in ships with machinery aft. In the case of ships with an electrical propulsion plant, both the generator room and the engine room are to be enclosed by watertight bulkheads.

2.1.2 Additional bulkheads

As a guidance, the minimum number of main transverse watertight bulkheads versus ship lengths can be estimated from Tab 1.

Irrespective of Tab 1, the number and spacing of main transverse watertight bulkheads are to be such as to comply with stability criteria (see Ch 3, Sec 3).

Table 1 : Minimum number of bulkheads

Length, in m	Total number of bulkheads	
	Machinery amidships	Machinery aft **(1)**
$L < 65$	4	3
$65 \le L < 85$	4	4
$85 \le L < 90$	5	5
$90 \le L < 105$	5	5
$105 \le L < 115$	6	5
$115 \le L < 125$	6	6
$125 \le L < 145$	7	6
$145 \le L < 165$	8	7
$165 \le L < 190$	9	8
$L \ge 190$	to be considered individually	
(1) With aft bulkhead forming after boundary of machinery space.		

2.2 Number of auxiliary watertight bulkheads

2.2.1 Criteria

The number of auxiliary watertight bulkheads is defined with respect to the operational constraints and to fulfill the damage stability criteria (see Ch 3, Sec 3).

2.3 Bulkhead arrangement

2.3.1 Bulkhead effectiveness

To be effective, the distance between two adjacent main watertight bulkheads cannot be lower than 3,0 m plus 3% of the length L_{bp} of the ship or 10,5 m, whichever is the lesser.

2.3.2 Stepped bulkheads

Where it is not practicable to arrange watertight bulkhead in one plane, a stepped bulkhead may be fitted provided that [2.3.1] is fulfilled. In this case, the part of the deck which forms the step is to be watertight and equivalent in strength to the bulkhead.

3 Collision bulkhead

3.1 Arrangement of collision bulkhead

3.1.1 A fore peak or collision bulkhead is to be fitted which is to be watertight up to the watertight deck. This bulkhead is to be located at a distance, in m, from the forward perpendicular of not less than 5% of the length L of the ship and not more than 3,0 m plus 5% of the length L of the ship.

3.1.2 Where any part of the ship below the waterline extends forward of the fore perpendicular, e.g. a bulbous bow, the distances, in metres, stipulated in [3.1.1] are to be measured from a point either:

- at mid length of such an extension, or
- at a distance 1,5% of the length L of the ship forward of the fore perpendicular, or
- at a distance 3,0 m forward of the fore perpendicular; whichever gives the smallest measurement.

3.1.3 The bulkhead may have steps or recesses provided they are within the limits prescribed in [3.1.1] or [3.1.2].

No door, manhole, ventilation duct or any other opening is to be fitted in this bulkhead.

3.1.4 The Society may, on a case by case basis, accept a distance from the collision bulkhead to the fore perpendicular greater than the maximum specified in [3.1.1] and [3.1.2], provided that subdivision and stability calculations show that, when the ship is in upright condition on full load, flooding of the space forward of the collision bulkhead will not result in any part of the bulkhead deck becoming submerged, or in any unacceptable loss of stability.

4 After peak, machinery space bulkheads and stern tubes

4.1 General

4.1.1 An after peak bulkhead, and bulkheads dividing the machinery space from the cargo and personnel spaces forward and aft, are also to be fitted and made watertight up to the watertight deck. The after peak bulkhead may be stepped, provided the degree of safety of the ship as regards subdivision is not thereby diminished.

5 Openings and crossings in watertight bulkheads and decks

5.1 Definitions

5.1.1 Openings mean a passage of large size, through which the passage and the movement of personnel or material through bulkheads, decks and hull are possible as well as the crossings of air ducts, of engine discharges and intakes.

Crossings are intended to be passages of small size for cables or pipes.

Note 1: The passages for shafting are considered as crossings.

5.2 Regulations

5.2.1 Openings and crossings in various elements are allowed according to Tab 2, provided they are watertight or weathertight as necessary to comply with intact and damage stability criteria. Additional requirements are also provided in Part C.

Openings and crossings in transverse watertight bulkheads inside the V-line (as defined in Ch 3, App 4) may be not watertight apart from particular prescriptions. The number of openings in a watertight deck (W.D.) are to be the minimum compatible with the internal arrangements and general plans. Such openings are to be supplied with devices which make them watertight.

Vertical crossings of pipes, air ducts or electrical cables in the watertight deck (W.D.) are to be supplied with a structural watertight device.

Table 2 : Allowed openings and crossings in several water(weather)tight elements

Interested element	Hatches and bolted closures	Doors, panels, hatches	Portlights	Trunks and ventilation inlets	Engine inlets and discharges**(1)**	Cable crossings	Pipe crossings

Shell							
Below W.D.	no	no **(7)**	no	no	no	no **(3)**	yes
Between B.D. & W.D.	yes	yes	yes	yes	no	yes	yes
Between B.D. & E.D.	yes	yes	yes	yes	yes	yes	yes
Other elements							
Tanks	yes	no	no	no	no	yes	yes
Double bottoms	yes	no	no	no	no	yes	yes
Watertight elements below W.D.	yes	yes	no	yes	no	yes	yes
Cofferdams	yes	no	no	no	no	yes	yes

(1) Submerged discharges are considered as pipe crossings.
(2) Provided that the watertightness of ducts between W.D. and B.D. is assured.
(3) Except for particular applications (sonar, hull sensors, ecosounders...).
(4) In case all the main transversal watertight bulkheads are extended above the watertight deck (W.D.) up to the bulkhead deck (B.D.) by an auxiliary watertight bulkhead, the tightness integrity of the first deck is to be applied to the second.
(5) With the exception of the watertight door in the bulkhead bounding the steering gear local, which is to be approved in the contract.
(6) Subject to [5.2.2].
(7) With the exception of a limited number of doors which can be accepted; such doors have to be enclosed with watertight boundaries (bulkhead and access doors) inside the ship, so that this watertight envelop provides sufficient tightness to avoid any progressive flooding.

5.2.2 Bolted openings in more watertight bulkheads below the watertight deck may be accepted if mentioned in the technical specifications and on a case by case basis, provided that they are:

- necessary for maintenance purposes
- permanently closed at sea
- designed and constructed, to the satisfaction of the Society, so as to maintain the fire, smoke and watertight integrity of the bulkhead as well as their structural strength to shock.

6 Doors

6.1 General

6.1.1 Doors are not allowed in main transverse watertight bulkheads below the watertight deck (see Tab 2).

6.1.2 Doors located in auxiliary transverse watertight bulkheads between the watertight deck and the bulkhead deck are to be watertight and fitted with a notice to show if the door is normally open, normally closed or permanently closed.

6.1.3 Doors which may be immersed by the "V-lines" damage waterline as described in Ch 3, App 4 are to be normally closed at sea, i.e. kept closed, used if authorized by the notice affixed on the door, and closed again after use.

6.1.4 Watertight doors located between the watertight deck and the bulkhead deck are to be strengthened such as to resist to the static head equivalent to a water height equal to the distance between the watertight deck and the bulkhead deck.

When detailed information on the head of water after damage is available and justified, such information can be considered for the strengthening of the doors.

Section 2 Compartment Arrangement

1 Flooding management

1.1 Protection

1.1.1 The requirements for openings in watertight bulkheads and decks are given in Ch 2, Sec 1, [5] and Ch 2, Sec 3, [1.1.2].

1.1.2 All cables and piping penetrations located within the watertight boundaries of flooded compartments and below the V-line damage waterline have to be watertight when closed to the maximum waterhead.

1.2 Detection

1.2.1 For detection system applicable for **AUT-QAS** notation, see Pt E, Ch 4, Sec 1.

1.3 Pumping

1.3.1 Floodable dry spaces have to be provided with a fixed water pumping installation or access for movable pumps from above the damage control deck as defined in Ch 1, Sec 2, [6.5].

1.3.2 The pumping capacity is to be at least as required in Pt C, Ch 1, Sec 10, [6.6.3].

2 Cofferdams

2.1 Definition

2.1.1 A cofferdam means an empty space arranged so that compartments on each side have no common boundary; a cofferdam may be located vertically or horizontally. As a rule, a cofferdam is to be of sufficient size to allow inspection.

2.2 Cofferdam arrangement

2.2.1 Cofferdams are to be provided between the compartments intended for liquid hydrocarbons (fuel oil, lubricating oil) and those intended for fresh water (drinking water, water for propelling machinery and boilers) as well as between ammunition stores and tanks intended for the carriage of liquid hydrocarbons.

2.2.2 Cofferdams are only required between fuel oil double bottoms and tanks immediately above where the inner bottom plating is subjected to the head of fuel oil contained therein, as in the case of a double bottom with its top raised at the sides.

Where a corner to corner situation occurs, tanks are not considered to be adjacent.

Adjacent tanks not separated by cofferdams are to have adequate dimensions to ensure easy inspection.

2.2.3 A cofferdam is to be provided to separate tanks containing JP5 NATO(F44) carried as cargo or for the purpose of replenishment of aircraft from any of the following spaces:

- tanks containing other liquid hydrocarbons. The cofferdam between JP5 NATO(F44) tanks and tanks containing other liquid hydrocarbons may however be omitted provided that at least one JP5 NATO(F44) tank on board doesn't have any common boundary with tanks containing other liquid hydrocarbons
- tanks for drinking water and stores containing provisions intended for human consumption
- category A machinery spaces
- ammunition stores
- accommodation spaces. The cofferdam between JP5 tanks and accommodation spaces may however be omitted where the adjacent bulkhead or deck is not provided with any access opening and is coated with a layer of material ensuring gastightness.

Cofferdams of this type may be used as spaces for the installation of JP5-NATO (F44) pumps.

Note 1: Machinery spaces of category A are defined in Pt C, Ch 4, Sec 1, [2.22].

3 Ballast compartments

3.1 General

3.1.1 Water ballast may not be carried in tanks intended for fuel oil.

4 Double bottoms

4.1 Auxiliary ships

4.1.1 A double bottom is to be fitted extending from the collision bulkhead to the after peak bulkhead, as far as this is practicable and compatible with the design and proper working of the ship.

4.2 Frontline ships

4.2.1 A double bottom is to be required as far as practicable within the machinery spaces.

5 Compartments forward of the collision bulkhead

5.1 General

5.1.1 The fore peak and other compartments located forward of the collision bulkhead may not be arranged for the carriage of fuel oil.

6 Machinery compartments

6.1 General

6.1.1 When longitudinal bulkheads are fitted in machinery spaces, adequate self-operating arrangements are to be provided in order to avoid excessive heel after damage.

Where such arrangements constitute a cross-flooding system, their area is to be calculated in accordance with the requirements in Ch 3, App 3. In addition, such systems are to comply with the criteria in Ch 3, Sec 3.

6.2 Two machinery compartments

6.2.1 When the ship is fitted with two machinery compartments, the requirements in Ch 2, Sec 1, [4.1.1] are to be applied.

7 Shaft tunnels

7.1 General

7.1.1 Shaft tunnels are to be watertight to possible internal flooding.

8 Watertight ventilators and trunks

8.1 General

8.1.1 Watertight ventilators and trunks are to be carried at least up to the V-line damage waterline as described in Ch 3, App 4.

9 Fuel oil tanks

9.1 General

9.1.1 The arrangements for the storage, distribution and utilization of the fuel oil are to be such as to ensure the safety of the ship and persons on board.

9.1.2 The requirements of Pt C, Ch 1, Sec 10, [11.5.1] have also to be taken into account.

10 Ammunition storage compartments

10.1 General

10.1.1 Particular care is to be taken for the arrangement of ammunition storage compartments to prevent risk of explosion or ship loss in case of explosion.

11 Tanks containing chemical treatment fluids for exhaust gas pollution prevention system

11.1 Tank protection and segregation

11.1.1 Tanks containing chemical treatment fluids for exhaust gas pollution prevention system are to comply with requirements of Pt C, Ch 1, Sec 11, [3.2] for tank containing urea.

Section 3 Access and Openings Arrangement

1 General

1.1 Number and size of access and openings

1.1.1 The number and size of manholes for trimming and access openings to tanks or other enclosed spaces are to be kept to the minimum consistent with the satisfactory operation of the ship.

1.1.2 Opening tightness

All openings located within the watertight boundaries used for the damage stability calculations, giving access to a flooded compartment and outside the V line (as defined in Ch 3, App 4), are to be watertight when closed to the maximum waterhead.

2 Double bottom

2.1 Inner bottom manholes

2.1.1 Inner bottom manholes are to be not less than 400 mm x 400 mm or 500 mm x 380 mm clear light. Their number and location are to be so arranged as to provide convenient access to any part of the double bottom.

2.1.2 Inner bottom manholes are to be closed by watertight plate covers.

Doubling plates are to be fitted on the covers, where secured by bolts.

Where no ceiling is fitted, covers are to be adequately protected from damage by the cargo.

2.2 Floor and girder manholes

2.2.1 Manholes are to be provided in floors and girders so as to provide convenient access to all parts of the double bottom.

2.2.2 The size of manholes and lightening holes in floors and girders is, in general, to be less than 50 per cent of the local height of the double bottom.

Where manholes of greater sizes are needed, edge reinforcement by means of flat bar rings or other suitable stiffeners may be required.

2.2.3 Manholes may not be cut into the continuous centreline girder or floors and girders below pillars, except where allowed by the Society on a case by case basis.

3 Tanks, water ballast tanks and cofferdams

3.1 General

3.1.1 Tanks, water ballast tanks and cofferdams are to be served by at least one manhole and one ladder.

3.1.2 External openings required to be watertight are to be of sufficient strength and, except for hatch covers, are to be fitted with indicator in the safety control room.

3.2 Access through decks

3.2.1 Opening protection

If an access is to remain open for operational efficiency, it is to be fitted with a light panel, or equivalent device, to prevent falls of a person when the hatchway remains open.

3.3 Access within tanks

3.3.1 Manholes

Where manholes are fitted, as indicated in [2.2.2], access is to be facilitated, as far as practicable, by means of steps and hand grips with platform landings on each side.

3.4 Construction of ladders

3.4.1 General

In general, the ladders are to be vertical. The flights of ladders are not to be more than 9 m in actual length. Resting platforms of adequate dimensions are to be provided.

3.4.2 Construction

Ladders and handrails are to be constructed of steel of adequate strength and stiffness and securely attached to the tank structure by stays. The method of support and length of stay are to be such that vibration is reduced to a practical minimum.

External ladders and handrails in composites are acceptable, except if they are used to access the life saving appliances.

Side stringers are to be flat bars of not less than 60 mm by 6 mm in section, or equivalent.

3.4.3 Width of ladders

The width of ladders between stringers is not to be less than 400 mm.

3.4.4 Treads

The treads are to be equally spaced at a distance apart measured vertically not exceeding 300 mm. They are to be formed of two square steel bars of not less than 16 mm by 16 mm in section fitted to form an horizontal step with the edges pointing upward, or of equivalent construction. The treads are to be welded to the side stringers.

3.4.5 Sloping ladders

All sloping ladders are to be provided with handrails of substantial construction on both sides fitted at a convenient distance above the treads.

4 Air pipes

4.1 General

4.1.1 Internal open end of air pipes

The open end of air pipes terminating within a superstructure is to be fitted inside the V line (as defined in Ch 3, App 4) or above the V-line damage waterline when located outside the V line.

Appendix 5	Evaluation of the Heeling Moment due to Athwart Wind (Intact Vessel)
Appendix 6	Sea-Keeping Calculations

Section 1 General

1 Definitions

1.1

1.1.1 General

Except otherwise specified, the definition of the parameters and ship components mentioned in this Chapter are given in Ch 1, Sec 2.

2 General

2.1 Application

2.1.1 All ships may be assigned class only after it has been demonstrated that their intact and damage stability is adequate for the service intended.

Except otherwise specified, adequate intact and damage stability means compliance with the requirements specified in this Chapter taking into account the ship's size and type. In any case, the level of intact and damage stability is not to be less than that provided by the rules of Ch 3, Sec 2 and Ch 3, Sec 3.

Additional requirements maybe indicated in the relevant chapters of Part E corresponding to the intended service notation.

2.1.2 Approval of the Naval Authority

Evidence of approval by the Naval Authority concerned may be accepted for the purpose of classification.

3 Examination procedure

3.1 Documents to be submitted

3.1.1 List of documents

For the purpose of the examination of the stability, the documentation listed in Ch 1, Sec 3, [1.1.2] is to be submitted for information.

The stability documentation to be submitted for approval, as indicated in Ch 1, Sec 3, is as follows:

- Inclining lightship test report for the ship, as required in [3.2] or:
  - where the stability data is based on a sister ship, the inclining test report of that sister ship along with the lightship measurement report for the ship in question, or
  - where lightship particulars are determined by methods other than inclining of the ship or its sister, the lightship measurement report of the ship along with a summary of the method used to determine those particulars
- trim and stability booklet, as required in Ch 3, App 2
- damage stability calculations, as required in Ch 3, Sec 3, [1.1.1]
- damage control documentation, as required in Ch 3, Sec 3, [1.2].

A copy of the trim and stability booklet, the damage control documentation and the loading computer documentation is to be available on board for the attention of the Captain.

3.1.2 Provisional documentation

The Society reserves the right to accept or demand the submission of provisional stability documentation for examination.

Provisional stability documentation includes loading conditions based on estimated lightship values.

3.1.3 Final documentation

Final stability documentation based on the results of the inclining test or the lightweight check is to be submitted for examination.

3.2 Inclining test - Lightweight check

3.2.1 Definitions

a) Lightweight

   The lightship weight definition is given in Ch 1, Sec 2, [5.1].

b) Inclining test

The inclining test is a procedure which involves moving a series of known weights, normally in the transverse direction, and then measuring the resulting change in the equilibrium heel angle of the ship. By using this information and applying basic naval architecture principles, the ship's vertical centre of gravity (VCG or KG) is determined.

c) Lightweight check

The lightweight check is a procedure which involves auditing all items which are to be added, deducted or relocated on the ship at the time of the inclining test so that the observed condition of the ship can be adjusted to the lightship condition. The weight and longitudinal, transverse and vertical location of each item are to be accurately determined and recorded. The lightship displacement and the longitudinal centre of gravity (LCG) can be obtained using this information, as well as the static waterline of the ship at the time of the inclining test as determined by measuring the distance between the waterline and a reference deck verified draught marks of the ship, the ship hydrostatic data relevant to the actual trim and the sea water density.

3.2.2 General

Any ship for which a stability investigation is requested in order to comply with class requirements is to be initially subjected to an inclining test permitting the evaluation of the position of the lightship centre of gravity, or a light-weight check of the lightship displacement, so that the stability data can be determined.

3.2.3 Inclining test

The inclining test is required in the following cases:

- any new ship, after its completion
- any ship, if deemed necessary by the Society, where any alterations are made so as to materially affect the stability.

3.2.4 Detailed procedure

A detailed procedure for conducting an inclining test and the lightweight is included in Ch 3, App 1.

Section 2 Intact Stability

1 General

1.1 Information for the Captain

1.1.1 Stability booklet

Each ship is to be provided with a stability booklet approved by the Society, which contains sufficient information to enable the Captain to operate the ship in compliance with the applicable requirements contained in this Section.

Where any alterations are made to the ship so as to materially affect the stability information supplied to the Captain, amended stability information is to be provided. If necessary the ship is to be re-inclined.

Stability data and associated plans are to be drawn up in the official language or languages of the issuing country. If the languages used are neither English nor French, the text is to include a translation into one of these languages.

The format of the trim and stability booklet and the information included are specified in Ch 3, App 2.

1.1.2 Periodical lightweight and stability check

At a time not exceeding ten years of the delivery, a lightweight survey is to be carried out to verify any changes in lightship displacement and longitudinal centre of gravity.

A new survey will have to be performed at midterm of the design ship life time.

In both case, the full process as defined in Ch 3, App 1 is to be applied.

1.1.3 Loading instrument

As a supplement to the approved stability booklet, a loading instrument approved by the Society is to be provided to facilitate the stability calculations mentioned in Ch 3, App 2.

A simple and straightforward instruction manual is to be provided.

In order to validate the proper functioning of the computer hardware and software, pre-defined loading conditions are to be run in the loading instrument periodically, at least at every periodical class survey, and the print-out is to be maintained on board as check conditions for future reference in addition to the approved test conditions booklet.

The procedure to be followed, as well as the list of technical details to be sent in order to obtain loading instrument approval, are given in Ch 10, Sec 2, [4].

1.2 Permanent ballast

1.2.1 If used, permanent ballast is to be located in accordance with a plan approved by the Society and in a manner that prevents shifting of position. Permanent ballast is not to be removed from the ship or relocated within the ship without the approval of the Society. Permanent ballast particulars are to be noted in the ship's stability booklet.

1.2.2 No liquid permanent ballast is allowed.

Permanent solid ballast is to be installed under the supervision of the Society.

2 Design criteria

2.1 General intact stability criteria

2.1.1 General

The intact stability criteria specified in [2.3] to [2.8] are to be complied with for the loading conditions mentioned for project verification in Ch 1, Sec 2, [5.2], Ch 1, Sec 2, [5.4].

2.1.2 Elements affecting stability

A number of influences such as beam-wind on ships with large windage area, icing of topsides, water trapped on deck, rolling characteristics, etc., which adversely affect stability are to be taken into account.

2.1.3 Elements reducing stability

Provisions are to be made for a safe margin of stability at all stages of the voyage, regard being given to additions of weight, such as those due to absorption of water and icing and to loss as of weight such as those due to consumption of fuel and stores.

All deck areas where water can be trapped will have to be considered with the maximum possible water level.

Effect of ship turning, crowding of special personnel, wind and rolling, liquid free surfaces, icing, cargo lifting are covered by [2.3] to [2.8].

The intact stability characteristics of the ship are to be investigated through the following analysis:

a) righting arms (GZ curve) of the ship in the different loading conditions

b) behaviour of the ship under heeling actions such as:

   1) severe wind and rolling

   2) ice accretion

   3) high speed turning

   4) heavy cargo lifting

   5) crowding of special personnel on one side of the ship

   6) Simultaneous effect of wind and special personnel crowding.

The requirement of the reactions of the ship to the above heeling actions and the criteria which the ship is to comply with are dependent on her type.

2.1.4 Ship mass evolution

Except otherwise specified, the stability is to be assessed taking into account an evolution of mass per year on the ship life time due to modernization, maintenance, etc., as defined in Tab 1.

Table 1 : Ship mass evolution

Type of ship	Displacement in % of light ship mass	Centre of gravity
All ships	+ 0,3% / year	+ 0,2% / year

2.1.5 Definition of angles of righting arms curves

θ_d : Ultimate angle of dynamic stability

It is the angle over which the reserve of dynamic stability is not sufficient any more (the dynamic capsizing happens) to face a constant inclining moment (invariable with the heeling), suddenly applied to the ship. Its value corresponds to that of the angle at which the value of the area A is the same as the value of the area B (Fig 1)

θ_0 : Limit of static stability

It is the angle corresponding to the maximum heeling moment (this moment is applied to the ship increasingly to the purpose of avoiding all the dynamic effects) which the ship may face before the capsizing

θ_s : Capsizing angle (over this angle the capsizing of the ship happens even if the inclining moment disappears)

θ_f : Flooding angle (i.e. the lowest angle at which the first opening not closed is reached)

This is the angle corresponding to the minimum angle of heel to which at least one unprotected point (see [2.1.6]) is immersed

θ_r : Rolling angle

θ_c : Static equilibrium angle caused by an external action

θ_e : Equilibrium angle after damage (without external actions).

2.1.6 Location of the flooding angle

The points of flooding are only the unprotected points which may endanger the stability or the efficiency of the ship (openings leading to large volumes and of size such that the emptying means present on board are not sufficient to face the input of sea water through them), i.e. ventilators in the engine room (see Fig 2, Fig 3 and Fig 4).

In the case of a trunk supplied with a closure device or an on-off valve, two cases may rise:

a) either the devise or the valve are proper for the hydrostatic head correspondent to a heeling angle of 70°; in such a case, the trunk is not considered as a point of flooding unprotected, or

b) the device or the valve are proper for a hydrostatic head h lesser than that of item a). In such a case, the point of flooding is to be positioned raised of the value h.

Figure 1 : Righting arms curve and angles

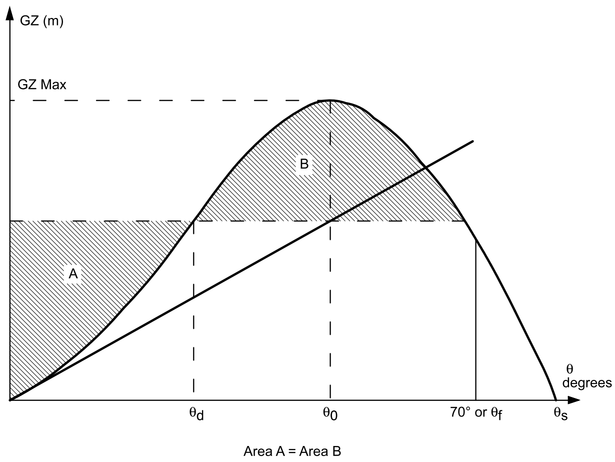

Figure 2 : Flooding angle - Example 1

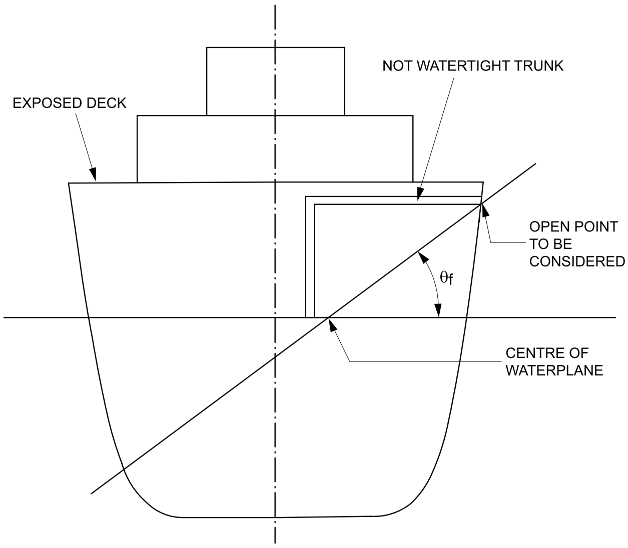

Figure 3 : Flooding angle - Example 2

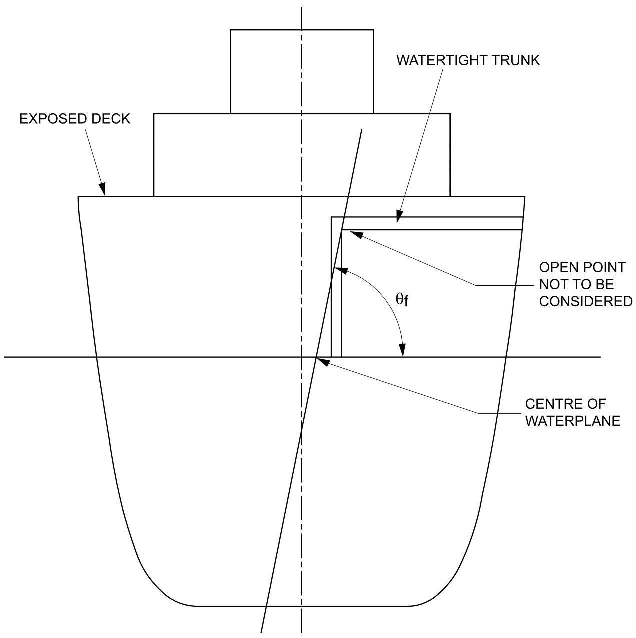

Figure 4 : Flooding angle - Example 3

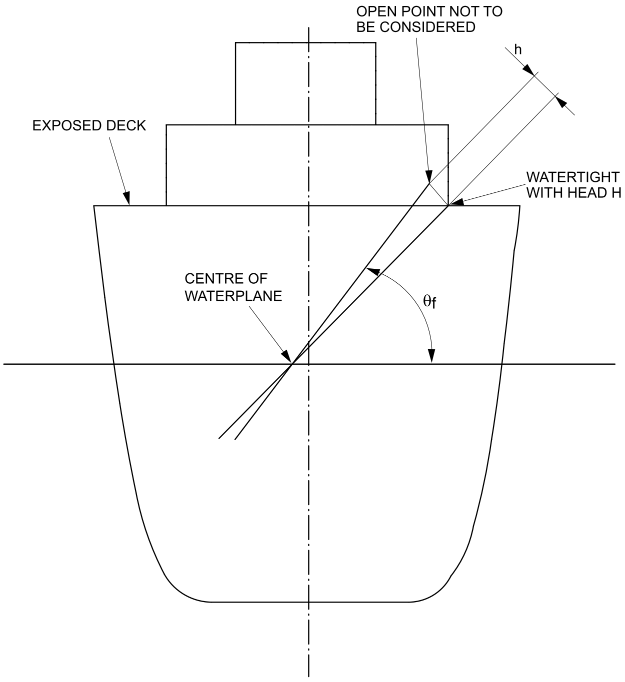


2.1.7 Righting arms curve

In creating the righting arms curve, the following rules are to be taken into account: the calculation of the righting arms for the considered heeling angles is to be carried out taking in account the change of trim and the free surface effects.

The arms curve is to be stopped when the smallest of the following values is reached:

a) 70°

b) θ_f (angle at which openings not supplied with at least weathertight devices remain submerged), or

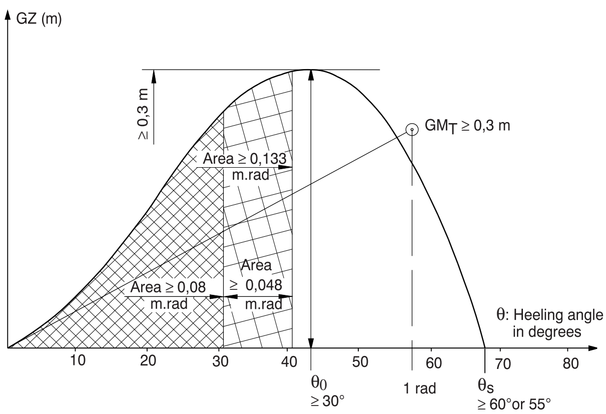
c) θ_s (capsizing angle).

2.1.8 Requirements for the righting arms curve

The righting arm curve is to be in compliance with the requirements listed in Tab 2 and represented in Fig 5.

The maximum value of the righting arm curve (GZ Max) is to be identified as per Fig 6 and is to be taken, in any case, between 30° and 50°.

Figure 5 : Righting arms curve criteria



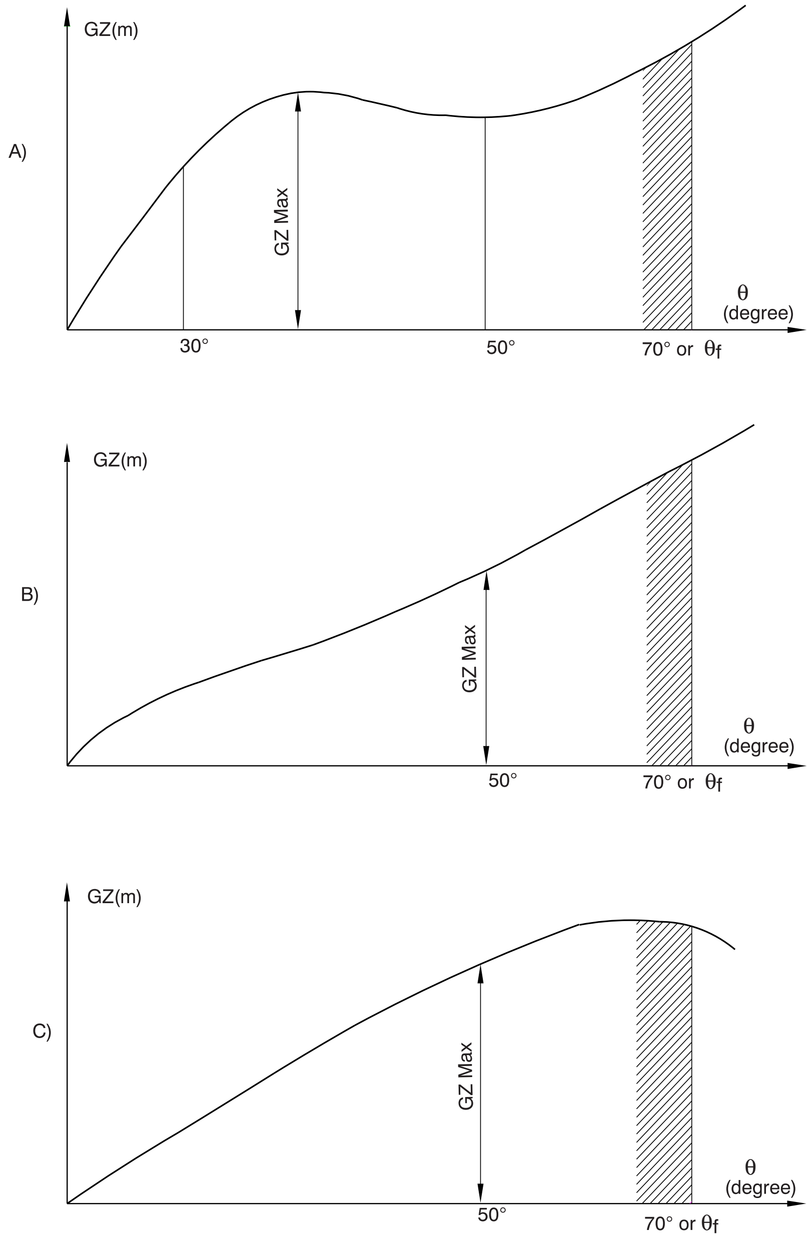
θ_0 : Extreme angle of static stability

θ_s : Capsizing angle.

Table 2 : Minimum values required for the righting arms curve in intact condition

Area under the righting arm curve (GZ) up to 30° or θ_f	Not less than 0,080 m rad (15 feet degree)
Area under the righting lever (GZ) up to 40° or θ_f	Not less than 0,133 m rad (25 feet degree)
Area under the righting arm curve (GZ) between 30° and 40°	Not less than 0,048 m rad (9 feet degree)
Value of the maximum righting arm curve between 30° and 50° (GZ Max)	Not less than 0,3 m (1 foot)
Heeling angle corresponding to the maximum righting arm curve (GZ Max)	Not less than 30°
Value of the initial metacentric height corrected for free surface effect (GM_{corr})	Not less than 0,3 m (1 foot)
Value of the capsizing angle (θ_s)	• Higher than 60° for ships with lightship displacement less than or equal to 5000 t • Higher than 55° for ships with lightship displacement greater than 5000 t

Figure 6 : GZ Max to be considered



If $\theta_f < 50°$, the value of GZ Max is to be considered between 30° and θ_f.

The criteria reported in Tab 2 define the minimum requirements, not the maximum.

Anyway, it is recommended not to exceed the value of GM in order to avoid high dangerous accelerations.

2.2 Effect of free surfaces of liquids in tanks

2.2.1 Tanks for liquids

For all loading conditions, the initial metacentric height and the righting lever curve are to be corrected for the effect of free surfaces of liquids in tanks.

2.2.2 Decks

Decks are provided with efficient drainage arrangement to prevent accumulation of entrapped water due to weather conditions, cleaning or fire fighting. In particular, the effect of accumulation of water is to be investigated for one single large space.

If the drainage arrangement is not considered efficient by the Society, free surface effects may be required, case by case, for the stability calculations.

2.2.3 Consideration of free surface effects

Free surface effects are to be considered whenever the filling level in a tank is less than 98% of full condition.

Free surface effects need not be considered where a tank is normally full, i.e. filling level is 98% or above.

Free surface effects for small tanks may be ignored under the condition in [2.2.9].

2.2.4 Categories of tanks

Tanks which are taken into consideration when determining the free surface correction may be one of two categories:

- tanks with fixed filling level (e.g. water ballast):

  The free surface correction is to be defined for the actual filling level to be used in each tank.
- tanks with variable filling level (e.g. consumable liquids such as fuel oil, diesel oil, and fresh water):

  Except as permitted in [2.2.6] and [2.2.7], the free surface correction is to be the maximum value attainable among the filling limits envisaged for each tank, consistent with any operating instructions.

2.2.5 Consumable liquids

In calculating the free surface effect in tanks containing consumable liquids, it is to be assumed that, for each type of liquid, at least one transverse pair or a single centreline tank has a free surface and the tank or combination of tanks taken into account is to be the one where the effect of free surface is the greatest. In particular, for the departure conditions where tanks are 100% filled, one maximum free surface for each type of liquid is to be considered. Otherwise, the free surface corresponding to the actual filling is to be considered for each capacity.

2.2.6 Water ballast tanks

Where water ballast tanks, including anti-rolling tanks and anti-heeling tanks, are to be filled or discharged during the course of a voyage, the free surface effect is to be calculated to take account of the most onerous transitory stage relating to such operations.

2.2.7 GM_0 and GZ curve corrections

The corrections to the initial metacentric height and to the righting lever curve are to be addressed separately as indicated in a) and b) below:

a) In determining the correction to the initial metacentric height, the transverse moments of inertia of the tanks are to be calculated at 0° angle of heel according to the categories indicated in [2.2.4].

b) The righting lever curve may be corrected by any of the following methods:
   - correction based on the actual moment of fluid transfer for each angle of heel calculated according to the categories indicated in [2.2.4]
   - correction based on the moment of inertia, calculated at 0° angle of heel, modified at each angle of heel calculated; corrections may be calculated according to the categories indicated in [2.2.4]
   - correction based on the summation of M_{fs} values for all tanks taken into consideration, as specified in [2.2.9].

Whichever method is selected for correcting the righting lever curve, only that method is to be presented in the ship's trim and stability booklet. However, where an alternative method is described for use in manually calculated loading conditions, an explanation of the differences which may be found in the results, as well as an example correction for each alternative, are to be included.

2.2.8 Remainder of liquid

The usual remainder of liquids in the empty tanks need not be taken into account in calculating the corrections, providing the total of such residual liquids does not constitute a significant free surface effect.

2.2.9 Small tanks

Small tanks which satisfy the following conditions using the values of k corresponding to an angle of inclination of 30° need not be included in the correction:

$$\frac{M_{fs}}{\Delta_{min}} < 0,01\,m$$

where:

Δ_{min} : Minimum operational condition ship displacement, in t (see Ch 1, Sec 2, [5.4.1]).

2.3 Severe wind and rolling

2.3.1 Purpose

A ship is to be able to withstand weather and marine adverse conditions without risking its own safety.

The wind and rolling verification ensure a good level of safety for such condition.

The speed of the wind is ruled in Tab 3.

2.3.2 Stability requirements

The wind and rolling verification shall be carried out, comparing the righting arms curve and the heeling arms curve.

The characteristics of speed and distribution of wind are specified in [2.3.3].

2.3.3 Wind speed

The wind action is to be considered cross directed, its speeds are those reported in Tab 3.

Such speeds are different according to the navigation the ship is to follow and its age (less or more than 10 years).

The heeling action of the wind is to be calculated according to Ch 3, App 5.

2.3.4 Dynamic effects

For the purpose of taking account of the heeling caused by wind combined with rolling, the value of the heeling arm GZ1 in the proximity of the angle of static equilibrium (θ_c) is to be less than 60% of the maximum value of the righting arm (GZ Max).

2.3.5 Rolling and reserve of stability

The value of the rolling angle used for the check is to be 25°.

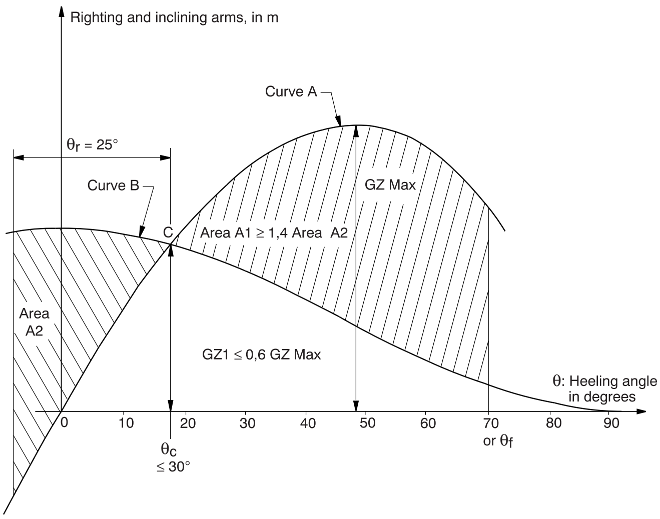
The ship is considered in condition of static equilibrium (point C in Fig 7); from that point a rolling angle of 25° is taken into account.

The following areas are considered:

- "A2", heeling area
- "A1", righting area.

To ensure a sufficient level of safety, area "A1" is to be at least 40% greater than area "A2".

Figure 7 : Severe wind and rolling criteria



Curve A: Righting arms curve (GZ)

Curve B: Wind inclining arms curve.

2.3.6 Maximum value of the angle of static equilibrium

The maximum allowable value of the static equilibrium (θ_c) is 30°.

That to be sure that the ship operates safely.

2.3.7 Stability requirements for wind and rolling

The stability requirements for wind and rolling actions are as follows:

a) GZ1 ≤ 0,6 GZ Max

b) A1 ≥ 1,4 A2

c) $\theta_c \leq 30°$.

Table 3 : Theoretical speed of the wind

Service of the ship	Speed for ships with age of service less than 10 years	Speed for ships with age of service not less than 10 years
UNRESTRICTED SERVICE		
a) Ships expected to withstand the full force of tropical cyclones	100 knots	90 knots
b) Ships expected to avoid centres of tropical cyclones	80 knots	70 knots
COASTAL SERVICE		
a) Ships expected to withstand the full force of tropical cyclones	100 knots	90 knots
b) Ships expected to avoid centres of tropical cyclones	80 knots	70 knots
c) Ships which have to return into harbour with wind force 8	60 knots	50 knots
SERVICE IN HARBOUR	60 knots	50 knots

2.4 Icing

2.4.1 General

For ships which may operate in areas North of latitude 65° and South of latitude 60° and anyway in seas where icing, in winter periods, is expected, the heeling actions due to ice accretion on superstructures and decks are to be taking into account.

In such areas, an icing mass is expected in the more exposed zones of the ship to the adverse conditions (fore part), with the triple effect of:

- the increasing of displacement
- the trim changing
- the centre of gravity elevation.

2.4.2 Calculation assumption

For the purpose of evaluating the stability of a ship in the condition of ice accretion, the following assumptions are to be considered:

a) the curve of righting arms relevant to the loading conditions is to take into account the effects of the ice accretion mass (see [2.4.3]) and the free surfaces

b) the check of the stability of the ship under the combined action of wind and rolling is to be performed similarly to [2.3], but taking into account values of wind speeds 30% less than those in Tab 3.

For ships where devices for removing ice are available, the action of such devices is to be disregarded.

2.4.3 Guidance relating to ice accretion

For ships with lightship displacement not greater than 1000 t, the weight of ice accretion to be considered is 10% of its full load displacement.

For ships with lightship displacement greater than 1000 t, the weight distribution of the ice accretion to be considered is as follows:

- just the fore third of the length of the ship from the exposed deck and the decks above, including the sides, is to be taken into account. Masts are excluded from the calculation.

A uniform weight distribution of ice accretion, of 140 kg/m^2 for the horizontal areas and 70 kg/m^2 for the vertical or oblique areas, is to be considered.

2.4.4 Centre of gravity of ice accretion

For ships with lightship displacement not greater than 1000 t, the centre of gravity of the ice accretion is to be considered coincident with the centre of gravity of the ship in the different loading conditions.

For ships with lightship displacement greater than 1000 t, the centre of gravity of the ice accretion is to be considered in its own position.

2.4.5 Stability requirements for icing and wind

The effect of ice accretion is to be considered in accordance with the requirements of Tab 4 and Fig 9.

For the effects of wind and roll, the following criteria are to be complied with:

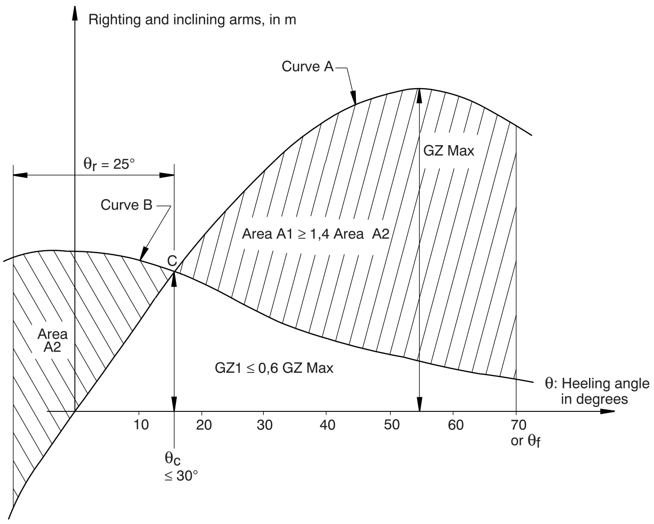
a) GZ1 ≤ 0,6 GZ Max

b) A1 ≥ 1,4 A2

c) $\theta_c \leq 30°$.

See Fig 8.

Figure 8 : Icing criteria with wind



Curve A : Righting arms curve corrected for icing

Curve B : Wind inclining arms curve.

Figure 9 : Icing criteria without wind

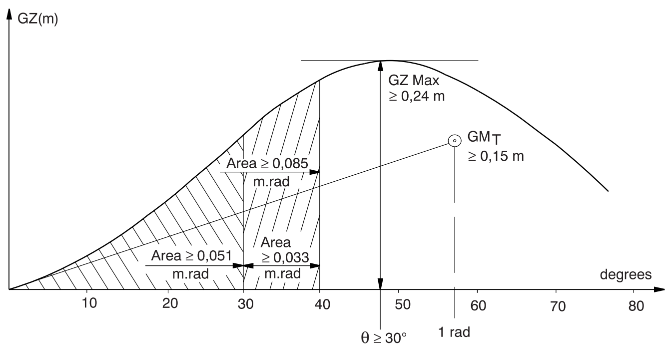


Table 4 : Requirement for righting lever curve for the loading conditions with ice accretion

Area under the righting lever curve (GZ curve) up to 30°, or θ_c, if less than 30°	Higher than 0,051 m·rad (9,60 feet-degrees)
Area under the righting lever curve (GZ curve) up to 40°, or θ_c, if less than 40°	Higher than 0,085 m·rad (16 feet-degrees)
Area under the righting lever curve (GZ curve) between the angles of heel 30° and 40°, or θ_c, if less than 40°	Higher than 0,033 m·rad (6,20 feet-degrees)
The maximum righting lever GZ	At least 0,24 m (0,8 feet)
Heeling angle corresponding to the maximum righting arm (GZ Max)	Higher than 30° (not less than 25°)
Initial metacentric height (liquid) corrected for the actions of free surfaces moments (GM_{corr})	Not less than 0,15 m (0,5 feet)

2.5 High speed turning

2.5.1 When the ship turns at high speed, an inclining moment arises which may be prominent.

The purpose of the stability checking for high speed turning is the behaviour of the ship in such an occasion.

2.5.2 High speed turning

The inclining lever (IL) due to the high speed turning is to be considered based on the following formula:

$$IL = \left(\frac{V^2}{R}\right) \cdot \left(\frac{a\cos\theta}{g}\right)$$

where:

V : Speed, in m/sec, of the ship in the turning operating. Such a value may be assumed equal to 80% of the maximum speed when the ship starts the turning

R : Turning radius, in m (if unknown, it may be assumed equal to 3,3 L_{bp})

g : Gravity acceleration

a : Vertical distance, in m, between the centre of gravity of the ship and its drifting centre (if unknown, it may be taken the half of mean draught)

θ : Heeling angle, in degrees (see Fig 10).

2.5.3 Stability requirements for high speed turning

The stability requirements for high speed turning are the following (see Fig 10):

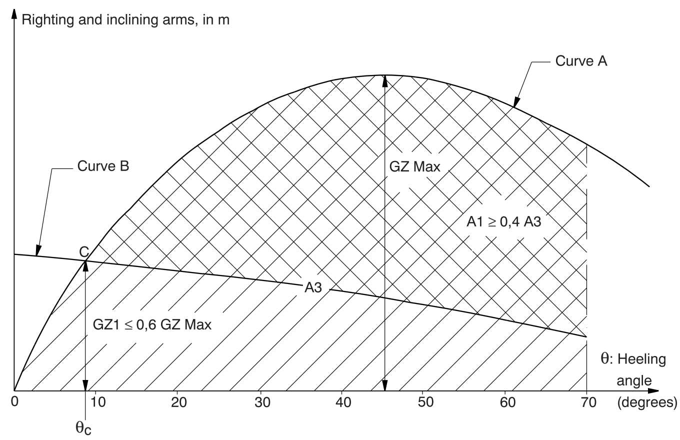
a) GZ1 ≤ 0,6 GZ Max

b) A1 ≥ 0,4 A3

c) $\theta_c \leq 15°$

Note 1: Such a value corresponds to the maximum value of the equilibrium angle corresponding to that allowable for a good working of the essential devices of the ship.

Figure 10 : High speed turning criteria



Curve A : Righting arms curve of the ship in the intact condition

Curve B : Inclining arms (IL) curve for evolution at high speed

A1 : Area between righting curve (curve A) and inclining curve (curve B)

A3 : Total area below the righting arms curve.

2.6 Heavy cargo lifting in still water

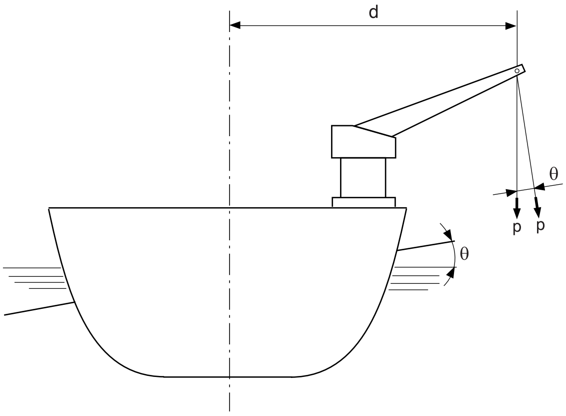
2.6.1 The lifting of weights is a decisive factor in checking the stability of a ship of small dimensions.

In fact the lifted mass, applied to the upper end of the derrick, raises the centre of gravity, reducing, consequently, the value of the initial metacentric height (see Fig 11).

The present sub-article deals with raising of weights in still water.

It is strongly suggested to avoid raising of weights in rough sea. For that, if essential, particular considerations are required.

Figure 11 : Heavy cargo lifting



2.6.2 Intact stability criteria

Two cases may arise:

a) The weight of the cargo is known:

In such a case the stability requirements in [2.6.3] are to be complied with.

b) The weight of the cargo is unknown:

In such a case, the maximum allowable weight, complying with requirement [2.6.3], is to be determined.

In both cases, the righting arms curve (GZ) built, taking into account the increasing of:

- displacement
- raising of the centre of gravity, and
- conditions set up in [2.1.7],

is to be compared with the heeling arms curve defined according to the following formula:

$$H_a = \frac{p\ d\cos\theta}{\Delta}$$

where:

H_a : Heeling arms, in m

p : Weight to be raised, in t

d : Transverse distance, in m, between the centreline of the ship and the more external end of the derrick

Δ : Displacement, in t, of the ship with the raised weight

θ : Heeling angle, in degrees.

2.6.3 Stability requirements for heavy cargo lifting

To comply the stability criteria, the ship is to meet the following requirements (see Fig 12):

a) The value of the static equilibrium angle θ_c caused by the heeling for the cargo raising is to be not more than 15° or the value of the dynamic equilibrium angle θ_d (see [2.1.5]), if lesser:

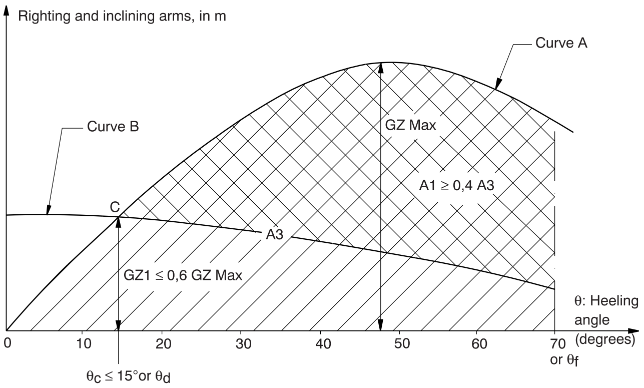
$\theta_c \leq$ Min (15° ; θ_d)

b) GZ1 ≤ 0,6 GZ Max (as in [2.3.4]).

c) The value of the area of the residual stability diagram, represented as area A1 in Fig 12, is to be not less than 40% of the total area below the stability curve, represented by area A3 in Fig 12:

A1 ≥ 0,4 A3.

Figure 12 : Heavy cargo lifting criteria



Curve A : Righting arms curve of the ship in the intact condition

Curve B : Inclining arms (H_a) curve due to cargo lifting

A1 : Area between righting curve (curve A) and inclining curve (curve B)

A3 : Total area below the righting arms curve.

2.7 Crowding of special personnel on one side

2.7.1 The crowding of special personnel (as defined in Ch 1, Sec 2, [7.3.1]) on a ship of small dimensions where a large number of personnel is embarked may be the cause of stability problems. In fact, the crowding on one side of the ship causes a heeling moment which produces a considerable reduction of the dynamic stability reserve.

2.7.2 Calculation assumption

All the special personnel is considered crowded on the upper deck where the personnel is allowed to be located and as more as possible at side, taking into account the following requirements:

a) 4 persons by square metre

b) mean weight of each person: 75 kg.

The heeling arms curve is to be calculated (see [2.7.3]) and compared with the righting lever curve defined in [2.1.7].

2.7.3 Heeling arms calculation

The heeling arms H_a (see Fig 13), in m, caused by the transversal movement of special personnel is calculated by the following formula:

$$H_a = \frac{p\ d\cos\theta}{\Delta}$$

where:

p : Weight of moved special personnel, in t

d : Transverse distance, in m, from the centreline of the ship to the centre of gravity of the area on which the special personnel is crowed

Δ : Displacement of the ship, in t

θ : Heeling angle, in degrees.

2.7.4 Stability requirements for crowding of special personnel

To fulfil the stability criteria, the ship is to comply with the following requirements (see Fig 13):

a) The value of the static equilibrium angle (θ_c) caused by the crowding of special personnel at side is to be not higher than 15° or the value of the dynamic equilibrium angle θ_d (see [2.1.5]), if lesser:

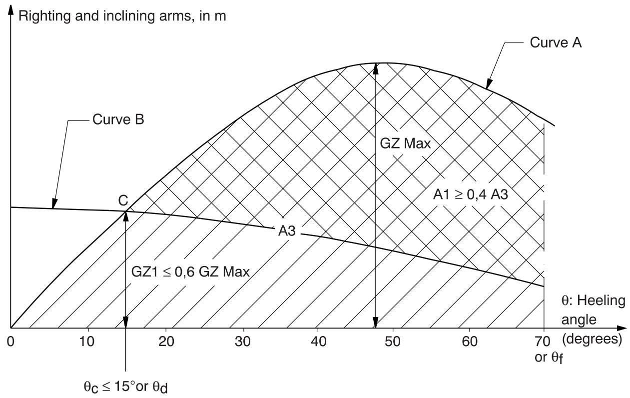
$\theta_c \leq$ Min (15° ; θ_d)

b) GZ1 ≤ 0,6 GZ Max

c) The value of the area of the residual stability diagram, consequent to the crowding of special personnel at side, represented as area A1 in Fig 13 is to be not less than 40% of the total area below the stability curve, represented by area A3 in the same Figure:

A1 ≥ 0,4 A3.

Figure 13 : Special personnel crowding criteria

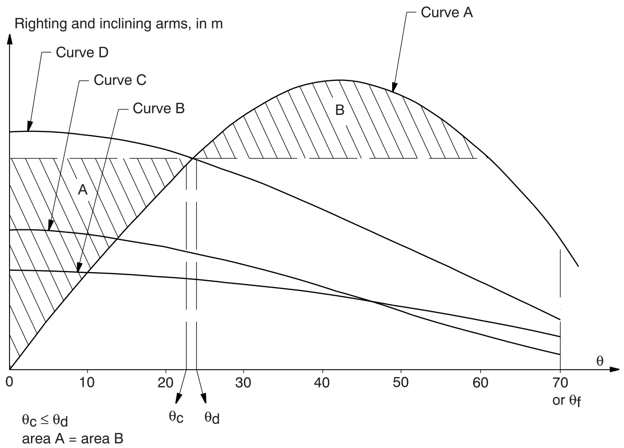


Curve A : Righting arms curve of the ship in the intact condition
Curve B : Inclining arms (H_a) curve due to special personnel crowding
A1 : Area between righting curve (curve A) and inclining curve (curve B)
A3 : Total area below the righting arms curve.

2.8 Simultaneous effect of wind and special personnel crowding

2.8.1 The heeling action reported in [2.3] and [2.7] may be arranged together considered simultaneously. Anyway, in such a case, the only requirement is that the static equilibrium angle resulting from both heeling actions be not higher than the value of the dynamic equilibrium angle θ_d as defined in [2.1.5] and Fig 14. The wind speed to be considered is the maximum speed for which special personnel is allowed to be located on the exposed decks.

Figure 14 : Special personnel crowding criteria with wind



θ_d : Extreme angle of dynamic stability
θ_c : Balancing angle
Curve A : Righting arms curve of the ship in the intact condition
Curve B : Inclining arms curve due to special personnel crowding
Curve C : Wind inclining arms curve
Curve D : Inclining arms curve due to both actions of wind and special personnel crowding.

Section 3 Damage Stability

1 General

1.1 On board supports

1.1.1 Damage stability documentation

For all ships, documents including damage stability calculations are to be submitted.

The damage stability calculations are to include:

a) the list of characteristics (volume, centre of gravity, permeability) of each compartment which can be damaged

b) a table of openings in bulkheads, decks and side shell reporting all the information about:
- identification of the opening
- vertical, transverse and horizontal location
- type of closure: sliding, hinged or rolling for doors
- type of tightness: watertight, weathertight or unprotected
- operating system: remote control, local operation, indicators on the bridge, television surveillance, water leakage detection, audible alarm, as applicable; foreseen utilisation: open at sea, normally closed at sea, kept closed at sea

c) the list of all damage cases corresponding to the applicable requirements

d) the detailed results of damage stability calculations for all the loading conditions foreseen in the applicable requirements

e) the limiting GM/KG curve, if foreseen in the applicable requirements

f) the capacity plan

g) the arrangement of cross flooding pipes, showing the location of remote controls for valves or special mechanical means for correcting the list due to flooding, if any

h) a plan showing the doors (location, tightness), if this information is not already included in the general arrangement plan.

1.1.2 Loading instrument

As a supplement to the approved damage stability documentation, a loading instrument, approved by the Society, is to be provided to facilitate the damage stability calculations mentioned in [1.1.1].

The following loading instrument documentation is to be provided:
- loading instrument approved by Society
- on board user's manual for examination.

The procedure to be followed, as well as the list of technical details to be sent in order to obtain loading instrument approval, are given in Ch 10, Sec 2, [4.6].

1.2 Damage control

1.2.1 Documentation to be supplied

The Captain of the ship is to be supplied with the data necessary to maintain sufficient intact stability under service conditions to enable the ship to withstand the critical damage. In the case of ships requiring cross-flooding, the Captain of the ship is to be informed of the conditions of stability on which the calculations of heel are based and be warned that excessive heeling might result should the ship sustain damage when in less favourable condition.

The data referred to above, to enable the Captain to maintain sufficient intact stability, are to include information which indicates the maximum permissible height of the ship's centre of gravity above keel (KG), or alternatively, the minimum permissible metacentric height (GM) for a range of draught or displacements sufficient to include all service conditions. The information is to show the influence of various trims taking into account the operational limits.

1.2.2 Damage control documentation

The damage control documentation is to include a damage control plan which is intended to provide ship's officers with clear information on the ship's watertight compartmenting and equipment related to maintaining the boundaries and effectiveness of the compartmentation so that, in the event of damage causing flooding, proper precautions can be taken to prevent progressive flooding through openings therein and effective action can be taken quickly to mitigate and, where possible, recover the ship's loss of stability.

The damage control documentation is to be clear and easy to understand. It is not to include information which is not directly relevant to damage control and is to be provided in the language or languages of the ship's officers.

Plans showing clearly, for each deck and hold, the boundaries of the watertight compartments, the openings therein with the means of closure and position of any controls thereof, and the arrangements for the correction of any list due to flooding are to be permanently exhibited for the guidance of the officer in charge of the ship. In addition, booklets containing the aforementioned information are to be made available to the officers of the ship.

Watertight doors that may be permitted to remain open during navigation are to be indicated in the damage control plan with the indication that “doors are always to be ready for immediate closure”, Detailed description of the information to be included in the damage control documentation is reported in [2.4].

1.2.3 Draught marks

Each ship is to be provided with scales of draughts marked clearly at the bow and stern.

In the case where the draught marks are not located where they are easily readable, or operational constraints trade make it difficult to read the draught marks, then the ship is also to be fitted with a reliable draught indicating system by which the bow and stern draught can be determined.

2 Conditions and criteria

2.1 Approaches to be followed for damage stability investigation

2.1.1 General

Damage stability calculations are required in order to achieve a minimum degree of safety after flooding.

The metacentric height (GM), stability levers (GZ) and centre of gravity positions for judging the final surviving conditions are to be calculated by the constant displacement (lost buoyancy) method.

2.1.2 Methodology

The approach is based on standard dimensions of damage extending anywhere along the ship's length or between transverse bulkheads depending on the relevant requirements.

The consequence of such standard of damage is the creation of a group of damage cases, the number of which, as well as the number of compartments involved in each case, depends on the ship's dimensions and internal subdivision.

For each loading condition, each damage case is to be considered and all the applicable criteria are to be complied with.

2.2 Progressive flooding

2.2.1 Definition

Progressive flooding is the additional flooding of spaces which were not previously assumed to be damaged. Such additional flooding may occur through openings or pipes, as indicated in [2.2.2] and [2.2.3], which are located within the V lines as described in Ch 3, App 4.

2.2.2 Openings

The openings may be listed in the following categories, depending on their means of closure:

a) Unprotected

Unprotected openings are openings which are not fitted with at least weathertight means of closure.

Unprotected openings which form part of the limit of the enclosed spaces included in the damage stability calculations and which are located below the waterline after damage (at any stage of flooding) are not allowed; see also [2.4.8] item a).

b) Weathertight

Openings fitted with weathertight means of closure are not able to sustain a constant head of water, but they can be intermittently immersed within the positive range of stability.

Weathertight openings may lead to progressive flooding if they are located below the waterline after damage (at any stage of flooding).

c) Watertight

Internal openings fitted with watertight means of closure are able to sustain a constant head of water corresponding to the distance between the lowest edge of this opening and the bulkhead deck. When detailed information on the head of water after damage is available and justified, such information can be considered for the determination of the constant head of water.

Air pipe closing devices may not be considered watertight, unless additional arrangements are fitted in order to demonstrate that such closing devices are effectively watertight.

Manhole covers may be considered watertight provided the cover is fitted with bolts located such that the distance between their axes is less than five times the bolt's diameter.

Access hatch covers leading to holds may be considered watertight.

Watertight openings do not lead to progressive flooding.

2.2.3 Pipes

Progressive flooding through pipes coming out into internal spaces of the ship may occur when:

a) the pipes and connected valves are located within the assumed damage, and no valves are fitted outside the damage

b) the pipes, even if located outside the damage, satisfy all of the following conditions:
   - the pipe connects a damaged space to one or more space(s) located outside the damage
   - the highest vertical position of the pipe is below the waterline, and
   - no valves are fitted.

The possibility of progressive flooding through ballast piping passing through the assumed extent of damage, where positive action valves are not fitted to the ballast system at the open ends of the pipes in the tanks served, is to be considered. Where remote control systems are fitted to ballast valves and these controls pass through the assumed extend of damage, then the effect of damage to the system is to be considered to ensure that the valves would remain closed in that event.

If pipes, ducts or tunnels are situated within assumed flooded compartments, arrangements are to be made to ensure that progressive flooding cannot thereby extend to compartments other than those assumed flooded.

2.3 General

2.3.1 Loading conditions

The damage stability criteria specified in [2.4] are to be complied with for the loading conditions mentioned in Ch 1, Sec 2, [5.2] and Ch 1, Sec 2, [5.4] and the loading conditions allowing to take into account the possible evolution of mass during the ship life as given in Ch 3, Sec 2, [2.1.2].

However, the lightship condition not being an operational loading case, no verification are required for this case.

2.3.2 Calculation assumptions

Calculations are to be performed in accordance with [2.4.2] to [2.4.7] and to take into consideration the proportions and design characteristics of the ship and the arrangement and configuration of the damaged compartments. For these calculations, the ship is to be assumed in the worst anticipated service condition as regards stability.

Effects of free surfaces of liquids in tanks are to be taken into account as defined in Ch 3, Sec 2, [2.2].

Damaged compartments, when filled of liquid, are to be subject to run-off, when relevant.

Where it is proposed to fit decks, inner skins or longitudinal bulkheads of sufficient tightness to seriously restrict the flow of water, the Society is to be satisfied that proper consideration is given to such restrictions in the calculations.

2.4 Damage and criteria

2.4.1 Introduction

The present sub-article defines the stability requirements to be complied with when a ship is in damage conditions.

The compliance with such requirements assumes the floating of the ship after several damage cases and the survival such that the return to the harbour is possible.

2.4.2 Damage

The damage to take into account is a continuous breach in the hull of the ship caused by a combat shot or an event at sea.

The damage is applied anywhere within the ship's length L.

All positions of the damage along the ship are to be considered.

a) Longitudinal damage extension
   1) Ships of length L not greater than 91,5 m

      The extension of the damage causes the flooding of two adjacent watertight compartments (see Ch 1, Sec 2, [6.7] and Fig 1)
   2) Ships of length L greater than 91,5 m

      They are divided into two categories:
      - Category I

        Major warships, excluding corvettes, auxiliary ships or ships employed for carriage of important operational equipment. The longitudinal extension to be taken into account for such a category is 15% of L at each point of L. Nevertheless, if the general specification states it, such a length may be reduced to an extension interesting three adjacent compartments (see Ch 1, Sec 2, [6.7] and Fig 1)
      - Category II

        Ships supplied with a basin or a hangar of remarkable dimensions and all the ships which are not included in category I. The longitudinal extension of the damage to be taken into account is equivalent to the extension of two adjacent compartments (see Fig 1).

b) Vertical damage extension

   The vertical extension of the damage is to be such that all the deck closures and platforms within the damaged area are destroyed (see Fig 2).

c) Transversal damage extension

The transversal extension of the damage may reach the centre line of the ship without nevertheless including it (see Fig 3).

If any damage of lesser, above indicate, would result in a more severe condition regarding the compliance with the following damage stability criteria, such damage is to be assumed in the calculations.

Figure 1 : Standard damage case - Longitudinal extension (example of damage on the shell and extension of flooding)

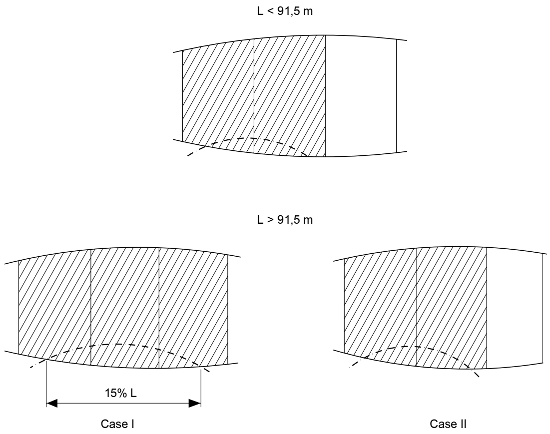


Figure 2 : Standard damage case - Vertical extension (example of vertical penetration and flooding extension)

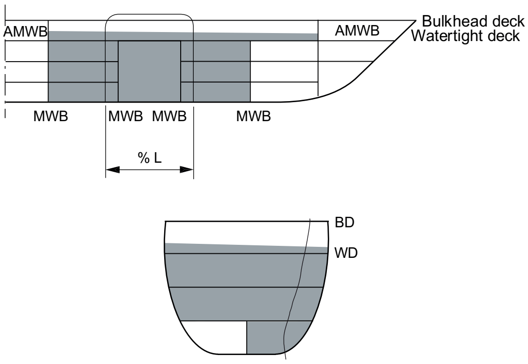

Figure 3 : Standard damage case - Transversal extension (example of transversal penetration and flooding extension)

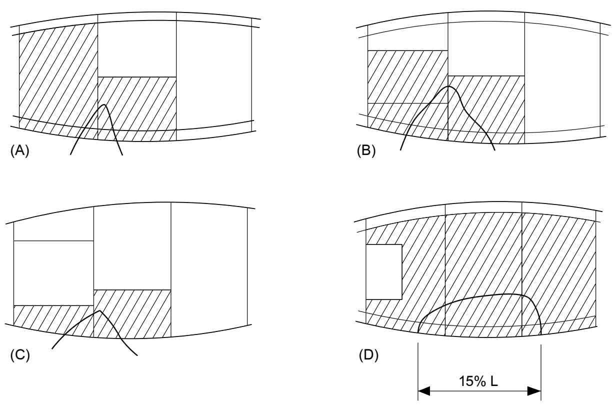


(A) and (B): Flooding of two compartments where the longitudinal bulkhead remains undamaged

(C) : Flooding of two compartments where the longitudinal lateral bulkheads remain watertight and may generate a stability condition more unfavourable caused by the heeling

(D) : Other case of flooding.

Table 1 : Values of permeability

Spaces	Permeability
Diesel engine and auxiliaries	0,85
Steam engines	0,90
Boilers	0,80
Pumps, steering gears and stabilisators	0,90
Mooring chains storage	0,65
Technical activities	0,95
Stores and refrigerated goods	0,80**(1)**
Intended for liquids	0 or 0,98**(2)**
Accommodation and military operational areas	0,95
Ammunition storage	0,80**(1)**
Void compartments	0,97

(1) when partially loaded: 0,95 (see Ch 1, Sec 2, [5.3]).
(2) whichever results in the more severe requirements.

2.4.3 Permeability

For the damage stability calculations, the volume and surface permeabilities are to be in general as reported in Tab 1. Other values can be accepted when duly justified.

The permeability for cargo spaces intended for the stowage of land vehicles, barges, helicopters and containers is to be derived by calculation in which the land vehicles, barges, helicopters and containers are to be assumed as non-watertight and their permeability equal to 0,65.

In no case is the permeability of cargo spaces in which the goods, vehicles and containers are carried to be taken less than 0,60.

2.4.4 Free surface effects

For partially filled tanks, a free surface effect is to be considered as defined in Ch 3, Sec 2, [2.2.3].

2.4.5 Run-off weights after damage

When a tank is involved in a damage, its content runs-off through the consequent breach. Such content is called run-off weight and is to be taken into account in damage stability calculation.

2.4.6 Calculation of closed openings

a) Below the watertight deck

   Access in decks and watertight doors below the watertight deck may be considered open or closed. In such a case, the more unfavourable condition is to be considered in the damage stability analysis.

b) Above the watertight deck (included)

   All the watertight doors (outside the "V" line), when laying out of the damaged area, are to be considered closed.

2.4.7 Cross-flooding and equalisation

a) Cross-flooding

   The cross-flooding to be taken into account in the damage stability calculations may be accepted under the following conditions:

   1) self acting cross-connection
   2) the system is independent without any power supply
   3) the flooding is to be completed in the time:
      - for $D < 4500t$: time < 2 min
      - for $4500t < D < 10000t$: time $< 0,1(D/1000)^2$ min
      - for $D > 10000t$: time < 10 min

      where:

      D : Full load displacement.

   Suitable information concerning the use of cross-flooding fittings is to be supplied to the Captain of the ship.

   For cross-flooding verification, see Ch 3, App 3.

b) Passive equalisation

Passive equalisation complements the effect of cross-flooding, but uses controls means which are manually operated from above the damage control deck (opening of valves). The controls are to be operable with a maximum heel angle of 20°. The equalisation system is to be independent without any power supply. The time needed for passive equalisation may not exceed 15 min.

c) Active equalisation

After the passive equalisation of the ship, all active equalisation measures including mechanically driven ones (like transfer of content of fuel tanks) may be used, if not explicitly prohibited by the stability manual, in order to right itself the ship.

2.4.8 Residual stability after damage

The residual stability of the ship at the end of flooding is calculated taking the following into account:

- characteristics of the righting arms curves for all the damage cases
- relating such curves with the heeling arms curves caused by the wind athwartship.

a) Righting arms curve

1) Characteristics of righting arms curve

Such a curve is to comply with the following requirements:

- it is to be carried out by the loss of buoyancy method. Such a method, recognised by IMO (International Maritime Organisation), studies the damage maintaining constant the displacement of the ship (the flooded volume does not take part in buoyancy of the ship)
- the calculation of the righting arms at several angles is to be performed at equilibrium of longitudinal moment (changeable trim), corrected for free surface effects
- the hull is limited to the bulkhead deck
- the righting arms curves are extending to the smallest of the following angles:
  - θ_s (capsizing angle)
  - θ_f (angle at which the first opening results submerged)
  - 45°

2) Stability criteria required

- Before the passive equalisation of the ship, if present:
  - survival condition

    Provided that particular requirements are present in the contract or in the specification, the ship at the end of flooding is to reach an equilibrium heeling angle not more than 20°:

    $\theta_e < 20°$
  - initial metacentric height

    The initial metacentric height value at a null angle is to be calculated.

  Particular considerations are necessary if, in such a case, such a value results negative or too small. Surely the value of the initial metacentric height at null angle points out the possibility of a lolling. In such a case the passive equalisation by movement of weights onboard may result dangerous. The analysis is to take into account actions (change of trim, lowering of centre of gravity, etc.) which allow the reaching of a positive value of the initial metacentric height, and therefore to avoid the lolling.
- After the passive equalisation of the ship, if present, or at the end of flooding, in any case:
  - survival condition

    Provided that particular requirements are present in the contract or in the specification, the ship at the end of flooding is to reach an equilibrium heeling angle not more than 15°:

    $\theta_e < 15°$
  - initial metacentric height

    The initial metacentric height value at a null angle is to be positive:

    $GM_{corr} > 0$
  - waterline after damage (margin line)

    At the end of flooding and passive equalisation, the trim and equilibrium angle is to be such that the requirements as defined in Ch 1, Sec 2, [3.2.1] are complied with.
  - stability reserve (see Fig 4)

    The area A_1, representative of the righting energy, is to be higher than the value calculated from Tab 2. It represents the results of a statistic research among several ships, and gives the amount of minimum righting energy such that face the heeling energy caused by a moderate sea.

    $A_1 > RSA$

b) Comparison between the righting arms and heeling arms curves for severe wind and rolling

1) Method to evaluate the stability

The method is the same as defined in Ch 3, Sec 2, [2.3]. Nevertheless, the values of rolling and speed of wind to be taken into account are those presented in Tab 3 and Tab 4.

2) Stability requirements

- Before the equalisation of the ship, at the end of flooding, for the contemporary action of severe wind and rolling as reported in item 1), the ship is to maintain positive initial metacentric height, i.e. she is never to capsize. The maximum value of the righting arm reduced by the value of the heeling arm at the same angle is to be positive:

  $GZ\ Max - GZ_{Heel} > 0$

- After the equalisation of the ship, if present, or at the end of flooding in any case:
  - the ship is to have a stability reserve such to make possible her return in the harbour. To this purpose the value of the maximum righting arm reduced by the value of the heeling arm at the same angle is to be not less than 0,08 m:

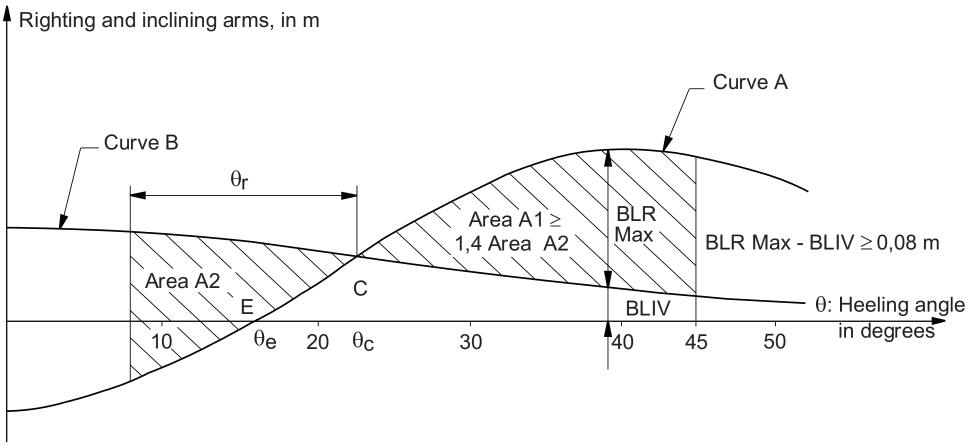
    $GZ\ Max - GZ_{Heel} > 0{,}08$
  - the value of the area A_1 is to be not less than area A_2 increased by 40%:

    $A_1 > 1{,}4\ A_2$

    See Fig 4.

  The area A_2 is limited to the value of rolling angle θ_r determined from Tab 4.

Figure 4 : Righting arms curve and heeling arms caused by severe wind and rolling



Curve A : Righting arms curve at the end of the flooding

Curve B : Heeling arms curve caused by severe wind and rolling.

Table 2 : Values of the areas representative of the stability reserve required at the end of the flooding (as a function of the displacement)

Section 4 Sea-Keeping

1 General

1.1 Introduction

1.1.1 Ship operability

The operability of a military ship is directly linked to the task performance of the crew, the operability of the weapons systems and equipment and the ability of the ship to transit as required. The task performance of the crew is influenced by seasickness, fatigue and motion induced interruptions, whereas ship motions and accelerations limit the operability of weapons systems and equipment.

1.1.2 Operation limits

The operation limits depend on the specific operation the ship is to perform. For transit operations, the operation limits ensure that ship motions and accelerations do not adversely affect the ship structure, systems and equipment needed for the mission nor the task performance of the crew.

Operation limits for the hull are set to prevent structural damage caused by slamming or wetness (water on deck), and to prevent degradation of the ship operability due to propeller emergence.

1.1.3 Verification approach

It is a basic requirement that sea-keeping assessment is performed in order to verify the ability of the ship to transit as required during transit operations. This verification is treated in the current section.

Verification of a vessel’s sea-keeping characteristics with respect to operational limits for other specific operations, such as flight and replenishment at sea operations, is covered by additional class notations and, as such, subject to the requirements in Pt E, Ch 9, Sec 3.

1.1.4 Transit operations (TRAN)

The TRAN mission models the situation where the ship is sailing from one place to another, with the crew performing routine shipboard activities for transit and patrol. In terms of a vessel’s sea-keeping characteristics, this mission depends upon the ship's ability to transit as required across the seas.

Survivability in extreme seas is therefore a special subset of the TRAN mission. Two aspects of survivability are of major importance: the ultimate stability and the ultimate strength. As such, it is necessary to determine and take into account extreme values for wave induced bending moments.

By default, the wave induced bending moments are to be taken as described in Ch 5, Sec 2, [3]. As an alternative, the designer may perform direct computations in order to derive design values that may be used instead. In such a case, the principles and criteria to be adopted in a long term sea-keeping assessment used to derive these values are provided in Ch 3, App 6. The applicability of results of long term sea-keeping assessments as an alternative to the requirements in Ch 5, Sec 2, [3] are to be approved by the Society on a case-by-case basis.

Other requirements for the hull and equipment in the context of the TRAN mission are given in Article [2].

1.2 Assessment procedure

1.2.1 Parameters

The methods for calculating the parameters to be considered for the sea-keeping assessment are defined in Article [2].

1.2.2 Evaluation

The values of the ship sea-keeping parameters are to be assessed by means of computer calculations and/or small-scale model tests in a model basin.

The computer calculations are to be performed as described in Ch 3, App 6, and the following documentation is to be provided:

- justification of the validity of the used software
- parameters to be calculated
- computation input data
- computation results
- model test results that verify and/or replace calculated results.

Concerning model tests, the following documentation is to be provided:

- parameters to be measured
- detailed test program
- analysis procedure of measured data
- sea- and ship loading-condition during the tests
- test results and their analysis.

1.3 Environmental conditions

1.3.1 Sea state

Sea state is an expression used to categorise wave conditions and normally a sea state comprises a significant wave height Hs and a wave period.

Unless otherwise specified, the environmental conditions to be considered for sea-keeping analyses are to be taken from NATO STANAG 4154 Ed. 4.

Whenever computer calculations or model scale tests are used, i.e. when the environmental conditions are selectable, the sea states used for the verification of the criteria in [2.3] are to be defined as described in [1.3.2] and [1.3.3].

The limiting sea state defines the sea state up to and including which the sea-keeping criteria can be satisfied for the TRAN mission.

1.3.2 Wave height

Generally, the references to the wave height are to be taken as the significant wave height Hs, i.e. the average of the 1/3 largest wave heights in a sea state.

The description of sea states shown in Ch 3, App 6, Tab 2 defines the significant wave height as ranges, not absolute values. For this reason, sea states are to be referred to not only by their number, but also whether it is a low, mid or high sea state. For example, for the sea states defined as per STANAG 4154, a low sea state 6 has Hs = 4,0 m, mid sea state 6 has Hs = 5,0 m and high sea state 6 has Hs = 6,0 m.

The wave height to be considered for the verifications is to be the largest significant wave height relative to the specified sea state; for example, if a mid sea state 6 is specified, Hs is to be taken as 5,0 m, but if only sea state 6 is specified, Hs is to be taken equal to 6,0 m.

1.3.3 Wave period

Generally, references to the wave period are to be taken as the modal wave period, as per STANAG 4154.

For the TRAN mission, at least three periods are to be considered, the values of which are to be taken from STANAG 4154. For other cases, one period value will, in general, be sufficient.

1.4 Requirements to be complied with

1.4.1 The requirements of Article [2] are equivalent to the requirements in NATO STANAG 4154 Ed.4

2 Hull

2.1 General

2.1.1 Scope

The sea-keeping performance is to be evaluated in order to ensure that the ship motions do not become so severe that slamming, water on deck and propeller emergences can damage the hull structure or equipment, and verify that they do not prevent the ship from transiting in weather conditions where the ship is expected to carry out its mission.

2.1.2 Requirements

It is to be ensured that the ship is able to perform the TRAN mission by verifying that the parameters evaluated do not exceed the criteria defined in [2.3].

Unless otherwise specified, the parameters evaluated are to comply with the criteria for a limiting sea state not less than mid sea state 5 as defined in STANAG 4154.

2.2 Parameters

2.2.1 Wetness index

The wetness index is defined as the number of occurrences of water on deck in an hour. This index is to be based on the variance ($m_{0,M}$) of the relative vertical motion at the bow combined with the distance between the deepest subdivision load line and the weather deck at the same location:

$WI = N_Z \, F(D_F)$

where:

$$F(D_F) = \exp\left(-\left(\frac{D_F}{\sqrt{2m_{0,M}}}\right)^2\right)$$

$$N_Z = \frac{3600}{2\pi}\sqrt{\frac{m_{2,M}}{m_{0,M}}}$$

$m_{0,M}$: Zero order spectral moment of relative vertical motion response

$m_{2,M}$: Second order spectral moment of relative vertical motion response.

2.2.2 Slamming index

The slamming index is defined as the number of times in an hour a keel emergence is followed by a re-entry in water that exceeds a certain threshold velocity:

$SI = N_Z\ F(V_{TH})\ F(T_{SL})$

where:

$F(V_{TH})$: Probability of exceeding the threshold velocity:

$$F(V_{TH}) = \exp\left(-\left(\frac{V_{TH}}{\sqrt{2m_{0,V}}}\right)^2\right)$$

$F(T_{SL})$: Probability of keel emergence:

$$F(T_{SL}) = \exp\left(-\left(\frac{T_{SL}}{\sqrt{2m_{0,M}}}\right)^2\right)$$

$$N_Z = \frac{3600}{2\pi}\sqrt{\frac{m_{2,M}}{m_{0,M}}}$$

$m_{0,V}$: Zero order spectral moment of relative vertical velocity response

$m_{0,M}$: Zero order spectral moment of relative vertical motion response

$m_{2,M}$: Second order spectral moment of relative vertical motion response.

The location of the slamming assessment is to be at the keel at 3/20 L behind the fore perpendicular.

The vertical threshold velocity is based on the ship length, and defined, in m/s, as:

$$V_{TH} = 3,66\sqrt{\frac{L}{158,5}}$$

2.2.3 Propeller emergence

Propeller emergence is defined as the number of times the highest quarter part of the propeller diameter (D_{PROP}) emerges from the sea surface in an hour. This index is to be based on the variance ($m_{0,M}$) of the relative vertical motion at the propeller location combined with the distance from the propeller axis to the calm water sea surface (Z_{PROP}).

According to the above definitions and the dimensions shown in Fig 1, propeller emergence occurs when the relative motion exceeds Z_{PE} defined as:

$$Z_{PE} = Z_{PROP} - \frac{1}{4}D_{PROP}$$

The number of propeller emergences in an hour can now be determined as:

$PE = N_Z\ F(Z_{PE})$

where:

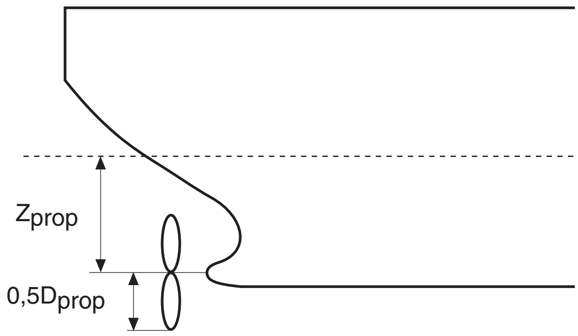
$$F(Z_{PE}) = \exp\left(-\left(\frac{Z_{PE}}{\sqrt{2m_{0,M}}}\right)^2\right)$$

$$N_Z = \frac{3600}{2\pi}\sqrt{\frac{m_{2,M}}{m_{0,M}}}$$

$m_{0,M}$: Zero order spectral moment of relative vertical motion response

$m_{2,M}$: Second order spectral moment of relative vertical motion response.

Figure 1 : Dimensions for calculation of relative motion Z_{PE}



2.3 Criteria

2.3.1 The criteria that ensure that wetness, slamming and propeller emergence events do not become excessive are given in Tab 1 for all monohull ships.

Ships with sponsons are also to comply with the additional criteria given in Tab 2.

Table 1 : Hull criteria limits

MONOHULL		
Parameter	Limit	Location
Wetness index (WI)	30/hr	Forward perpendicular
Slamming index (SI)	20/hr	Keel, 3/20 L aft of FP
Propeller emergence (PE)	90/hr	1/4 propeller diameter above shaft center / Top of water jet inlet

Table 2 : Additional hull criteria limits for ships with sponsons

Parameter	Limit	Location
Slamming index (SI)	20/hr	Sponson

Appendix 1 Inclining Test and Lightweight Check

1 Inclining test and lightweight check

1.1 General

1.1.1 General conditions of the ship

Prior to the test, the Society's Surveyor is to be satisfied of the following:

- the weather conditions are to be favourable
- the ship is to be moored in a quiet, sheltered area free from extraneous forces, such as to allow unrestricted heeling. The ship is to be positioned in order to minimise the effects of possible wind, stream and tide
- the ship is to be transversely upright and the trim is to be taken not more than 1% of the length between perpendiculars. Otherwise, hydrostatic data and sounding tables are to be available for the actual trim
- cranes, derrick, lifeboats and liferafts capable of inducing oscillations are to be secured
- main and auxiliary boilers, pipes and any other system containing liquids are to be filled
- the bilge and the decks are to be thoroughly dried
- preferably, all tanks are to be empty and clean, or completely full. The number of tanks containing liquids is to be reduced to a minimum taking into account the above-mentioned trim. In particular the filling of slack tanks is to be less than 80% to avoid any influence of structural elements. The shape of the tank is to be such that the free surface effect can be accurately determined and remain almost constant during the test. All cross connections are to be closed
- the weights necessary for the inclination are to be already on board, located in the correct place
- all work on board is to be suspended and crew or personnel not directly involved in the inclining test is to leave the ship
- the ship is to be as complete as possible at the time of the test. The number of weights to be removed, added or shifted is to be limited to a minimum. Temporary material, tool boxes, staging, sand, debris, etc., on board is to be reduced to an absolute minimum.

1.1.2 Inclining weights

The total weight used is preferably to be sufficient to provide a minimum inclination of one degree and a maximum of four degrees of heel to each side. The Society may, however, accept a smaller inclination angle for large ships provided that the requirement on pendulum deflection or U-tube difference in height specified in [1.1.4] is complied with. Test weights are to be compact and of such a configuration that the VCG (vertical centre of gravity) of the weights can be accurately determined. Each weight is to be marked with an identification number and its weight. Re-certification of the test weights is to be carried out prior to the incline. A crane of sufficient capacity and reach, or some other means, is to be available during the inclining test to shift weights on the deck in an expeditious and safe manner. Water ballast is generally not acceptable as inclining weight.

1.1.3 Water ballast as inclining weight

Where the use of solid weights to produce the inclining moment is demonstrated to be impracticable, the movement of ballast water may be permitted as an alternative method. This acceptance would be granted for a specific test only, and approval of the test procedure by the Society is required. As a minimal prerequisite for acceptability, the following conditions are to be required:

- inclining tanks are to be wall-sided and free of large stringers or other internal members that create air pockets
- tanks are to be directly opposite to maintain ship's trim
- specific gravity of ballast water is to be measured and recorded
- pipelines to inclining tanks are to be full. If the ship's piping layout is unsuitable for internal transfer, portable pumps and pipes/hoses may be used
- blanks must be inserted in transverse manifolds to prevent the possibility of liquids being "leaked" during transfer. Continuous valve control is to be maintained during the test
- all inclining tanks are to be manually sounded before and after each shift
- vertical, longitudinal and transverse centres are to be calculated for each movement
- accurate sounding/ullage tables are to be provided. The ship's initial heel angle is to be established prior to the incline in order to produce accurate values for volumes and transverse and vertical centres of gravity for the inclining tanks at every angle of heel. The draught marks amidships (port and starboard) are to be used when establishing the initial heel angle
- verification of the quantity shifted may be achieved by a flowmeter or similar device
- the time to conduct the inclining is to be evaluated. If time requirements for transfer of liquids are considered too long, water may be unacceptable because of the possibility of wind shifts over long periods of time.

1.1.4 Pendulums

The use of three pendulums is recommended but a minimum of two are to be used to allow identification of bad readings at any one pendulum station. However, for ships of a length equal to or less than 30 m, only one pendulum can be accepted. They are each to be located in an area protected from the wind. The pendulums are to be long enough to give a measured deflection, to each side of upright, of at least 10 cm. To ensure recordings from individual instruments are kept separate, it is suggested that the pendulums be physically located as far apart as practical.

The use of an inclinometer or U-tube is to be considered in each separate case. It is recommended that inclinometers or other measuring devices only be used in conjunction with at least one pendulum.

1.1.5 Means of communications

Efficient two-way communications are to be provided between central control and the weight handlers, and between central control and each pendulum station. One person at a central control station is to have complete control over all personnel involved in the test. The internal means of communication inside the ship may be used for this purpose.

1.1.6 Documentation

The person in charge of the inclining test is to have available a copy of the following plans at the time of the test:

- hydrostatic curves or hydrostatic data
- general arrangement plan of decks, holds, inner bottoms, etc
- capacity plan showing capacities and vertical and longitudinal centres of gravity of cargo spaces, tanks, etc. When water ballast is used as inclining weights, the transverse and vertical centres of gravity for the applicable tanks, for each angle of inclination, are to be available
- tank sounding tables
- draught mark locations
- docking drawing with keel profile and draught mark corrections (if available).

1.1.7 Determination of the displacement

The Society's Surveyor is to carry out all the operations necessary for the accurate evaluation of the displacement of the ship at the time of the inclining test, as listed below:

- draught mark readings are to be taken at aft, midship and forward, at starboard and port sides
- the mean draught (average of port and starboard readings) is to be calculated for each of the locations where draught readings are taken and plotted on the ship's lines drawing or outboard profile to ensure that all readings are consistent and together define the correct waterline. The resulting plot is to yield either a straight line or a waterline which is either hogged or sagged. If inconsistent readings are obtained, the freeboards/ draughts are to be retaken
- the specific gravity of the sea water is to be determined. Samples are to be taken from a sufficient depth of the water to ensure a true representation of the sea water and not merely surface water, which could contain fresh water from run off of rain. A hydrometer is to be placed in a water sample and the specific gravity read and recorded. For large ships, it is recommended that samples of the sea water be taken forward, midship and aft, and the readings averaged. For small ships, one sample taken from midship is sufficient. The temperature of the water is to be taken and the measured specific gravity corrected for deviation from the standard, if necessary. A correction to water specific gravity is not necessary if the specific gravity is determined at the inclining experiment site. Correction is necessary if specific gravity is measured when the sample temperature differs from the temperature at the time of the inclining (e.g., if the check of specific gravity is performed at the office). Where the value of the average calculated specific gravity is different from that reported in the hydrostatic curves, adequate corrections are to be made to the displacement curve
- all double bottoms, as well as all tanks and compartments which can contain liquids, are to be checked, paying particular attention to air pockets which may accumulate due to the ship's trim and the position of air pipes, and also taking into account the provisions of [1.1.1]
- it is to be checked that the bilge is dry, and an evaluation of the liquids which cannot be pumped, remaining in the pipes, boilers, condenser, etc., is to be carried out
- the entire ship is to be surveyed in order to identify all items which need to be added, removed or shifted to bring the ship to the lightship condition. Each item is to be clearly identified by its weight and the location of its centre of gravity
- the possible solid permanent ballast is to be clearly identified and listed in the report.

1.1.8 The incline

The standard test generally employs eight distinct weight movements as shown in Fig 1.

The weights are to be transversely shifted, so as not to modify the ship's trim and the vertical position of the centre of gravity.

After each weight shifting, the new position of the transverse centre of gravity of the weights is to be accurately determined.

After each weight movement, the distance the weight was moved (centre to centre) is to be measured and the heeling moment calculated, multiplying the distance by the amount of weight moved. The tangent is calculated for each pendulum, dividing the deflection by the length of the pendulum. The resultant tangents are plotted on the graph as shown in Fig 2.

The pendulum deflection is to be read when the ship has reached a final position after each weight shifting.

During the reading, no movement of personnel is allowed.

For ships with a length equal to or less than 30 m, six distinct weight movements may be accepted.

Figure 1 : Weight shift procedure

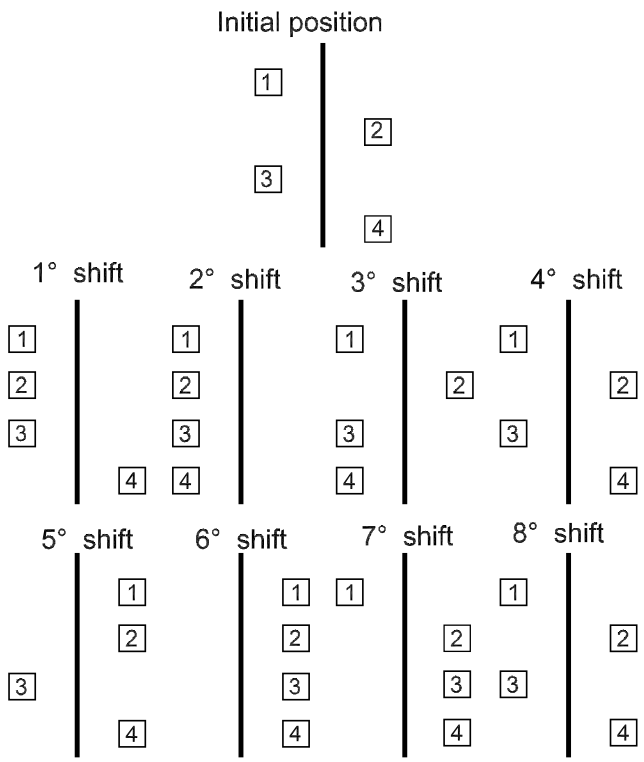


Figure 2 : Graph of resultant tangents

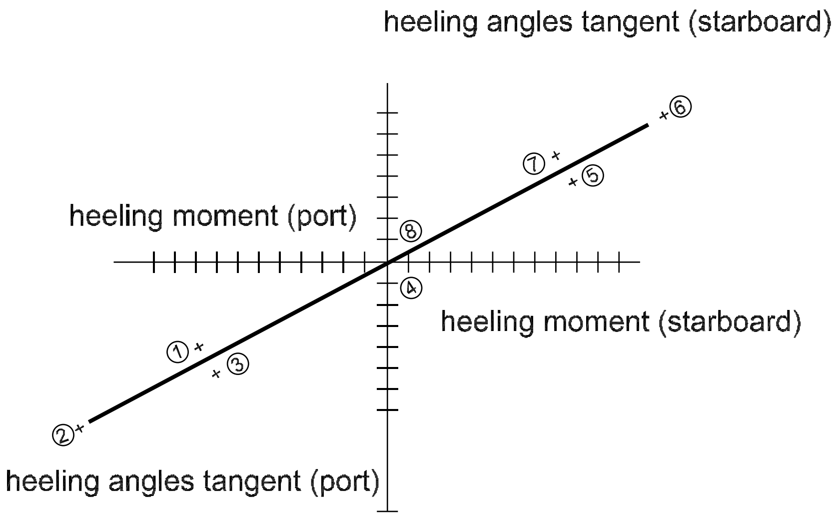


Appendix 2 Trim and Stability Booklet

1 Trim and stability booklet

1.1 Information to be included in the trim and stability booklet

1.1.1 General

A trim and stability booklet is a stability manual, to be approved by the Society, which is to contain sufficient information to enable the Captain to operate the ship in compliance with the applicable requirements contained in the Rules.

The format of the stability booklet and the information included vary depending on the ship type and operation.

1.1.2 List of information

The following information is to be included in the trim and stability booklet:

- a general description of the ship, including:
  - the ship's name and the Society classification number
  - the ship type and service notation
  - the class notations
  - the yard, the hull number and the year of delivery
  - the moulded dimensions
  - the draught corresponding to the minimum operational loaded ship (defined in Ch 1, Sec 2, [5.4]), the draught corresponding to the assigned full loaded ship (defined in Ch 1, Sec 2, [5.2])
  - the displacement corresponding to the above-mentioned draughts
- clear instructions on the use of the booklet
- general arrangement and capacity plans indicating the assigned use of compartments and spaces (cargo, stores, accommodation, etc.)
- a sketch indicating the position of the draught marks referred to the ship's perpendiculars
- hydrostatic curves or tables corresponding to the design trim, and, if significant trim angles are foreseen during the normal operation of the ship, curves or tables corresponding to such range of trim are to be introduced. A clear reference relevant to the sea density, in t/m^3, is to be included as well as the draught measure (from keel or underkeel)
- cross curves (or tables) of stability calculated on a free trimming basis, for the ranges of displacement and trim anticipated in normal operating conditions, with indication of the volumes which have been considered in the computation of these curves
- tank sounding tables or curves showing capacities, centres of gravity, and free surface data for each tank
- lightship data from the inclining test, as indicated in Ch 3, Sec 1, [3.2], including lightship displacement, centre of gravity co-ordinates, place and date of the inclining test, as well as the Society approval details specified in the inclining test report. It is suggested that a copy of the approved test report be included.

  Where the above-mentioned information is derived from a sister ship, the reference to this sister ship is to be clearly indicated, and a copy of the approved inclining test report relevant to this sister ship is to be included
- standard loading conditions and examples for developing other acceptable loading conditions using the information contained in the booklet
- intact stability results (total displacement and its centre of gravity co-ordinates, draughts at perpendiculars, GM, GM corrected for free surfaces effect, GZ values and curve, criteria as indicated in Ch 3, Sec 2 as well as possible additional criteria specified in Part D when applicable, reporting a comparison between the actual and the required values) are to be available for each of the above-mentioned operating conditions. The method and assumptions to be followed in the stability curve calculation are specified in [1.2]
- damage stability results (total displacement and its maximum permissible centre of gravity height, draughts at perpendiculars, GM, GM corrected for free surfaces effect, GZ values and curve, criteria as indicated in Ch 3, Sec 3 as well as possible additional criteria specified in Part D when applicable, reporting a comparison between the actual and the required values)

are to be available for each of the above-mentioned operating conditions. The method and assumptions to be followed in the stability curve calculation are specified in [1.2]

- information on loading restrictions (maximum allowable load on double bottom, maximum KG or minimum GM curve or table which can be used to determine compliance with the applicable intact and damage stability criteria) when applicable
- information about openings (location, tightness, means of closure), pipes or other progressive flooding sources. the opening used for the calculation of the down flooding angle has to be clearly identified
- information concerning the use of any special cross-flooding fittings with descriptions of damage conditions which may require cross-flooding, when applicable
- any other necessary guidance for the safe operation of the ship
- a table of contents and index for each booklet.

1.2 Stability curve calculation

1.2.1 General

Hydrostatic and stability curves are normally prepared on a designed trim basis. However, where the operating trim or the form and arrangement of the ship are such that change in trim has an appreciable effect on righting arms, such change in trim is to be taken into account.

1.2.2 Superstructures, deckhouses, etc. which may be taken into account

Enclosed superstructures complying with Ch 1, Sec 2 may be taken into account.

The second tier of similarly enclosed superstructures may also be taken into account.

Deckhouses on the main deck may be taken into account, provided that they comply with the conditions for enclosed superstructures laid down in Ch 1, Sec 2.

Where deckhouses comply with the above conditions, except that no additional exit is provided to a deck above, such deckhouses are not to be taken into account; however, any deck openings inside such deckhouses are to be considered as closed even where no means of closure are provided.

Deckhouses, the doors of which do not comply with the requirements of Ch 8, Sec 4, [1.5.4], are not to be taken into account; however, any deck openings inside the deckhouse are regarded as closed where their means of closure comply with the requirements of Ch 8, Sec 7, [8.3] or Ch 8, Sec 7, [9.2], as relevant.

Deckhouses on decks above the main deck are not to be taken into account, but openings within them may be regarded as closed.

Superstructures and deckhouses not regarded as enclosed may, however, be taken into account in stability calculations up to the angle at which their openings are flooded (at this angle, the static stability curve is to show one or more steps, and in subsequent computations the flooded spaces are to be considered non-existent).

Trunks may be taken into account. Hatchways may also be taken into account having regard to the effectiveness of their closures.

1.2.3 Angle of flooding

In cases where the ship would sink due to flooding through any openings, the stability curve is to be cut short at the corresponding angle of flooding and the ship is to be considered to have entirely lost its stability.

Small openings such as those for passing wires or chains, tackle and anchors, and also holes of scuppers, discharge and sanitary pipes are not to be considered as open if they submerge at an angle of inclination more than 30°. If they submerge at an angle of 30° or less, these openings are to be assumed open if the Society considers this to be a source of significant progressive flooding; therefore such openings are to be considered on a case by case basis.

Appendix 3 Calculation Method for Cross-Flooding Arrangements

1 Calculation method for cross-flooding arrangements

1.1 Cross-flooding area

1.1.1 Cross-flooding area calculation

The cross-flooding area S, in m^2, can be calculated from the following formula:

$$S = \frac{2W}{tF(\sqrt{2gH_o} + \sqrt{2gH_F})}$$

where:

W : Volume, in m^3, of water entering the equalising compartments during the period considered

t : Time, in s, necessary to complete the equalisation

F : Factor, to be taken equal to:

$$F = \frac{1}{\sqrt{1 + \sum k}}$$

In general, a value of F equal to 0,65 may be used. Anyway, for particular shape of pipes, appropriate values of k are to be used in the above formula

k : Dimensionless factor of reduction of speed through the duct, being a function of bends, valves, etc., in the cross-flooding system, to be obtained from [1.1.2], as the case may be

g : Gravity acceleration, in m/s^2:

$g = 9{,}81\ m/s^2$

H_o : Initial head of water, in m

H_F : Final head of water after cross-flooding, in m.

1.1.2 Factor of reduction k

The factor of reduction is to be calculated depending on the following cases:

- Case 1: 90° circular bend
- Case 2: Radius bend R/D = 2
- Case 3: Mitre bend
- Case 4: 90° double mitre bend
- Case 5: Pipe inlet
- Case 6: Pipe outlet
- Case 7: Non-return valve
- Case 8: Pipe friction losses
- Case 9: Gate valve
- Case 10: Butterfly valve
- Case 11: Disc valve.

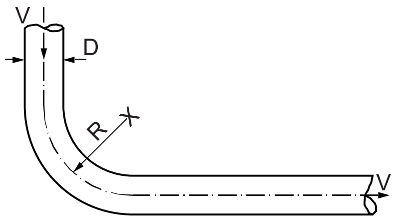
Case 1: 90° CIRCULAR BEND (see Fig 1)

The factor k is defined in Tab 1.

Table 1 : Values of factor k

R/D	2	3	4	5	6	7
k	0,30	0,26	0,23	0,20	0,18	0,17

Figure 1 : 90° circular bend



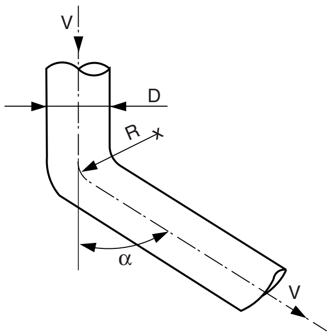
Case 2: RADIUS BEND R/D = 2 (see Fig 2)

The factor k is defined in Tab 2.

Table 2 : Values of factor k

α°	15	30	45	60	75	90
k	0,06	0,12	0,18	0,24	0,27	0,30

Figure 2 : Radius bend R/D = 2



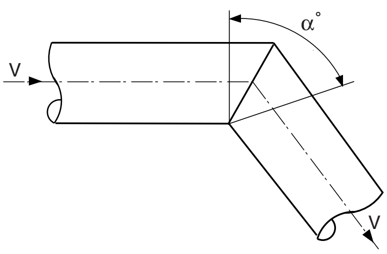
Case 3: MITRE BEND (see Fig 3)

The factor k is defined in Tab 3.

Table 3 : Values of factor k

α°	5	15	30	45	60	90
k	0,02	0,06	0,17	0,32	0,68	1,26

Figure 3 : Mitre bend



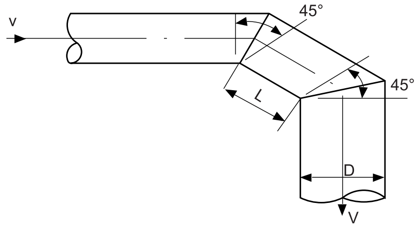
Case 4: 90° DOUBLE MITRE BEND (see Fig 4)

The factor k is defined in Tab 4.

Table 4 : Values of factor k

L/D	1	2	3	4	5	6
k	0,41	0,40	0,43	0,46	0,46	0,44

Figure 4 : 90° double mitre bend



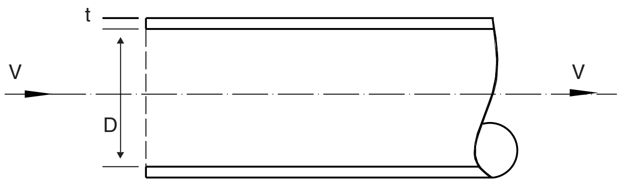
Case 5: PIPE INLET (see Fig 5)

The factor k is defined in Tab 5.

Table 5 : Values of factor k

t/D	0,01	0,02	0,03	0,04	0,05	> 0,05
k	0,83	0,68	0,53	0,46	0,44	0,43

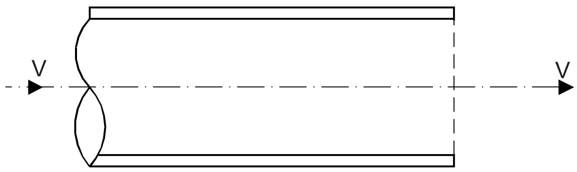
Figure 5 : Pipe inlet



Case 6: PIPE OUTLET (see Fig 6)

k = 1,0

Figure 6 : Pipe outlet

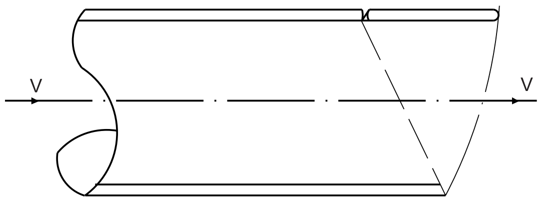


Case 7: NON-RETURN VALVE (see Fig 7)

k = 0,5

The value of k actually increases with decrease in Froude number, particularly below speeds of 2m/sec.

Figure 7 : Non-return valve



Case 8: PIPE FRICTION LOSSES

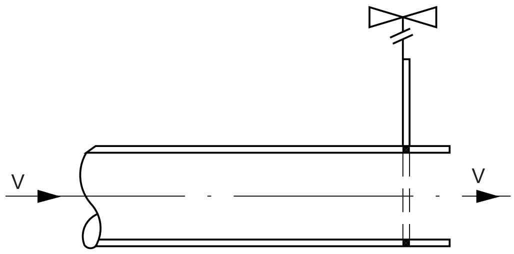
k = 0,02/D per unit length

The coefficient above is a mean value and does in fact vary as Reynold's number (i.e. varies with V for constant D and v) as well as with relative roughness.

Case 9: GATE VALVE (see Fig 8)

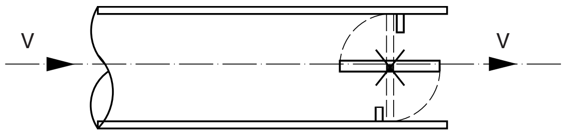
k = 0,3

Figure 8 : Gate valve



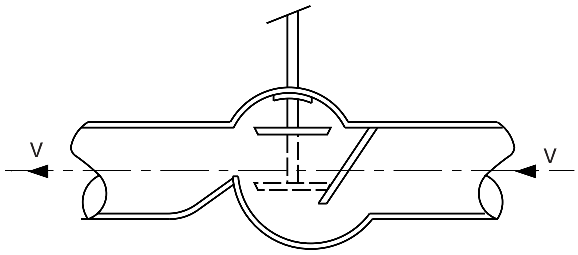
Case 10: BUTTERFLY VALVE (see Fig 9)
k = 0,8

Figure 9 : Butterfly valve



Case 11: DISC VALVE (see Fig 10)
k = 6,0

Figure 10 : Disc valve



1.1.3 Overflows

In general, the area of overflows relevant to the connected compartments is to be not less than S/10, where S is defined in [1.1.1].

Appendix 4 Buoyancy Reserve - "V" Line Method

1 Buoyancy reserve

1.1 Purpose

1.1.1 This method allows to define the zones of flooding interested in damage cases.

The buoyancy check assures that the water couldn't exceed the margin line after the ship reaches the equilibrium at the end of the flooding.

It is necessary to take into account the dynamic effect of the rolling, which may cause a progressive flooding with considerable reduction of the stability characteristics of the ship.

The purpose of the "V" Line calculation is to determine, at the design stage, the areas which may be flooded after damage. If the waterline at the equilibrium after damage cannot be located above the margin line, the dynamic effects, such as rolling of the ship, waves, may cause water to be above the margin line. In this respect, progressive flooding may occur to spaces not previously flooded. Consequently it is necessary to define watertight boundaries in order to keep sufficient buoyancy and stability to the ship.

1.1.2 Method

The longitudinal envelope of the waterlines at the end of each symmetrical flooding for all examined loading conditions is to be taken into account.

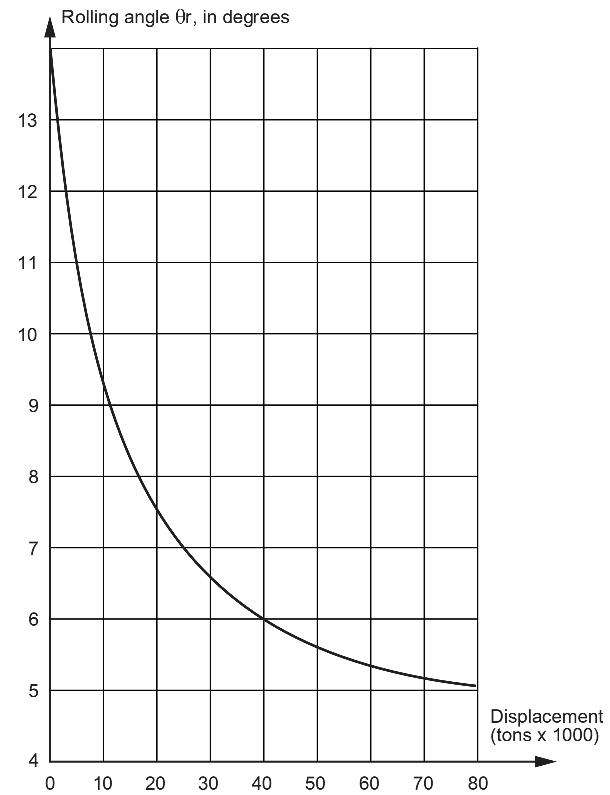
In each transversal section interested by such envelope, proceed as follows (see Fig 2):

a) an heeling angle equal to 15° is to be considered (safety target). This angle may be reduced when obtained from direct damage stability calculations

b) a further rolling angle is applied as shown in Fig 1

c) an elevation of the consequent level of 1,25 m is added to the waterline to consider the movement of the water inside the ship.

Figure 1 : Rolling angles to be taken into account in damage stability calculations, valid also in "V" Line tracing



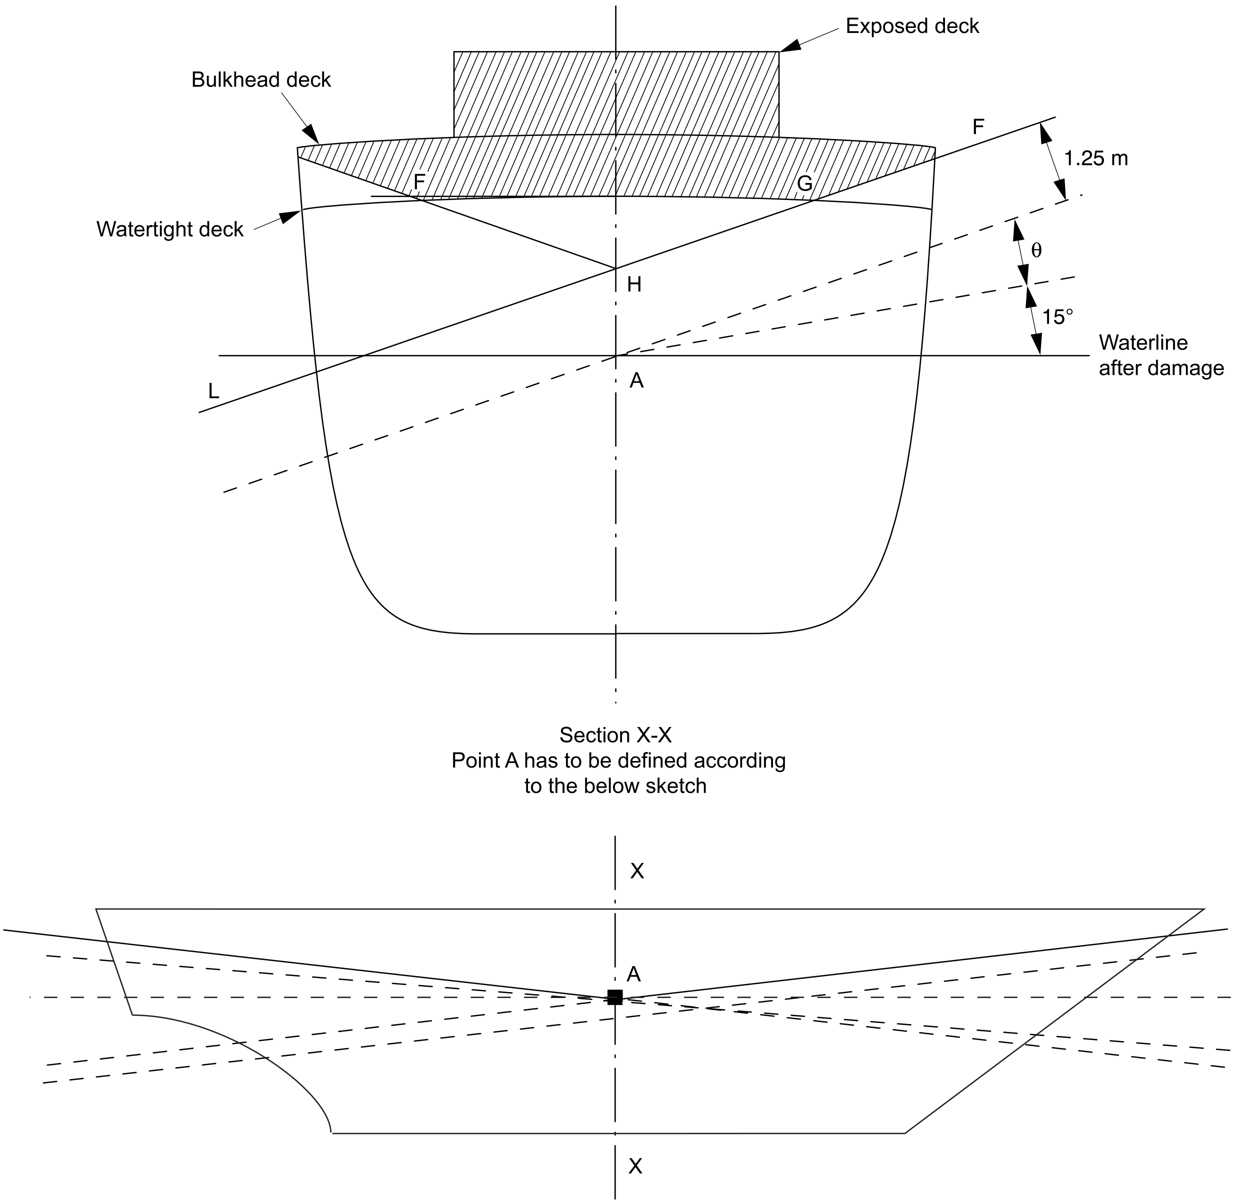
1.1.3 Interpretation of the obtained “V” Line

The “V” Line identifies, in each transversal section, two different zones above the watertight deck:

a) **zone inside “V” Line**, where it is possible to cross the auxiliary transversal bulkheads and the bulkhead deck without particular requirements relevant to the restoring of watertight integrity

b) **zone outside “V” Line**, where each crossing and/or opening is to be provided with a system of watertight closure as described in Ch 2, Sec 3.

Figure 2 : “V” Line example



Appendix 5 Evaluation of the Heeling Moment due to Athwart Wind (Intact Vessel)

1 Evaluation of the heeling moment due to athwart wind (intact vessel)

1.1 Intact stability

1.1.1 The inclining moment, IM, in t·m, caused by the wind is carried out with the following formula:

$$IM = \frac{0,0195 V^2 A h \cos^2 \theta}{1000}$$

where (see Fig 2):

V : Wind speed, in knots

h : Vertical distance, in m, between the windage centre surface and the driftage centre surface which may be considered at middle of draught

A : Area of windage surface, in m², above the waterline

θ : Transverse heeling angle, in degrees.

1.1.2 To obtain the value of the inclining arm, the value obtained from [1.1.1] is to be divided by the displacement of the vessel at the loading condition in question.

1.1.3 To define the heeling moment curve caused by the wind together with the result of the formula in [1.1.1], Fig 1 is to be used. In that Figure, the changing of the wind speed is represented as a function of the height above the waterline for a theoretical speed of 100 knots at 10 m. The value of the wind on the windage area is to be corrected by the ratio with such a curve.

1.1.4 For the purpose of facilitating the task, the values reported in Tab 1 may be used; they give, calculated from the formula in [1.1.1], the values of the inclining moment, taking account of the gradient of the wind speed as a function of the height above the waterline.

Figure 1 : Speed of the wind as a function of the height above the waterline

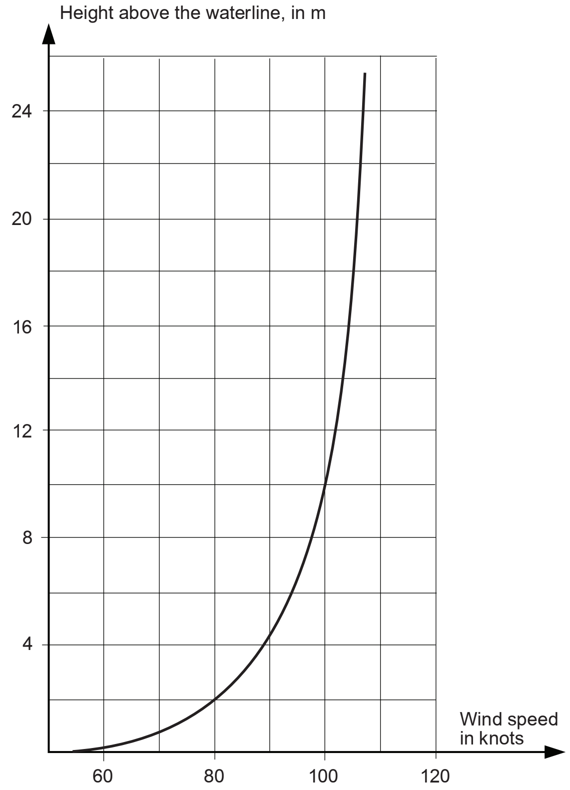


Figure 2 : Example showing the elements used in carrying out the heeling arms caused by the wind

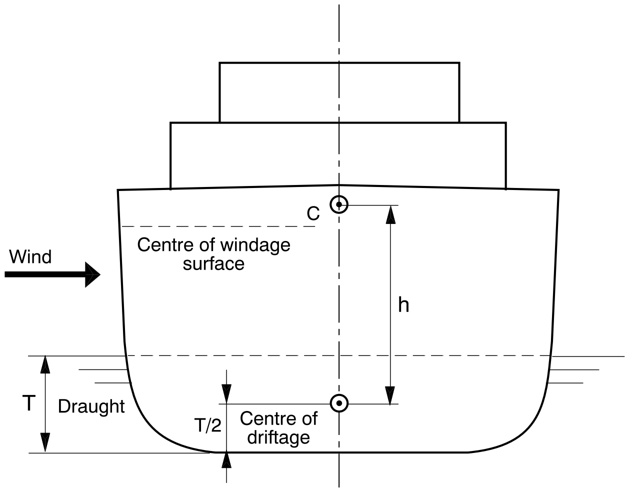

Table 1 : Inclining moment (t·m) per m² for a theoretical wind speed of 100 knots

Height above waterline (in m)	Ship centre of lateral resistance below waterline (in m)

1.1.5 Calculation procedure

a) The windage area is to be divided into strips 2 m in height starting from the considered waterline

b) The surface of each strip is to be calculated, in m^2

c) The vertical position of the centre of driftage area is to be evaluated (corresponding approximately to the half draught) and each strip is to be assigned a moment value as indicated in Tab 1

d) Each surface calculated in item b) is to be multiplied by its assigned moment value obtained in item c)

e) All the moments so obtained are to be added in order to have a moment corresponding to a theoretical wind speed of 100 knots

f) For a wind speed different from 100 knots, the value obtained in item e) is to be multiplied by the following value:

$$\left(\frac{V}{100}\right)^2$$

1.2 Damage stability

1.2.1 The same approach as in [1.1.1] is to be followed, taking account of:

h : Vertical distance, in m, between the windage centre surface and the driftage centre surface (which may be considered at middle of draught) in the final equilibrium after damage.

Appendix 6 Sea-Keeping Calculations

1 Introduction

1.1 General

1.1.1 This Appendix applies to ships with typical hull shape. Ships of unusual type or design are to be considered by the Society on a case by case basis.

The requirements are based on the assumption that a frequency domain strip theory sea-keeping code is being used for the calculations. The software to be used are to be documented and supported by validation documents.

1.2 Scope

1.2.1 The scope of the present Appendix is to supply details on how the sea-keeping calculations are to be performed. Requirements are given primarily on how to perform the short term assessments, but also some recommendations concerning long term assessments are given.

The short term assessments comprise all analyses of the ship behaviour in a single sea state, and thus short term assessments yield all necessary information for the determination of:

- wetness index
- slamming index
- propeller emergence
- Motion Induced Interruption
- RMS values of all ship motions and accelerations.

Long term assessments of the sea-keeping yield estimates of, e.g., the long term distribution of the vertical bending moment.

2 Short term assessment

2.1 General

2.1.1 Short term assessments serve to analyse a ship sea-keeping behaviour in a given sea state. The sea states to be considered for the required rule checks are defined in Ch 3, Sec 4.

2.2 Loading conditions

2.2.1 The sea-keeping verifications should be carried out for following loading conditions:

- auxiliary ships: full load and operational condition
- front and second line ships: operational condition.

2.3 Ship speed

2.3.1 Unless otherwise specified, a discrete set of ship speeds to be agreed with the Society is to be considered for the short term sea-keeping calculations.

2.4 Wave spectrum

2.4.1 General

The wave spectrum to be applied in the short term sea-keeping calculations is based on the characteristics of the sea area where the ship is going to operate:

- open ocean conditions: Bretschneider spectrum with both short and long crested seas
- limited fetch sea areas (e.g. North Sea): JONSWAP spectrum with short crested sea.

2.4.2 Bretschneider spectrum

The Bretschneider spectrum, or two parameter Pierson-Moskowitz spectrum, is defined as:

$$S(\omega) = \frac{H_S^2}{4\pi}\left(\frac{2\pi}{T_Z}\right)^4 \omega^{-5} \exp\left(-\frac{1}{\pi}\left(\frac{2\pi}{T_Z}\right)^4 \omega^{-4}\right)$$

where:

H_S : Significant wave height, in m

ω : Angular wave frequency, in rad/s

T_Z : Zero up-crossing period, in s.

2.4.3 JONSWAP spectrum

The JONSWAP spectrum is defined as:

$$S(\omega)=173\frac{H_S^2 T_S (T_S\omega)^{-5}}{F_1 F_2^4}\exp(-692(F_2 T_S\omega)^{-4})\gamma^{\exp[-(0,206F_2T_S\omega-1)^2/2\sigma^2]}$$

where:

H_S : Significant wave height, in m

ω : Angular wave frequency, in rad/s

T_S : Mean wave period, in s

γ : JONSWAP peakedness parameter

$$\sigma = \begin{cases} 0,07 \text{ for } \omega \le (0,206F_2T_S)^{-1} \\ 0,09 \text{ for } \omega > (0,206F_2T_S)^{-1} \end{cases}$$

The values of F_1 and F_2 are given in Tab 1.

Unless otherwise agreed with the Society, the peakedness parameter γ should be taken to 3,3, corresponding to the mean JONSWAP spectrum.

Table 1 : F_1 and F_2 values as function of γ

γ	F_1	F_2
1	1,00	1,00
2	1,24	0,95
3	1,46	0,93
3,3 **(1)**	1,52	0,92
4	1,66	0,91
5	1,86	0,90
6	2,04	0,89
(1) Mean JONSWAP spectrum		

2.4.4 Wave spreading

In case of short crested sea a spreading function is to be applied to the wave spectrum when calculating the spectral moments of the response processes. The spreading function is defined as:

$$D(\psi) = \frac{2}{\pi}\cos^2(\bar{\psi}-\psi)$$

where:

ψ : Heading angle

ψ : Angle ranging from $(\psi - \pi/2)$ to $(\psi + \pi/2)$.

2.5 Hydrodynamic model

2.5.1 Short term assessment of the sea-keeping behaviour is to imply that RAO's (Response Amplitude Operators) are to be calculated for:

- A suitable range of wave frequencies to cover the range of the sea spectrum (typically 0,2-2,0 rad/s, with not less than 20 frequencies). Most frequencies are to be placed in the range where most wave energy is present, and the calculation of RAO's at irregular frequencies, or for wave frequencies where the encounter frequency approaches zero, is to be avoided.
- At least 12 evenly distributed heading angles: 0°, 30°, 60°, … , 330° (with 0° being the following sea).

2.6 Spectral moments

2.6.1 The n'th order response spectral moments are to be determined as follows:

- Short crested sea:

$$m_n = \int_0^{\infty}\int_{\bar{\psi}-\frac{\pi}{2}}^{\psi+\frac{\pi}{2}}\left|\omega-\frac{\omega^2 V}{g}\cos\psi\right|^n |\phi(\omega)|^2 S(\omega)D(\psi)d\psi d\omega$$

- Long crested sea:

$$m_n = \int_0^{\infty}\left|\omega-\frac{\omega^2 V}{g}\cos\psi\right|^n |\phi(\omega)|^2 S(\omega)d\omega$$

where:

V : Ship speed, in m/s

g : Gravity acceleration ($g = 9,81$ m/s^2)

ψ : Heading angle

$D(\psi)$: Spreading function

$\phi(\omega)$: RAO

$S(\omega)$: Wave spectrum

ω : Wave frequency, in rad/s.

2.7 RMS values

2.7.1 The Root Mean Square (RMS) value of a response is defined as:

$$RMS = \sqrt{m_0}$$

where m_0 is the zero'th order spectral moment of the response.

3 Long term assessment

3.1 General

3.1.1 Long term assessments serve to estimate long term distributions of the various ship responses, typically the wave induced amidships vertical bending moment.

Such a long term distribution can thence be used to obtain estimates of the extreme responses, e.g. the most probable largest response in 10^8 wave cycles.

3.2 Hydrodynamic model

3.2.1 Unless otherwise agreed with the Society, the long term assessments should be carried out with the following hydrodynamic model:

- zero forward speed
- Bretschneider wave spectrum
- short crested sea
- a suitable range of wave frequencies to cover the range of the sea spectrum (typically 0,2-2,0 rad/s with not less than 20 frequencies). Most frequencies are to be placed in the range where most wave energy is present, and the calculation of RAO's at irregular frequencies is to be avoided
- at least 12 evenly distributed heading angles
- uniform distribution of heading angles, meaning that the same probability (e.g. 1/12 if 12 heading angles are considered) is assigned to each considered heading
- extreme responses are to be determined at 10^{-8} probability of exceeding.

3.3 Sea state scatter diagram

3.3.1 The scatter diagram to be applied in the spectral approach relates the probability of occurrence to a wide range of sea states, characterised by their significant wave height and zero up-crossing period.

When considering unrestricted service the scatter diagram shown in Tab 2 is to be applied. However, in case of ship with a restricted navigation notation, different scatter diagrams may be applied when agreed on with the Society.

Table 2 : Recommended sea state scatter diagram for unrestricted service

Note 1: H_S is the significant wave height and T_Z is the zero up-crossing period of the short term sea states. The probability of a sea state is given as fractions of 100.000.

Part B
Hull and Stability

CHAPTER 4
STRUCTURE DESIGN PRINCIPLES

Section 1	Materials
Section 2	Net Scantling Approach
Section 3	Strength Principles
Section 4	Bottom Structure
Section 5	Side Structure
Section 6	Deck Structure
Section 7	Bulkhead Structure

Section 1 Materials

1 General

1.1 Characteristics of materials

1.1.1 Materials used during construction of ships are to comply with the applicable requirements of NR216 Materials and Welding.

1.1.2 Materials other than those covered in [1.1.1] may be accepted, provided that their specification (e.g. manufacture, chemical composition, mechanical properties, welding, etc.) is submitted to the Society for approval.

1.2 Testing of materials

1.2.1 Materials are to be tested in compliance with the applicable requirements of NR216 Materials and Welding.

1.3 Manufacturing processes

1.3.1 The requirements of this Section presume that welding and other cold or hot manufacturing processes are carried out in compliance with current sound working practice and the applicable requirements of NR216 Materials and Welding.

In particular:

- parent material and welding processes are to be approved within the limits stated for the specified type of material for which they are intended
- specific preheating may be required before welding
- welding or other cold or hot manufacturing processes may need to be followed by an adequate heat treatment.

2 Steels for hull structure

2.1 Application

2.1.1 Steel having a specified minimum yield stress equal to 235 N/mm² is regarded as normal strength steel and is denoted “NSS”. Steel having a higher specified minimum yield stress is regarded as higher strength steel and is denoted “HSS”.

Steel grades are referred to as follows:

- A, B, D and E denote normal strength steel grades
- AH, DH and EH denote higher strength steel grades.

Tab 1 gives the mechanical characteristics of steels generally used in the construction of ships.

Higher strength steels other than those indicated in Tab 1 are considered by the Society on a case-by-case basis.

2.1.2 When steels with a minimum guaranteed yield stress R_{eH} other than 235 N/mm² are used on a ship, hull scantlings are to be determined, taking into account the material factor k defined in [2.3].

2.1.3 Characteristics of steels with specified through thickness properties are given in NR216, Ch 3, Sec 1, [12].

Table 1 : Mechanical properties of hull steels

Steel grades	t, in mm	R_{eH}, in N/mm²	R_m, in N/mm²
A-B-D-E	≤ 100	235	400 - 520
AH32-DH32-EH32	≤ 100	315	440 - 570
FH32	≤ 50		
AH36-DH36-EH36	≤ 100	355	490 - 630
FH36	≤ 50		
AH40-DH40-EH40 FH40	≤ 50	390	510 - 660
Note 1: Refer to NR216 Materials and Welding, Ch 2, Sec 1, [2]. t : Gross thickness R_{eH} : Minimum yield stress R_m : Ultimate minimum tensile strength.			

2.2 Information to be kept on board

2.2.1 A plan indicating the steel types and grades adopted for the hull structures is to be kept on board. Where steels other than those indicated in Tab 1 are used, their mechanical and chemical properties, as well as any workmanship requirements or recommendations, are to be available on board together with the above plan. When materials with sensitive know-how are used, it may be accepted that they are only documented on case by case for repair in service.

2.3 Material factor k

2.3.1 Unless otherwise specified, the material factor k has the values defined in Tab 2, as a function of the minimum guaranteed yield stress R_{eH}.

For intermediate values of R_{eH} , k may be obtained by linear interpolation.

Table 2 : Material factor k

R_{eH} , in N/mm²	k
235	1,00
315	0,78
355	0,72
390	0,68

2.3.2 Steels with a yield stress lower than 235 N/mm² or greater than 390 N/mm² are considered by the Society on a case-by-case basis.

When steels with a yield stress greater than 390 N/mm² are used, the material factor k is limited to 0,68 for scantlings calculations under Rules loads.

2.3.3 For strength checks as detailed in Part B, Chapter 7 and Part B, Chapter 8 under local loads whose frequency of appearance is not liable to create fatigue damage (e.g. helicopter landing), the minimum yield stress of the material R_y may be considered equal to R_{eH} , subject to the special agreement of the Society on a case-by-case basis.

2.4 Grades of steel

2.4.1 For the purpose of the selection of steel grades to be used for the various structural members, the latter are divided into categories (SECONDARY, PRIMARY and SPECIAL), as indicated in Tab 3.

Tab 3 also specifies the classes (I, II and III) of the materials to be used for the various categories of structural members.

2.4.2 Materials are to be of a grade not lower than that indicated in Tab 3 or in Tab 5 for front line or second line ships, depending on the material class and structural member gross thickness (see [2.4.5]).

2.4.3 For strength members not mentioned in Tab 3, grade A/AH may generally be used.

2.4.4 Single strakes required to be of class III or of grade E/EH are to have a breadth within 0,4L amidships not less than (800 + 5 L) mm, but not necessarily greater than 1800 mm.

2.4.5 The steel grade is to correspond to the as-fitted gross thickness when this one is greater than the gross thickness obtained from the net thickness required by the Rules, according to Ch 4, Sec 2, [1].

2.4.6 Steel grades of plates or sections of gross thickness greater than the limiting thicknesses in Tab 1 are considered by the Society on a case-by-case basis.

2.4.7 In specific cases, such as in [2.4.8], with regard to stress distribution along the hull girder, the classes required within 0,4 L amidships may be extended beyond that zone, on a case-by-case basis.

2.4.8 The material classes required for the strength deck plating, the sheerstrake and the upper strake of longitudinal bulkheads within 0,4 L amidships are to be maintained over an adequate length across the poop front and at the ends of the bridge, where fitted.

2.4.9 Rolled products used for welded attachments on hull plating, such as gutter bars and bilge keels, are to be of the same grade (or equivalent) as the one used for the hull plating in way.

Where it is necessary to weld attachments to the sheerstrake or stringer plate, attention is to be given to the appropriate choice of material and design, the workmanship and welding and the absence of prejudicial undercuts and notches, with particular regard to any free edges of the material.

2.4.10 In the case of full penetration welded joints located in positions where high local stresses may occur perpendicular to the continuous plating, the Society may, on a case-by-case basis, require the use of rolled products having adequate ductility properties in the through thickness direction, such as to prevent the risk of lamellar tearing (Z type steel, see NR216 Materials and Welding). For such situation involving small weight of plates, a case-by-case consideration is to be given.

2.4.11 In highly stressed areas other than Class III according to Tab 3, the Society may require that plates of gross thickness greater than 20 mm are of grade D/DH or E/EH.

Table 3 : Application of material classes and grades

Structural member category	Material class or grade	
	Within 0,4 L amidships	Outside 0,4 L amidships
SECONDARY: Lower strake in longitudinal bulkhead Deck plating exposed to weather (in general) Side plating	I	A / AH**(6)**
PRIMARY: Bottom plating (including keel plate) Strength deck plating **(1)** Continuous longitudinal members above strength deck (excluding continuous longitudinal hatch coamings of ships equal to or greater than 90 m in length) Upper strake in longitudinal bulkhead Vertical strake (hatch side girder) and upper sloped strake in topside tank	II	A / AH **(7)**
SPECIAL: Sheerstrake at strength deck **(2)** Stringer plate in strength deck**(2)** Deck strake at longitudinal bulkhead Bilge strake **(3)** **(4)** Continuous longitudinal hatch coamings of ships equal to or greater than 90 m in length **(6)**	III	II **(8)** (I outside 0,6 L amidships)

(1) Plating at corners of large hatch openings to be considered on a case-by-case basis. Class III or grade E/EH to be applied in positions where high local stresses may occur
(2) To be not less than grade E/EH within 0,4L amidships in ships greater than 250 m in length
(3) May be of class II in ships less than 150 m in length and having a double bottom over the full breadth
(4) To be not less than grade D/DH in ships greater than 250 m in length
(5) To be not less than grade D/DH
(6) To be of class I for front line or second line ships
(7) To be of class II for front line and second line ships
(8) To be of class III for front line and second line ships.

Note 1: Plating materials for sternframes, rudders, rudder horns and shaft brackets are generally to be of grades not lower than those corresponding to class II.
For rudder and rudder blade plates subjected to stress concentrations (e.g. in way of lower support of semi-spade rudders or at upper part of spade rudders), class III is to be applied.

Note 2: Bedplates of seats for propulsion and auxiliary engines inserted in the inner bottom are to be of class I. In other cases, the steel may be generally of grade A. Different grades may be required by the Society on a case-by-case basis.

Note 3: Plating at corners of large hatch openings on decks located below the strength deck, in the case of hatches of holds for refrigerated cargoes, and insert plates at corners of large openings on side shell plating are generally to be of class III.

Table 4 : Material grade requirements for classes I, II and III

Class	I		II		III	
Gross thickness, in mm	NSS	HSS	NSS	HSS	NSS	HSS
$t \leq 15$	A	AH	A	AH	A	AH
$15 < t \leq 20$	A	AH	A	AH	B	AH
$20 < t \leq 25$	A	AH	B	AH	D	DH
$25 < t \leq 30$	A	AH	D	DH	D	DH
$30 < t \leq 35$	B	AH	D	DH	E	EH
$35 < t \leq 40$	B	AH	D	DH	E	EH
$40 < t \leq 50$	D	DH	E	EH	E	EH

Note 1: see [2.1.1] for definitions of NSS and HSS.

2.5 Grades of steel for structures exposed to low air temperatures

2.5.1 For ships intended to operate in areas with low air temperatures (–20°C or below), e.g. regular service during winter seasons to Arctic or Antarctic waters, the materials in exposed structures are to be selected based on the design temperature t_D , to be taken as defined in [2.5.2].

2.5.2 The design temperature t_D is to be taken as the lowest mean daily average air temperature in the area of operation, where:

Mean : Statistical mean over observation period (at least 20 years)

Average : Average during one day and night

Lowest : Lowest during one year.

Fig 1 illustrates the temperature definition.

For seasonally restricted service, the lowest value within the period of operation applies.

2.5.3 For the purpose of the selection of steel grades to be used for the structural members above the lowest ballast waterline and exposed to air, the latter are divided into categories (SECONDARY, PRIMARY and SPECIAL), as indicated in Tab 5.

Tab 5 also specifies the classes (I, II and III) of the materials to be used for the various categories of structural members.

For non-exposed structures and structures below the lowest ballast waterline, see [2.4].

2.5.4 Materials may not be of a lower grade than that indicated in Tab 6 to Tab 8 depending on the material class, the structural member gross thickness and design temperature t_D.

For design temperatures $t_D < -55°C$, materials are to be specially considered by the Society on a case-by-case basis.

2.5.5 Single strakes required to be of class III or of grade E/EH or FH are to have breadths not less than (800+5L) mm, but not necessarily greater than 1800 mm.

Figure 1 : Commonly used definitions of temperatures

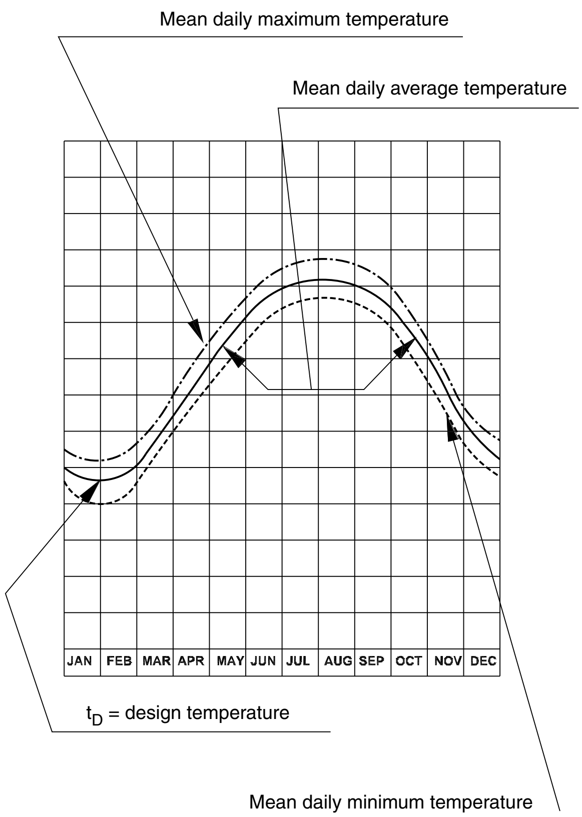

Table 5 : Application of material classes and grades - Structures exposed to low air temperatures

Structural member category	Material class	
	Within 0,4 L amidships	Outside 0,4 L amidships
SECONDARY: Deck plating exposed to weather (in general) Side plating above T_B **(1)** Transverse bulkheads above T_B **(1)**	I	I
PRIMARY: Strength deck plating **(2)** Continuous longitudinal members above strength deck (excluding longitudinal hatch coamings of ships equal to or greater than 90 m in length) Longitudinal bulkhead above T_B **(1)** Topside tank bulkhead above T_B **(1)**	II	I
SPECIAL: Sheerstrake at strength deck **(3)** Stringer plate in strength deck **(3)** Deck strake at longitudinal bulkhead Continuous longitudinal hatch coamings of ships equal to or greater than 90 m in length **(4)**	III	II

(1) T_B is the draught in light ballast condition, defined in Ch 5, Sec 1, [2.4.3]
(2) Plating at corners of large hatch openings to be considered on a case-by-case basis. Class III or grade E/EH to be applied in positions where high local stresses may occur
(3) To be not less than grade E/EH within 0,4 L amidships in ships greater than 250 m in length
(4) To be not less than grade D/DH.
Note 1: Plating materials for sternframes, rudder horns, rudders and shaft brackets are to be of grades not lower than those corresponding to the material classes in [2.4].

Table 6 : Material grade requirements for class I at low temperatures

Gross thickness, in mm	−20°C / −25°C		−26°C / −35°C		−36°C / −45°C		−46°C / −55°C

40 < t ≤ 50	N.A.	FH	N.A.	FH	N.A.	N.A.	N.A.	N.A.

Note 1: see [2.1.1] for definitions of NSS and HSS.
Note 2: N.A. = Not applicable.

2.6 Grades of steel within refrigerated spaces

2.6.1 For structural members within or adjacent to refrigerated spaces, when the design temperature is below 0°C, the materials are to be of grade not lower than those indicated in Tab 9, depending on the design temperature, the structural member gross thickness and its category (as defined in Tab 3).

2.6.2 Unless a temperature gradient calculation is carried out to assess the design temperature and the steel grade in the structural members of the refrigerated spaces, the temperatures to be assumed are specified below:

- temperature of the space on the uninsulated side, for plating insulated on one side only, either with uninsulated stiffening members (i.e. fitted on the uninsulated side of plating) or with insulated stiffening members (i.e. fitted on the insulated side of plating)
- mean value of temperatures in the adjacent spaces, for plating insulated on both sides, with insulated stiffening members, when the temperature difference between the adjacent spaces is generally not greater than 10°C (when the temperature difference between the adjacent spaces is greater than 10°C, the temperature value is established by the Society on a case-by-case basis)
- in the case of non-refrigerated spaces adjacent to refrigerated spaces, the temperature in the non-refrigerated spaces is to be conventionally taken equal to 0°C.

2.6.3 Situations other than those mentioned in [2.6.1] and [2.6.2] or special arrangements are to be considered by the Society on a case-by-case basis.

2.6.4 Irrespective of the provisions of [2.6.1], [2.6.2] and Tab 9, steel having grades lower than those required in [2.4], Tab 3 and Tab 4 and in relation to the class and the gross thickness of the structural member considered may not be used.

Table 9 : Material grade requirements for members within or adjacent to refrigerated spaces

Design temperature, in °C	Gross thickness, in mm	Structural member category	
		Secondary	Primary or Special
$-10 \le t_D < 0$	t ≤ 20	B / AH	B / AH
	20 < t ≤ 25	B / AH	D / DH
	t > 25	D / DH	E / EH
$-25 \le t_D < -10$	t ≤ 15	B / AH	D / DH
	15 < t ≤ 25	D / DH	E / EH
	t > 25	E / EH	E / EH
$-40 \le t_D < -25$	t ≤ 25	D / DH	E / EH
	t > 25	E / EH	E / EH

3 Steels for forging and casting

3.1 General

3.1.1 Mechanical and chemical properties of steels for forging and casting to be used for structural members are to comply with the applicable requirements of NR216 Materials and Welding.

3.1.2 Steels of structural members intended to be welded are to have mechanical and chemical properties deemed appropriate for this purpose by the Society on a case-by-case basis.

3.1.3 The steels used are to be tested in accordance with the applicable requirements of NR216 Materials and Welding.

3.2 Steels for forging

3.2.1 For the purpose of testing, which is to be carried out in accordance with the applicable requirements of NR216 Materials and Welding, the above steels for forging are assigned to class 1 (see NR216 Materials and Welding, Ch 2, Sec 3, [1.2]).

3.2.2 Rolled bars may be accepted in lieu of forged products, after consideration by the Society on a case-by-case basis.

In such case, compliance with the requirements of NR216 Materials and Welding, Ch 2, Sec 1, relevant to the quality and testing of rolled parts accepted in lieu of forged parts, may be required.

3.3 Steels for casting

3.3.1 Cast parts intended for stems, sternframes, rudders, parts of steering gear and deck machinery in general may be made of C and C-Mn weldable steels of quality 1, having tensile strength R_m equal to 400 N/mm² or 440 N/mm², in accordance with the applicable requirements of NR216 Materials and Welding, Ch 2, Sec 4.

Items which may be subjected to high stresses may be required to be of quality 2 steels of the above types.

3.3.2 For the purpose of testing, which is to be carried out in accordance with NR216 Materials and Welding, Ch 2, Sec 4, [1.11], the above steels for casting are assigned to class 1 irrespective of their quality.

3.3.3 The welding of cast parts to main plating contributing to hull strength members is considered by the Society on a case-by-case basis.

The Society may require additional properties and tests for such casting, in particular impact properties which are appropriate to those of the steel plating on which the cast parts are to be welded and non-destructive examinations.

3.3.4 Heavily stressed cast parts of steering gear, particularly those intended to form a welded assembly and tillers or rotors mounted without key, are to be subjected to non-destructive examination to check their internal structure.

4 Aluminium alloy structures

4.1 General

4.1.1 The characteristics of aluminium alloys are to comply with the requirements of NR216 Materials and Welding, Ch 3, Sec 2.

Series 5000 aluminium-magnesium alloys or series 6000 aluminium-magnesium-silicon alloys are generally to be used (see NR216 Materials and Welding, Ch 3, Sec 2, [2]).

4.1.2 In the case of structures subjected to low service temperatures or intended for other specific applications, the alloys to be employed are defined in each case by the Society, which states the acceptability requirements and conditions.

4.2 Extruded plating

4.2.1 Extrusions with built-in plating and stiffeners, referred to as extruded plating, may be used.

4.2.2 In general, the application is limited to decks, bulkheads, superstructures and deckhouses and any other element not contributing to the hull girder strength. Other uses may be permitted by the Society on a case-by-case basis.

4.2.3 Extruded plating is preferably to be oriented so that the stiffeners are parallel to the direction of main stresses.

4.2.4 Connections between extruded plating and primary members are to be given special attention.

4.3 Influence of welding on mechanical characteristics

4.3.1 Welding heat input lowers locally the mechanical strength of aluminium alloys hardened by work hardening (series 5000 other than condition 0 or H111) or by heat treatment (series 6000).

4.3.2 Consequently, where necessary, a drop in the mechanical characteristics of welded structures with respect to those of the parent material is to be considered in the heat-affected zone.

The heat-affected zone may be taken to extend 25 mm on each side of the weld axis.

4.3.3 Aluminium alloys of series 5000 in 0 condition (annealed) or in H111 condition (annealed flattened) are not subject to a drop in mechanical strength in the welded areas.

4.3.4 Aluminium alloys of series 5000 other than condition 0 or H111 are subject to a drop in mechanical strength in the welded areas.

The mechanical characteristics to consider are normally those of condition 0 or H111.

Higher mechanical characteristics may be taken into account, provided they are duly justified.

4.3.5 Aluminium alloys of series 6000 are subject to a drop in mechanical strength in the vicinity of the welded areas.

The mechanical characteristics to be considered are normally indicated by the supplier.

4.4 Material factor k

4.4.1 The material factor k for aluminium alloys is to be obtained from the following formula:

$$k = \frac{235}{R'_{lim}}$$

where:

R'_{lim} : Minimum guaranteed yield stress of the parent metal in welded condition $R'_{p0,2}$, in N/mm², but not to be taken greater than 70% of the minimum guaranteed tensile strength of the parent metal in welded condition R'_m, in N/mm²

$R'_{p0,2} = \eta_1 \, R_{p0,2}$

$R'_m = \eta_2 \, R_m$

$R_{p0,2}$: Minimum guaranteed yield stress, in N/mm², of the parent metal in delivery condition

R_m : Minimum guaranteed tensile stress, in N/mm², of the parent metal in delivery condition.

η_1 and η_2 are given in Tab 10.

4.4.2 In the case of welding of two different aluminium alloys, the material factor k to be considered for the scantlings is the greater material factor of the aluminium alloys of the assembly.

4.4.3 For welded constructions in hardened aluminium alloys (series 5000 other than condition 0 or H111 and series 6000), greater characteristics than those in welded condition may be considered, provided that welded connections are located in areas where stress levels are acceptable for the alloy considered in annealed or welded condition.

Table 10 : Aluminium alloys for welded construction

Aluminium alloy	η_1	η_2
Alloys without work-hardening treatment (series 5000 in annealed condition 0 or annealed flattened condition H111)	1	1
Alloys hardened by work hardening (series 5000 other than condition 0 or H111)	$R'_{p0,2}/R_{p0,2}$	R'_m / R_m
Alloys hardened by heat treatment (series 6000) **(1)**	$R'_{p0,2}/R_{p0,2}$	0,6

(1) When no information is available, coefficient η is to be taken equal to the metallurgical efficiency coefficient β defined in Tab 11.

Note 1:

$R'_{p0,2}$: Minimum guaranteed yield stress, in N/mm², of material in welded condition (see [4.3]).

R'_m : Minimum guaranteed tensile stress, in N/mm², of material in welded condition (see [4.3]).

Table 11 : Aluminium alloys Metallurgical efficiency coefficient β

Aluminium alloy	Temper condition	Gross thickness	β
6005 A (Open sections)	T5 or T6	$t \le 6$ mm	0,45
		$t > 6$ mm	0,40
6005 A (Closed sections)	T5 or T6	all	0,50
6061 (Sections)	T6	all	0,53
6082 (Sections)	T6	all	0,45

5 Other materials and products

5.1 General

5.1.1 Other materials and products such as parts made of iron castings, where allowed, products made of copper and copper alloys, rivets, anchors, chain cables, cranes, masts, derrick posts, derricks, accessories and wire ropes are generally to comply with the applicable requirements of NR216 Materials and Welding.

5.1.2 The use of plastics or other special materials not covered by these Rules is to be considered by the Society on a case-by-case basis. In such cases, the Society states the requirements for the acceptance of the materials concerned.

5.1.3 Materials used in welding processes are to comply with the applicable requirements of NR216 Materials and Welding.

5.2 Iron cast parts

5.2.1 As a rule, the use of grey iron, malleable iron or spheroidal graphite iron cast parts with combined ferritic/perlitic structure is allowed only to manufacture low stressed elements of secondary importance.

5.2.2 Ordinary iron cast parts may not be used for windows or sidescuttles; the use of high grade iron cast parts of a suitable type is to be considered by the Society on a case-by-case basis.

Symbols

t_C : Rule corrosion addition, in mm, see Article [3]
w_N : Net section modulus, in cm^3, of ordinary stiffeners
w_G : Gross section modulus, in cm^3, of ordinary stiffeners.

1 Application criteria

1.1 General

1.1.1 The scantlings obtained by applying the criteria specified in Part B are net scantlings, i.e. those which provide the strength characteristics required to sustain the loads, excluding any addition for corrosion. Exceptions are the scantlings of:

- bow and inner doors in Ch 8, Sec 5
- side doors and stern doors in Ch 8, Sec 6
- rudder structures and hull appendages in Part B, Chapter 9
- massive pieces made of steel forgings, steel castings or iron castings,

which are gross scantlings, i.e. they include additions for corrosion.

1.1.2 The required strength characteristics are:

- thickness, for plating including that which constitutes primary supporting members
- section modulus, shear area, moments of inertia and local thickness, for ordinary stiffeners and, as the case may be, primary supporting members
- section modulus, moments of inertia and single moment for the hull girder.

1.1.3 The ship is to be built at least with the gross scantlings obtained by adding the corrosion additions, specified in Tab 2, to the net scantlings.

2 Net strength characteristic calculation

2.1 Designer's proposal based on gross scantlings

2.1.1 General criteria

If the Designer provides the gross scantlings of each structural element without providing the corrosion additions, the structural checks are to be carried out on the basis of the net strength characteristics, derived as specified in [2.1.2] to [2.1.6].

2.1.2 Plating

The net thickness is to be obtained by deducting t_c from the gross thickness.

2.1.3 Ordinary stiffeners

The net transverse section is to be obtained by deducting t_C from the gross thickness of the elements which constitute the stiffener profile. For bulb profiles, an equivalent angle profile, as specified in Ch 4, Sec 3, [3.1.2], may be considered.

The net strength characteristics are to be calculated for the net transverse section. As an alternative, the net section modulus may be obtained from the following formula:

$$w_N = w_G(1 - \alpha t_C) - \beta t_C$$

where α and β are the coefficients defined in Tab 1.

Table 1 : Coefficients α and β

Type of ordinary stiffeners	α	β
Flat bars	0,035	2,8
Flanged profiles	0,060	14,0
Bulb profiles: $w_G \le 200$ cm^3 $w_G > 200$ cm^3	 0,070 0,035	 0,4 7,4

2.1.4 Primary supporting members analysed through an isolated beam structural model

The net transverse section is to be obtained by deducting t_C from the gross thickness of the elements which constitute the primary supporting members.

The net strength characteristics are to be calculated for the net transverse section.

2.1.5 Primary supporting members analysed through a three dimensional model or a complete ship model

The net thickness of plating which constitutes primary supporting members is to be obtained by deducting 0,5 t_c from the gross thickness.

2.1.6 Hull girder net strength characteristics

For the hull girder, the net hull transverse sections are to be considered as being constituted by plating and stiffeners having net scantlings calculated on the basis of the corrosion additions t_C , according to [2.1.2] to [2.1.4].

2.2 Designer's proposal based on net scantlings

2.2.1 Net strength characteristics and corrosion additions

If the Designer provides the net scantlings of each structural element, the structural checks are to be carried out on the basis of the proposed net strength characteristics.

The Designer is also to provide the corrosion additions or the gross scantlings of each structural element. The proposed corrosion additions are to be not less than the values specified in [3].

2.2.2 Hull girder net strength characteristic

For the hull girder, the net hull transverse sections are to be considered as being constituted by plating and stiffeners having the net scantlings proposed by the Designer.

It is to be checked whether:

$Z_{NAD} \geq 0,9\ Z_{GD}$

where:

Z_{NAD} : Net midship section modulus, in m^3, calculated on the basis of the net scantlings proposed by the Designer

Z_{GD} : Gross midship section modulus, in m^3, calculated on the basis of the gross scantlings proposed by the Designer.

Where the above condition is not satisfied, the hull girder normal and shear stresses, to be used for the checks of plating, ordinary stiffeners and primary supporting members analysed through an isolated beam structural model, are to be obtained by dividing by 0,9 those obtained by considering the hull girder transverse sections with their gross scantlings.

3 Corrosion additions

3.1 Values of corrosion additions

3.1.1 General

The values of the corrosion additions specified in this Article are to be applied in relation to the relevant protective coatings required by the Rules.

The Designer may define values of corrosion additions greater than those specified in [3.1.2].

The values of corrosion additions as given in Tab 2 apply to structure scantlings resulting from loads under normal operation at sea in peace time.

3.1.2 Corrosion additions for steel other than stainless steel

In general, the corrosion addition to be considered for plating forming the boundary between two compartments of different types is the sum of the values specified in Tab 2 for one side exposure to each compartment.

For an internal member within a given compartment, or for plating forming the boundary between two compartments of the same type, the corrosion addition to be considered is twice the value specified in Tab 2 for one side exposure to that compartment.

When, according to Tab 2, a structural element is affected by more than one value of corrosion additions (e.g. a side frame in a dry bulk cargo hold extending above the lower zone), the scantling criteria are generally to be applied considering the value of corrosion addition applicable at the lowest point of the element.

3.1.3 Corrosion additions for stainless steel

For structural members made of stainless steel, the corrosion addition t_c is to be taken equal to 0.

3.1.4 Corrosion additions for non-alloyed steel clad with stainless steel

For plates made of non-alloyed steel clad with stainless steel, the corrosion addition t_c is to be taken equal to 0 only for the plate side clad with stainless steel.

3.1.5 Corrosion additions for aluminium alloys

For structural members made of aluminium alloys, the corrosion addition t_c is to be taken equal to 0.

Table 2 : Corrosion additions t_c, in mm, for each exposed side

</table>

Section 3 Strength Principles

Symbols

E : Young's modulus, in N/mm^2, to be taken equal to:
- for steels in general:
  $E = 2{,}06 \cdot 10^5$ N/mm^2
- for stainless steels:
  $E = 1{,}95 \cdot 10^5$ N/mm^2
- for aluminium alloys:
  $E = 7{,}0 \cdot 10^4$ N/mm^2

s : Spacing, in m, of ordinary stiffeners or primary supporting members, as the case may be

ℓ : Span, in m, of an ordinary stiffener or a primary supporting member, as the case may be, measured between the supporting members (see Fig 2 to Fig 5)

ℓ_b : Length, in m, of brackets (see Fig 4 and Fig 5)

h_w : Web height, in mm, of an ordinary stiffener or a primary supporting member, as the case may be

t_w : Net web thickness, in mm, of an ordinary stiffener or a primary supporting member, as the case may be

b_f : Face plate width, in mm, of an ordinary stiffener or a primary supporting member, as the case may be

t_f : Net face plate thickness, in mm, of an ordinary stiffener or a primary supporting member, as the case may be

t_p : Net thickness, in mm, of the plating attached to an ordinary stiffener or a primary supporting member, as the case may be

w : Net section modulus, in cm^3, of an ordinary stiffener or a primary supporting member, as the case may be, with attached plating of width b_p

I : Net moment of inertia, in cm^4, of an ordinary stiffener or a primary supporting member, as the case may be, without attached plating, around its neutral axis parallel to the plating (see Fig 4 and Fig 5)

I_B : Net moment of inertia, in cm^4, of an ordinary stiffener or a primary supporting member, as the case may be, with bracket and without attached plating, around its neutral axis parallel to the plating, calculated at mid-length of the bracket (see Fig 4 and Fig 5).

1 General principles

1.1 Structural continuity

1.1.1 The variation in scantlings between the midship region and the fore and aft parts is to be gradual.

1.1.2 Attention is to be paid to the structural continuity:
- in way of changes in the framing system
- at the connections of primary supporting members or ordinary stiffeners
- in way of the ends of the fore and aft parts (see Ch 8, Sec 1 and Ch 8, Sec 2) and machinery space (see Ch 8, Sec 3)
- in way of ends of superstructures (see Ch 8, Sec 4).

1.1.3 Longitudinal members contributing to the hull girder longitudinal strength, according to Ch 6, Sec 1, [2], are to extend continuously over a sufficient distance towards the ends of the ship.

Ordinary stiffeners contributing to the hull girder longitudinal strength are generally to be continuous when crossing primary supporting members. Otherwise, the detail of connections is considered by the Society on a case-by-case basis.

Longitudinals of the bottom, bilge, sheerstrake, deck, upper and lower longitudinal bulkhead and inner side strakes, as well as the latter strakes themselves, the lower strake of the centreline bottom girder and the upper strake of the centreline deck girder, where fitted, are to be continuous through the transverse bulkheads. Alternative solutions may be examined by the Society on a case-by-case basis, provided they are equally effective.

1.1.4 Where stress concentrations may occur in way of structural discontinuities, adequate compensation and reinforcements are to be provided.

1.1.5 Openings are to be avoided, as far as practicable, in way of highly stressed areas.

Where necessary, the shape of openings is to be specially designed to reduce the stress concentration factors.

Openings are to be generally well rounded with smooth edges.

1.1.6 Primary supporting members are to be arranged in such a way that they ensure adequate continuity of strength. Abrupt changes in height or in cross-section are to be avoided.

1.2 Connections with higher strength steel

1.2.1 The vertical extent of higher strength steel is to comply with the requirements of Ch 6, Sec 2, [4.5].

1.2.2 When a higher strength steel is adopted at deck, members not contributing to the longitudinal strength and welded on the strength deck (e.g. hatch coamings, strengthening of deck openings) are also generally to be made of the same higher strength steel.

1.3 Connections between steel and aluminium

1.3.1 Any direct contact between steel and aluminium alloy is to be avoided (e.g. by means of zinc or cadmium plating of the steel parts and application of a suitable coating on the corresponding light alloy parts).

1.3.2 Any heterogeneous jointing system is considered by the Society on a case-by-case basis.

1.3.3 The use of transition joints made of aluminium/steel-clad plates or profiles is considered by the Society on a case-by-case basis (see NR216 Materials and Welding, Ch 3, Sec 2, [4]).

2 Plating

2.1 Insert plates and doublers

2.1.1 A local increase in plating thickness is generally to be achieved through insert plates. Local doublers, which are normally only allowed for temporary repair, may however be accepted by the Society on a case-by-case basis.

In any case, doublers and insert plates are to be made of materials of a quality at least equal to that of the plates on which they are welded.

2.1.2 Doublers having a width, in mm, greater than:

- 20 times their thickness, for thicknesses equal to or less than 15 mm
- 25 times their thickness, for thicknesses greater than 15 mm,

are to be fitted with slot welds, to be effected according to Ch 11, Sec 1, [2.6].

2.1.3 When doublers fitted on the outer shell and strength deck within 0,6 L amidships are accepted by the Society, their width and thickness are to be such that slot welds are not necessary according to the requirements in [2.1.2]. Outside this area, the possibility of fitting doublers requiring slot welds is to be considered by the Society on a case-by-case basis.

3 Ordinary stiffeners

3.1 General

3.1.1 Stiffener not perpendicular to the attached plating

Where the stiffener is not perpendicular to the attached plating, the actual net section modulus may be obtained, in cm^3, from the following formula:

$$w = w_0 \sin \alpha$$

where:

w_0 : Actual net section modulus, in cm^3, of the stiffener assumed to be perpendicular to the plating

α : Angle between the stiffener web and the attached plating.

3.1.2 Bulb section: equivalent angle profile

A bulb section may be taken as equivalent to an angle profile.

The dimensions of the equivalent angle profile are to be obtained, in mm, from the following formulae:

$$h_w = h'_w - \frac{h'_w}{9,2} + 2$$

$$t_w = t'_w$$

$$b_f = \alpha\left[t'_w + \frac{h'_w}{6,7} - 2\right]$$

$$t_f = \frac{h'_w}{9,2} - 2$$

where:

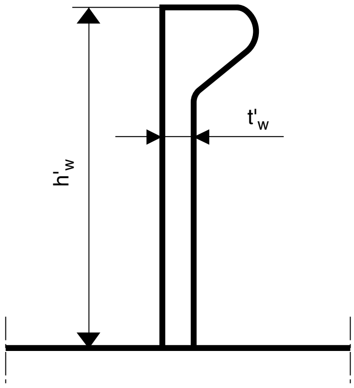
h'_w, t'_w : Height and net thickness of the bulb section, in mm, as shown in Fig 1

α : Coefficient equal to:

$$1{,}1 + \frac{(120 - h'_w)^2}{3000} \quad \text{for } h'_w \le 120$$

$$1 \quad \text{for } h'_w > 120$$

Figure 1 : Dimensions of a bulb section



3.2 Span of ordinary stiffeners

3.2.1 General

The span ℓ of ordinary stiffeners is to be measured as shown in Fig 2 to Fig 5.

Figure 2 : Ordinary stiffener without brackets

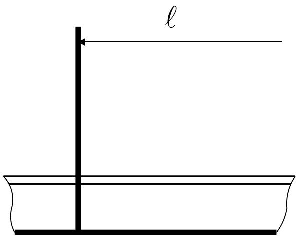


Figure 3 : Ordinary stiffener with a stiffener at one end

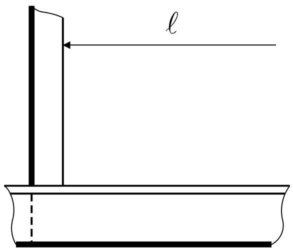

Figure 4 : Ordinary stiffener with end bracket

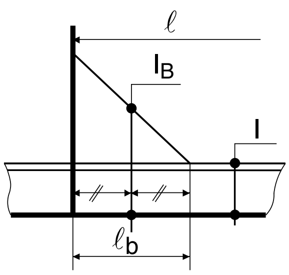

Figure 5 : Ordinary stiffener with a bracket and a stiffener at one end

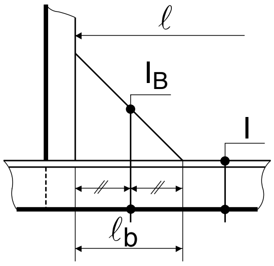
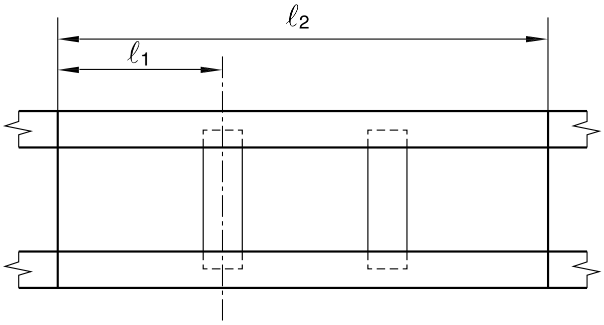


3.2.2 Open floors

The span ℓ of transverse ordinary stiffeners connected by struts is to be taken as the greater of 1,4 ℓ_1 and 0,7 ℓ_2, where ℓ_1 and ℓ_2 are the spans defined in Fig 6.

Figure 6 : Span of ordinary stiffeners in the case of open floors



3.3 Width of attached plating

3.3.1 The width of the attached plating to be considered for the yielding check of ordinary stiffeners is to be obtained, in m, from the following formulae:

- where the plating extends on both sides of the ordinary stiffener:

  $b_P = s$

- where the plating extends on one side of the ordinary stiffener (i.e. ordinary stiffeners bounding openings):

  $b_P = 0,5\ s$

3.3.2 Buckling check and ultimate strength check

The attached plating to be considered for the buckling and ultimate strength check of ordinary stiffeners is defined in Ch 7, Sec 2, [4.1] and Ch 7, Sec 2, [5.2], respectively.

3.4 Geometric properties

3.4.1 Built section

The geometric properties of built sections as shown in Fig 7 may be calculated as indicated in the following formulae. These formulae are applicable provided that:

$A_a \geq t_f b_f$

$\frac{h_w}{t_p} \geq 10$

$\frac{h_w}{t_f} \geq 10$

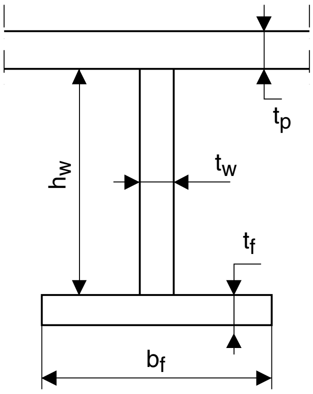
where:

A_a : Net sectional area, in mm², of the attached plating.

The net shear sectional area of a built section with attached plating is to be obtained, in cm², from the following formula:

$$A_{Sh} = \frac{h_w t_w}{100}$$

Figure 7 : Dimensions of a built section



The net section modulus of a built section with attached plating is to be obtained, in cm³, from the following formula:

$$w = \frac{h_w t_f b_f}{1000} + \frac{t_W h_W^2}{6000}\left(1 + \frac{A_a - t_f b_f}{A_a + \frac{t_W h_W}{2}}\right)$$

The distance from the face plate to the neutral axis is to be obtained, in cm, from the following formula:

$$v = \frac{h_W(A_a + 0,5 t_W h_W)}{10(A_a + t_f b_f + t_W h_W)}$$

The net moment of inertia of a built section with attached plating is to be obtained, in cm⁴, from the following formula:

$I = w\ v$

3.4.2 Corrugations

The net section modulus of a corrugation is to be obtained, in cm³, from the following formula:

$$w = \frac{td}{6}(3b + c)10^{-3}$$

where:

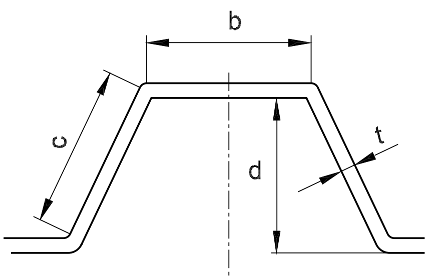
t : Net thickness of the plating of the corrugation, in mm

d, b, c : Dimensions of the corrugation, in mm, shown in Fig 8.

Where the web continuity is not ensured at ends of the bulkhead, the net section modulus of a corrugation is to be obtained, in cm³, from the following formula:

$w = 0,5\ b\ t\ d\ \ 10^{-3}$

Figure 8 : Dimensions of a corrugation



3.5 End connections

3.5.1 Where ordinary stiffeners are continuous through primary supporting members, they are to be connected to the web plating so as to ensure proper transmission of loads, e.g. by means of one of the connection details shown in Fig 9 to Fig 12.

Connection details other than those shown in Fig 9 to Fig 12 may be considered by the Society on a case-by-case basis. In some cases, the Society may require the details to be supported by direct calculations submitted for review.

Figure 9 : End connection of ordinary stiffener - Without collar plate

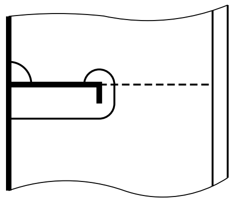


Figure 10 : End connection of ordinary stiffener - Collar plate

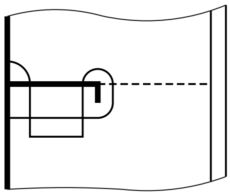

Figure 11 : End connection of ordinary stiffener - One large collar plate

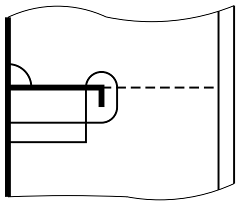

Figure 12 : End connection of ordinary stiffener - Two large collar plates

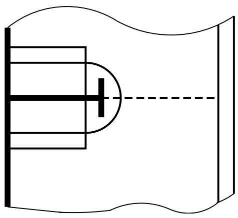
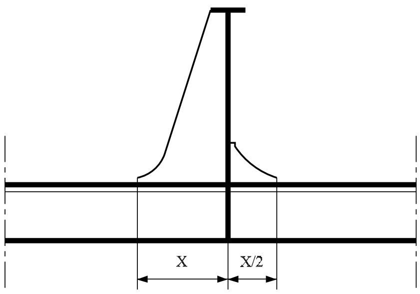


3.5.2 Where ordinary stiffeners are cut at primary supporting members, brackets are to be fitted to ensure the structural continuity. Their net section modulus and their net sectional area are to be not less than those of the ordinary stiffeners.

The net thickness of brackets is to be not less than that of ordinary stiffeners. Brackets with net thickness, in mm, less than 15 L_b , where L_b is the length, in m, of the free edge of the end bracket, are to be flanged or stiffened by a welded face plate. As a Rule, the net sectional area, in cm^2, of the flanged edge or face plate is to be at least equal to 10 L_b . Other dimensions of the net sectional area of the flanged edge or face plate may be accepted if deemed equivalent or validated by experience.

3.5.3 Where necessary, the Society may require backing brackets to be fitted, as shown in Fig 13, in order to improve the fatigue strength of the connection (see also [4.7.4]).

Figure 13 : End connection of ordinary stiffener - Backing bracket



4 Primary supporting members

4.1 Span of primary supporting members

4.1.1 The span of primary supporting members is to be determined in accordance with [3.2].

4.2 Width of attached plating

4.2.1 General

The width of the attached plating to be considered for the yielding check of primary supporting members analysed through beam structural models is to be obtained, in m, from the following formulae:

- where the plating extends on both sides of the primary supporting member:

  $b_P = \text{Min}\ (s\ ;\ 0{,}2\ \ell)$

- where the plating extends on one side of the primary supporting member (i.e. primary supporting members bounding openings):

  $b_P = 0{,}5\ \text{Min}\ (s\ ;\ 0{,}2\ \ell)$

4.2.2 Corrugated bulkheads

The width of attached plating of corrugated bulkhead primary supporting members is to be determined as follows:

- when primary supporting members are parallel to the corrugations and are welded to the corrugation flanges, the width of the attached plating is to be calculated in accordance with [4.2.1] and is to be taken not greater than the corrugation flange width
- when primary supporting members are perpendicular to the corrugations, the width of the attached plating is to be taken equal to the width of the primary supporting member face plate.

4.3 Geometric properties

4.3.1 Standard roll sections

The geometric properties of primary supporting members made of standard roll sections may be determined in accordance with [3.4.1], reducing the web height h_w by the depth of the cut-out for the passage of ordinary stiffeners, if any (see [4.6.1]).

4.3.2 Built sections

The geometric properties of primary supporting members made of built sections (including primary supporting members of double skin structures, such as double bottom floors and girders) are generally determined in accordance with [3.4.1], reducing the web height h_w by the depth of the cut-out for the passage of ordinary stiffeners, if any (see [4.6.1]).

Additional requirements relevant to the net shear sectional area are provided in [4.3.3].

4.3.3 Net shear sectional area in the case of web large openings

Where large openings are fitted in the web of primary supporting members (e.g. where a pipe tunnel is fitted in the double bottom, see Fig 14), their influence is to be taken into account by assigning an equivalent net shear sectional area to the primary supporting member.

This equivalent net shear sectional area is to be obtained, in cm², from the following formula:

$$A_{Sh} = \frac{A_{Sh1}}{1 + \dfrac{0{,}0032\,\ell^2 A_{Sh1}}{I_1}} + \frac{A_{Sh2}}{1 + \dfrac{0{,}0032\,\ell^2 A_{Sh2}}{I_2}}$$

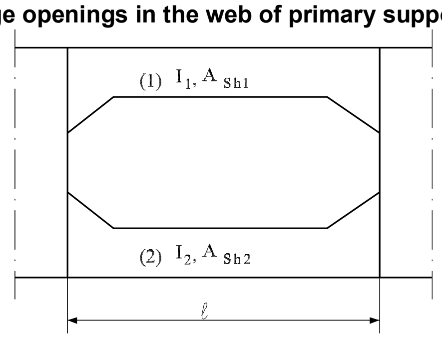
where (see Fig 14):

I_1, I_2 : Net moments of inertia, in cm⁴, of deep webs (1) and (2), respectively, with attached plating around their neutral axes parallel to the plating

A_{Sh1}, A_{Sh2} : Net shear sectional areas, in cm², of deep webs (1) and (2), respectively, to be calculated according to [4.3.2]

ℓ : Span, in cm, of deep webs (1) and (2).

Figure 14 : Large openings in the web of primary supporting members



4.4 Bracketed end connections

4.4.1 The following requirements in [4.4.2] to [4.4.7] may be replaced by equivalent arrangements based on direct analysis of bending stress and shear stress in way of connections. In such a situation, case-by-case analysis or approval of details booklet is requested.

4.4.2 Arm lengths of end brackets are to be equal, as far as practicable.

With the exception of primary supporting members of transversely framed single sides (see Ch 4, Sec 5, [3.2]), the height of end brackets is to be not less than that of the primary supporting member.

4.4.3 The net thickness of the end bracket web is generally to be not less than that of the primary supporting member web.

4.4.4 The net scantlings of end brackets are generally to be such that the net section modulus of the primary supporting member with end brackets is not less than that of the primary supporting member at mid-span.

4.4.5 Brackets with net thickness, in mm, less than 15 L_b, where L_b is the length, in m, of the free edge of the end bracket, are to be flanged or stiffened by a welded face plate. The width, in mm, of the face plate of end brackets is to be not less than 50 (L_b + 1). Other dimensions of width of the face plate may be accepted if deemed equivalent or validated by experience.

Moreover, the net thickness of the face plate is to be not less than that of the bracket web.

4.4.6 Stiffening of end brackets is to be designed such that it provides adequate buckling web stability.

As a guidance, the following prescriptions may be applied:

- where the length L_b is greater than 1,5 m, the web of the bracket is to be stiffened
- the net sectional area, in cm^2, of web stiffeners is to be not less than 16,5 ℓ, where ℓ is the span, in m, of the stiffener
- tripping flat bars are to be fitted to prevent lateral buckling of web stiffeners. Where the width of the symmetrical face plate is greater than 400 mm, additional backing brackets are to be fitted.

4.4.7 In addition to the above requirements, the net scantlings of end brackets are to comply with the applicable requirements given in Ch 4, Sec 4 to Ch 4, Sec 7.

4.5 Bracketless end connections

4.5.1 In the case of bracketless crossing between primary supporting members (see Fig 15), the net thickness of the common part of the web is to be not less than the value obtained, in mm, from the following formula:

$$t = 15{,}75\frac{w}{\Omega}$$

where:

w : The lesser of w_1 and $w_{2,MAX}$

w_1 : Gross section modulus, in cm^3, of member 1

$w_{2,MAX}$: The greater value, in cm^3, of the gross section moduli of members 2 and 3

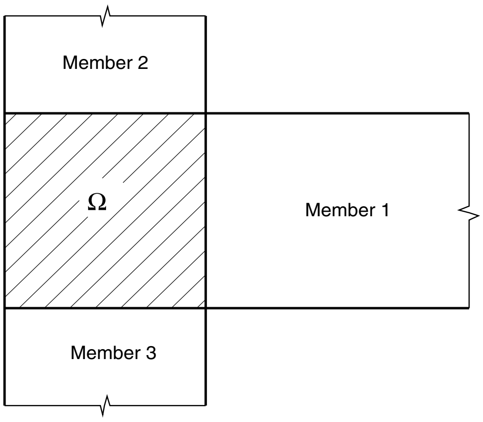
Ω : Area, in cm^2, of the common part of members 1, 2 and 3.

In the absence of one of members 2 and 3 shown in Fig 15, the value of the relevant gross section modulus is to be taken equal to zero.

4.5.2 In no case may the net thickness calculated according to [4.5.1] be less than the smallest web net thickness of the members forming the crossing.

4.5.3 In general, the continuity of the face plates is to be ensured.

Figure 15 : Bracketless end connections of primary supporting members



4.6 Cut-outs and holes

4.6.1 Cut-outs for the passage of ordinary stiffeners are to be as small as possible and well rounded with smooth edges.

In general, the depth of cut-outs is to be not greater than 50% of the depth of the primary supporting member.

4.6.2 Where openings such as lightening holes are cut in primary supporting members, they are to be equidistant from the face plate and corners of cut-outs. Other arrangement may be considered on a case-by-case basis.

4.6.3 Openings may not be fitted in way of toes of end brackets.

4.6.4 Over half of the span of primary supporting members, the length of openings is to be not greater than the distance between adjacent openings.

At the ends of the span, the length of openings is to be not greater than 25% of the distance between adjacent openings.

4.6.5 In the case of large openings as shown in Fig 16, the secondary stresses in primary supporting members are to be considered for the reinforcement of the openings.

The secondary stresses may be calculated in accordance with the following procedure.

Members (1) and (2) are subjected to the following forces, moments and stresses:

$$F = \frac{M_A + M_B}{2d}$$

$$m_1 = \left|\frac{M_A - M_B}{2}\right| K_1$$

$$m_2 = \left|\frac{M_A - M_B}{2}\right| K_2$$

$$\sigma_{F1} = 10\frac{F}{S_1}$$

$$\sigma_{F2} = 10\frac{F}{S_2}$$

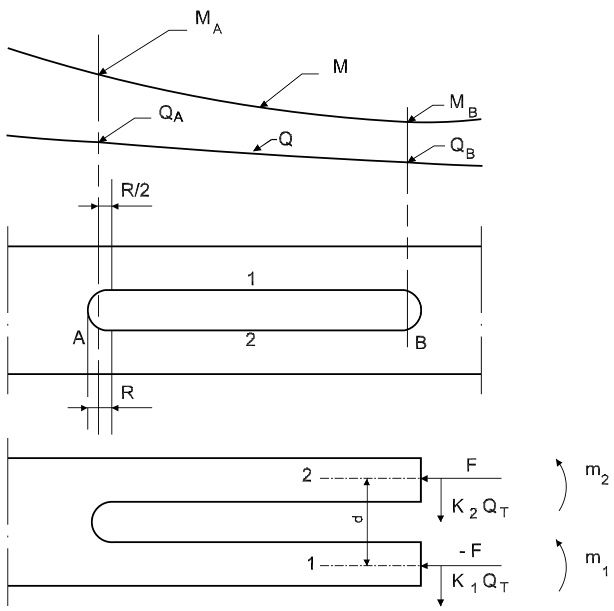
$$\sigma_{m1} = \frac{m_1}{w_1}10^3$$

$$\sigma_{m2} = \frac{m_2}{w_2}10^3$$

$$\tau_1 = 10\frac{K_1 Q_T}{S_{w1}}$$

$$\tau_2 = 10\frac{K_2 Q_T}{S_{w2}}$$

Figure 16 : Large openings in primary supporting members - Secondary stresses



where:

M_A, M_B : Bending moments, in kN·m, in sections A and B of the primary supporting member

m_1, m_2 : Bending moments, in kN·m, in (1) and (2)

d : Distance, in m, between the neutral axes of (1) and (2)

σ_{F1}, σ_{F2} : Axial stresses, in N/mm², in (1) and (2)

σ_{m1}, σ_{m2} : Bending stresses, in N/mm², in (1) and (2)

Q_T : Shear force, in kN, equal to Q_A or Q_B, whichever is greater

τ_1, τ_2 : Shear stresses, in N/mm², in (1) and (2)

w_1, w_2 : Net section moduli, in cm³, of (1) and (2)

S_1, S_2 : Net sectional areas, in cm², of (1) and (2)

S_{w1}, S_{w2} : Net sectional areas, in cm², of webs in (1) and (2)

I_1, I_2 : Net moments of inertia, in cm⁴, of (1) and (2) with attached plating

$$K_1 = \frac{I_1}{I_1 + I_2}$$

$$K_2 = \frac{I_2}{I_1 + I_2}$$

The combined stress σ_C calculated at the ends of members (1) and (2) is to be obtained from the following formula:

$$\sigma_c = \sqrt{(\sigma_F + \sigma_m)^2 + 3\tau^2}$$

The combined stress σ_C is to comply with the checking criteria in Ch 7, Sec 3, [2.6] or Ch 7, Sec 3, [3.3], as applicable. Where these checking criteria are not complied with, the cut-out is to be reinforced according to one of the solutions shown in Fig 17 to Fig 19:

- continuous face plate (solution 1), see Fig 17
- straight face plate (solution 2), see Fig 18
- compensation of the opening (solution 3), see Fig 19
- combination of the above solutions.

Other arrangements may be accepted provided they are supported by direct calculations submitted to the Society for review.

Figure 17 : Stiffening of large openings in primary supporting members - Solution 1

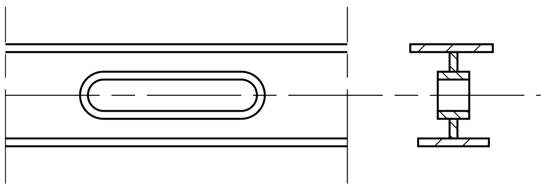


Figure 18 : Stiffening of large openings in primary supporting members - Solution 2

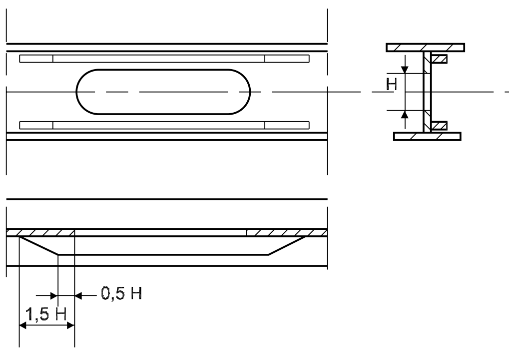

Figure 19 : Stiffening of large openings in primary supporting members - Solution 3

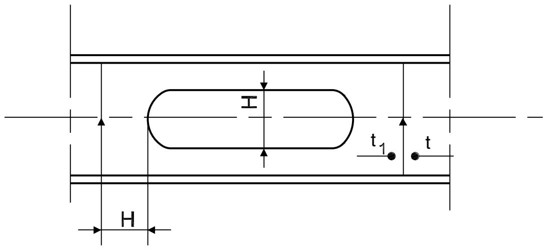
Inserted plate



4.7 Stiffening arrangement

4.7.1 Webs of primary supporting members are generally to be stiffened where the height, in mm, is greater than 100 t, where t is the web net thickness, in mm, of the primary supporting member.

In general, the web stiffeners of primary supporting members are to be spaced not more than 110 t.

4.7.2 Where primary supporting member web stiffeners are welded to ordinary stiffener face plates, their net sectional area at the web stiffener mid-height is to be not less than the value obtained, in cm^2, from the following formula:

$$A = 0{,}1\ k_1\ (\gamma_{S2}\ p_S + \gamma_{W2}\ p_W)\ s\ \ell$$

where:

k_1 : Coefficient depending on the web connection with the ordinary stiffener, to be taken as:

- k_1 = 0,300 for connections without collar plate (see Fig 9)
- k_1 = 0,225 for connections with a collar plate (see Fig 10)
- k_1 = 0,200 for connections with one or two large collar plates (see Fig 11 and Fig 12)

p_S, p_W : Still water and wave pressure, respectively, in kN/m^2, acting on the ordinary stiffener, defined in Ch 7, Sec 2, [3.3.2]

γ_{S2}, γ_{W2} : Partial safety factors, defined in Ch 7, Sec 2, Tab 1 for yielding check (general).

4.7.3 The net section modulus of web stiffeners of non-watertight primary supporting members is to be not less than the value obtained, in cm^3, from the following formula:

$$w = 2{,}5\ s^2\ t\ S_s^2$$

where:

s : Length, in m, of web stiffeners

t : Web net thickness, in mm, of the primary supporting member

S_s : Spacing, in m, of web stiffeners.

Moreover, web stiffeners located in areas subject to compression stresses are to be checked for buckling in accordance with Ch 7, Sec 2, [4].

4.7.4 Tripping brackets (see Fig 20) welded to the face plate are generally to be fitted:

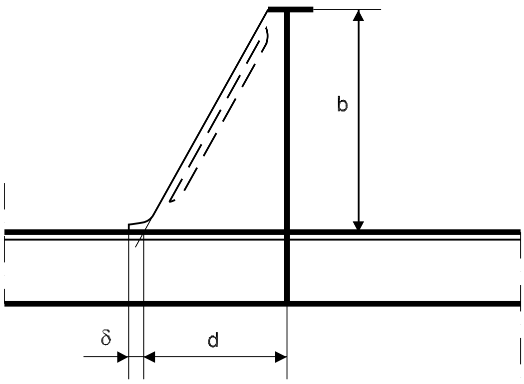
- in way of ordinary stiffeners and spaced not more than 4 m
- at the toe of end brackets
- at rounded face plates
- in way of cross ties
- in way of concentrated loads.

However, when d, calculated according to [4.7.6] with net thickness of tripping bracket equal to the minimum of thicknesses of ordinary stiffener and primary member webs, is less than 100 mm, the tripping bracket may be omitted.

Where the width of the symmetrical face plate is greater than 400 mm, backing brackets are to be fitted in way of the tripping brackets.

4.7.5 In general, the width of the primary supporting member face plate is to be not less than one tenth of the depth of the web, where tripping brackets are spaced as specified in [4.7.4].

Figure 20 : Primary supporting member: web stiffener in way of ordinary stiffener



4.7.6 The arm length of tripping brackets is to be not less than the greater of the following values, in m:

$d = 0,38\ b$

$$d = 0,85b\sqrt{\frac{s_t}{t}}$$

where:

b	:	Height, in m, of tripping brackets, shown in Fig 20
s_t	:	Spacing, in m, of tripping brackets
t	:	Net thickness, in mm, of tripping brackets.

It is recommended that the bracket toe should be designed as shown in Fig 20.

4.7.7 Tripping brackets with a net thickness, in mm, less than 15 L_b are to be flanged or stiffened by a welded face plate.

The net sectional area, in cm^2, of the flanged edge or the face plate is to be not less than 10 L_b, where L_b is the length, in m, of the free edge of the bracket. Other dimensions of the net sectional area of the flanged edge or face plate may be accepted if deemed equivalent or validated by experience.

Where the depth of tripping brackets is greater than 3 m, an additional stiffener is to be fitted parallel to the bracket free edge.

Section 4 Bottom Structure

1 General

1.1 Application

1.1.1 The requirements of this Section apply to longitudinally or transversely framed single and double bottom structures.

1.2 General arrangement

1.2.1 In general the bottom is to be longitudinally framed.

1.2.2 The bottom structure is to be checked by the Designer to make sure that it withstands the loads resulting from the dry-docking of the ship.

1.2.3 The bottom is to be locally stiffened where concentrated loads are envisaged.

1.2.4 Girders or floors are to be fitted under each line of pillars, when deemed necessary by the Society on the basis of the loads carried by the pillars.

1.2.5 Adequate tapering is to be provided between double bottom and adjacent single bottom structures. Similarly, adequate continuity is to be provided in the case of height variation in the double bottom. Where such a height variation occurs within 0,6 L amidships, the inner bottom is generally to be maintained continuous by means of inclined plating.

1.2.6 Provision is to be made for the free passage of water from all parts of the bottom to the suctions, taking into account the pumping rate required.

1.2.7 When solid ballast is fitted, it is to be securely positioned. If necessary, intermediate floors may be required for this purpose.

1.3 Drainage and openings for air passage

1.3.1 Holes are to be cut into floors and girders to ensure the free passage of air and liquids from all parts of the double bottom.

1.3.2 Air holes are to be cut as near to the inner bottom and draining holes as near to the bottom shell as practicable.

2 Longitudinally framed single bottom

2.1 General

2.1.1 Single bottom ships are to be fitted with a centre girder formed by a vertical continuous or intercostal web plate and a horizontal face plate continuous over the floors.

Intercostal web plates are to be aligned and welded to floors.

2.1.2 In general, girders are to be fitted spaced not more than 2,5 m apart and formed by a vertical intercostal web plate and a horizontal face plate continuous over the floors.

Intercostal web plates are to be aligned and welded to floors.

2.1.3 Centre and side girders are to be extended as far aft and forward as practicable.

2.1.4 Where side girders are fitted in lieu of the centre girder, the scarfing is to be adequately extended and additional stiffening of the centre bottom may be required.

2.1.5 Longitudinal girders are to be fitted in way of each line of pillars.

2.1.6 Floors are to be made with a welded face plate between the collision bulkhead and 0,25L from the fore end.

2.2 Floors

2.2.1 In general, the floor spacing is to be not greater than 5 frame spacings.

2.3 Longitudinal ordinary stiffeners

2.3.1 Longitudinal ordinary stiffeners are generally to be continuous when crossing primary members.

3 Transversely framed single bottom

3.1 General

3.1.1 The requirements in [2.1] apply also to transversely framed single bottoms.

3.2 Floors

3.2.1 Floors are to be fitted at every frame.

3.2.2 The height, in m, of floors at the centreline is to be not less than B/16. In the case of ships with considerable rise of floor, this height may be required to be increased so as to assure a satisfactory connection to the frames.

4 Longitudinally framed double bottom

4.1 General

4.1.1 The centre girder is to be continuous and extended over the full length of ship and the spacing of adjacent longitudinal girders is generally to be not greater than 6,5 m.

4.2 Double bottom height

4.2.1 The double bottom height is to be sufficient to ensure access to all parts and, in way of the centre girder, is to be not less than 0,7 m.

4.2.2 Where the height of the double bottom varies, the variation is generally to be made gradually and over an adequate length; the knuckles of inner bottom plating are to be located in way of plate floors.

Where this is impossible, suitable longitudinal structures such as partial girders, longitudinal brackets etc., fitted across the knuckle are to be arranged.

4.2.3 In ships without a flat bottom, the height of double bottom specified in [4.2.1] may be required to be adequately increased such as to ensure sufficient access to the areas towards the sides.

4.3 Floors

4.3.1 The spacing of plate floors, in m, is generally to be not greater than 0,05L or 3,8 m, whichever is the lesser.

Additional plate floors are to be fitted in way of transverse watertight bulkheads.

4.3.2 Plate floors are generally to be provided with stiffeners in way of longitudinal ordinary stiffeners.

4.3.3 Where the double bottom height exceeds 0,9 m, watertight floors are to be fitted with stiffeners having a net section modulus not less than that required for tank bulkhead vertical stiffeners.

4.4 Bottom and inner bottom longitudinal ordinary stiffeners

4.4.1 Bottom and inner bottom longitudinal ordinary stiffeners are generally to be continuous through the floors.

4.5 Brackets to centreline girder and margin plate

4.5.1 In general, intermediate brackets are to be fitted connecting either the margin plate or the centre girder to the nearest bottom and inner bottom ordinary stiffeners.

4.5.2 Such brackets are to be stiffened at the edge with a flange having a width not less than 1/10 of the local double bottom height.

If necessary, the Society may require a welded flat bar to be arranged in lieu of the flange.

4.5.3 Where the side shell is transversely stiffened, margin plate brackets are to be fitted at every frame.

4.6 Duct keel

4.6.1 Where a duct keel is arranged, the centre girder may be replaced by two girders conveniently spaced, generally no more than 2 m apart.

4.6.2 The structures in way of the floors are to ensure sufficient continuity of the latter.

4.7 Bilge wells

4.7.1 Bilge wells arranged in the double bottom are to be limited in depth and formed by steel plates having a net thickness not less than the greater of that required for watertight floors and that required for the inner bottom.

4.7.2 In ships subject to subdivision requirements, such bilge wells are to be fitted so that the distance of their bottom from the shell plating is not less than 460 mm.

4.7.3 Where there is no margin plate, well arrangement is considered by the Society on a case by case basis.

5 Transversely framed double bottom

5.1 General

5.1.1 The requirements in [4.1], [4.2], [4.5], [4.6] and [4.7] apply also to transversely framed double bottoms.

5.2 Floors

5.2.1 Plate floors are to be fitted at every frame forward of 0,75L from the aft end.

Plate floors are also to be fitted:

- in way of transverse watertight bulkheads
- in way of double bottom steps.

Elsewhere, plate floors may be arranged at a distance not exceeding 3 m.

5.2.2 In general, plate floors are to be continuous between the centre girder and the margin plate.

5.2.3 Open floors are to be fitted in way of intermediate frames.

5.2.4 Where the double bottom height exceeds 0,9 m, plate floors are to be fitted with vertical stiffeners spaced not more than 1,5 m apart.

These stiffeners may consist of flat bars with a width equal to one tenth of the floor depth and a net thickness, in mm, not less than $0,8L^{0,5}$.

5.3 Girders

5.3.1 Side girders are to be arranged in such a way that their distance to adjacent girders or margin plate does not generally exceed 4,5 m.

5.3.2 Where the double bottom height exceeds 0,9 m, longitudinal girders are to be fitted with vertical stiffeners spaced not more than 1,5 m apart.

These stiffeners may consist of flat bars with a width equal to one tenth of the girder height and a net thickness, in mm, not less than $0,8L^{0,5}$.

5.3.3 In way of open floors, side girders are to be provided with stiffeners having a web height which is generally to be not less than 150 mm.

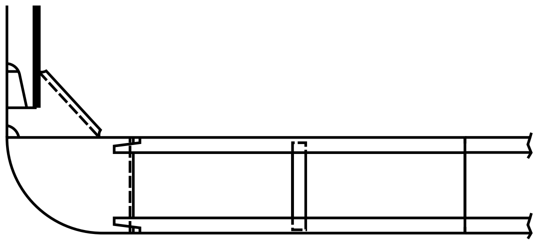
5.4 Open floors

5.4.1 At each frame between plate floors, open floors are to be arranged consisting of a frame connected to the bottom plating and a reverse frame connected to the inner bottom plating (see Fig 1).

5.4.2 Open floors are to be attached to the centreline girder and to the margin plate by means of flanged brackets having a width of flange not less than 1/10 of the local double bottom height.

5.4.3 Where frames and reverse frames are interrupted in way of girders, double brackets are to be fitted.

Figure 1 : Open floor



6 Bilge keel

6.1 Arrangement, scantlings and connections

6.1.1 Material

The material of the bilge keel and that of the ground bar is to be at least of the same yield stress as the material of the bilge plating to which they are attached.

In addition, when the bilge keel extends over a length greater than 0,15 L, the material of the ground bar and that of the bilge keel are to be, at least, of the same grade and of the same material class as the material of the bilge plating to which they are attached.

Exceptions will be specially considered by the Society on the basis of justification to be provided by the Designer, if it is shown that the bilge keel is able to resist the loads imposed on it.

6.1.2 Design

The design of single web bilge keels is to be such that failure of the web occurs before failure of the ground bar. This may be achieved by ensuring that the following conditions are both satisfied:

- the web thickness of the bilge keel does not exceed that of the ground bar
- the yield stress of the material of the bilge keel does not exceed that of the ground bar.

Other design principles which ensure that the bilge keel fails first without causing damage to the hull will be specially considered by the Society.

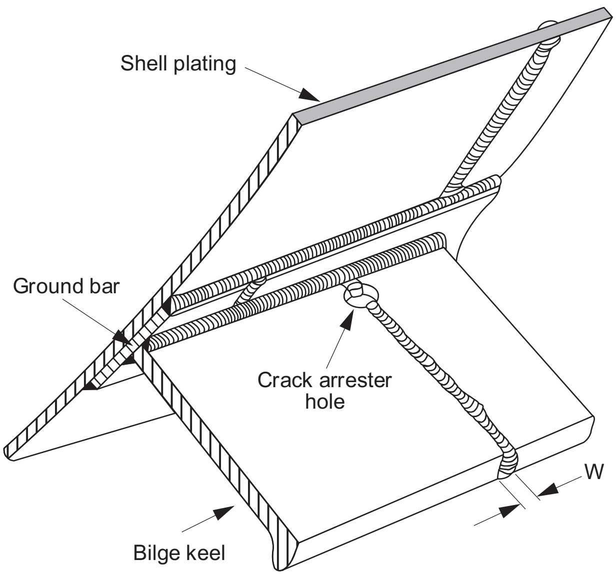
In general, scallops and cut-outs are not to be used. Crack arresting holes are to be drilled in the bilge keel butt welds as close as practicable to the ground bar. The diameter of the hole is to be greater than the width W of the butt weld and is to be a minimum of 25 mm (see Fig 2). Where the butt weld has been subject to non-destructive examination, the crack arresting hole may be omitted.

Bilge keels of a design different from that shown in Fig 2 are to be specially considered by the Society.

The design of box type bilge keels will be examined on a case-by-case basis, taking into account the following requirements:

- such designs and their connections to the shell are to account for the possibility that they may lead to damage to the hull, as well as the degree of inspection that will be possible
- such designs are to be watertight
- the thickness of the longitudinal members enclosing the bilge keel is not to exceed that of the surrounding plating
- as a rule, internal stiffening members are not to be attached to the shell.

Figure 2 : Single web bilge keel arrangement



6.1.3 Ground bars

Single web bilge keels are not to be welded directly to the shell plating. A ground bar, or doubler, is to be fitted on the shell plating as shown in Fig 2 to Fig 4. In general, the ground bar is to be continuous.

The gross thickness of the ground bar is not to be less than the gross thickness of the bilge plating or 14 mm, whichever is the lesser.

In the case of box type bilge keels:

- For designs directly attached to the shell plating (i.e. without doubler), insert plates having well-rounded corners and gross thickness at least 50 percent greater than the gross thickness of the surrounding plating are to be fitted at the ends.
- Other arrangements for attachment to the hull will be specially considered by the Society on the basis of justification to be provided by the Designer. This justification is to account for the possibility of crack initiation at the attachments to the shell.

Figure 3 : Single web bilge keel design

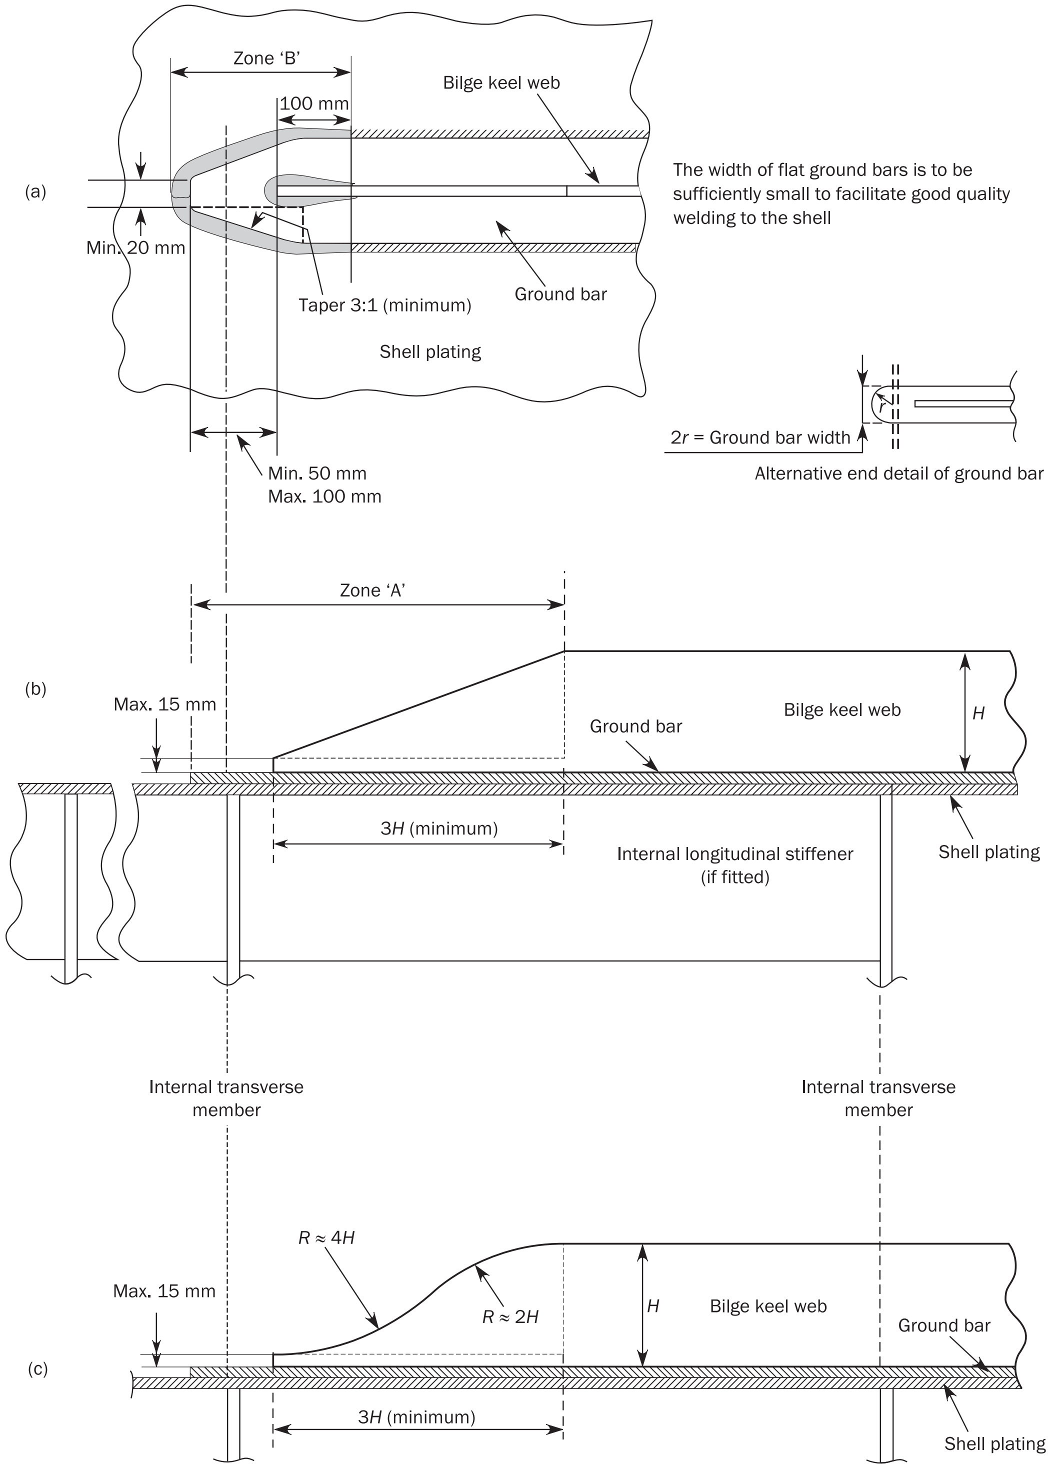


Figure 4 : Single web bilge keel design

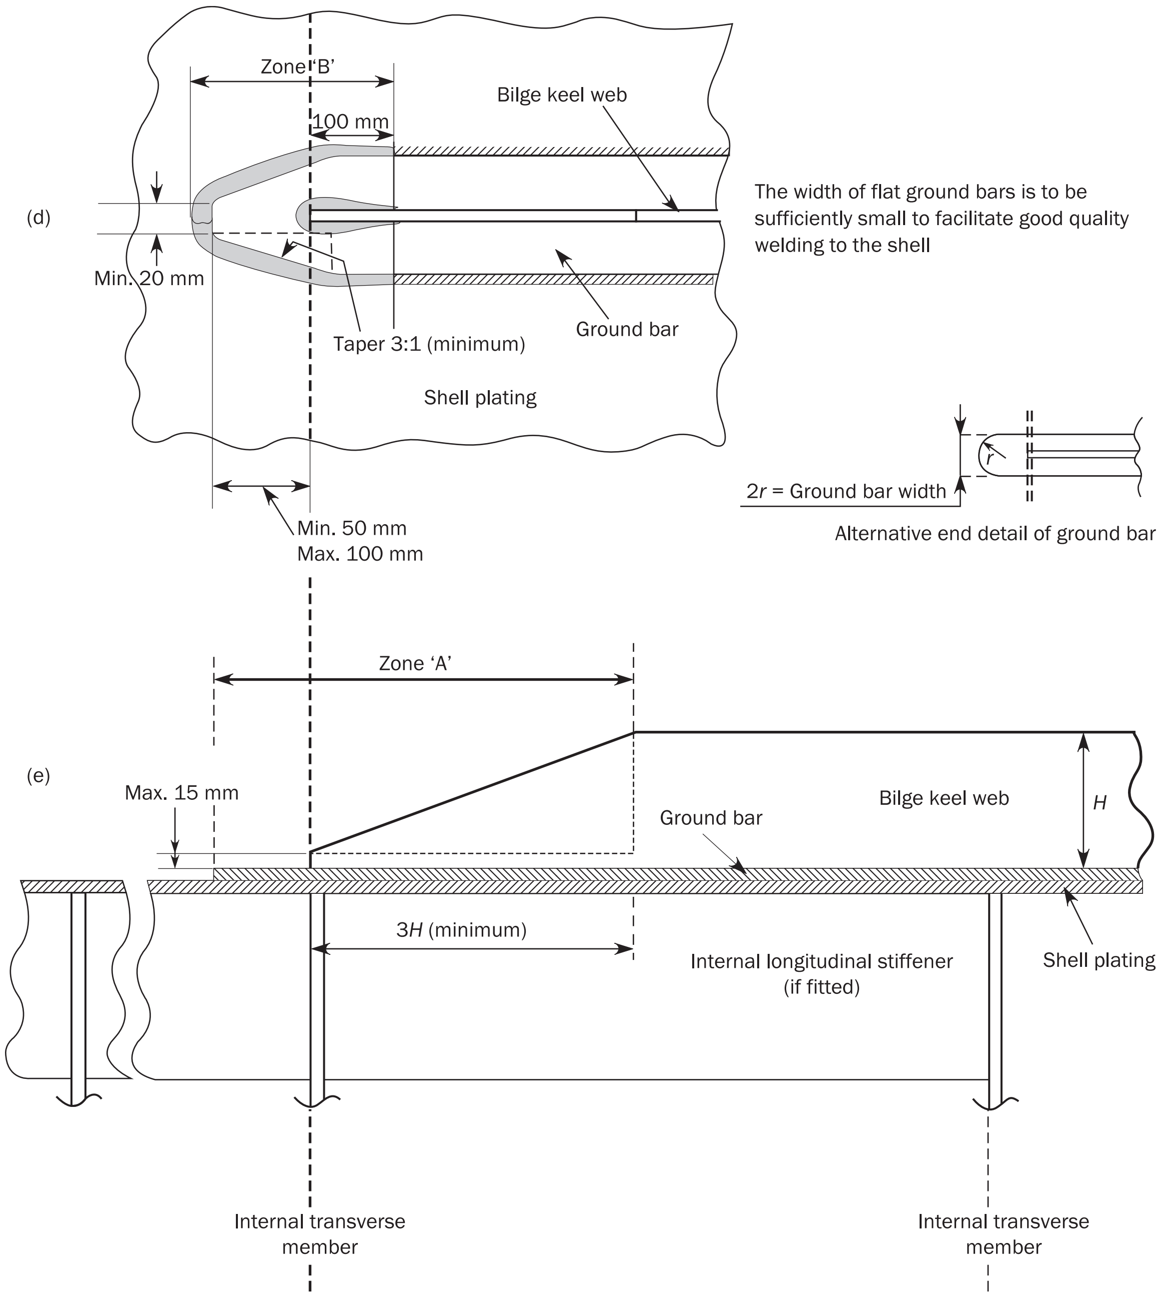

6.1.4 End details

The ground bar and bilge keel ends are to be tapered or rounded. Tapering is to be gradual with a minimum ratio of 3:1, see Fig 3 items (a) and (b), and Fig 4items (d) and (e).

Rounded ends are to be as shown in Fig 3 item (c). Cutouts on the bilge keel web within zone A (see Fig 3, item (b) and Fig 4 item (e) are not permitted.

The end of the bilge keel web is to be not less than 50 mm and not greater than 100 mm from the end of the ground b ar, see Fig 3, item (a) and Fig 4, item (d).

Ends of the bilge keel and ground bar are to be supported by either transverse or longitudinal members inside the hull, as indicated as follows:

- transverse support member is to be fitted at mid-length between the end of the bilge keel web and the end of the ground bar, see Fig 3 items (a), (b) and (c)
- longitudinal stiffener is to be fitted in line with the bilge keel web, it is to extend to at least the nearest transverse member forward and aft of zone A (see Fig 3 item (b) and Fig 4 item (e)).

Alternative end arrangements may be considered by the Society on a case-by-case basis.

For box type bilge keels, end details will be examined on a case-by-case basis, paying due attention to structural continuity at the ends with respect to the stiffening members of the hull.

Section 5 Side Structure

1 General

1.1 Application

1.1.1 The requirements of this Section apply to longitudinally or transversely framed side structures.

1.1.2 The transversely framed side structures are built with transverse frames possibly supported by side girders (see [5.3.1]).

1.1.3 The longitudinally framed side structures are built with longitudinal ordinary stiffeners supported by side vertical primary supporting members.

1.2 General arrangement

1.2.1 Unless otherwise specified, side girders are to be fitted aft of the collision bulkhead up to 0,2L aft of the fore end, in line with fore peak girders.

1.2.2 Side vertical primary supporting members are to be fitted in way of hatch end beams.

1.3 Sheerstrake

1.3.1 The width of the sheerstrake is to be not less than the value obtained, in m, from the following formula:

$$b = 0,715 + 0,425\frac{L}{100}$$

For strength deck, the width of the sheerstrake is to be not less than the value given in Ch 4, Sec 1, [2.4.4].

1.3.2 The sheerstrake may be either welded to the stringer plate or rounded. If it is rounded, the radius, in mm, is to be not less than $17t_S$, where t_S is the net thickness, in mm, of the sheerstrake.

1.3.3 The upper edge of the welded sheerstrake is to be rounded and free of notches.

1.3.4 The transition from a rounded sheerstrake to an angled sheerstrake associated with the arrangement of superstructures at the ends of the ship is to be carefully designed so as to avoid any discontinuities.

Plans showing details of this transition are to be submitted for approval to the Society.

2 Longitudinally framed single side

2.1 Longitudinal ordinary stiffeners

2.1.1 Longitudinal ordinary stiffeners are generally to be continuous when crossing primary members.

2.2 Primary supporting members

2.2.1 In general, the side vertical primary supporting member spacing may not exceed 5 frame spacings.

2.2.2 In general, the side vertical primary supporting members are to be bracketed to the double bottom transverse floors.

3 Transversely framed single side

3.1 Frames

3.1.1 Transverse frames are to be fitted at every frame.

3.1.2 Frames are generally to be continuous when crossing primary members.

Otherwise, the detail of the connection is to be examined by the Society on a case by case basis.

3.1.3 In general, the net section modulus of ‘tween deck frames is to be not less than that required for frames located immediately above.

3.2 Primary supporting members

3.2.1 In 'tweendecks of more than 4 m in height, side girders or side vertical primary supporting members or both may be required by the Society.

3.2.2 Side girders are to be flanged or stiffened by a welded face plate.

The width of the flanged edge or face plate is to be not less than 22t, where t is the web net thickness, in mm, of the girder.

3.2.3 The height of end brackets is to be not less than half the height of the primary supporting member.

4 Longitudinally framed double side

4.1 General

4.1.1 Adequate continuity of strength is to be ensured in way of breaks or changes in width of the double side.

In particular, scarfing of the inner side is to be ensured beyond the cargo hold region.

4.1.2 Knuckles of the inner side are to be adequately stiffened by longitudinal stiffeners. Equivalent arrangement may be considered by the Society on a case by case basis.

4.2 Primary supporting members

4.2.1 The height of side vertical primary supporting members may be gradually tapered from bottom to deck. The maximum acceptable taper, however, is 8 cm per metre.

4.2.2 Side vertical primary supporting members supported by a strut and two diagonals converging on the former are to be considered by the Society on a case by case basis.

5 Transversely framed double side

5.1 General

5.1.1 The requirements in [4.1] also apply to transversely framed double side.

5.1.2 Transverse frames may be connected to the vertical ordinary stiffeners of the inner side by means of struts.

Struts are generally to be connected to transverse frames and vertical ordinary stiffeners of the inner side by means of vertical brackets.

5.2 Frames

5.2.1 Transverse frames are to be fitted at every frame.

5.3 Primary supporting members

5.3.1 Unless otherwise specified, transverse frames are to be supported by side girders if $D \geq 6{,}0$ m.

These girders are to be supported by side vertical primary supporting members spaced no more than 3,8 m apart.

5.3.2 In the case of ships having $4{,}5\text{m} < D < 6{,}0\text{m}$, side vertical primary supporting members are to be fitted, in general not more than 5 frame spacings apart.

6 Frame connections

6.1 General

6.1.1 End connections of frames are to be bracketed.

Other arrangement may be accepted on a case by case basis, when deemed equivalent.

6.1.2 'Tweendeck frames are to be bracketed at the top and welded or bracketed at the bottom to the deck.

In the case of bulb profiles, a bracket may be required to be fitted at bottom.

6.1.3 Brackets are normally connected to frames by lap welds. The length of overlap is to be not less than the depth of frames.

6.1.4 Arrangement and scantlings of bracketed ends other than those shown in [6.2] [6.3]may be accepted on a case by case basis, based on strength analysis.

6.2 Upper brackets of frames

6.2.1 The arm length of upper brackets connecting frames to deck beams is to be not less than the value obtained, in mm, from the following formula:

$$d = \varphi\sqrt{\frac{w + 30}{t}}$$

where:

φ : Coefficient equal to:

- for unflanged brackets:
  $\varphi = 48$
- for flanged brackets:
  $\varphi = 43,5$

w : Required net section modulus of the stiffener, in cm^3, given in [6.2.2] and [6.2.3] and depending on the type of connection

t : Bracket net thickness, in mm.

6.2.2 For connections of perpendicular stiffeners located in the same plane (see Fig 1) or connections of stiffeners located in perpendicular planes (see Fig 2), the required net section modulus is to be taken equal to:

$w = w_2$ if $w_2 \leq w_1$

$w = w_1$ if $w_2 > w_1$

where w_1 and w_2 are the required net section moduli of stiffeners, as shown in Fig 1 and Fig 2.

Figure 1 : Connections of perpendicular stiffeners in the same plane

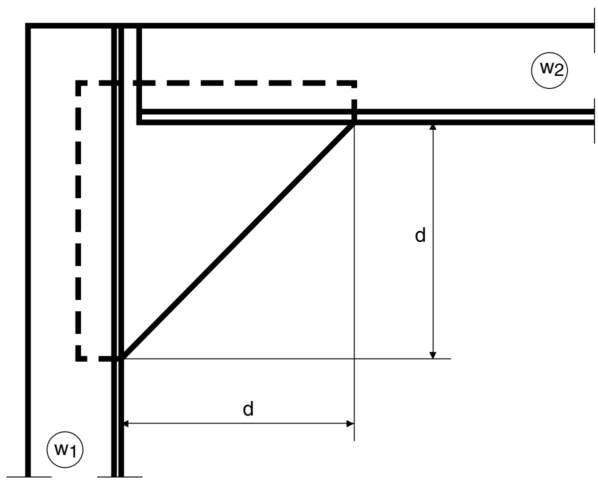

Figure 2 : Connections of stiffeners located in perpendicular planes

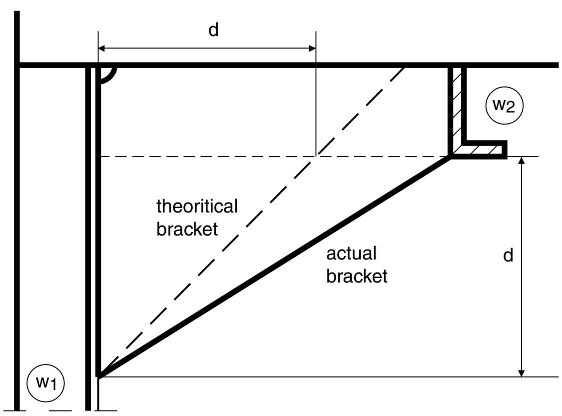


6.2.3 For connections of frames to deck beams (see Fig 3), the required net section modulus is to be taken equal to:

- for bracket "A":

  $w_A = w_1$ if $w_2 \le w_1$

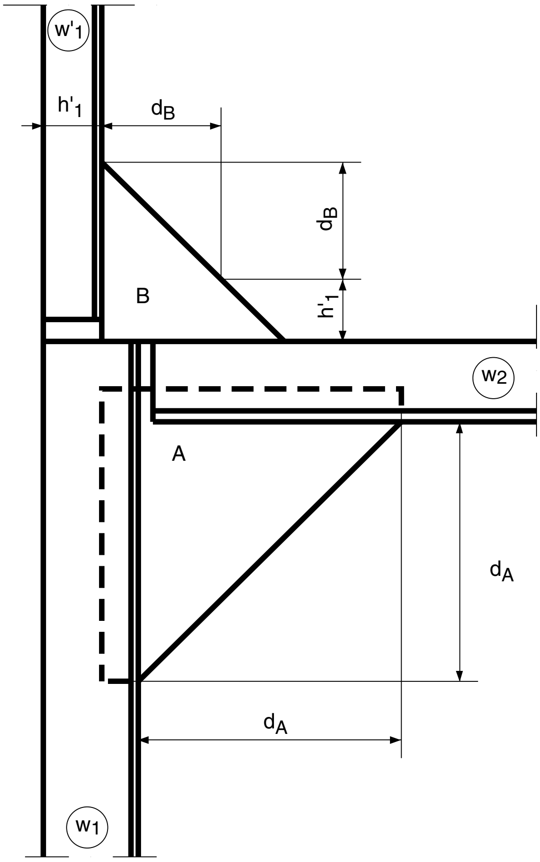
  $w_A = w_2$ if $w_2 > w_1$

- for bracket "B":

  $w_B = w'_1$ need not be greater than w_1

where w_1 , w'_1 and w_2 are the required net section moduli of stiffeners, as shown in Fig 3.

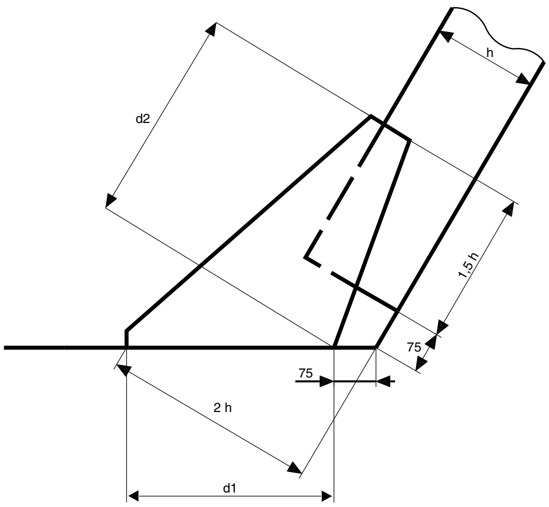
Figure 3 : Connections of frames to deck beams



6.3 Lower brackets of frames

6.3.1 In general, frames are to be bracketed to the inner bottom or to the face plate of floors as shown in Fig 4.

Figure 4 : Lower brackets of main frames



6.3.2 The arm lengths d_1 and d_2 of lower brackets of frames are to be not less than the value obtained, in mm, from the following formula:

$$d = \varphi\sqrt{\frac{w+30}{t}}$$

where:

φ : Coefficient equal to:
- for unflanged brackets:
  $\varphi = 50$
- for flanged brackets:
  $\varphi = 45$

w : Required net section modulus of the frame, in cm^3

t : Bracket net thickness, in mm.

6.3.3 Where the bracket net thickness, in mm, is less than $15L_b$, where L_b is the length, in m, of the bracket free edge, the free edge of the bracket is to be flanged or stiffened by a welded face plate.

The net sectional area, in cm^2, of the flange or the face plate is to be not less than $10L_b$.

7 Openings in the shell plating

7.1 Position of openings

7.1.1 Openings in the shell plating are to be located at a vertical distance from the decks at side not less than:
- two times the opening diameter, in case of circular opening
- the opening minor axis, in case of elliptical openings.

See also Ch 4, Sec 6, Fig 1.

7.2 Local strengthening

7.2.1 Openings in the ship sides, e.g. for cargo ports, are to be well rounded at the corners and located well clear of superstructure ends or any openings in the deck areas at sides of hatchways.

7.2.2 Openings for sea intakes are to be well rounded at the corners and, within 0,6 L amidships, located outside the bilge strakes. Where arrangements are such that sea intakes are unavoidably located in the curved zone of the bilge strakes, such openings are to be elliptical with the major axis in the longitudinal direction. Openings for stabiliser fins are considered by the Society on a case by case basis. The thickness of sea chests is generally to be not less than that of the local shell plating.

7.2.3 Openings in [7.2.1] and [7.2.2] and, when deemed necessary by the Society, other openings of considerable size are to be adequately compensated by means of insert plates of increased thickness or doublers sufficiently extended in length. Such compensation is to be partial or total depending on the stresses occurring in the area of the openings.

Circular openings on the sheerstrake need not be compensated where their diameter does not exceed 20% of the sheerstrake minimum width, defined in [1.3], or 380 mm, whichever is the lesser, and where they are located away from openings on deck at the side of hatchways or superstructure ends.

Section 6 Deck Structure

1 General

1.1 Application

1.1.1 The requirements of this Section apply to longitudinally or transversely framed deck structures.

1.2 General arrangement

1.2.1 The deck supporting structure consists of ordinary stiffeners (beams or longitudinals), longitudinally or transversely arranged, supported by primary supporting members which may be sustained by pillars.

1.2.2 Where beams are fitted in a hatched deck, these are to be effectively supported by at least two longitudinal girders located in way of hatch side girders to which they are to be connected by brackets and/or clips.

1.2.3 In ships greater than 120 m in length, the zones outside the line of openings of the strength deck and other decks contributing to longitudinal strength are, in general, to be longitudinally framed.

Where a transverse framing type is adopted for such ships, it is considered by the Society on a case-by-case basis.

1.2.4 Adequate continuity of strength is to be ensured in way of:

- stepped or knuckled decks contributing to longitudinal strength
- changes in the framing system.

Details of structural arrangements are to be submitted for review to the Society.

1.2.5 Where applicable, deck transverses of reinforced scantlings are to be aligned with floors.

1.2.6 Inside the line of openings, a transverse structure is generally to be adopted for cross-deck structures, beams are to be adequately supported by girders and, in ships greater than 120 m in length, extend up to the second longitudinal from the hatch side girders toward the bulwark.

Where this is impracticable, intercostal stiffeners are to be fitted between the hatch side girder and the second longitudinal.

Other structural arrangements may be accepted, subject to their strength verification. In particular, their buckling strength against the transverse compression loads is to be checked. Where needed, deck transverses may be required to be fitted.

1.2.7 Deck supporting structures under deck machinery, cranes and king posts are to be adequately stiffened.

1.2.8 Pillars or other supporting structures are generally to be fitted under heavy concentrated weights.

1.2.9 Special arrangements, such as girders supported by cantilevers, are considered by the Society on a case-by-case basis.

1.2.10 Where devices for vehicle lashing arrangements and/or corner fittings for containers are directly attached to deck plating, provision is to be made for the fitting of suitable additional reinforcements of the sizes required by the load carried.

1.2.11 Stiffeners are also to be fitted in way of the ends and corners of deck houses and partial superstructures.

1.3 Construction of watertight decks

1.3.1 Watertight decks are to be of the same strength as watertight bulkheads at corresponding levels. The means used for making them watertight, and the arrangements adopted for closing openings in them, are to be to the satisfaction of the Society.

1.4 Stringer plate

1.4.1 As a Rule, the width of the stringer plate is to be not less than the value obtained, in m, from the following formula:

$$b = 0{,}35 + 0{,}5\frac{L}{100}$$

However, the stringer plate is also to comply with the requirements in Ch 4, Sec 1, [2.4.4] and Ch 4, Sec 1, [2.5.5].

1.4.2 Stringer plates of lower decks not extending over the full ship's length are to be gradually tapered or overlapped by adequately sized brackets.

2 Longitudinally framed deck

2.1 General

2.1.1 Deck longitudinals are to be continuous, as far as practicable, in way of deck transverses and transverse bulkheads.

Other arrangements may be considered, provided adequate continuity of longitudinal strength is ensured.

2.1.2 In general, the spacing of deck transverses is not to exceed 5 frame spacings.

2.2 Longitudinal ordinary stiffeners

2.2.1 In ships equal to or greater than 120 m in length, strength deck longitudinal ordinary stiffeners are to be continuous through the watertight bulkheads and/or deck transverses.

2.2.2 Frame brackets, in ships with transversely framed sides, are generally to have their horizontal arm extended to the adjacent longitudinal ordinary stiffener.

3 Transversely framed deck

3.1 General

3.1.1 In general, deck beams are to be fitted at each frame.

4 Pillars

4.1 General

4.1.1 Pillars are to be fitted, as far as practicable, in the same vertical line.

4.1.2 In general, pillars are to be fitted below winches, cranes, windlasses and steering gear, in the engine room and at the corners of deckhouses.

4.1.3 In tanks, solid or open section pillars are generally to be fitted. Pillars located in spaces intended for products which may produce explosive gases are to be of open section type.

4.1.4 Tight or non-tight bulkheads may be considered as pillars, provided that their arrangement complies with Ch 4, Sec 7, [4].

4.2 Connections

4.2.1 Heads and heels of pillars are to be attached to the surrounding structure by means of brackets, insert plates so that the loads are well distributed.

Insert plates may be replaced by doubling plates, except in the case of pillars which may also work under tension such as those in tanks.

In general, the net thickness of doubling plates is to be not less than 1,5 times the net thickness of the pillar.

4.2.2 Pillars are to be attached at their heads and heels by continuous welding.

4.2.3 Pillars are to be connected to the inner bottom at the intersection of girders and floors.

4.2.4 Where pillars connected to the inner bottom are not located in way of intersections of floors and girders, partial floors or girders or equivalent structures suitable to support the pillars are to be arranged.

4.2.5 Manholes may not be cut in the girders and floors below the heels of pillars.

4.2.6 Where pillars are fitted in tanks, head and heel brackets may be required if tensile stresses are expected.

4.2.7 Where side pillars are not fitted in way of hatch ends, vertical stiffeners of bulkheads supporting hatch side girders or hatch end beams are to be bracketed at their ends.

5 Hatch supporting structures

5.1 General

5.1.1 Hatch side girders and hatch end beams of reinforced scantlings are to be fitted in way of cargo hold openings.

In general, hatched end beams and deck transverses are to be in line with bottom and side transverse structures, so as to form a reinforced ring.

5.1.2 Clear of openings, adequate continuity of strength of longitudinal hatch coamings is to be ensured by underdeck girders.

5.1.3 The details of connection of deck transverses to longitudinal girders and web frames are to be submitted to the Society for approval.

6 Openings in the strength deck

6.1 Position of openings and local strengthening

6.1.1 Openings in the strength deck are to be kept to a minimum and spaced as far apart from one another and from breaks of effective superstructures as practicable. Openings are generally to be cut outside the hatched areas; in particular, they are to be cut as far as practicable from hatchway corners.

The dashed areas in Fig 1 are those where openings are generally to be avoided. The meaning of the symbols in Fig 1 is as follows:

c, e : Longitudinal and transverse dimensions of hatched area:

$c = 0{,}07\,\ell + 0{,}10\,b$ without being less than $0{,}25\,b$

$e = 0{,}25\,(B - b)$

a : Transverse dimension of openings

g : Transverse dimension of the area where openings are generally to be avoided in way of the connection between deck and side (as shown in Fig 1), deck and longitudinal bulkheads, deck and large deck girders:

- in the case of circular openings: $g = 2\,a$
- in the case of elliptical openings: $g = a$

Figure 1 : Position of openings in the strength deck

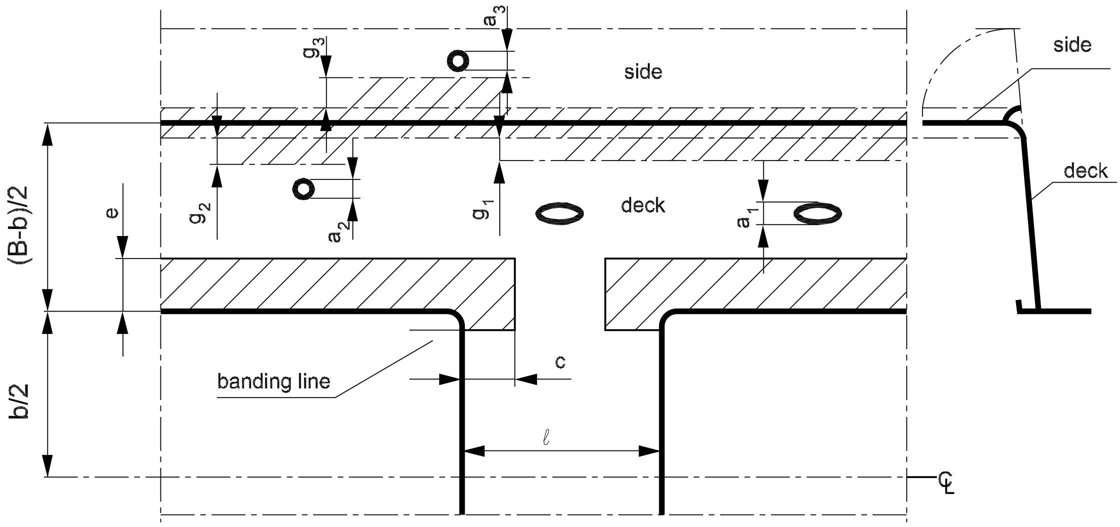


Figure 2 : Circular openings in the strength deck

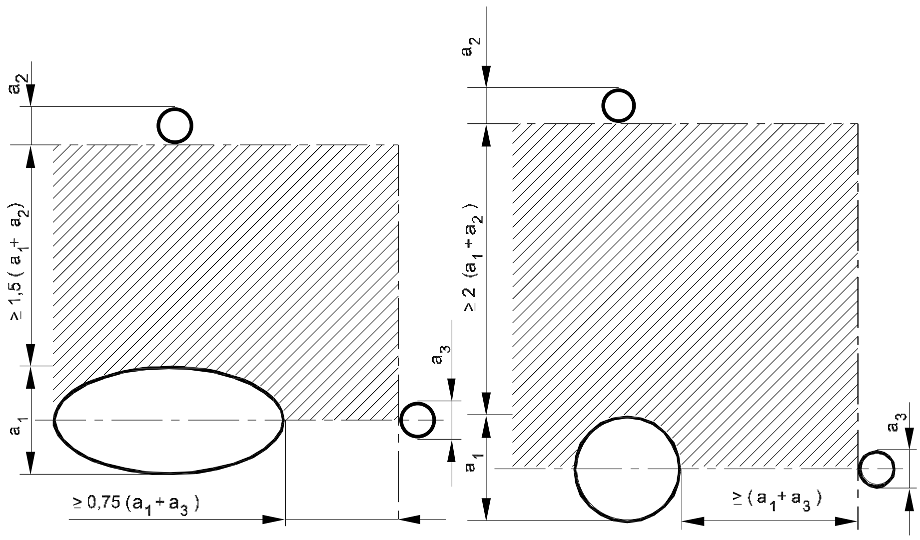

6.1.2 No compensation is required where the openings are:

- circular of less than 350 mm in diameter and at a distance from any other opening in compliance with Fig 2
- elliptical with the major axis in the longitudinal direction and the ratio of the major to minor axis not less than 2.

6.1.3 Other criteria proposed by the shipyard may be accepted by the Society, if considered as equivalent with respect to [6.1.1] and [6.1.2].

6.2 Corners of hatchways

6.2.1 For hatchways located within the central part, insert plates, whose thickness is to be determined according to [6.2.3], are generally to be fitted in way of corners where the plating cut-out has a circular profile.

The radius of circular corners is to be not less than:

- 5% of the hatch width, where a continuous longitudinal deck girder is fitted below the hatch coaming
- 8% of the hatch width, where no continuous longitudinal deck girder is fitted below the hatch coaming.

Corner radiusing, in the case of the arrangement of two or more hatchways athwartship, is considered by the Society on a case-by-case basis.

6.2.2 For hatchways located in the positions specified in [6.2.1], insert plates are, in general, not required in way of corners where the plating cut-out has an elliptical or parabolic profile and the half axes of elliptical openings, or the half lengths of the parabolic arch, are not less than:

- 1/20 of the hatchway width or 600 mm, whichever is the lesser, in the transverse direction
- twice the transverse dimension, in the fore and aft direction.

6.2.3 Where insert plates are required, their thickness is obtained, in mm, from the following formula:

$$t_{INS} = \left(0{,}8 + 0{,}4\frac{\ell}{b}\right)t$$

without being taken less than t or greater than 1,6 t

where:

ℓ : Width, in m, in way of the corner considered, of the cross deck strip between two consecutive hatchways, measured in the longitudinal direction (see Fig 1)

b : Width, in m, of the hatchway considered, measured in the transverse direction (see Fig 1)

t : Actual thickness, in mm, of the deck at the side of the hatchways.

For the extreme corners of end hatchways, the thickness of insert plates is to be 60% greater than the actual thickness of the adjacent deck plating. A lower thickness may be accepted by the Society on the basis of calculations showing that stresses at hatch corners are lower than permissible values.

6.2.4 Where insert plates are required, the arrangement shown in Sheet 3.1 of Ch 11, App 2 of is to be complied with.

6.2.5 For hatchways located in positions other than those in [6.2.1], a reduction in the thickness of the insert plates in way of corners may be considered by the Society on a case-by-case basis.

6.2.6 Other reinforcements deemed equivalent by the Society or alternative arrangements justified by direct calculations may be accepted.

7 Openings in decks other than the strength deck

7.1 General

7.1.1 The requirements for such openings are similar to those in [6.1] for the strength deck. However, circular openings need not to be compensated.

7.1.2 Corners of hatchway openings are to be rounded, as specified in [6.2] for the strength deck; insert plates may be omitted, however, when deemed acceptable by the Society.

Section 7 Bulkhead Structure

1 General

1.1 Application

1.1.1 The requirements of this Section apply to longitudinal or transverse bulkhead structures which may be plane or corrugated.

1.1.2 Bulkheads may be horizontally or vertically stiffened.

Horizontally framed bulkheads consist of horizontal ordinary stiffeners supported by vertical primary supporting members.

Vertically framed bulkheads consist of vertical ordinary stiffeners which may be supported by horizontal girders.

1.2 General arrangement

1.2.1 The number and location of watertight bulkheads are to be in accordance with the relevant requirements given in Ch 2, Sec 1.

1.2.2 Transverse corrugated bulkheads having horizontal corrugations are to be fitted with vertical primary supporting members of number and size sufficient to ensure the required vertical stiffness of the bulkhead.

1.2.3 Where an inner bottom terminates on a bulkhead, the lowest strake of the bulkhead forming the watertight floor of the double bottom is to extend at least 300 mm above the inner bottom.

1.2.4 Longitudinal bulkheads are to terminate at transverse bulkheads and are to be effectively tapered to the adjoining structure at the ends and adequately extended in the machinery space, where applicable.

1.2.5 Where the longitudinal watertight bulkheads contribute to longitudinal strength, the plating thickness is to be uniform for a distance of at least 0,1D from the deck and bottom.

1.2.6 The structural continuity of the bulkhead vertical and horizontal primary supporting members with the surrounding supporting structures is to be carefully ensured.

1.2.7 The height of vertical primary supporting members of longitudinal bulkheads may be gradually tapered from bottom to deck. The maximum acceptable taper, however, is 8 cm per metre.

1.3 Watertight bulkheads of trunks, tunnels, etc.

1.3.1 Watertight trunks, tunnels, duct keels and ventilators are to be of the same strength as watertight bulkheads at corresponding levels. The means used for making them watertight, and the arrangements adopted for closing openings in them, are to be to the satisfaction of the Society.

1.4 Openings in watertight bulkheads

1.4.1 Openings may not be cut in the collision bulkhead below the watertight deck.

The number of openings in the collision bulkhead above the watertight deck is to be kept to the minimum compatible with the design and proper working of the ship.

All such openings are to be fitted with means of closing to weathertight standards.

1.4.2 Certain openings below the watertight deck are permitted in the other bulkheads, but these are to be kept to a minimum compatible with the design and proper working of the ship and to be provided with watertight doors having strength such as to withstand the head of water to which they may be subjected. Ch 2, Sec 1, Tab 2 is to be referred to.

1.5 Watertight doors

1.5.1 The net thickness of watertight doors is to be not less than that of the adjacent bulkhead plating, taking account of their actual spacing.

1.5.2 Where vertical stiffeners are cut in way of watertight doors, reinforced stiffeners are to be fitted on each side of the door and suitably overlapped; cross-bars are to be provided to support the interrupted stiffeners.

1.5.3 Watertight doors are to be framed and capable of being secured watertight by handle-operated wedges which are suitably spaced and operable at both sides.

2 Plane bulkheads

2.1 General

2.1.1 Where a bulkhead does not extend up to the uppermost continuous deck (such as the after peak bulkhead), suitable strengthening is to be provided in the extension of the bulkhead.

2.1.2 Bulkheads are to be stiffened in way of deck girders.

2.1.3 The stiffener webs of hopper and topside tank watertight bulkheads are generally to be aligned with the webs of inner hull longitudinal stiffeners.

2.1.4 A primary supporting member is to be provided in way of any vertical knuckle in longitudinal bulkheads. The distance between the knuckle and the primary supporting member is to be taken not greater than 70 mm.

2.1.5 Plate floors are to be fitted in the double bottom in way of plane transverse bulkheads.

2.1.6 A doubling plate of the same net thickness as the bulkhead plating is to be fitted on the after peak bulkhead in way of the sterntube, unless the net thickness of the bulkhead plating is increased by at least 60%.

2.2 End connections of ordinary stiffeners

2.2.1 The crossing of ordinary stiffeners through a watertight bulkhead is to be watertight.

2.2.2 In general, end connections of ordinary stiffeners are to be bracketed (see [2.3]). However, stiffeners of watertight bulkheads in upper ‘tweendecks may be sniped, provided the scantling of such stiffeners are modified accordingly.

2.2.3 Where hull lines do not enable compliance with the requirements of [2.2.2], sniped ends may be accepted, provided the scantlings of stiffeners are modified accordingly.

2.2.4 Where sniped ordinary stiffeners are fitted, the snipe angle is to be not greater than 30° and their ends are to be extended, as far as practicable, to the boundary of the bulkhead.

2.3 Bracketed ordinary stiffeners

2.3.1 Where bracketed ordinary stiffeners are fitted, the arm lengths of end brackets of ordinary stiffeners, as shown in Fig 1 and Fig 2, are to be not less than the following values, in mm:

- for arm length a:
  - brackets of horizontal stiffeners and bottom bracket of vertical stiffeners: $a = 100\,\ell$
  - upper bracket of vertical stiffeners: $a = 80\,\ell$
- for arm length b, the greater of:

$$b = 80\sqrt{\frac{w+20}{t}}$$

$$b = \alpha\frac{ps\ell}{t}$$

where:

ℓ : Span, in m, of the stiffener measured between supports

w : Net section modulus, in cm^3, of the stiffener

t : Net thickness, in mm, of the bracket

p : Design pressure, in kN/m^2, calculated at mid-span

α : Coefficient equal to:

$\alpha = 4,9$ for tank bulkheads

$\alpha = 3,6$ for watertight bulkheads.

2.3.2 The connection between the stiffener and the bracket is to be such that the net section modulus of the connection is not less than that of the stiffener.

2.3.3 Scantlings of bracketed ends other than those calculated in [2.3.1] may be accepted by the Society on a case-by-case basis, based on strength analysis.

Figure 1 : Bracket at upper end of ordinary stiffener on plane bulkhead

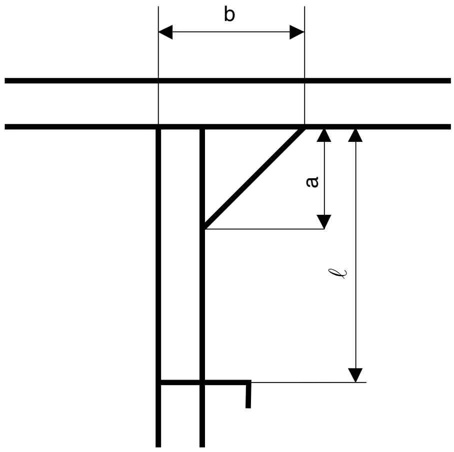

Figure 2 : Bracket at lower end of ordinary stiffener on plane bulkhead

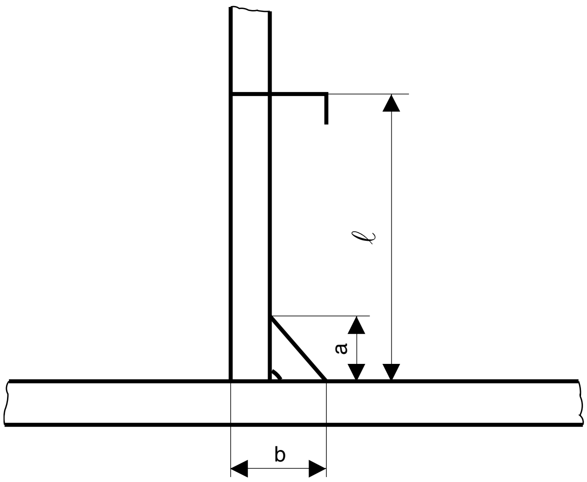


3 Corrugated bulkheads

3.1 General

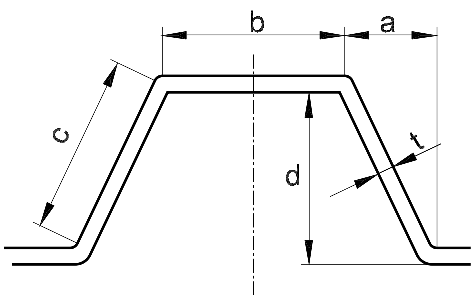
3.1.1 The main dimensions a, b, c and d of corrugated bulkheads are defined in Fig 3.

3.1.2 Unless otherwise specified, the following requirement is to be complied with:

$a \leq 1{,}2\ d$

Moreover, in some cases, the Society may prescribe an upper limit for the ratio b/t.

Figure 3 : Corrugated bulkhead



3.1.3 In general, the bending internal radius is to be not less than the following values, in mm:

- for normal strength steel: $R_i = 2,5\ t$
- for high tensile steel: $R_i = 3,0\ t$

where t is the net thickness, in mm, of the corrugated plate.

3.1.4 When butt welds in a direction parallel to the bend axis are provided in the zone of the bend, the welding procedures are to be submitted to the Society for approval, as a function of the importance of the structural element.

Moreover, when the gross thickness of the bulkhead plating is greater than 20 mm, the Society may require the use of steel grade E or EH.

3.1.5 In general, where girders or vertical primary supporting members are fitted on corrugated bulkheads, they are to be arranged symmetrically.

3.2 Structural arrangement

3.2.1 The strength continuity of corrugated bulkheads is to be ensured at ends of corrugations.

3.2.2 Where corrugated bulkheads are cut in way of primary members, attention is to be paid to ensure correct alignment of corrugations on each side of the primary member.

3.2.3 In general, where vertically corrugated transverse bulkheads are welded on the inner bottom, plate floors are to be fitted in way of the flanges of corrugations.

However, other arrangements ensuring adequate structural continuity may be accepted by the Society.

3.2.4 In general, where vertically corrugated longitudinal bulkheads are welded on the inner bottom, girders are to be fitted in way of the flanges of corrugations.

However, other arrangements ensuring adequate structural continuity may be accepted by the Society.

3.2.5 In general, the upper and lower parts of horizontally corrugated bulkheads are to be flat over a depth equal to 0,1 D.

3.2.6 Where stools are fitted at the lower part of transverse bulkheads, the net thickness of adjacent plate floors is to be not less than that of the stool plating.

3.3 Bulkhead stool

3.3.1 In general, plate diaphragms or web frames are to be fitted in bottom stools in way of the double bottom longitudinal girders or plate floors, as the case may be.

3.3.2 Brackets or deep webs are to be fitted to connect the upper stool to the deck transverses or hatch end beams, as the case may be.

3.3.3 The continuity of the corrugated bulkhead with the stool plating is to be adequately ensured. In particular, the upper strake of the lower stool is to be of the same net thickness and yield stress as those of the lower strake of the bulkhead.

4 Non-tight bulkheads

4.1 Non-tight bulkheads not acting as pillars

4.1.1 Non-tight bulkheads not acting as pillars are to be provided with vertical stiffeners with a maximum spacing equal to:

- 0,9 m for transverse bulkheads
- two frame spacings, with a maximum of 1,5 m, for longitudinal bulkheads.

4.2 Non-tight bulkheads acting as pillars

4.2.1 Non-tight bulkheads acting as pillars “(i.e. those that are designed to sustain the loads transmitted by a deck structure) are to be provided with vertical stiffeners with a maximum spacing equal to:

- two frame spacings, when the frame spacing does not exceed 0,75 m
- one frame spacing, when the frame spacing is greater than 0,75 m.

4.2.2 Each vertical stiffener, in association with a width of plating equal to 35 times the plating net thickness, is to comply with the applicable requirements for pillars in Ch 7, Sec 3, the load supported being determined in accordance with the same requirements.

4.2.3 In the case of non-tight bulkheads supporting longitudinally framed decks, vertical girders are to be provided in way of deck transverses.

5 Wash bulkheads

5.1 General

5.1.1 The requirements in [5.2] apply to transverse and longitudinal wash bulkheads whose main purpose is to reduce the liquid motions in partly filled tanks.

5.2 Openings

5.2.1 The total area of openings in a transverse wash bulkhead is generally to be between 10% and 30% of the total bulkhead area.

In the upper, central and lower portions of the bulkhead (the depth of each portion being 1/3 of the bulkhead height), the areas of openings, expressed as percentages of the corresponding areas of these portions, are to be within the limits given in Tab 1.

5.2.2 In any case, the distribution of openings is to fulfil the strength requirements specified in [4.2].

5.2.3 In general, openings may not be cut within 0,15 D from bottom and from deck.

Table 1 : Areas of openings in transverse wash bulkheads

Bulkhead portion	Lower limit	Upper limit
Upper	10 %	15 %
Central	10 %	50 %
Lower	2 %	10 %

DESIGN LOADS

Section 1 General

Section 2 Hull Girder Loads

Section 3 Ship Motions and Accelerations

Section 4 Load Cases

Section 5 Sea Pressures

Section 6 Internal Pressures and Forces

Appendix 1 Inertial Pressure for Typical Tank Arrangement

Symbols used in this Chapter

F : Froude's number:

$F = 0.164\ V_{max} / L^{0.5}$

V_{max} : Maximum ahead service speed, in knots

T_1 : Draught, in m, defined in Pt B, Ch 5, Sec 1, [2.4.3] or Pt B, Ch 5, Sec 1, [2.5.3], as the case may be

g : Gravity acceleration, in m/s^2:

$g = 9{,}81$ m/s^2,

x, y, z : X, Y and Z co-ordinates, in m, of the calculation point with respect to the reference co-ordinate system defined in Pt B, Ch 1, Sec 2, [6].

Section 1 General

1 Definitions

1.1 Cargo

1.1.1 Cargo are liquids and dry units (e.g. containers, vehicles, etc.) carried inside compartments and on decks.

1.2 Still water loads

1.2.1 Still water loads are those acting on the ship at rest in calm water.

1.3 Wave loads

1.3.1 Wave loads are those due to wave pressures and ship motions, which can be assumed to have the same wave encounter period.

1.4 Dynamic loads

1.4.1 Dynamic loads are those that have a duration much shorter than the period of the wave loads.

1.5 Local loads

1.5.1 Local loads are pressures and forces which are directly applied to the individual structural members: plating panels, ordinary stiffeners and primary supporting members.

- Still water local loads are constituted by the hydrostatic external sea pressures and the static pressures and forces induced by the weights carried in the ship spaces.
- Wave local loads are constituted by the external sea pressures due to waves and the inertial pressures and forces induced by the ship accelerations applied to the weights carried in the ship spaces.
- Dynamic local loads are constituted by the impact and sloshing pressures.

1.5.2 For the structures which constitute the boundary of spaces not intended to carry liquids and which do not belong to the outer shell, the still water and wave pressures in flooding conditions are also to be considered.

1.6 Hull girder loads

1.6.1 Hull girder loads are (still water, wave and dynamic) forces and moments which result as effects of local loads acting on the ship as a whole and considered as a beam.

1.7 Loading condition

1.7.1 A loading condition is a distribution of weights carried in the ship spaces arranged for their storage.

1.8 Load case

1.8.1 A load case is a state of the ship structures subjected to a combination of hull girder and local loads.

2 Application criteria

2.1 Fields of application

2.1.1 General

The wave induced and dynamic loads defined in this Chapter corresponds to an operating life of the ship equal to 30 years.

Loads for an operating life different from 30 years are considered by the Society on a case-by-case basis.

2.1.2 Requirements applicable to all types of ships

The still water, wave induced and dynamic loads defined in this Chapter are to be used for the determination of the hull girder strength and structural scantlings in the central part (see Ch 1, Sec 1) of ships, according to the requirements in Part B, Chapter 6 and Part B, Chapter 7.

2.1.3 Requirements applicable to specific ship types

The design loads applicable to specific ship types are to be defined in accordance with the requirements in Part D.

2.1.4 Load direct calculation

As an alternative to the formulae in Ch 5, Sec 2 and Ch 5, Sec 3, the Society may accept the values of wave induced loads and dynamic loads derived from direct calculations, when justified on the basis of the ship's characteristics and intended service. The calculations are to be submitted to the Society for approval.

2.2 Hull girder loads

2.2.1 The still water, wave and dynamic hull girder loads to be used for the determination of:

- the hull girder strength, according to the requirements of Part B, Chapter 6, and
- the structural scantling of plating, ordinary stiffeners and primary supporting members contributing to the hull girder strength, in combination with the local loads given in Ch 5, Sec 5 and Ch 5, Sec 6, according to the requirements in Part B, Chapter 7,

are specified in Ch 5, Sec 2.

2.3 Local loads

2.3.1 Load cases

The local loads defined in [1.5] are to be calculated in each of the mutually exclusive load cases described in Ch 5, Sec 4.

Dynamic loads are to be taken into account and calculated according to the criteria specified in Ch 5, Sec 5 and Ch 5, Sec 6.

2.3.2 Ship motions and accelerations

The wave local loads are to be calculated on the basis of the reference values of ship motions and accelerations specified in Ch 5, Sec 3.

2.3.3 Calculation and application of local loads

The criteria for calculating:

- still water local loads, and
- wave local loads on the basis of the reference values of ship motions and accelerations,

are specified in Ch 5, Sec 5 for sea pressures and in Ch 5, Sec 6 for internal pressures and forces.

2.3.4 Flooding conditions

The still water and wave pressures in flooding conditions are specified in Ch 5, Sec 6, [6]. The pressures in flooding conditions applicable to specific ship types are to be defined in accordance with the requirements in Part D.

2.4 Load definition criteria to be adopted in structural analyses based on plate or isolated beam structural models

2.4.1 Application

The requirements of this sub-article apply for the definition of local loads to be used in the scantling checks of:

- plating, according to Ch 7, Sec 1
- ordinary stiffeners, according to Ch 7, Sec 2
- primary supporting members for which a three-dimensional structural model is not required, according to Ch 7, Sec 3, [2].

2.4.2 Full load and operational load distributions

When calculating the local loads for the structural scantling of an element which separates two adjacent compartments, the latter may not be considered simultaneously loaded. The local loads to be used are those obtained considering the two compartments individually loaded.

For elements of the outer shell, the local loads are to be calculated considering separately:

- the still water and wave external sea pressures, considered as acting alone without any counteraction from the ship interior
- the still water and wave differential pressures (internal pressure minus external sea pressure) considering the compartment adjacent to the outer shell as being loaded.

2.4.3 Draught associated with full load and operational load

Local loads are to be calculated on the basis of the ship's draught T_1 corresponding to the full load or operational load distribution considered according to the criteria in [2.4.2]. The ship draught is to be taken as the distance measured vertically on the hull transverse section at the middle of the length L, from the moulded base line to the waterline in:

- full load condition, when:
  - one or more compartments are considered as being loaded and the ballast tanks are considered as being empty
  - the still water and wave external pressures are considered as acting alone without any counteraction from the ship's interior

- operational load condition, when one or more ballast tanks are considered as being loaded and the other compartments are considered as being empty. In the absence of more precise information, the ship's draught in light ballast condition may be obtained, in m, from the following formulae:

  $T_B = 0,03\ L \leq 7,5$ m

2.5 Load definition criteria to be adopted in structural analyses based on three- dimensional structural models

2.5.1 Application

The requirements of this sub-article apply for the definition of local loads to be used in the scantling checks of primary supporting members for which a three-dimensional structural model is required, according to Ch 7, Sec 3, [3].

2.5.2 Loading conditions

For all ship types for which analyses based on three-dimensional models are required according to Ch 7, Sec 3, [3], the most severe loading conditions for the structural elements under investigation are to be considered. These loading conditions are to be selected among those envisaged in the ship loading manual.

Further criteria applicable to specific ship types are specified in Part D.

2.5.3 Draught associated with each loading condition

Local loads are to be calculated on the basis of the ship's draught T_1 corresponding to the loading condition considered according to the criteria in [2.5.2].

Section 2 Hull Girder Loads

Symbols

For symbols not defined in this Section, refer to the list at the beginning of this Chapter.

C : Wave parameter:

$$C = (118 - 0,36L)\frac{L}{1000} \quad \text{for } 65\,m \le L < 90\,m$$

$$C = 10,75 - \left(\frac{300 - L}{100}\right)^{1,5} \quad \text{for } 90\,m \le L < 300\,m$$

$$C = 10,75 \quad \text{for } 300\,m \le L \le 350\,m$$

$$C = 10,75 - \left(\frac{L - 350}{150}\right)^{1,5} \quad \text{for } L > 350\,m$$

H : Wave parameter:

$$H = 8,13 - \left(\frac{250 - 0,7L}{125}\right)^3$$

without being taken greater than 8,13

H_A : Wave parameter:

$$H_A = \frac{CL}{200}$$

without being taken greater than 0,8 C

F_{CH} : Characteristic Froude number:

$$F_{CH} = 0,164\frac{V_{CH}}{\sqrt{L}}$$

V_{CH} : Characteristic ship speed; to be taken as the greatest between V_{cruise} and 0,75 V_{max}

V_{cruise} : Cruise speed, in knots.

1 General

1.1 Application

1.1.1 The requirements of this Section apply to ships having the following characteristics:

L / B > 5

B / D < 2,5

$C_B \ge 0,4$

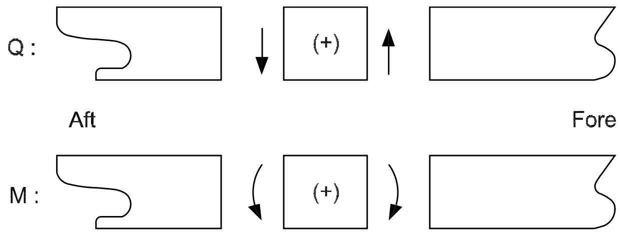
Ships not having one or more of these characteristics and ships of unusual type or design are considered by the Society on a case-by-case basis.

1.2 Sign conventions of vertical bending moments and shear forces

1.2.1 The sign conventions of bending moments and shear forces at any ship transverse section are as shown in Fig 1, namely:

- the vertical bending moment M is positive when it induces tensile stresses in the strength deck (hogging bending moment); it is negative in the opposite case (sagging bending moment)
- the vertical shear force Q is positive in the case of downward resulting forces preceding and upward resulting forces following the ship transverse section under consideration; it is negative in the opposite case.

Figure 1 : Sign conventions for shear forces Q and bending moments M



2 Still water loads

2.1 General

2.1.1 Still water load calculation

For all ships, the longitudinal distributions of still water bending moment and shear force are to be calculated, for each of the loading conditions in [2.1.2], on the basis of realistic data related to the amount of ballast, fuel, lubricating oil and fresh water.

The actual hull lines and lightweight distribution are to be taken into account in the calculations. The lightweight distribution may be replaced, if the actual values are not available, by a statistical distribution of weights accepted by the Society.

The designer is to supply the data necessary to verify the calculations of still water loads.

Ships with large openings are specially considered by the Society on a case-by-case basis.

2.1.2 Loading conditions

Still water loads are to be calculated at least for the design loading conditions corresponding to full load condition (end of life) and minimum operational load condition (at delivery) on which the approval of hull structural scantlings is based (see Ch 5, Sec 1, [1.2]). If other loading conditions are expected to be more severe than the above conditions, corresponding still water loads are also to be calculated.

For all ships, the following loading conditions are to be considered:

- homogeneous loading conditions at maximum draught
- operational load conditions
- special loadings (e.g. light load conditions at less than the maximum draught, etc., where applicable)
- short voyage or harbour conditions, where applicable
- loading and unloading transitory conditions, where applicable
- docking condition afloat
- ballast exchange at sea, if applicable.

2.2 Still water bending moments

2.2.1 The design still water bending moments $M_{SW,H}$ and $M_{SW,S}$ at any hull transverse section are the maximum still water bending moments calculated, in hogging and sagging conditions, respectively, at that hull transverse section for the loading conditions specified in [2.1.2].

Where no sagging bending moments act in the hull section considered, the value of $M_{SW,S}$ is to be taken as specified in Part B, Chapter 6 and Part B, Chapter 7.

2.2.2 If the design still water bending moments are not defined, at a preliminary design stage, at any hull transverse section, the longitudinal distributions shown in Fig 2 may be considered.

In Fig 2, M_{SW} is the design still water bending moment amidships, in hogging or sagging conditions, whose absolute values are to be taken not less than those obtained, in kN.m, from the following formulae:

- hogging conditions:

  $M_{SWM,H} = 175\ C\ L^2\ B\ (C_B + 0{,}7)\ 10^{-3} - M_{WV,H}$

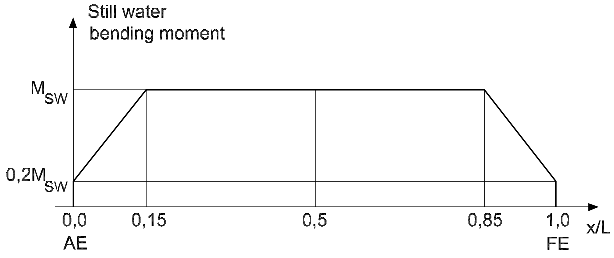
- sagging conditions:

  $M_{SWM,S} = 175\ C\ L^2\ B\ (C_B + 0{,}7)\ 10^{-3} + M_{WV,S}$

where $M_{WV,H}$ and $M_{WV,S}$ are the vertical wave bending moments, in kN.m, defined in [3.1].

The final structural checks are, in any case, to be carried out on the basis of the design still water bending moments as specified [2.2.1].

Figure 2 : Preliminary still water bending moment distribution



2.3 Still water shear force

2.3.1 The design still water shear force Q_{SW} at any hull transverse section is the maximum positive or negative shear force calculated, at that hull transverse section, for the loading conditions specified in [2.1.2].

3 Wave loads

3.1 Vertical wave bending moments

3.1.1 The vertical wave bending moments at any hull transverse section are obtained, in kN.m, from the following formulae:

- hogging conditions:

  $M_{WV,H} = 150\ F_M\ C\ L^2\ B\ C_B\ (1 + C_A)\ 10^{-3}$

- sagging conditions:

  $M_{WV,S} = -\ 85\ F_M\ C\ L^2\ B\ (C_B + 0{,}7)\ (1 + C_A)\ 10^{-3}$

where:

F_M : Distribution factor defined in Tab 1 and Fig 3

C_A : Coefficient equal to:

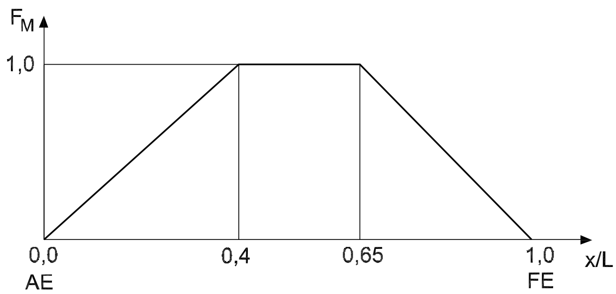
$$C_A = \frac{7{,}1 H_A (1 + 1{,}26 F_{CH})^2}{L}$$

3.1.2 The effects of bow flare impact are to be taken into account, for the cases specified in [4.1.1], according to [4.2.1].

Table 1 : Distribution factor F_M

Hull transverse section location	Distribution factor F_M
$0 \leq x < 0{,}4\ L$	$2{,}5\frac{x}{L}$
$0{,}4\ L \leq x \leq 0{,}65\ L$	1,00
$0{,}65\ L < x \leq L$	$2{,}86\left(1 - \frac{x}{L}\right)$

Figure 3 : Distribution factor F_M



3.2 Horizontal wave bending moment

3.2.1 The horizontal wave bending moment at any hull transverse section is obtained, in kN.m, from the following formula:

$M_{WH} = 0{,}42\ F_M\ H_A\ L^2\ T\ C_B$

where F_M is the distribution factor defined in [3.1.1].

3.3 Wave torque

3.3.1 The wave torque at any hull transverse section is to be calculated considering the ship in two different conditions:

- condition 1: ship direction forming an angle of 60° with the prevailing sea direction
- condition 2: ship direction forming an angle of 120° with the prevailing sea direction.

The values of the wave torques in these conditions, calculated with respect to the section centre of torsion, are obtained, in kN.m, from the following formula:

$$M_{WT} = \frac{HL}{4}(F_{TM}C_M + F_{TQ}C_Q d)$$

where:

F_{TM}, F_{TQ} : Distribution factors defined in Tab 2 for ship conditions 1 and 2 (see also Fig 4 and Fig 5)

C_M : Wave torque coefficient:

$C_M = 0{,}38\ B^2\ C_W^2$

C_Q : Horizontal wave shear coefficient:

$C_Q = 2{,}8\ T\ C_B$

C_W : Waterplane coefficient, to be taken not greater than the value obtained from the following formula:

$C_W = 0{,}165 + 0{,}95\ C_B$

where C_B is to be assumed not less than 0,6. In the absence of more precise determination, C_W may be taken equal to the value provided by the above formula

d : Vertical distance, in m, from the centre of torsion to a point located 0,6 T above the baseline.

Table 2 : Distribution factors F_{TM} and F_{TQ}

Ship condition	Distribution factor F_{TM}	Distribution factor F_{TQ}
1	$1 - \cos\frac{2\pi x}{L}$	$\sin\frac{2\pi x}{L}$
2	$1 - \cos\frac{2\pi(L-x)}{L}$	$\sin\frac{2\pi(L-x)}{L}$

Figure 4 : Ship condition 1 - Distribution factors F_{TM} and F_{TQ}

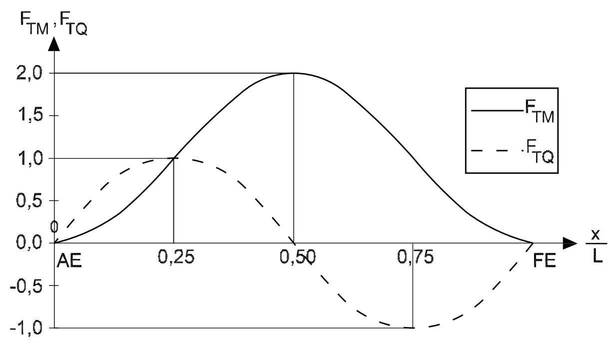


Figure 5 : Ship condition 2 - Distribution factors F_{TM} and F_{TQ}

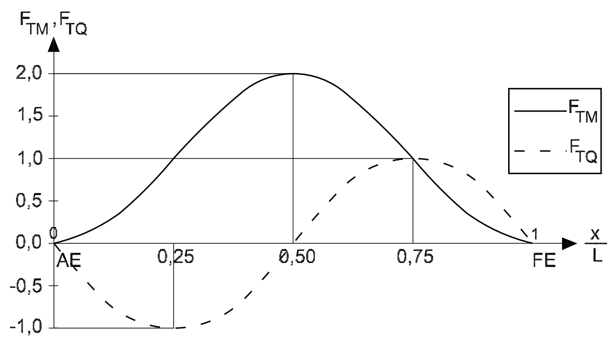


3.4 Vertical wave shear force

3.4.1 The vertical wave shear force at any hull transverse section is obtained, in kN, from the following formula:

$Q_{WV} = 30\ F_Q\ C\ L\ B\ (C_B + 0{,}7)\ 10^{-2}$

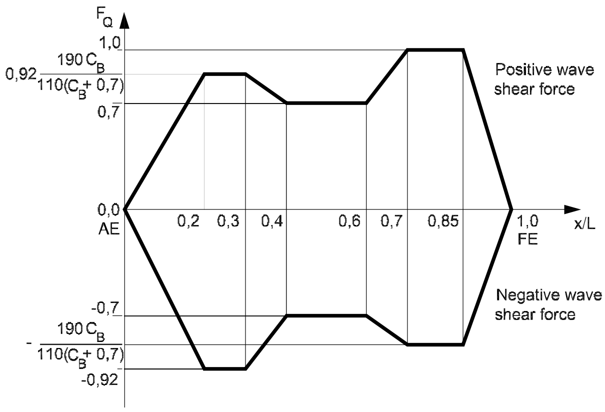
where:

F_Q : Distribution factor defined in Tab 3 for positive and negative shear forces (see also Fig 6).

Table 3 : Distribution factor F_Q

Hull transverse section location	Distribution factor F_Q	
	Positive wave shear force	Negative wave shear force
$0 \le x < 0{,}2\ L$	$4{,}6A\frac{x}{L}$	$-4{,}6\frac{x}{L}$
$0{,}2\ L \le x \le 0{,}3\ L$	0,92 A	– 0,92
$0{,}3\ L < x < 0{,}4\ L$	$(9{,}2A-7)\left(0{,}4-\frac{x}{L}\right)+0{,}7$	$-2{,}2\left(0{,}4-\frac{x}{L}\right)-0{,}7$
$0{,}4\ L \le x \le 0{,}6\ L$	0,70	– 0,70
$0{,}6\ L < x < 0{,}7\ L$	$3\left(\frac{x}{L}-0{,}6\right)+0{,}7$	$-(10A-7)\left(\frac{x}{L}-0{,}6\right)-0{,}7$
$0{,}7\ L \le x \le 0{,}85\ L$	1,00	– A
$0{,}85\ L < x \le L$	$6{,}67\left(1-\frac{x}{L}\right)$	$-6{,}67A\left(1-\frac{x}{L}\right)$
Note 1: $A = \dfrac{190C_B}{110(C_B+0{,}7)}$		

Figure 6 : Distribution factor F_Q



4 Dynamic loads due to bow flare impact

4.1 Application

4.1.1 The effects of bow flare impact are to be considered where all the following conditions occur:

- $V_{cruise} \ge 17{,}5$ knots
- $\dfrac{100FA_S}{LB} > 1$

where:

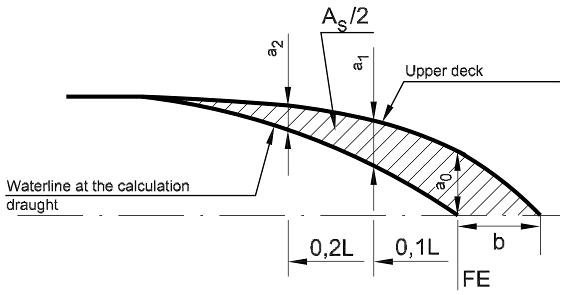
A_S : Twice the shaded area shown in Fig 7, to be obtained, in m², from the following formula:

$A_S = b\ a_0 + 0{,}1\ L\ (a_0 + 2\ a_1 + a_2)$

b, a_0, a_1, a_2 : Distances, in m, shown in Fig 7.

For multideck ships, the upper deck shown in Fig 7 is to be taken as the deck (including superstructures) which extends up to the extreme forward end of the ship and has the largest breadth forward of 0,2 L from the fore end.

Figure 7 : Area A_S



4.1.2 When the effects of bow flare impact are to be considered, according to [4.1.1], the sagging wave bending moment is to be increased as specified in [4.2.1] and [4.2.2].

4.1.3 The Society may require the effects of bow flare impact to be considered also when one of the conditions in [4.1.1] does not occur, if deemed necessary on the basis of the ship's characteristics.

In such cases, the increase in sagging wave bending moment is defined on a case-by-case basis.

4.2 Increase in sagging wave bending moment

4.2.1 General

The sagging wave bending moment at any hull transverse section, defined in [3.1], is to be multiplied by the coefficient F_D obtained from the formulae in Tab 4, which takes into account the dynamic effects of bow flare impact.

Where at least one of the conditions in [4.1.1] does not occur, the coefficient F_D may be taken equal to 1.

Table 4 : Coefficient F_D

Hull transverse section location	Coefficient F_D
$0 \le x < 0,4\ L$	1,0
$0,4\ L \le x < 0,5\ L$	$1 + 10(C_D - 1)\left(\frac{x}{L} - 0,4\right)$
$0,5\ L \le x \le L$	C_D
Note 1: $C_D = 262,5\dfrac{A_S}{CLB(C_B + 0,7)} - 0,6$ without being taken greater than 1,2 nor less than 1,0. A_S : Area, in m², defined in [4.1.1].	

4.2.2 Direct calculations

As an alternative to the formulae in [4.2.1], the Society may accept the evaluation of the effects of bow flare impact from direct calculations, when justified on the basis of the ship's characteristics. The calculations are to be submitted to the Society for approval.

Section 3 Ship Motions and Accelerations

Symbols

For the symbols not defined in this Section, refer to the list at the beginning of this Chapter.

a_B : Motion and acceleration parameter:

$$a_B = 0,76F + 1,875\frac{h_W}{L}$$

h_W : Wave parameter, in m:

$$h_W = 11,44 - \left|\frac{L-250}{110}\right|^3 \quad \text{for} \quad L < 350 \text{ m}$$

$$h_W = \frac{200}{\sqrt{L}} \quad \text{for} \quad L \geq 350 \text{ m}$$

a_{SU} : Surge acceleration, in m/s², defined in [2.1]

a_{SW} : Sway acceleration, in m/s², defined in [2.2]

a_H : Heave acceleration, in m/s², defined in [2.3]

α_R : Roll acceleration, in rad/s², defined in [2.4]

α_P : Pitch acceleration, in rad/s², defined in [2.5]

α_Y : Yaw acceleration, in rad/s², defined in [2.6]

T_{SW} : Sway period, in s, defined in [2.2]

T_R : Roll period, in s, defined in [2.4]

T_P : Pitch period, in s, defined in [2.5]

A_R : Roll amplitude, in rad, defined in [2.4]

A_P : Pitch amplitude, in rad, defined in [2.5].

1 General

1.1

1.1.1 Ship motions and accelerations are defined, with their signs, according to the reference co-ordinate system in Ch 1, Sec 2, [10].

1.1.2 Ship motions and accelerations are assumed to be periodic. The motion amplitudes, defined by the formulae in this Section, are half of the crest to through amplitudes.

1.1.3 As an alternative to the formulae in this Section, the Society may accept the values of ship motions and accelerations derived from direct calculations or obtained from model tests, when justified on the basis of the ship's characteristics. In general, the values of ship motions and accelerations to be calculated are those which can be reached with a probability of 10^{-5}. In any case, the model tests or the calculations, including the assumed sea scatter diagrams and spectra, are to be submitted to the Society for approval.

2 Ship absolute motions and accelerations

2.1 Surge

2.1.1 The surge acceleration a_{SU} is to be taken equal to 0,5 m/s².

2.2 Sway

2.2.1 The sway period and acceleration are obtained from the formulae in Tab 1.

Table 1 : Sway period and acceleration

Period T_{SW}, in s	Acceleration a_{SW}, in m/s²
$\dfrac{0,8\sqrt{L}}{1,22F+1}$	$0,775\, a_B\, g$

2.3 Heave

2.3.1 The heave acceleration is obtained, in m/s², from the following formula:

$a_H = a_B\, g$

2.4 Roll

2.4.1 The roll amplitude, period and acceleration are obtained from the formulae in Tab 2.

Table 2 : Roll amplitude, period and acceleration

Amplitude A_R, in rad	Period T_R, in s	Acceleration α_R, in rad/s²
$a_B\sqrt{E}$ without being taken greater than 0,35	$2{,}2\dfrac{\delta}{\sqrt{GM}}$	$A_R\left(\dfrac{2\pi}{T_R}\right)^2$

Note 1:

$E = 1{,}39\dfrac{GM}{\delta^2}B_{WS}$ to be taken not less than 1,0

GM : Distance, in m, from the ship's centre of gravity to the transverse metacentre, for the loading considered; when GM is not known, the following values may be assumed: $GM = 0{,}07\ B_{WS}$

δ : Roll radius of gyration, in m, for the loading considered; when δ is not known, it may be taken equal to: $\delta = 0{,}35\ B_{WS}$

2.5 Pitch

2.5.1 The pitch amplitude, period and acceleration are obtained from the formulae in Tab 3.

Table 3 : Pitch amplitude, period and acceleration

Amplitude A_P, in rad	Period T_P, in s	Acceleration α_P, in rad/s²
$0{,}328a_B\left(1{,}32-\dfrac{h_W}{L}\right)\left(\dfrac{0{,}6}{C_B}\right)^{0{,}75}$	$0{,}575\sqrt{L}$	$A_P\left(\dfrac{2\pi}{T_P}\right)^2$

2.6 Yaw

2.6.1 The yaw acceleration is obtained, in rad/s², from the following formula:

$$\alpha_Y = 1{,}581\frac{a_B g}{L}$$

3 Ship relative motions and accelerations

3.1 Definitions

3.1.1 Ship relative motions

The ship relative motions are the vertical oscillating translations of the sea waterline on the ship side. They are measured, with their sign, from the waterline at draught T_1.

3.1.2 Accelerations

At any point, the accelerations in X, Y and Z direction are the acceleration components which result from the ship motions defined in [2.1] to [2.6].

3.2 Ship conditions

3.2.1 General

Ship relative motions and accelerations are to be calculated considering the ship in the following conditions:

- upright ship condition
- inclined ship condition.

3.2.2 Upright ship condition

In this condition, the ship encounters waves which produce ship motions in the X-Z plane, i.e. surge, heave and pitch.

3.2.3 Inclined ship condition

In this condition, the ship encounters waves which produce ship motions in the X-Y and Y-Z planes, i.e. sway, roll and yaw.

3.3 Ship relative motions

3.3.1 The reference value of the relative motion in the upright ship condition is obtained, at any hull transverse section, from the formulae in Tab 4.

Table 4 : Reference value of the relative motion h_1 in the upright ship condition

Location	Reference value of the relative motion h_1 in the upright ship condition, in m
$x = 0$	$0{,}7\left(\frac{4{,}35}{\sqrt{C_B}} - 3{,}25\right)h_{1,M}$
$0 < x < 0{,}3\ L$	$h_{1,AE} - \frac{h_{1,AE} - h_{1,M}}{0{,}3}\frac{x}{L}$
$0{,}3\ L \le x \le 0{,}7\ L$	$0{,}42\ C\ (C_B + 0{,}7)$ without being taken greater than the minimum of T_1 and $D - 0{,}9\ T$
$0{,}7\ L < x < L$	$h_{1,M} + \frac{h_{1,FE} - h_{1,M}}{0{,}3}\left(\frac{x}{L} - 0{,}7\right)$
$x = L$	$\left(\frac{4{,}35}{\sqrt{C_B}} - 3{,}25\right)h_{1,M}$

Note 1:
C : Wave parameter defined in Ch 5, Sec 2
$h_{1,AE}$: Reference value h_1 calculated for $x = 0$
$h_{1,M}$: Reference value h_1 calculated for $x = 0{,}5\ L$
$h_{1,FE}$: Reference value h_1 calculated for $x = L$.

3.3.2 The reference value, in m, of the relative motion in the inclined ship condition is obtained, at any hull transverse section, from the following formula:

$$h_2 = 0{,}5 h_1 + A_R \frac{B_W}{2}$$

where:

h_1 : Reference value, in m, of the relative motion in the upright ship, calculated according to [3.3.1]

B_W : Moulded breadth, in m, measured at the waterline at draught T_1 at the hull transverse section considered.

3.4 Accelerations

3.4.1 The reference values of the longitudinal, transverse and vertical accelerations at any point are obtained from the formulae in Tab 5 for upright and inclined ship conditions.

Table 5 : Reference values of the accelerations a_X, a_Y and a_Z

Direction		Upright ship condition	Inclined ship condition
X - Longitudinal	a_{X1} and a_{X2} in m/s²	$a_{X1} = \sqrt{a_{SU}^2 + [A_P g + \alpha_p (z - T_1)]^2}$	$a_{X2} = 0$
Y - Transverse	a_{Y1} and a_{Y2} in m/s²	$a_{Y1} = 0$	$a_{Y2} = \sqrt{a_{SW}^2 + [A_R g + \alpha_R (z - T_1)]^2 + \alpha_Y^2 K_X L^2}$
Z - Vertical	a_{Z1} and a_{Z2} in m/s²	$a_{Z1} = \sqrt{a_H^2 + \alpha_p^2 K_X L^2}$	$a_{Z2} = \sqrt{0,25 a_H^2 + \alpha_R^2 y^2}$

Note 1:

$K_X = 1{,}2\left(\frac{x}{L}\right)^2 - 1{,}1\frac{x}{L} + 0{,}2$ without being taken less than 0,018

Section 4 Load Cases

Symbols

h_1 : Reference value of the ship relative motion in the upright ship condition, defined in Ch 5, Sec 3, [3.3]
h_2 : Reference value of the ship relative motion in the inclined ship condition, defined in Ch 5, Sec 3, [3.3]
a_{X1}, a_{Y1}, a_{Z1}: Reference values of the accelerations in the upright ship condition, defined in Ch 5, Sec 3, [3.4]
a_{X2}, a_{Y2}, a_{Z2}: Reference values of the accelerations in the inclined ship condition, defined in Ch 5, Sec 3, [3.4]
M_{WV} : Reference value of the vertical wave bending moment, defined in Ch 5, Sec 2, [3.1]
M_{WH} : Reference value of the horizontal wave bending moment, defined in Ch 5, Sec 2, [3.2]
M_{WT} : Reference value of the wave torque, defined in Ch 5, Sec 2, [3.3]
Q_{WV} : Reference value of the vertical wave shear force, defined in Ch 5, Sec 2, [3.4].

1 General

1.1 Load cases for structural analyses based on partial ship models

1.1.1 The load cases described in this Section are those to be used for structural element analyses which do not require complete ship modelling. They are:

- the analyses of plating (see Ch 7, Sec 1)
- the analyses of ordinary stiffeners (see Ch 7, Sec 2)
- the analyses of primary supporting members through isolated beam structural models or three-dimensional structural models (see Ch 7, Sec 3)
- the fatigue analysis of the structural details of the above elements (see Ch 7, Sec 4).

1.1.2 These load cases are the mutually exclusive load cases “a”, “b”, “c” and “d” described in Article [2].

Load cases “a” and “b” refer to the ship in upright conditions (see Ch 5, Sec 3, [3.2]), i.e. at rest or having surge, heave and pitch motions.

Load cases “c” and “d” refer to the ship in inclined conditions (see Ch 5, Sec 3, [3.2]), i.e. having sway, roll and yaw motions.

1.2 Load cases for structural analyses based on complete ship models

1.2.1 When primary supporting members are to be analysed through complete ship models according to Ch 7, Sec 3, [1.1.2], specific load cases are to be considered.

These load cases are to be defined considering the ship as sailing in regular waves with different length, height and heading angle, each wave being selected in order to maximise a design load parameter. The procedure for the determination of these load cases is specified in Ch 7, App 3.

2 Load cases

2.1 Upright ship conditions (load cases “a” and “b”)

2.1.1 Ship condition

The ship is considered to encounter a wave which produces (see Fig 1 for load case “a” and Fig 2 for load case “b”) a relative motion of the sea waterline (both positive and negative) symmetric on the ship sides and induces wave vertical bending moment and shear force in the hull girder. In load case “b”, the wave is also considered to induce heave and pitch motions.

2.1.2 Local loads

The external pressure is obtained by adding to or subtracting from the still water head a wave head corresponding to the relative motion.

The internal loads are the still water loads induced by the weights carried, including those carried on decks. For load case “b”, those induced by the accelerations are also to be taken into account.

2.1.3 Hull girder loads

The hull girder loads are:

- the vertical still water bending moment and shear force
- the vertical wave bending moment and the shear force.

Figure 1 : Wave loads in load case "a"

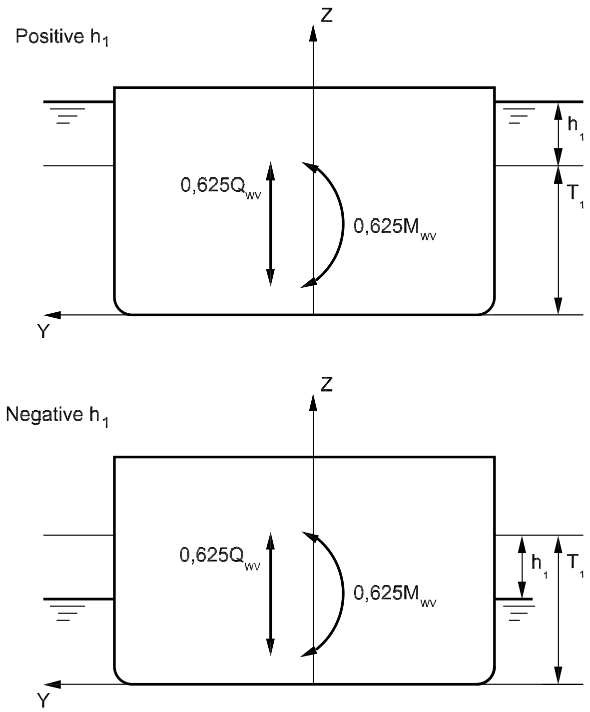


Figure 2 : Wave loads in load case "b"

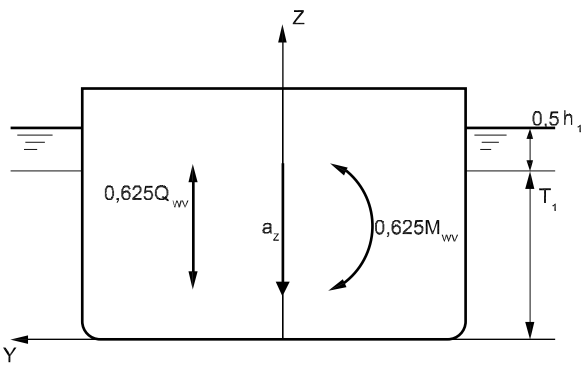

2.2 Inclined ship conditions (load cases "c" and "d")

2.2.1 Ship condition

The ship is considered to encounter a wave which produces (see Fig 3 for load case "c" and Fig 4 for load case "d"):

- sway, roll and yaw motions
- a relative motion of the sea waterline anti-symmetric on the ship sides,

and induces:

- vertical wave bending moment and shear force in the hull girder
- horizontal wave bending moment in the hull girder
- in load case "c", torque in the hull girder.

2.2.2 Local loads

The external pressure is obtained by adding or subtracting from the still water head a wave head linearly variable from positive values on one side of the ship to negative values on the other.

The internal loads are the still water loads induced by the weights carried, including those carried on decks, and the wave loads induced by the accelerations.

Figure 3 : Wave loads in load case "c"

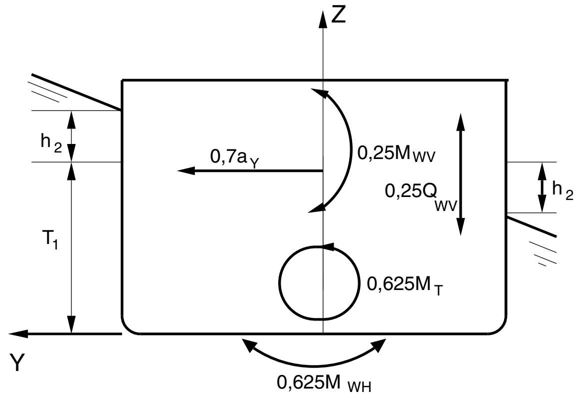

Figure 4 : Wave loads in load case "d"

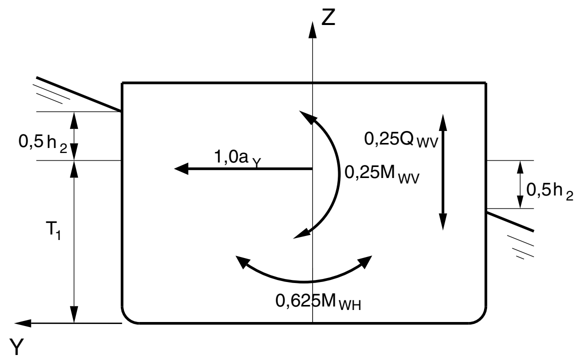


2.2.3 Hull girder loads

The hull girder loads are:

- the still water bending moment and shear force
- the vertical wave bending moment and shear force
- the horizontal wave bending moment
- the wave torque (for load case "c").

2.3 Summary of load cases

2.3.1 The wave local and hull girder loads to be considered in each load case are summarised in Tab 1 and Tab 2, respectively. These loads are obtained by multiplying, for each load case, the reference value of each wave load by the relevant combination factor.

Table 1 : Wave local loads in each load case

Ship condition	Load case	Relative motions		Accelerations a_X, a_Y, a_Z	
		Reference value	Combination factor	Reference value	Combination factor
Upright	"a"	h_1	1,0	a_{X1} ; 0; a_{Z1}	0,0
	"b" **(1)**	h_1	0,5	a_{X1} ; 0; a_{Z1}	1,0
Inclined	"c" **(2)**	h_2	1,0	0; a_{Y2} ; a_{Z2}	0,7
	"d" **(2)**	h_2	0,5	0; a_{Y2} ; a_{Z2}	1,0

(1) For a ship moving with a positive heave motion:
- h_1 is positive
- the acceleration a_{X1} is directed towards the positive part of the X axis
- the acceleration a_{Z1} is directed towards the negative part of the Z axis

(2) For a ship rolling with a negative roll angle:
- h_2 is positive for the points located in the positive part of the Y axis and, vice-versa, it is negative for the points located in the negative part of the Y axis
- the acceleration a_{Y2} is directed towards the positive part of the Y axis
- the acceleration a_{Z2} is directed towards the negative part of the Z axis for the points located in the positive part of the Y axis and, vice-versa, it is directed towards the positive part of the Z axis for the points located in the negative part of the Y axis.

Table 2 : Wave hull girder loads in each load case

Ship condition	Load case	Vertical bending moment		Vertical shear force		Horizontal bending moment		Torque	
		Reference value	Comb. factor	Reference value	Comb. factor	Reference value	Comb. factor	Reference value	Comb. factor
Upright	"a"	0,625 M_{WV}	1,0	0,625 Q_{WV}	1,0	0,625 M_{WH}	0,0	0,625 M_T	0,0
	"b"	0,625 M_{WV}	1,0	0,625 Q_{WV}	1,0	0,625 M_{WH}	0,0	0,625 M_T	0,0
Inclined	"c"	0,625 M_{WV}	0,4	0,625 Q_{WV}	0,4	0,625 M_{WH}	1,0	0,625 M_T	1,0
	"d"	0,625 M_{WV}	0,4	0,625 Q_{WV}	0,4	0,625 M_{WH}	1,0	0,625 M_T	0,0
Note 1: The sign of the hull girder loads, to be considered in association with the wave local loads for the scantling of plating, ordinary stiffeners and primary supporting members contributing to the hull girder longitudinal strength, is defined in Part B, Chapter 7.									

Section 5 Sea Pressures

Symbols

For the symbols not defined in this Section, refer to the list at the beginning of this Chapter.

ρ : Sea water density, taken equal to 1,025 t/m^3

h_1 : Reference values of the ship relative motions in the upright ship condition, defined in Ch 5, Sec 3, [3.3]

h_2 : Reference values of the ship relative motions in the inclined ship conditions, defined in Ch 5, Sec 3, [3.3].

1 Still water pressure

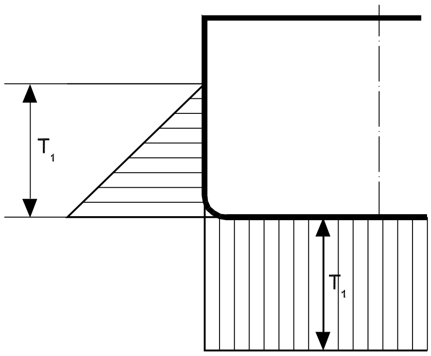
1.1 Pressure on sides and bottom

1.1.1 The still water pressure at any point of the hull is obtained from the formulae in Tab 1 (see also Fig 1).

Table 1 : Still water pressure

Location	Still water pressure p_S, in kN/m^2
Points at and below the waterline ($z \le T_1$)	$\rho\ g\ (T_1 - z)$
Points above the waterline ($z > T_1$)	0

Figure 1 : Still water pressure



2 Wave pressure

2.1 Upright ship conditions (load cases "a" and "b")

2.1.1 Pressure on sides and bottom

The wave pressure at any point of the sides and bottom is obtained from the formulae in Tab 4 (see also Fig 2 for load case "a" and Fig 3 for load case "b").

Figure 2 : Wave pressure in load case "a"

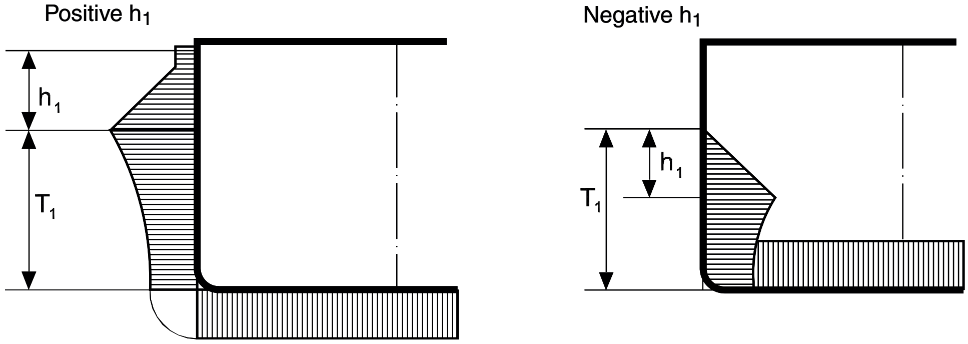


Figure 3 : Wave pressure in load case “b”

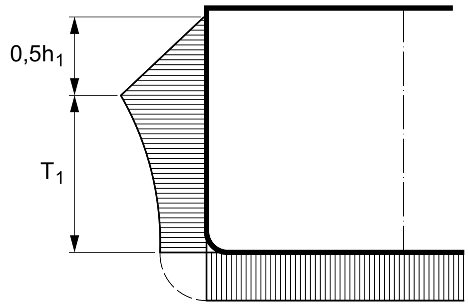

2.2 Inclined ship conditions (load cases “c” and “d”)

2.2.1 The wave pressure at any point of the sides and bottom is obtained from the formulae in Tab 5 (see also Fig 4 for load case “c” and Fig 5 for load case “d”).

Figure 4 : Wave pressure in load case “c”

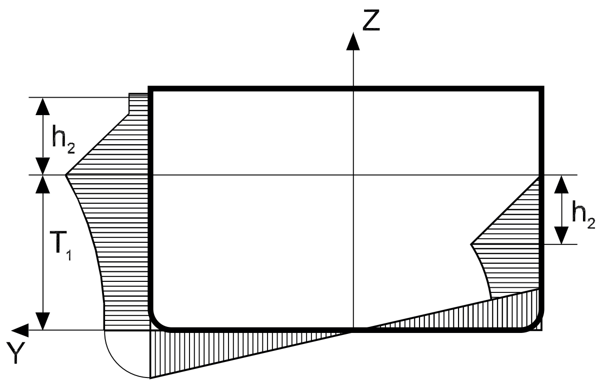

Figure 5 : Wave pressure in load case “d”

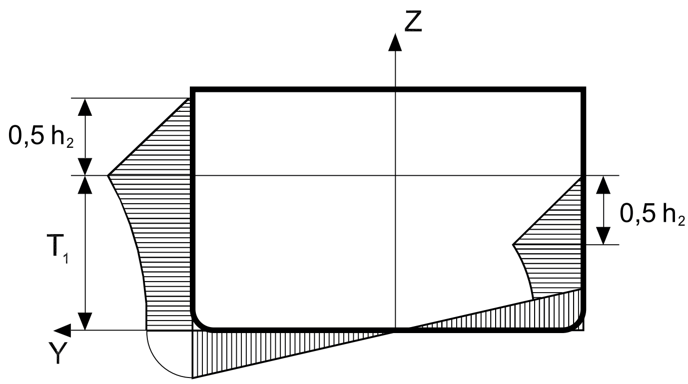


3 Exposed decks

3.1 Application

3.1.1 The pressures defined in [3.2] for exposed decks are to be considered independently of the pressures due to dry uniform cargoes, dry unit cargoes or wheeled cargoes, if any, as defined in Ch 5, Sec 6, [2], Ch 5, Sec 6, [3] and Ch 5, Sec 6, [4] respectively.

3.2 Sea pressures on exposed decks

3.2.1 Still water pressure

The still water pressure on exposed decks p_S, in kN/m², is to be taken equal to $10.\varphi_1.\varphi_2$, where φ_1 is defined in Tab 2 and φ_2 in Tab 3.

3.2.2 Green sea loads

The wave pressure on exposed decks due to green sea is obtained from the formulae in Tab 3 and Tab 5.

Table 2 : Coefficient for pressure on exposed decks

Exposed deck location	φ_1
Watertight deck and below	1,00
Top of lowest tier	0,75
Top of second tier	0,56
Top of third tier	0,42
Top of fourth tier	0,32
Top of fifth tier	0,25
Top of sixth tier	0,20
Top of seventh tier	0,15
Top of eighth tier and above	0,10

Table 3 : Wave pressure on exposed decks in upright ship conditions (load cases “a” and “b”)

Location	Wave pressure p_W, in kN/m²	
	Crest	Through
$0 \le x \le 0,5\ L$	$17,5\varphi_1\varphi_2$	0
$0,5\ L < x < 0,75\ L$	$\left\{17,5 + \left[\frac{19,6\sqrt{H_F} - 17,5}{0,25}\right]\left(\frac{x}{L} - 0,5\right)\right\}\varphi_1\varphi_2$	0
$0,75\ L \le x \le L$	$19,6\varphi_1\varphi_2\sqrt{H}$	0

Note 1:

$$H = C_{F1}\left[2,66\left(\frac{x}{L} - 0,7\right)^2 + 0,14\right]\sqrt{\frac{VL}{C_B}} - (z - T_1)$$ without being taken less than 0,8

φ_1 : Coefficient defined in Tab 2

φ_2 : Coefficient taken equal to:

- $\varphi_2 = 1$ if $L \ge 120$ m
- $\varphi_2 = L/120$ if $L < 120$ m

H_F : Value of H calculated at $x = 0,75\ L$

C_{F1} : Combination factor, to be taken equal to:

- $C_{F1} = 1,0$ for load case “a”
- $C_{F1} = 0,5$ for load case “b”

V : Maximum ahead service speed, in knots, to be taken not less than 13 knots.

Table 4 : Wave pressure on sides and bottom in upright ship conditions (load cases “a” and “b”)

Location	Wave pressure p_W, in kN/m²	
	Crest	Trough
Bottom and sides below the waterline ($z \le T_1$)	$\rho g h e^{\frac{-2\pi(T_1 - z)}{L}}$	$-\rho g h e^{\frac{-2\pi(T_1 - z)}{L}}$ without being taken less than $\rho\, g\, (z - T_1)$
Sides above the waterline ($z > T_1$)	$\rho\, g\, (T_1 + h - z)$ without being taken, for case “a” only, less than $0,15\ \varphi_1\ \varphi_2\ L$	0,0

Note 1:

$h = C_{F1}\ h_1$

C_{F1} : Combination factor, to be taken equal to:

- $C_{F1} = 1,0$ for load case “a”
- $C_{F1} = 0,5$ for load case “b”.

Table 5 : Wave pressure on sides, bottom and exposed decks in inclined ship conditions (load cases “c” and “d”)

Location	Wave pressure p_W, in kN/m² (negative roll angle) **(1)**	
	$y \geq 0$	$y < 0$
Bottom and sides below the waterline ($z \leq T_1$)	$\beta C_{F2} \rho g \left[\frac{y}{B_W} h_1 e^{\frac{-2\pi(T_1 - z)}{L}} + A_R y e^{\frac{-\pi(T_1 - z)}{L}}\right]$	$\beta C_{F2} \rho g \left[\frac{y}{B_W} h_1 e^{\frac{-2\pi(T_1 - z)}{L}} + A_R y e^{\frac{-\pi(T_1 - z)}{L}}\right]$ without being taken less than $\rho g (z - T_1)$
Sides above the waterline ($z > T_1$)	$\rho g \left[T_1 + \beta C_{F2}\left(\frac{y}{B_W} h_1 + A_R y\right) - z\right]$ without being taken, for case “c” only, less than 0,15 φ_1 φ_2 L	0
Exposed decks	$0{,}4 \rho g \left[T_1 + \beta C_{F2}\left(\frac{y}{B_W} h_1 + A_R y\right) - z\right]$ without being taken, for case “c” only, less than 0,15 φ_1 φ_2 L	0

(1) In the formulae giving the wave pressure p_W, the ratio (y / B_W) is not to be taken greater than 0,5.

Note 1:

φ_1 : Coefficient defined in Tab 2

φ_2 : Coefficient defined in Tab 3

C_{F2} : Combination factor, to be taken equal to:
- C_{F2} = 1,0 for load case “c”
- C_{F2} = 0,5 for load case “d”

β : coefficient, to be taken as the minimum of:
- 1
- $T_1 / \left(0{,}5 h_1 + A_R \frac{B_W}{2}\right)$
- $(D - 0{,}9T) / \left(0{,}5 h_1 + A_R \frac{B_W}{2}\right)$

B_W : Moulded breadth, in m, measured at the waterline at draught T_1, at the hull transverse section considered

A_R : Roll amplitude, defined in Ch 5, Sec 3, [2.4.1].

4 Sea chests

4.1 Design pressure

4.1.1 The pressure to be considered for the scantling of sea chests is the maximum between:
- sea pressure as calculated in Articles [1] and [2] for sides and bottom
- pressure defined by the designer to consider the hazard of an overpressure due to the inlet grating cleaning system, to be taken not less than 200 kN/m².

Section 6 Internal Pressures and Forces

Symbols

For the symbols not defined in this Section, refer to the list at the beginning of this Chapter.

ρ_L : Density, in t/m^3, of the liquid carried

z_{TOP} : Z co-ordinate, in m, of the highest point of the tank in the z direction

z_L : Z co-ordinate, in m, of the highest point of the liquid:

$z_L = z_{TOP} + 0{,}5\ (z_{AP} - z_{TOP})$

z_{AP} : Z co-ordinate, in m, of the moulded deck line of the deck to which the air pipes extend, to be taken not less than z_{TOP}

p_{PV} : Setting pressure, in bar, of safety valves

M : Mass, in t, of a dry unit cargo carried

a_{X1} , a_{Y1} , a_{Z1} : Reference values of the accelerations in the upright ship condition, defined in Ch 5, Sec 3, [3.4], calculated in way of the centre of gravity:

- of the compartment, in general
- of any dry unit cargo, in the case of this type of cargo

a_{X2} , a_{Y2} , a_{Z2} : Reference values of the accelerations in the inclined ship condition, defined in Ch 5, Sec 3, [3.4], calculated in way of the centre of gravity:

- of the compartment, in general
- of any dry unit cargo, in the case of this type of cargo

C_{FA} : Combination factor, to be taken equal to:

- $C_{FA} = 0{,}7$ for load case “c”
- $C_{FA} = 1{,}0$ for load case “d”

H : Height, in m, of a tank, to be taken as the vertical distance from the bottom to the top of the tank, excluding any small hatchways

d_{AP} : Distance from the top of air pipe to the top of compartment, in m

d_0 : Distance, in m, to be taken equal to:

$d_0 = 0{,}02\ L$ for $65\ m \le L < 120\ m$

$d_0 = 2{,}4$ for $L \ge 120$ m.

1 Liquids

1.1 Still water pressure

1.1.1 Still water pressure

The still water pressure to be used in combination with the inertial pressure in [1.2] is the greater of the values obtained, in kN/m^2, from the following formulae:

$p_S = \rho_L\ g\ (z_L - z)$

$p_S = \rho_L\ g\ (z_{TOP} - z) + 100\ p_{PV}$

1.2 Inertial pressure

1.2.1 Inertial pressure

The inertial pressure is obtained from the formulae in Tab 1, or from Ch 5, App 1 for typical tank arrangements.

Moreover, the inertial pressure is to be taken such that:

$p_S + p_W \ge 0$

where p_S is defined in [1.1].

Table 1 : Liquids - Inertial pressure

Ship condition	Load case	Inertial pressure p_W, in kN/m²
Upright	"a"	No inertial pressure
	"b"	$\rho_L\ [0{,}5\ a_{X1}\ \ell_B + a_{Z1}\ (z_{TOP} - z)]$
Inclined (negative roll angle)	"c"	$\rho_L\ [a_{TY}\ (y - y_H) + a_{TZ}\ (z - z_H) + g\ (z - z_{TOP})]$
	"d"	

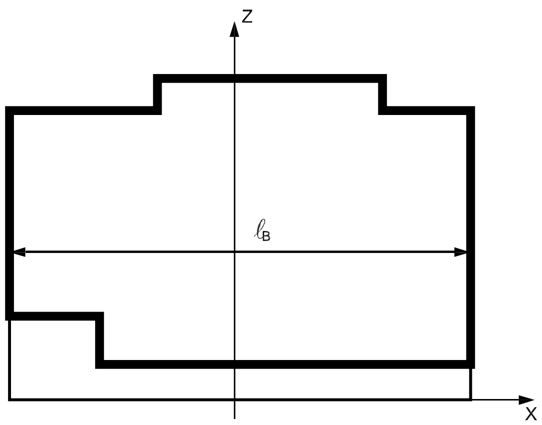
Note 1:

ℓ_B : Longitudinal distance, in m, between the transverse tank boundaries, without taking into account small recesses in the lower part of the tank (see Fig 1)

a_{TY} , a_{TZ} : Y and Z components, in m/s², of the total acceleration vector defined in [1.2.2] for load case "c" and load case "d"

y_H , z_H : Y and Z co-ordinates, in m, of the highest point of the tank in the direction of the total acceleration vector, defined in [1.2.3] for load case "c" and load case "d".

Figure 1 : Upright ship conditions - Distance ℓ_B



1.2.2 Total acceleration vector

The total acceleration vector is the vector obtained from the following formula:

$$\vec{A_T} = \vec{A} + \vec{G}$$

where:

A : Acceleration vector whose absolute values of X, Y and Z components are the longitudinal, transverse and vertical accelerations defined in Ch 5, Sec 3, [3.4]

G : Gravity acceleration vector.

The Y and Z components of the total acceleration vector and the angle it forms with the z direction are defined in Tab 2.

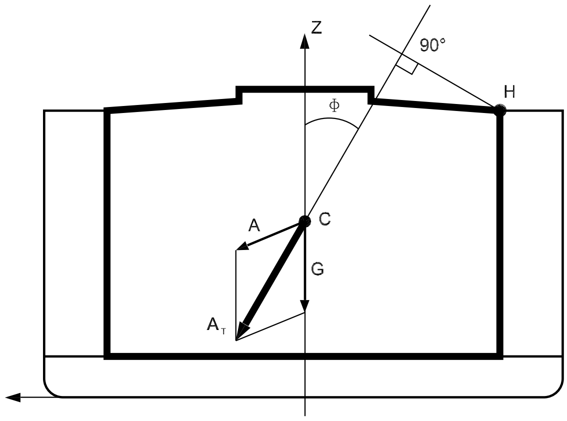
Table 2 : Inclined ship conditions Y and Z components of the total acceleration vector and angle Φ it forms with the z direction

Components (negative roll angle)		Angle Φ, in rad
a_{TY}, in m/s²	a_{TZ}, in m/s²	
$0{,}7\ C_{FA}\ a_{Y2}$	$-0{,}7\ C_{FA}\ a_{Z2} - g$	$\operatorname{atan}\dfrac{a_{TY}}{a_{TZ}}$

1.2.3 Highest point of the tank in the direction of the total acceleration vector

The highest point of the tank in the direction of the total acceleration vector A_T, defined in [1.2.2], is the point of the tank boundary whose projection on the direction forming the angle Φ with the vertical direction is located at the greatest distance from the tank's centre of gravity. It is to be determined for the inclined ship condition, as indicated in Fig 2, where A and G are the vectors defined in [1.2.2] and C is the tank's centre of gravity.

Figure 2 : Inclined ship conditions Highest point H of the tank in the direction of the total acceleration vector



2 Dry uniform loads

2.1 Still water and inertial pressures

2.1.1 General

The still water and inertial pressures are obtained, in kN/m², as specified in Tab 3.

Table 3 : Dry uniform loads Still water and inertial pressure

Ship condition	Load case	Still water pressure p_S and inertial pressure p_W, in kN/m²
Still water		The value of p_S is generally specified by the Designer; in any case, it may not be taken less than 10 kN/m². When the value of p_S is not specified by the Designer, it may be taken, in kN/m², equal to 6,9 h_{TD}, where h_{TD} is the compartment 'tweendeck height at side, in m
Upright (positive heave motion)	"a"	No inertial pressure
	"b"	$p_{W,Z} = p_S \frac{a_{Z1}}{g}$ in z direction
Inclined (negative roll angle)	"c"	$p_{W,Y} = p_S \frac{C_{FA} a_{Y2}}{g}$ in y direction
	"d"	$p_{W,Z} = p_S \frac{C_{FA} a_{Z2}}{g}$ in z direction

3 Dry unit cargoes

3.1 Still water and inertial forces

3.1.1 The still water and inertial forces transmitted to the hull structures are to be determined on the basis of the forces obtained, in kN, as specified in Tab 4 taking into account the elastic characteristics of the lashing arrangement and/or the structure which contains the unit.

Table 4 : Dry unit - Still water and inertial forces

Ship condition	Load case	Still water force F_S and inertial force F_W, in kN
Still water		$F_S = M g$
Upright (positive heave motion)	"a"	No inertial force
	"b"	$F_{W,X} = M a_{X1}$ in x direction $F_{W,Z} = M a_{Z1}$ in z direction
Inclined (negative roll angle)	"c"	$F_{W,Y} = M C_{FA} a_{Y2}$ in y direction
	"d"	$F_{W,Z} = M C_{FA} a_{Z2}$ in z direction

4 Vehicles and helicopters

4.1 Still water and inertial forces

4.1.1 Tyred vehicles and helicopters

The forces transmitted through the tyres are to be considered as a pressure uniformly distributed over the tyre print. With the exception of dimensioning of plating, such forces may be considered as concentrated in the tyre print centre.

The designer is to provide the following information for each tyred vehicle or helicopter:

- the number of axles and the relative arrangement of axles
- the number of wheels on axles and their arrangement
- the maximum mass of the vehicle or helicopter
- the distribution of load per axle
- the dimensions of the tyre prints
- the tyre pressures, if the dimensions of the tyre prints is not specified.

The above information is to be specified for all relevant operating and non-operating conditions.

In the case of vehicles having a Safe Working Load or maximum rated lifting capacity (for example, forklifts and movable cranes), the maximum mass and distribution of load per axle are to be specified with respect to these values.

The still water and inertial forces transmitted to the hull structures are to be determined on the basis of the forces obtained, in kN, as specified in Tab 5.

4.1.2 Non-tyred rolling vehicles

The requirements of [4.1.1] also apply to tracked vehicles; in this case the print to be considered is that below each wheel or wheelwork.

4.1.3 Other vehicles

For other vehicles on fixed supports, all the forces transmitted are to be considered as concentrated at the contact area centre.

Table 5 : Vehicles and helicopters Still water and inertial forces

Ship condition	Load case	Still water force F_S and inertial force F_W, in kN
Still water **(1) (2)**		$F_S = M\,g$
Upright (positive heave motion)**(1)**	"a"	No inertial force
	"b"	$F_{W,Z} = \alpha\,M\,a_{Z1}$ in z direction
Inclined (negative roll angle)**(2)**	"c"	$F_{W,Y} = M\,C_{FA}\,a_{Y2}$ in y direction
	"d"	$F_{W,Z} = M\,C_{FA}\,a_{Z2}$ in z direction
Harbour		$F_{W,X} = 0{,}035\,M\,g$ in x direction $F_{W,Y} = 0{,}087\,M\,g$ in y direction $F_{W,Z} = 0{,}100\,M\,g$ in z direction

(1) This condition defines the force, applied by one wheel, to be considered for the determination of scantlings of plating, ordinary stiffeners and primary supporting members, as defined in Part B, Chapter 7, where:

α : Coefficient taken equal to 0,5

M : Mass, in t, taken equal to:

$$M = \frac{Q_A}{n_W}$$

Q_A : Axle load, in t

n_W : Number of wheels for the axle considered.

(2) This condition is to be considered for the racking analysis, as defined in Ch 7, App 2, with M taken equal to the mass, in t, of wheeled loads located on the structural member under consideration.

5 Accommodation and ammunition storage

5.1 Still water and inertial pressures

5.1.1 The still water and inertial pressures transmitted to the deck structures are obtained, in kN/m², as specified in Tab 6 and Tab 7.

5.1.2 In addition to the pressures defined in [5.1.1], the effect of significant concentrated loads must be taken into account, when deemed necessary by the Society.

Table 6 : Accommodations and ammunition storage - Still water and inertial pressures

Ship condition	Load case	Still water pressure p_S and inertial pressure p_W, in kN/m²
Still water		The value of p_S is defined in Tab 7 depending on the type of the accommodation compartment
Upright (positive heave motion)	"a"	No inertial force
	"b"	$p_W = p_S \frac{a_{Z1}}{g}$
Inclined	"c"	The inertial pressure transmitted to the deck structures in inclined condition may generally be disregarded. Specific cases in which this simplification is not deemed permissible by the Society are considered individually
	"d"	

Table 7 : Still water deck pressure in operational and accommodation compartments

Type of operational and accommodation compartments	p_S, in kN/m²
Operational rooms (COC, COP, TLC, ECG, ADT, GE, RADAR room, EMPAR, METEO)	6,5
Cabins, hospitals, kitchens, baggage rooms	3,0
Galleys, restaurant, meeting rooms, briefing rooms, corridors, lounges	5,0
Other storages	10,0
Ammunition storages	**(1)**
(1) The value of p_S is to be specified by the Designer; in any case, it may not be less than 15,0 kN/m². This value may also be assumed for the scantling checks where, at a preliminary design stage, the value of p_S is not yet defined by the Designer.	

5.1.3 Manoeuvring areas are always to be considered as exposed areas, and as such, subject to the relevant loads in Ch 5, Sec 5.

5.1.4 For ammunition storages, the case of fire-extinguishing by flooding as per Pt C, Ch 4, Sec 6 is to be taken into consideration, in addition to Tab 7. Loads on decks and side walls are to be checked according to [1]. In case the water-spraying system is fitted with an automatic closing of the water supply valve when the water level reaches the top of the storage area, this maximum water level is to be clearly specified on relevant drawings and is to be considered for calculation of liquid pressure in Article [1].

Doors and hatches giving access to ammunition storage are to have a strength equivalent to the one of the surrounding structure.

For ammunition storages above the deepest waterline and fitted with scuppers, reduction of pressure may be considered on a case-by-case basis, based on justification provided by the Designer.

6 Machinery

6.1 Still water and inertial pressures

6.1.1 The still water and inertial pressures transmitted to the deck structures are obtained, in kN/m², as specified in Tab 8.

Table 8 : Machinery - Still water and inertial pressures

Ship condition	Load case	Still water pressure p_S and inertial pressure p_W, in kN/m²
Still water		$p_S = 10$
Upright (positive heave motion)	"a"	No inertial pressure
	"b"	$p_W = p_S \frac{a_{Z1}}{g}$
Inclined	"c"	The inertial pressure transmitted to the deck structures in inclined condition may generally be disregarded. Specific cases in which this simplification is not deemed permissible by the Society are considered individually
	"d"	

7 Flooding

7.1 Still water and inertial pressures

7.1.1 Unless otherwise specified, the still water pressure p_{SF}, in kN/m², and the inertial pressure p_{WF}, in kN/m², to be considered as acting on structural watertight elements defined as per Internal Watertight Plan and located below the deepest equilibrium waterline (excluding side shell structural elements) which constitute boundaries intended to stop vertical and horizontal flooding are obtained from the formulae in Tab 9.

Table 9 : Flooding - Still water and inertial pressures

Still water pressure p_{SF}, in kN/m²	Inertial pressure p_{WF}, in kN/m²
$\rho\, g\, (z_F - z)$ without being taken less than $0{,}4\, g\, d_0$	$0{,}6\, \rho\, a_{Z1}\, (z_F - z)$ without being taken less than $0{,}4\, g\, d_0$

Note 1:
z_F : Z co-ordinate, in m, at the deepest equilibrium waterline at side in way of the transverse section considered, obtained from the damage stability calculations, for which the transient conditions are to be taken into account
d_0 : Distance, in m, to be taken equal to:
$d_0 = 0{,}02\, L$ for $65\text{ m} \le L \le 120\text{ m}$
$d_0 = 2{,}4$ for $L > 120\text{ m}$.

8 Testing

8.1 Still water pressures

8.1.1 The still water pressure to be considered as acting on plates and stiffeners subject to tank testing is obtained, in kN/m², from the formulae in Tab 10.

No inertial pressure is to be considered as acting on plates and stiffeners subject to tank testing.

Table 10 : Testing - Still water pressures

Compartment or structure to be tested	Still water pressure p_{ST}, in kN/m²
Double bottom tanks	The greater of the following: $p_{ST} = 10\, [(z_{TOP} - z) + d_{AP}]$ $p_{ST} = 10\, [(z_{TOP} - z) + 2{,}4]$ $p_{ST} = 10\, (z_{BD} - z)$
Double side tanks, fore and after peaks used as tank, cofferdams	The greater of the following: $p_{ST} = 10\, [(z_{TOP} - z) + d_{AP}]$ $p_{ST} = 10\, [(z_{TOP} - z) + 2{,}4]$
Tank bulkheads, deep tanks, fuel oil bunkers	The greater of the following: $p_{ST} = 10\, [(z_{TOP} - z) + d_{AP}]$ $p_{ST} = 10\, [(z_{TOP} - z) + 2{,}4]$ $p_{ST} = 10\, [(z_{TOP} - z) + 10\, p_{PV}]$
Fore peak not used as tank	The greater of the following: $p_{ST} = 10\, (z_F - z)$ $p_{ST} = 10\, (z_{BD} - z)$
Watertight doors below bulkhead deck	$p_{ST} = 10\, (z_{BD} - z)$
Chain locker (if aft of collision bulkhead)	$p_{ST} = 10\, (z_{TOP} - z)$
Independent tanks and ammunition storage **(1)**	The greater of the following: $p_{ST} = 10\, [(z_{TOP} - z) + d_{AP}]$ $p_{ST} = 10\, [(z_{TOP} - z) + 0{,}9]$
Ballast ducts	Ballast pump maximum pressure

z_{BD} : Z co-ordinate, in m, of the bulkhead deck
z_F : As defined in Tab 9.
(1) Ammunition storage where the extinguishing system is not by flooding need not be subjected to testing

9 Weapons firing dynamic loads

9.1 Dynamic loads

9.1.1 General

The following weapons firing dynamic loads are to be specified by the Designer:

- missile blast dynamic pressure
- accidental missile ignition dynamic pressure
- gun blast dynamic pressure
- gun recoil dynamic force, for all the possible combinations of elevation and slewing angle of the weapon system.

As guidance, they may be obtained from the formulae specified in [9.2].

9.1.2 Other loads

Weapon firing dynamic loads other than those specified in [9.1.1], such as loads on vertical missile launching systems (VLS) and loads on rocket or missile launching systems with elevation and slewing capabilities, are generally to be specified by the weapon manufacturer. In any event, they are to be considered by the Society on a case-by-case basis.

9.1.3 Additional loads

At the request of the interested parties, additional weapon firing dynamic loads other than those specified in [9.1.1] and [9.1.2], such as collision or hitting against fixed devices fitted in way of the weapon system rail limits, may be considered by the Society on a case-by-case basis, together with the relevant weapon manufacturer specification.

9.2 Guidance values

9.2.1 Missile blast dynamic pressure

As guidance, the missile blast dynamic pressure may be obtained, in kN/m², from the following formula:

$$p_W = \frac{T\left(\sin\alpha + \left(\frac{0,0225}{\sin\alpha}\right)\right)}{A}$$

where (see Fig 3):

T : Total thrust, in kN, of the missile

α : Angle, in degrees, of incidence for missile blast with respect to the considered surface

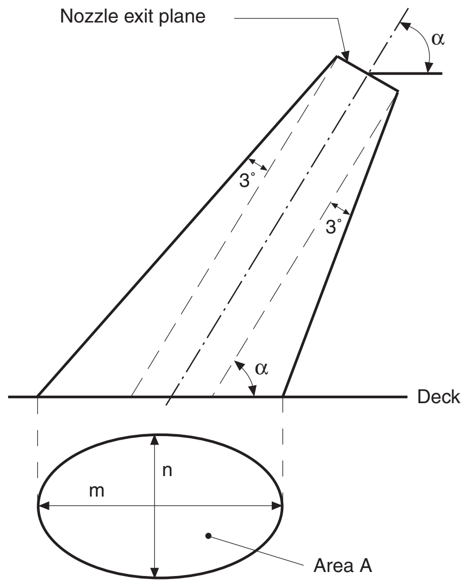
A : Impingement area, in m², of the considered surface bounded by the blast cone, i.e. the cone generated by rotating about the missile axis a line with a 3° divergence from the axis and passing through the circumference of the exit nozzle. The impingement area is to be obtained, in m², from the following formula:

$$A = \alpha m \frac{n}{4}$$

m : Major axis, in m, of the impingement area

n : Minor axis, in m, of the impingement area.

Figure 3 : Missile blast impingement area



9.2.2 Accidental missile ignition dynamic pressure

As guidance, the accidental missile ignition dynamic pressure may be obtained, in kN/m², from the following formula:

$$p_W = \frac{67,4R}{A_B}$$

where:

R : Burning rate, in kg / s, of the missile booster

A_B : Total area, in m², of blow-out opening.

9.2.3 Gun blast dynamic pressure

As guidance, the blast dynamic pressure for one gun may be obtained, in kN/m², from the following formula:

$$p_W = \frac{1380(1+\cos\beta)}{\left(\frac{r}{d}\right)^{1,5}}$$

where (see Fig 4):

β : Angle, in degrees, between the gun barrel axis and the straight line passing through the gun muzzle and the calculation point P

r : Distance, in mm, from the gun muzzle to the calculation point P

d : Gun diameter (calibre), in mm.

When two or more guns firing simultaneously are considered, the blast dynamic pressure is the greater of the values obtained by applying the above formula for each gun, considered as being firing independently from the others.

9.2.4 Gun recoil dynamic force

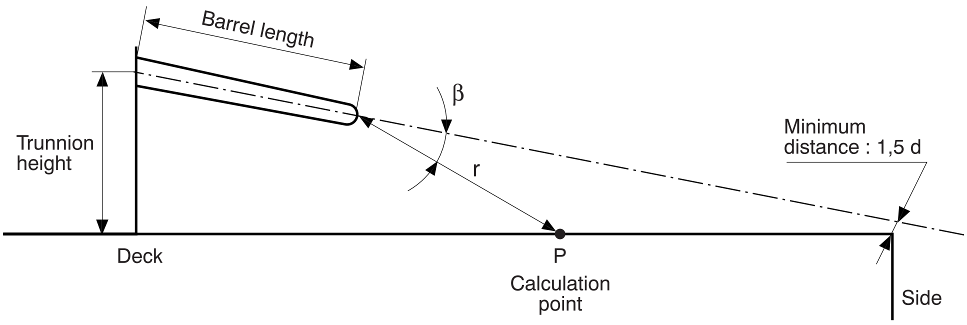
As guidance, the gun recoil dynamic force may be obtained, in kN, from the following formula:

$F_W = 1,3\ F_B$

where:

F_B : Rated brake load, in kN, of the recoil mechanism.

Figure 4 : Angle β and distance r for gun blast dynamic pressure calculation



Appendix 1 Inertial Pressure for Typical Tank Arrangement

1 Inertial ballast pressure

1.1 Introduction

1.1.1 Ch 5, Sec 6, [1] defines the criteria to calculate the inertial pressure p_W induced by ballast water in any type of tank. The relevant formulae are specified in Ch 5, Sec 6, Tab 1 and entail the definition of the highest point of the tank in the direction of the total acceleration vector. As specified in Ch 5, Sec 6, [1.2], this point depends on the geometry of the tank and the values of the acceleration. For typical tank arrangements, the highest point of the tank in the direction of the total acceleration vector can easily be identified and the relevant formulae written using the tank geometric characteristics.

1.1.2 This Appendix provides the formulae for calculating the inertial pressure p_W in the case of typical tank arrangements.

1.2 Formulae for the inertial pressure calculation

1.2.1 For typical tank arrangements, the inertial pressure transmitted to the hull structures at the calculation point P in inclined ship condition may be obtained from the formulae in Tab 1, obtained by applying to those tanks the general formulae in Ch 5, Sec 6, Tab 1.

Figure 1 : Distances b_L and d_H

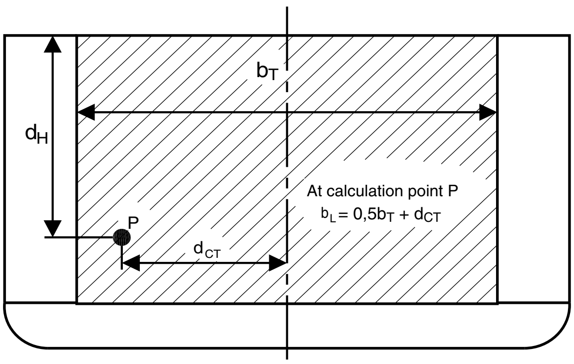


Table 1 : Inertial ballast pressure for typical tank arrangements

Ship condition	Load case	Inertial pressure p_W, in kN/m²
Inclined (negative roll angle)	"c"	$0,7\ C_{FA}\ \rho_L\ (a_{Y2}\ b_L + a_{Z2}\ d_H)$
	"d"	

Note 1:

C_{FA} : Combination factor, to be taken equal to:
- $C_{FA} = 0,7$ for load case "c"
- $C_{FA} = 1,0$ for load case "d"

ρ_L : Density, in t/m³, of the liquid carried

a_{Y2}, a_{Z2} : Reference values of the acceleration in the inclined ship condition, defined in Ch 5, Sec 3, [3.4], calculated in way of the centre of gravity of the tank

b_L, d_H : Transverse and vertical distances, in m, to be taken as indicated in Fig 1 to Fig 4 for various types of tanks; for the cases in Fig 1, where the central area is divided into two or more tanks by longitudinal bulkheads, b_L and d_H for calculation points inside each tank are to be taken as indicated in Fig 3 for the double side.

Figure 2 : Distances b_L and d_H

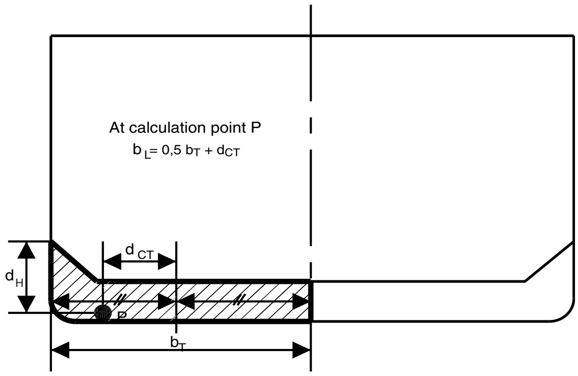

Figure 3 : Distances b_L and d_H

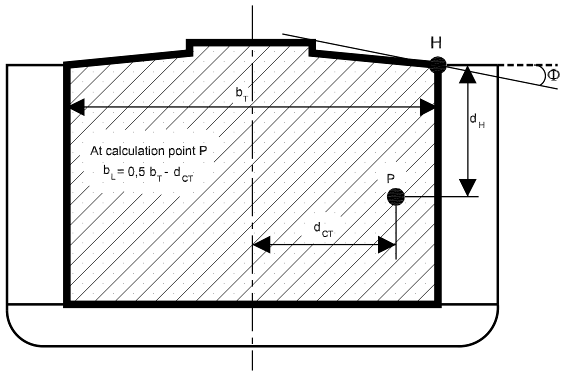

Figure 4 : Distances b_L and d_H

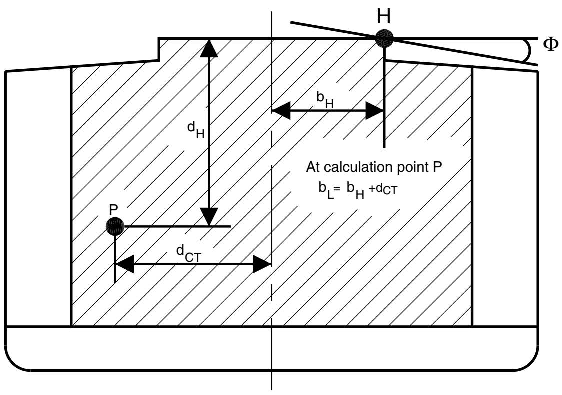


Part B
Hull and Stability

CHAPTER 6
HULL GIRDER STRENGTH

Section 1 Strength Characteristics of the Hull Girder Transverse Sections

Section 2 Yielding Checks

Section 3 Ultimate Strength Check

Appendix 1 Hull Girder Ultimate Strength

Symbols used in this Chapter

E : Young's modulus, in N/mm^2, to be taken equal to:
- for steels in general:
  $E = 2,06.10^5 \ N/mm^2$
- for stainless steels:
  $E = 1,95.10^5 \ N/mm^2$
- for aluminium alloys:
  $E = 7,0.10^4 \ N/mm^2$

M_{SW} : Still water bending moment, in kN.m:
- in hogging conditions:
  $M_{SW} = M_{SW,H}$
- in sagging conditions:
  $M_{SW} = M_{SW,S}$

$M_{SW,H}$: Design still water bending moment, in kN.m, in hogging condition, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [2.2],

$M_{SW,S}$: Design still water bending moment, in kN.m, in sagging condition, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [2.2], when the ship in still water is always in hogging condition, $M_{SW,S}$ is to be taken equal to 0,

M_{WV} : Vertical wave bending moment, in kN.m:
- in hogging conditions:
  $M_{WV} = M_{WV,H}$
- in sagging conditions:
  $M_{WV} = M_{WV,S}$

$M_{WV,H}$: Vertical wave bending moment, in kN.m, in hogging condition, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [3.1],

$M_{WV,S}$: Vertical wave bending moment, in kN.m, in sagging condition, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [3.1],

g : Gravity acceleration, in m/s^2:
$g = 9,81 \ m/s^2$.

Section 1 Strength Characteristics of the Hull Girder Transverse Sections

Symbols

For symbols not defined in this Section, refer to the list at the beginning of this Chapter.

1 Application

1.1 General

1.1.1 This Section specifies the criteria for calculating the hull girder strength characteristics to be used for the checks in Ch 6, Sec 2 and Ch 6, Sec 3, in association with the hull girder loads specified in Ch 5, Sec 2.

2 Calculation of the strength characteristics of hull girder transverse sections

2.1 Hull girder transverse sections

2.1.1 General

Hull girder transverse sections are to be considered as being constituted by the members contributing to the hull girder longitudinal strength, i.e. all continuous longitudinal members below the strength deck defined in [2.2], taking into account the requirements in [2.1.2] to [2.1.9].

These members are to be considered as having net scantlings (see also Ch 4, Sec 2).

2.1.2 Continuous trunks and continuous longitudinal hatch coamings

Continuous trunks and continuous longitudinal hatch coamings may be included in the hull girder transverse sections, provided they are effectively supported by longitudinal bulkheads or primary supporting members.

2.1.3 Longitudinal ordinary stiffeners or girders welded above the decks

Longitudinal ordinary stiffeners or girders welded above the decks (including the deck of any trunk fitted as specified in [2.1.2]) may be included in the hull girder transverse sections.

2.1.4 Longitudinal girders between hatchways

Where longitudinal girders are fitted between hatchways, the sectional area that can be included in the hull girder transverse sections is obtained, in m^2, from the following formula:

$A_{EFF} = A_{LG}\, a$

where:

A_{LG} : Sectional area, in m^2, of longitudinal girders

a : Coefficient:

- for longitudinal girders effectively supported by longitudinal bulkheads or primary supporting members:

  a = 1

- for longitudinal girders not effectively supported by longitudinal bulkheads or primary supporting members and having dimensions and scantlings such that $\ell_0 / r \le 60$:

  $$a = 0{,}6\left(\frac{s}{b_1} + 0{,}15\right)^{0{,}5}$$

- for longitudinal girders not effectively supported by longitudinal bulkheads or primary supporting members and having dimensions and scantlings such that $\ell_0 / r > 60$:

  a = 0

ℓ_0 : Span, in m, of longitudinal girders, to be taken as shown in Fig 1

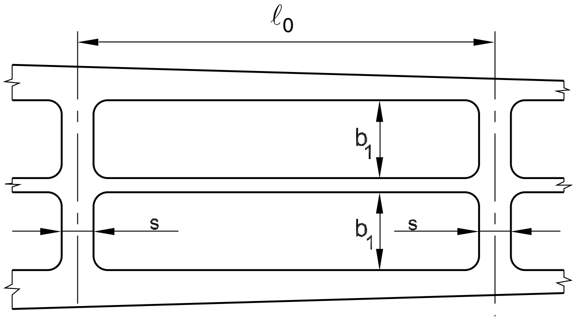
r : Minimum radius of gyration, in m, of the longitudinal girder transverse section

s, b_1 : Dimensions, in m, defined in Fig 1.

2.1.5 Longitudinal bulkheads with vertical corrugations

Longitudinal bulkheads with vertical corrugations may not be included in the hull girder transverse sections.

Figure 1 : Longitudinal girders between hatchways



2.1.6 Members in materials other than steel

Where a member contributing to the longitudinal strength is made in material other than steel with a Young's modulus E equal to 2,06 10^5 N/mm², the steel equivalent sectional area that may be included in the hull girder transverse sections is obtained, in m², from the following formula:

$$A_{SE} = \frac{E}{2{,}06 \cdot 10^5} A_M$$

where:

A_M : Sectional area, in m², of the member under consideration.

2.1.7 Large openings

Large openings are:

- elliptical openings exceeding 2,5 m in length or 1,2 m in breadth
- circular openings exceeding 0,9 m in diameter.

Large openings and scallops, where scallop welding is applied, are always to be deducted from the sectional areas included in the hull girder transverse sections.

2.1.8 Small openings

Smaller openings than those in [2.1.7] in one transverse section in the strength deck or bottom area need not be deducted from the sectional areas included in the hull girder transverse sections, provided that:

$\Sigma b_S \leq 0{,}06\ (B - \Sigma b)$

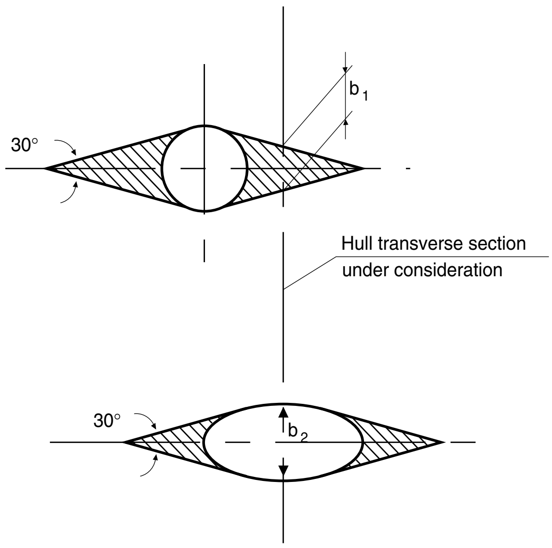
where:

Σb_S : Total breadth of small openings, in m, in the strength deck or bottom area at the transverse section considered, determined as indicated in Fig 2

Σb : Total breadth of large openings, in m, at the transverse section considered, determined as indicated in Fig 2.

Where the total breadth of small openings Σb_S does not fulfil the above criteria, only the excess of breadth is to be deducted from the sectional areas included in the hull girder transverse sections.

Figure 2 : Calculation of Σb and Σb_S



b_1 and b_2 included in Σ b and Σ bs

2.1.9 Lightening holes, draining holes and single scallops

Lightening holes, draining holes and single scallops in longitudinals need not be deducted if their height is less than 0,25 h_W 10^{-3}, without being greater than 75 mm, where h_W is the web height, in mm, defined in Ch 4, Sec 3.

Otherwise, the excess is to be deducted from the sectional area or compensated.

2.2 Strength deck

2.2.1 The strength deck is, in general, the uppermost continuous deck.

In the case of a superstructure or deckhouses contributing to the longitudinal strength, the strength deck is the deck of the superstructure or the deck of the uppermost deckhouse.

2.2.2 A superstructure extending at least 0,15 L within 0,4 L amidships may generally be considered as contributing to the longitudinal strength. For other superstructures and for deckhouses, their contribution to the longitudinal strength is to be assessed on a case by case basis, through a finite element analysis of the whole ship, which takes into account the general arrangement of the longitudinal elements (side, decks, bulkheads).

The presence of openings in the side shell and longitudinal bulkheads is to be taken into account in the analysis. This may be done in two ways:

- by including these openings in the finite element model
- by assigning to the plate panel between the side frames beside each opening an equivalent thickness, in mm, obtained from the following formula:

$$t_{EQ} = 10^3\left[\ell_P\left(\frac{Gh^2}{12EI_J} + \frac{1}{A_J}\right)\right]^{-1}$$

where (see Fig 3):

ℓ_P : Longitudinal distance, in m, between the frames beside the opening

h : Height, in m, of openings

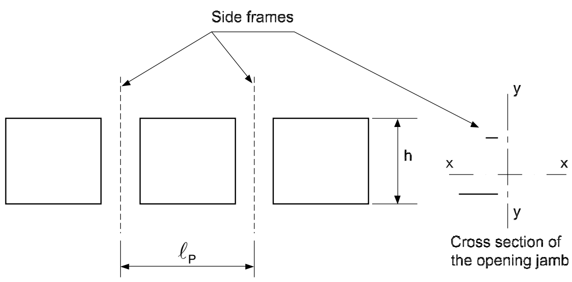
I_J : Moment of inertia, in m^4, of the opening jamb about the transverse axis y-y

A_J : Shear area, in m^2, of the opening jamb in the direction of the longitudinal axis x-x

G : Coulomb's modulus, in N/mm^2, of the material used for the opening jamb, to be taken equal to:

- for steels: $G = 8{,}0 \cdot 10^4$ N/mm²
- for aluminium alloys: $G = 2{,}7 \cdot 10^4$ N/mm².

Figure 3 : Side openings



2.3 Section modulus

2.3.1 The section modulus at any point of a hull transverse section is obtained, in m^3, from the following formula:

$$Z_A = \frac{I_Y}{|z - N|}$$

where:

I_Y : Moment of inertia, in m^4, of the hull transverse section defined in [2.1], about its horizontal neutral axis

z : Z co-ordinate, in m, of the calculation point with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [6]

N : Z co-ordinate, in m, of the centre of gravity of the hull transverse section defined in [2.1], with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [6].

2.3.2 The section moduli at bottom and at the equivalent deck line are obtained, in m^3, from the following formulae:

- at bottom:

$$Z_{AB} = \frac{I_Y}{N}$$

- at the equivalent deck line:

$$Z_{AD} = \frac{I_Y}{V_D}$$

where:

I_Y, N : Defined in [2.3.1]

V_D : Vertical distance to the equivalent deck line, in m:

- when no effective longitudinal members specified in [2.1.2] and [2.1.3] are positioned above a line extending from strength deck at side to a position $(z_D - N)/0,9$ from the neutral axis at the centreline:

  $V_D = z_D - N$

  where:

  z_D : Z co-ordinate, in m, of strength deck, defined in [2.2], with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [6]

- when effective longitudinal members specified in [2.1.2] and [2.1.3] are positioned above a line extending from strength deck at side to a position $(z_D - N)/0,9$ from the neutral axis at the centreline:

$$V_D = (z_T - N)\left(0,9 + 0,2\frac{y_T}{B}\right) \geq z_D - N$$

  where:

  y_T, z_T : Y and Z co-ordinates, in m, of the top of continuous trunk or hatch coaming or longitudinal ordinary stiffeners or girders welded above the strength deck, with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [6]; y_T and z_T are to be measured for the point which maximises the value of V_D

2.4 Moments of inertia

2.4.1 The moments of inertia I_Y and I_Z, in m^4, are those, calculated about the horizontal and vertical neutral axes, respectively, of the hull transverse sections defined in [2.1].

2.5 First moment

2.5.1 The first moment S, in m^3, at a level z above the baseline is that, calculated with respect to the horizontal neutral axis, of the portion of the hull transverse sections defined in [2.1] located above the z level.

2.6 Structural models for the calculation of normal warping stresses and shear stresses

2.6.1 The structural models that can be used for the calculation of normal warping stresses, induced by torque, and shear stresses, induced by shear forces or torque, are:

- three-dimensional finite element models
- thin walled beam models,

representing the members which constitute the hull girder transverse sections according to [2.1].

Section 2 Yielding Checks

Symbols

For symbols not defined in this Section, refer to the list at the beginning of this Chapter.

M_{WH} : Horizontal wave bending moment, in kN·m, defined in Ch 5, Sec 2, [3.2]

M_{WT} : Wave torque, in kN·m, defined in Ch 5, Sec 2, [3.3]

Q_{SW} : Design still water shear force, in kN, defined in Ch 5, Sec 2, [2.3]

Q_{WV} : Vertical wave shear force, to be calculated according to Ch 5, Sec 2, [3.4]:

- if $Q_{SW} \geq 0$, Q_{WV} is the positive wave shear force
- if $Q_{SW} < 0$, Q_{WV} is the negative wave shear force

k : Material factor, as defined in Ch 4, Sec 1, [2.3]

x : X co-ordinate, in m, of the calculation point with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [6]

I_Y : Moment of inertia, in m^4, of the hull transverse section about its horizontal neutral axis, to be calculated according to Ch 6, Sec 1, [2.4]

I_Z : Moment of inertia, in m^4, of the hull transverse section about its vertical neutral axis, to be calculated according to Ch 6, Sec 1, [2.4]

S : First moment, in m^3, of the hull transverse section, to be calculated according to Ch 6, Sec 1, [2.5]

Z_A : Section modulus, in cm^3, at any point of the hull transverse section, to be calculated according to Ch 6, Sec 1, [2.3.1]

Z_{AB},Z_{AD} : Section moduli, in cm^3, at bottom and deck, respectively, to be calculated according to Ch 6, Sec 1, [2.3.2]

C : Wave parameter defined in Ch 5, Sec 2.

1 Application

1.1 General

1.1.1 The requirements of this Section apply to ships having the following characteristics:

- $L < 500$ m
- $L / B > 5$
- $B / D < 2,5$
- $C_B \geq 0,4$

Ships not having one or more of these characteristics and ships of unusual type or design are considered by the Society on a case-by-case basis.

2 Hull girder stresses

2.1 Normal stresses induced by vertical bending moments

2.1.1 The normal stresses induced by vertical bending moments are obtained, in N/mm², from the following formulae:

- at any point of the hull transverse section:

$$\sigma_1 = \frac{M_{SW} + M_{WV}}{Z_A} 10^3$$

- at bottom:

$$\sigma_1 = \frac{M_{SW} + M_{WV}}{Z_{AB}} 10^3$$

- at the equivalent deck line:

$$\sigma_1 = \frac{M_{SW} + M_{WV}}{Z_{AD}} 10^3$$

2.1.2 The formulae given in [2.1.1] are valid only when the distribution of vertical bending stress across the hull girder transverse section can be assumed to be linear.

Table 1 : Torque and bending moments

Still water loads		Wave loads					
Vertical bending moment		Torque **(1)**		Vertical bending moment		Horizontal bending moment	
Reference value	Combination factor	Reference value	Combination factor	Reference value	Combination factor	Reference value	Combination factor
M_{SW}	1,0	M_{WT}	1,0	M_{WV}	0,4	M_{WH}	1,0
(1) To be considered only when deemed necessary by the Society (e.g. wave torque is not applicable to frigates).							

2.1.3 The normal stresses in a member made in material other than steel with a Young's modulus E equal to $2{,}06 \cdot 10^5$ N/mm², included in the hull girder transverse sections as specified in Ch 6, Sec 1, [2.1.6], are obtained from the following formula:

$$\sigma_1 = \frac{E}{2{,}06 \cdot 10^5}\sigma_{1S}$$

where:

σ_{1S} : Normal stress, in N/mm², in the member under consideration, calculated according to [2.1.1] considering this member as having the steel equivalent sectional area A_{SE} defined in Ch 6, Sec 1, [2.1.6].

2.2 Normal stresses induced by vertical and horizontal bending moments

2.2.1 The normal stresses induced by vertical and horizontal bending moments are to be calculated for the load case constituted by the hull girder loads specified in Tab 1 together with their combination factors. They are to be obtained, in N/mm², from the following formula:

$$\sigma_1 = \frac{M_{SW}}{Z_A} + \frac{0{,}4M_{WV}}{Z_A} + \frac{M_{WH}}{I_Z}y$$

where:

y : Y co-ordinate, in m, of the calculation point with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [6].

2.3 Shear stresses

2.3.1 The shear stresses induced by shear forces and torque are obtained through direct calculation analyses based on a structural model in accordance with Ch 6, Sec 1, [2.6].

2.3.2 The hull girder loads to be considered in these analyses are the vertical shear forces Q_{SW} and Q_{WV}.

When deemed necessary by the Society on the basis of the ship's characteristics and intended service, the horizontal shear force and torque are also to be calculated and taken into account in the calculation of shear stresses.

2.3.3 As an alternative to the above procedure, the shear stresses induced by the vertical shear forces Q_{SW} and Q_{WV} may be obtained through the simplified procedure in [2.4].

2.4 Simplified calculation of shear stresses induced by vertical shear forces

2.4.1 Ships without effective longitudinal bulkheads or with one effective longitudinal bulkhead

In this context, effective longitudinal bulkhead means a bulkhead extending from the bottom to the strength deck.

The shear stresses induced by the vertical shear forces in the calculation point are obtained, in N/mm², from the following formula:

$$\tau_1 = 0,5(Q_{SW} + Q_{WV})\frac{S}{I_Y t_S}$$

where:

t_S : Minimum thickness, in mm, of side plating (see Fig 1) according to Tab 2.

2.4.2 Single side ships with two effective longitudinal bulkheads

In this context, effective longitudinal bulkhead means a bulkhead extending from the bottom to the strength deck.

The shear stresses induced by the vertical shear force in the calculation point are obtained, in N/mm², from the following formula:

$$\tau_1 = [(Q_{SW} + Q_{WV})\delta]\frac{S}{I_Y t}$$

where:

δ : Shear distribution coefficient defined in Tab 2

t : Minimum thickness, in mm, of side, inner side and longitudinal bulkhead plating, as applicable (see Fig 2), according to Tab 2.

Table 2 : Shear stresses induced by vertical shear forces

Location	t, in mm	δ
Sides	t_S	$(1 - \Phi) / 2$
Longitudinal bulkheads	t_B	$\Phi / 2$

Note 1:
$\Phi = 0,3 + 0,21\ t_{BM} / t_{SM}$

t_S, t_B : Minimum net thicknesses, in mm, of side and longitudinal bulkhead plating, respectively

t_{SM}, t_{BM} : Mean thicknesses, in mm, over all the strakes of side and longitudinal bulkhead plating, respectively. They are calculated as: $\Sigma (\ell_i\ t_i) / \Sigma\ \ell_i$, where ℓ_i and t_i are the length, in m, and the thickness, in mm, of the i^{th} strake of side and longitudinal bulkheads.

Figure 1 : Single side ship without effective longitudinal bulkheads

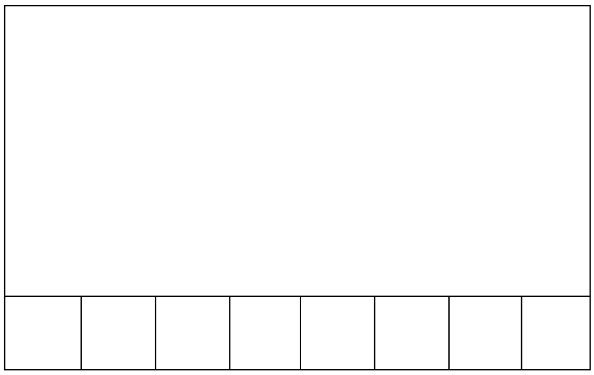


Figure 2 : Single side ship with two effective longitudinal bulkheads

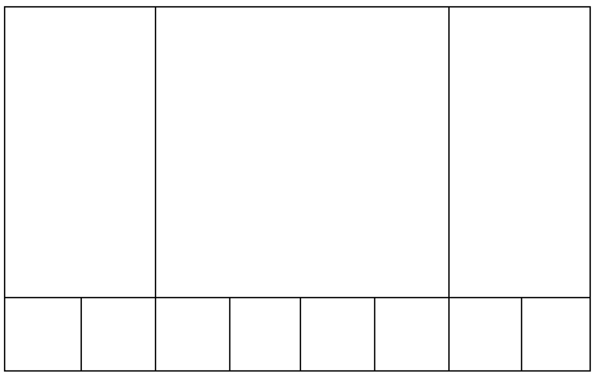


3 Checking criteria

3.1 General

3.1.1 The material factors k are to be defined with respect to the material used at each calculation point, for the members contributing to the longitudinal strength according to Ch 6, Sec 1, [2].

3.2 Normal stresses induced by vertical bending moments

3.2.1 It is to be checked that the normal stresses σ_1 calculated according to [2.1]with vertical wave bending moment M_{WV} increased by 10%, and, when applicable, [2.2] are in compliance with the following formula:

$\sigma_1 \leq \sigma_{1,ALL}$

where:

$\sigma_{1,ALL}$: Allowable normal stress, in N/mm², obtained from the following formulae:

$$\sigma_{1,\,ALL} = \frac{139}{k} \quad \text{for } \frac{x}{L} \le 0,1$$

$$\sigma_{1,\,ALL} = \frac{194}{k} + \frac{275}{k}\left(\frac{x}{L} - 0,3\right) \quad \text{for } 0,1 < \frac{x}{L} < 0,3$$

$$\sigma_{1,\,ALL} = \frac{194}{k} \quad \text{for } 0,3 \le \frac{x}{L} \le 0,7$$

$$\sigma_{1,\,ALL} = \frac{194}{k} - \frac{275}{k}\left(\frac{x}{L} - 0,7\right) \quad \text{for } 0,7 < \frac{x}{L} < 0,9$$

$$\sigma_{1,\,ALL} = \frac{139}{k} \quad \text{for } \frac{x}{L} \ge 0,9$$

Note 1: For naval ships having a service notation other than **frigate** or **aircraft carrier**, the increased of M_{WV} by 10% may generally be disregarded.

3.3 Shear stresses

3.3.1 It is to be checked that the shear stresses τ_1 calculated according to [2.3] are in compliance with the following formula:

$\tau_1 \le \tau_{1,ALL}$

where:

$\tau_{1,ALL}$: Allowable shear stress, in N/mm²

$\tau_{1,ALL} = 122/k$

4 Section modulus and moment of inertia

4.1 General

4.1.1 The requirements in [4.2] to [4.5] provide for the minimum hull girder section modulus, complying with the checking criteria indicated in [3], and the midship section moment of inertia required to ensure sufficient hull girder rigidity.

4.1.2 The material factors k are to be defined with respect to the materials used for the bottom and deck members contributing to the longitudinal strength according to Ch 6, Sec 1, [2]. When material factors for higher strength steels are used, the requirements in [4.5] apply.

4.2 Section modulus within 0,4L amidships

4.2.1 The section moduli Z_{AB} and Z_{AD} within 0,4 L amidships are to be not less than the value obtained, in m³, from the following formula:

$$Z_R = \frac{M_{SW} + nM_{WV}}{\sigma_{1,\,ALL}} 10^{-3}$$

where:

- n = 1,1 for service notation **frigate** or **aircraft carrier**
- n = 1,0 for the other service notations.

In addition, the section moduli Z_{AB} and Z_{AD} at the midship section are to be not less than the value obtained, in m³, from the following formula:

$$Z_{R\Delta} = \frac{M_{WV,\,H} + M_{WV,\,S}}{2\sigma_{\Delta,\,ALL}} 10^{-3}$$

where:

$\sigma_{\Delta,ALL}$: Allowable normal stress, in N/mm² to be taken equal to:

- 122 N/mm² for steel with R_{eH} = 235 N/mm²
- 155 N/mm² for steel with R_{eH} = 315 N/mm²
- 166 N/mm² for steel with R_{eH} = 355 N/mm² or 390 N/mm².

4.2.2 Where the total breadth Σb_S of small openings, as defined in Ch 6, Sec 1, [2.1.8], is deducted from the sectional areas included in the hull girder transverse sections, the values Z_R and $Z_{R\Delta}$ defined in [4.2.1] may be reduced by 3%.

4.2.3 Scantlings of members contributing to the longitudinal strength (see Ch 6, Sec 1, [2]) are to be maintained within 0,4 L amidships.

4.3 Section modulus outside 0,4L amidships

4.3.1 The net section moduli Z_{AB} and Z_{AD} outside 0,4 L amidships are to be not less than the value obtained, in m^3, from the following formula:

$$Z_R = \frac{M_{SW} + M_{WV}}{\sigma_{1,ALL}} 10^{-3}$$

4.4 Midship section moment of inertia

4.4.1 The midship section moment of inertia about its horizontal neutral axis is to be not less than the value obtained, in m^4, from the following formula:

$I_{YR} = 2{,}77\ Z'_{R\Delta}\ L\ 10^{-2}$

where:

$Z'_{R\Delta}$: Required midship section modulus $Z_{R\Delta}$, in m^3, calculated as specified in [4.2.1], but assuming $\sigma_{\Delta,ALL} = 130$ N/mm^2 in all cases.

4.5 Extent of higher strength steel

4.5.1 When a material factor for higher strength steel is used in calculating the required section modulus at bottom or at the equivalent deck line according to [4.2] or [4.3], and when the distribution of vertical bending stress across the hull girder transverse section can be assumed to be linear, the vertical extent of higher strength steel, $z_{hts,i}$ used in the deck zone or bottom zone and measured respectively from the equivalent deck line or baseline is not to be taken less the value obtained from the following formula:

$$z_{hts,i} = z_1 \left(1 - \frac{\sigma_{perm,i}}{\sigma_L}\right)$$

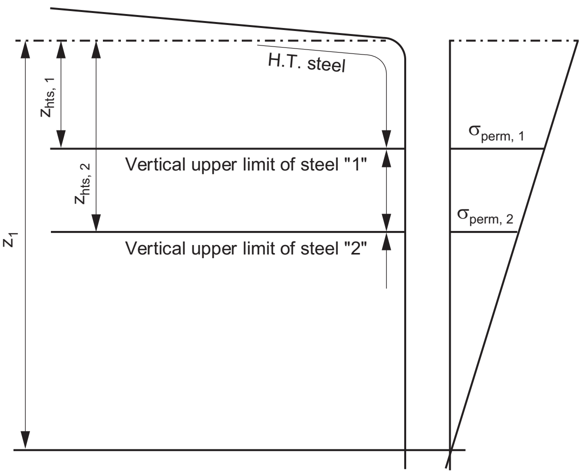
where:

σ_L : Normal stress, in N/mm^2, at the equivalent deck line or at bottom, calculated according to [2.1.1]

z_1 : Distance from horizontal neutral axis, to the equivalent deck line defined in Ch 6, Sec 1, [2.3.2], or to the baseline respectively, in m, with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [6]

$\sigma_{perm,i}$: Allowable normal stress defined in [3.1.1], in N/mm², for the adjacent zone of steel having lower strength (see Fig 3).

Figure 3 : Vertical extent of higher strength steel



4.5.2 The relevant higher strength steel is to be adopted for all members contributing to the longitudinal strength (see Ch 6, Sec 1, [2]) within the extent defined in [4.5.1].

4.5.3 The higher strength steel is to extend in length at least throughout 0,4 L amidships where it is required for strength purposes according to the provisions of Part B.

4.5.4 Longitudinal members not contributing to the hull girder longitudinal strength and welded to the strength deck or bottom plating and bilge strake, such as longitudinal hatch coamings, gutter bars, strengthening of deck openings, bilge keel, are to be made of steel with the same specified minimum yield stress as the strength deck or bottom structure steel.

4.5.5 The requirement in [4.5.4] is also applicable to non-continuous longitudinal stiffeners welded to the web of a primary structural member contributing to the hull girder longitudinal strength such as hatch coamings, stringers and girders or on the inner bottom when the hull girder stress in those members is higher than the permissible stress as defined in [3.1.1] for normal strength steel.

5 Permissible still water bending moment and shear force during navigation

5.1 Permissible still water bending moment

5.1.1 The permissible still water bending moment at any hull transverse section during navigation, in hogging or sagging conditions, is the value M_{SW} considered in the hull girder section modulus calculation according to Article [4].

In the case of structural discontinuities in the hull transverse sections, the distribution of permissible still water bending moments is considered on a case-by-case basis.

5.2 Permissible still water shear force

5.2.1 Direct calculations

Where the shear stresses are obtained through calculation analyses according to [2.3], the permissible positive or negative still water shear force at any hull transverse section is obtained, in kN, from the following formula:

$$Q_P = \varepsilon|Q_T| - Q_{WV}$$

where:

$\varepsilon = \mathrm{sgn}\,(Q_{SW})$

Q_T : Shear force, in kN, which produces a shear stress $\tau = 122/k$ N/mm^2 in the most stressed point of the hull transverse section.

5.2.2 Single side ships without effective longitudinal bulkheads

Where the shear stresses are obtained through the simplified procedure in [2.4.1], the permissible positive or negative still water shear force at any hull transverse section is obtained, in kN, from the following formula:

$$Q_P = \varepsilon\left(\frac{122}{0,5k} \cdot \frac{I_Y t_S}{S}\right) - Q_{WV}$$

where:

$\varepsilon = \mathrm{sgn}\,(Q_{SW})$

t_S : Minimum net thickness, in mm, of side plating according to Tab 2.

5.2.3 Single side ships with two effective longitudinal bulkheads

Where the shear stresses are obtained through the simplified procedure in [2.4.2], the permissible positive or negative still water shear force at any hull transverse section is obtained, in kN, from the following formula:

$$Q_P = \frac{1}{\delta}\left(\varepsilon\frac{122}{k} \cdot \frac{I_Y t}{S}\right) - Q_{WV}$$

where:

δ : Shear distribution coefficient defined in Tab 2

$\varepsilon = \mathrm{sgn}\,(Q_{SW})$

t : Minimum thickness, in mm, of side, inner side and longitudinal bulkhead plating, as applicable, according to Tab 2.

6 Permissible still water bending moment and shear force in harbour conditions

6.1 Permissible still water bending moment

6.1.1 The permissible still water bending moment at any hull transverse section in harbour conditions, in hogging or sagging conditions, is obtained, in kN·m, from the following formula:

$$M_{P,H} = M_P + 0,6\ M_W$$

where M_P is the permissible still water bending moment during navigation in KN·m, to be calculated according to [5.1.1].

6.2 Permissible shear force

6.2.1 The permissible positive or negative still water shear force at any hull transverse section, in harbour conditions, is obtained, in kN, from the following formula:

$$Q_{P,H} = \varepsilon\ Q_P + 0,7\ Q_{WV}$$

where:

$\varepsilon = \mathrm{sgn}(Q_{SW})$

Q_P : Permissible still water shear force during navigation, in kN, to be calculated according to [5.2].

Section 3 Ultimate Strength Check

Symbols

For symbols not defined in this Section, refer to the list at the beginning of this Chapter.

1 Application

1.1

1.1.1 The requirements of this Section apply to ships equal to or greater than 90 m in length.

2 General

2.1 Net scantlings

2.1.1 As specified in Ch 4, Sec 2, [1], the ultimate strength of the hull girder is to be checked on the basis of the net strength characteristics of the transverse section which is to be calculated according to Ch 4, Sec 2, [2].

2.2 Partial safety factors

2.2.1 The partial safety factors to be considered for checking the ultimate strength of the hull girder are specified in Tab 1.

Table 1 : Partial safety factors

Partial safety factor covering uncertainties on:	Symbol	Value
Still water hull girder loads	γ_{S1}	1,00
Wave induced hull girder loads	γ_{W1}	1,20
Material	γ_m	1,02
Resistance	γ_R	1,15

3 Hull girder ultimate strength check

3.1 Hull girder loads

3.1.1 Bending moments

The bending moment in sagging and hogging conditions, to be considered in the ultimate strength check of the hull girder, is to be obtained, in kN·m, from the following formula:

$M = \gamma_{S1} M_{SW} + \gamma_{W1} M_{WV}$

3.2 Hull girder ultimate bending moment capacities

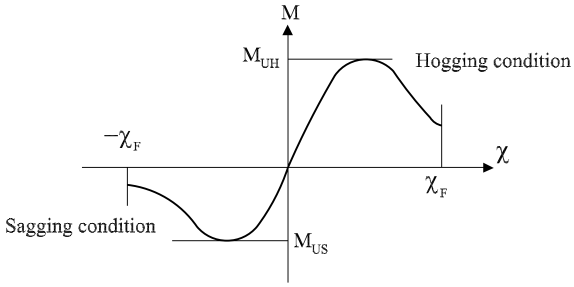
3.2.1 Curve M-χ

The ultimate bending moment capacities of a hull girder transverse section, in hogging and sagging conditions, are defined as the maximum values of the curve of bending moment capacity M versus the curvature χ of the transverse section considered (see Fig 1).

The curvature χ is positive for hogging condition and negative for sagging condition.

The curve M-χ is to be obtained through an incremental-iterative procedure according to the criteria specified in Ch 6, App 1.

Figure 1 : Curve bending moment capacity M versus curvature χ



3.2.2 Hull girder transverse sections

The hull girder transverse sections are constituted by the elements contributing to the hull girder longitudinal strength, considered with their net scantlings, according to Ch 6, Sec 1, [2].

3.3 Checking criteria

3.3.1 It is to be checked that the hull girder ultimate bending capacity at any hull transverse section is in compliance with the following formula:

$$\frac{M_U}{\gamma_R \gamma_m} \geq M$$

where:

M_U : Ultimate bending moment capacity of the hull transverse section considered, in kN·m:
- in hogging conditions: $M_U = M_{UH}$
- in sagging conditions: $M_U = M_{US}$

M_{UH} : Ultimate bending moment capacity in hogging conditions, defined in [3.2.1]

M_{US} : Ultimate bending moment capacity in sagging conditions, defined in [3.2.1]

M : Bending moment, in kN·m, defined in [3.1.1].

Appendix 1 Hull Girder Ultimate Strength

Symbols

For symbols not defined in this Appendix, refer to the list at the beginning of this Chapter.

R_{eH} : Minimum upper yield stress, in N/mm², of the material

I_Y : Moment of inertia, in m⁴, of the hull transverse section around its horizontal neutral axis, to be calculated according to Ch 6, Sec 1, [2.4]

Z_{AB}, Z_{AD} : Section moduli, in cm³, at bottom and deck, respectively, defined in Ch 6, Sec 1, [2.3.2]

s : Spacing, in m, of ordinary stiffeners

ℓ : Span, in m, of ordinary stiffeners, measured between the supporting members (see Ch 4, Sec 3, Fig 2 to Ch 4, Sec 3, Fig 5)

h_w : Web height, in mm, of an ordinary stiffener

t_w : Web net thickness, in mm, of an ordinary stiffener

b_f : Face plate width, in mm, of an ordinary stiffener

t_f : Face plate net thickness, in mm, of an ordinary stiffener

A_S : Net sectional area, in cm², of an ordinary stiffener

t_p : Net thickness, in mm, of the plating attached to an ordinary stiffener.

1 Hull girder ultimate strength check

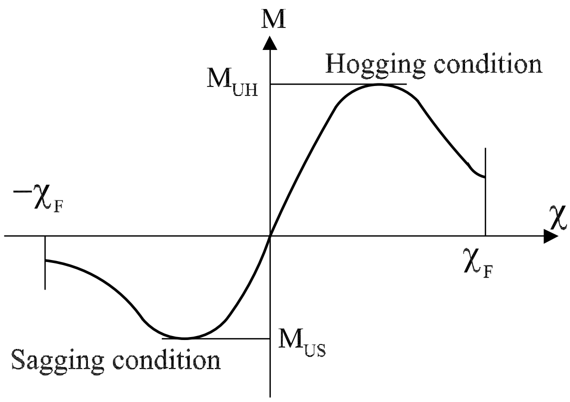
1.1 Introduction

1.1.1 Ch 6, Sec 3, [2] defines the criteria for calculating the ultimate bending moment capacities in hogging condition M_{UH} and sagging condition M_{US} of a hull girder transverse section.

As specified in Ch 6, Sec 3, [2], the ultimate bending moment capacities are defined as the maximum values of the curve of bending moment capacity M versus the curvature χ of the transverse section considered (see Fig 1).

1.1.2 This Appendix provides the criteria for obtaining the curve M-χ.

Figure 1 : Curve bending moment capacity M versus curvature χ



1.2 Criteria for the calculation of the curve M-χ

1.2.1 Procedure

The curve M-χ is to be obtained by means of an incremental-iterative approach, summarized in the flow chart in Fig 2.

Each step of the incremental procedure is represented by the calculation of the bending moment M_i which acts on the hull transverse section as the effect of an imposed curvature χ_i.

For each step, the value χ_i is to be obtained by summing an increment of curvature $\Delta\chi$ to the value relevant to the previous step χ_{i-1}. This increment of curvature corresponds to an increment of the rotation angle of the hull girder transverse section around its horizontal neutral axis.

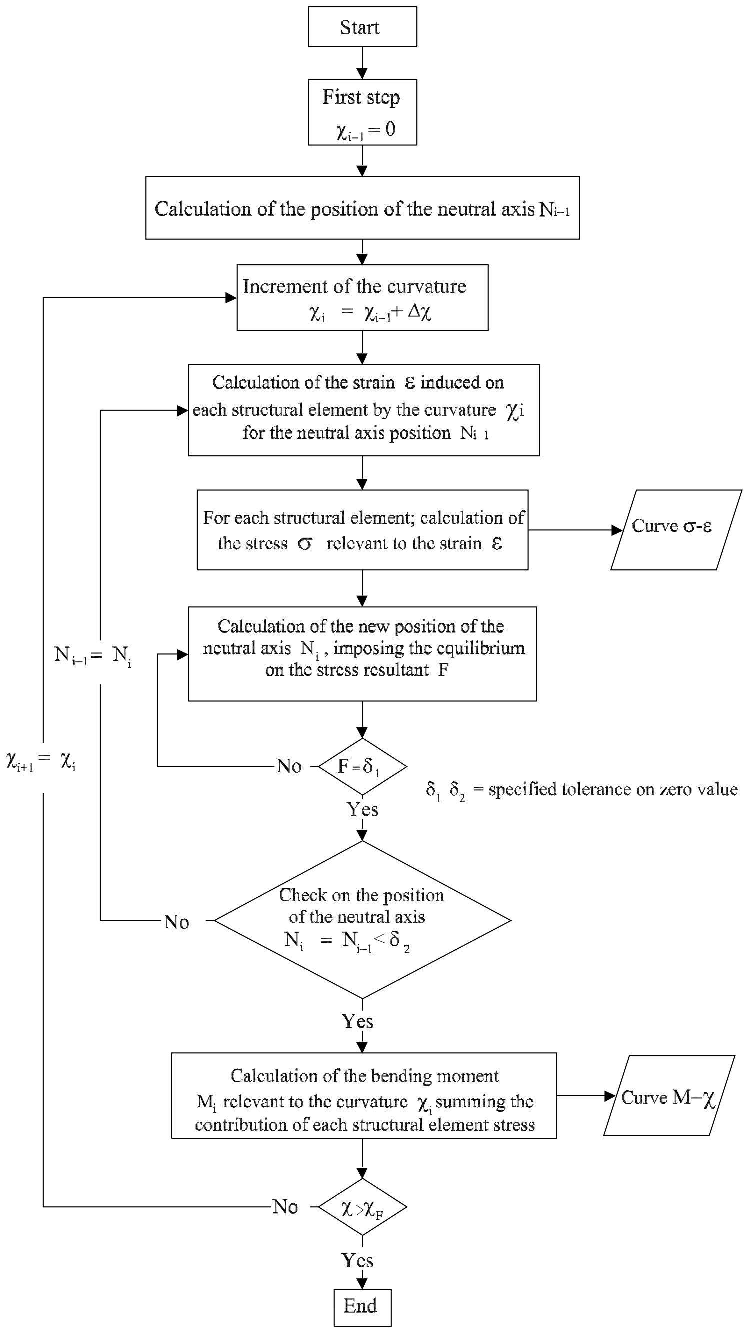
This rotation increment induces axial strains ε in each hull structural element, whose value depends on the position of the element. In hogging condition, the structural elements above the neutral axis are lengthened, while the elements below the neutral axis are shortened. Vice-versa in sagging condition.

The stress σ induced in each structural element by the strain ε is to be obtained from the load-end shortening curve σ-ε of the element, which takes into account the behaviour of the element in the non-linear elasto-plastic domain.

The distribution of the stresses induced in all the elements composing the hull transverse section determines, for each step, a variation of the neutral axis position, since the relationship σ-ε is non-linear. The new position of the neutral axis relevant to the step considered is to be obtained by means of an iterative process, imposing the equilibrium among the stresses acting in all the hull elements.

Once the position of the neutral axis is known and the relevant stress distribution in the section structural elements is obtained, the bending moment of the section M_i around the new position of the neutral axis, which corresponds to the curvature χ_i imposed in the step considered, is to be obtained by summing the contribution given by each element stress.

Figure 2 : Flow chart of the procedure for the evaluation of the curve M-χ



1.2.2 Assumption

In applying the procedure described in [1.2.1], the following assumptions are generally to be made:

- The ultimate strength is calculated at hull transverse sections between two adjacent reinforced rings.
- The hull girder transverse section remains plane during each curvature increment.
- The hull material has an elasto-plastic behaviour.
- The hull girder transverse section is divided into a set of elements, which are considered to act independently. These elements are:
  - transversely framed plating panels and/or ordinary stiffeners with attached plating, whose structural behaviour is described in [1.3.1]
  - hard corners, constituted by plating crossing, whose structural behaviour is described in [1.3.2].
- According to the iterative procedure, the bending moment M_i acting on the transverse section at each curvature value χ_i is obtained by summing the contribution given by the stress σ acting on each element. The stress σ, corresponding to the element strain ε, is to be obtained for each curvature increment from the non-linear load-end shortening curves σ-ε of the element.

  These curves are to be calculated, for the failure mechanisms of the element, from the formulae specified in [1.3]. The stress σ is selected as the lowest among the values obtained from each of the considered load-end shortening curves σ-ε.
- The procedure is to be repeated for each step, until the value of the imposed curvature reaches the value χ_F, in m^{-1}, in hogging and sagging condition, obtained from the following formula:

  $$\chi_F = \pm 0{,}003 \frac{M_Y}{EI_Y}$$

  where:

  M_Y : The lesser of the values M_{Y1} and M_{Y2}, in kN·m:

  $M_{Y1} = 10^{-3}\ R_{eH}\ Z_{AB}$

  $M_{Y2} = 10^{-3}\ R_{eH}\ Z_{AD}$

  If the value χ_F is not sufficient to evaluate the peaks of the curve M-χ, the procedure is to be repeated until the value of the imposed curvature permits the calculation of the maximum bending moments of the curve.

1.3 Load-end shortening curves σ-ε

1.3.1 Plating panels and ordinary stiffeners

Plating panels and ordinary stiffeners composing the hull girder transverse sections may collapse following one of the modes of failure specified in Tab 1.

1.3.2 Hard corners

Hard corners are sturdier elements composing the hull girder transverse section, which collapse mainly according to an elasto-plastic mode of failure. The relevant load-end shortening curve σ-ε is to be obtained for lengthened and shortened hard corners according to [1.3.3].

1.3.3 Elasto-plastic collapse

The equation describing the load-end shortening curve σ-ε for the elasto-plastic collapse of structural elements composing the hull girder transverse section is to be obtained from the following formula, valid for both positive (shortening) and negative (lengthening) strains (see Fig 3):

$\sigma = \Phi\ R_{eH}$

where:

Φ : Edge function:

$\Phi = -1$ for $\varepsilon < -1$

$\Phi = \varepsilon$ for $-1 < \varepsilon < 1$

$\Phi = 1$ for $\varepsilon > 1$

ε : Relative strain:

$$\varepsilon = \frac{\varepsilon_E}{\varepsilon_Y}$$

ε_E : Element strain

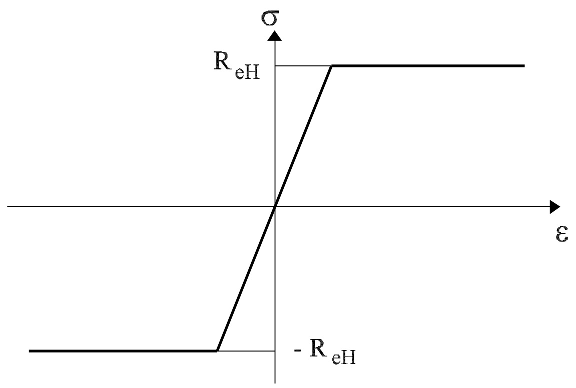
ε_Y : Strain inducing yield stress in the element:

$$\varepsilon_Y = \frac{R_{eH}}{E}$$

Table 1 : Modes of failure of plate panels and ordinary stiffeners

Element	Mode of failure	Curve σ-ε defined in
Lengthened plate panel or ordinary stiffeners	Elasto-plastic collapse	[1.3.3]
Shortened ordinary stiffeners	Beam columnbuckling	[1.3.4]
	Torsional buckling	[1.3.5]
	Web local buckling of flanged profiles	[1.3.6]
	Web local buckling of flat bars	[1.3.7]
Shortened transversely framed plate panel	Plate buckling	[1.3.8]
Shortened transversely framed curved plate panel	Curved plate buckling	[1.3.9]

Figure 3 : Load-end shortening curve σ-ε for elasto-plastic collapse



1.3.4 Beam column buckling

The equation describing the load-end shortening curve σ_{CR1}-ε for the beam column buckling of ordinary stiffeners composing the hull girder transverse section is to be obtained from the following formula (see Fig 4):

$$\sigma_{CR1} = \Phi\sigma_{C1}\frac{A_S + 10b_Et_P}{A_S + 10st_P}$$

where:

Φ : Edge function defined in [1.3.3]

σ_{C1} : Critical stress, in N/mm²:

$$\sigma_{C1} = \frac{\sigma_{E1}}{\varepsilon} \quad \text{for} \quad \sigma_{E1} \le \frac{R_{eH}}{2}\varepsilon$$

$$\sigma_{C1} = R_{eH}\left(1 - \frac{\Phi R_{eH}\varepsilon}{4\sigma_{E1}}\right) \quad \text{for} \quad \sigma_{E1} > \frac{R_{eH}}{2}\varepsilon$$

ε : Relative strain defined in [1.3.3]

σ_{E1} : Euler column buckling stress, in N/mm²:

$$\sigma_{E1} = \pi^2E\frac{I_E}{A_E\ell^2}10^4$$

I_E : Net moment of inertia of ordinary stiffeners, in cm⁴, with attached shell plating of width b_{E1}

b_{E1} : Width, in m, of the attached shell plating:

$$b_{E1} = \frac{s}{\beta_E} \quad \text{for} \quad \beta_E > 1{,}0$$

$$b_{E1} = s \quad \text{for} \quad \beta_E \le 1{,}0$$

$$\beta_E = 10^3\frac{s}{t_p}\sqrt{\frac{\varepsilon R_{eH}}{E}}$$

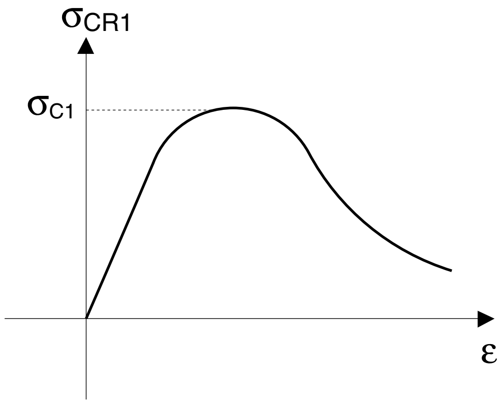
A_E : Net sectional area, in cm², of ordinary stiffeners with attached shell plating of width b_E

b_E : Width, in m, of the attached shell plating:

$$b_E = \left(\frac{2{,}25}{\beta_E} - \frac{1{,}25}{\beta_E^2}\right)s \quad \text{for} \quad \beta_E > 1{,}25$$

$$b_E = s \quad \text{for} \quad \beta_E \le 1{,}25$$

Figure 4 : Load-end shortening curve σ_{CR1}-ε for beam column buckling



1.3.5 Torsional buckling

The equation describing the load-end shortening curve σ_{CR2}-ε for the lateral-flexural buckling of ordinary stiffeners composing the hull girder transverse section is to be obtained according to the following formula (see Fig 5):

$$\sigma_{CR2} = \Phi\frac{A_S\sigma_{C2} + 10st_P\sigma_{CP}}{A_S + 10st_P}$$

where:

Φ : Edge function defined in [1.3.3]

σ_{C2} : Critical stress, in N/mm²:

$$\sigma_{C2} = \frac{\sigma_{E2}}{\varepsilon} \quad \text{for} \quad \sigma_{E2} \le \frac{R_{eH}}{2}\varepsilon$$

$$\sigma_{C2} = R_{eH}\left(1 - \frac{\Phi R_{eH}\varepsilon}{4\sigma_{E2}}\right) \quad \text{for} \quad \sigma_{E2} > \frac{R_{eH}}{2}\varepsilon$$

σ_{E2} : Euler torsional buckling stress, in N/mm², defined in Ch 7, Sec 2, [4.3.3]

ε : Relative strain defined in [1.3.3]

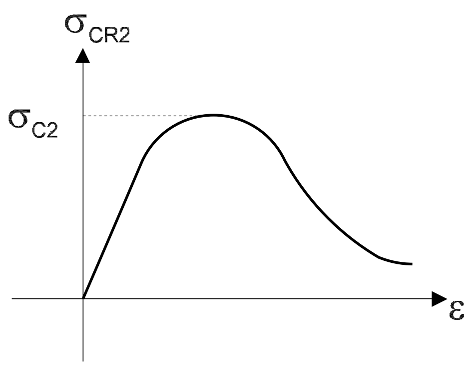
σ_{CP} : Buckling stress of the attached plating, in N/mm²:

$$\sigma_{CP} = \left(\frac{2,25}{\beta_E} - \frac{1,25}{\beta_E^2}\right)R_{eH} \quad \text{for} \quad \beta_E > 1,25$$

$$\sigma_{CP} = R_{eH} \quad \text{for} \quad \beta_E \le 1,25$$

β_E : Coefficient defined in [1.3.4].

Figure 5 : Load-end shortening curve σ_{CR2}-ε for flexural-torsional buckling



1.3.6 Web local buckling of flanged ordinary stiffeners

The equation describing the load-end shortening curve σ_{CR3}-ε for the web local buckling of flanged ordinary stiffeners composing the hull girder transverse section is to be obtained from the following formula:

$$\sigma_{CR3} = \Phi R_{eH}\frac{10^3 b_E t_P + h_{WE}t_W + b_F t_F}{10^3 s t_P + h_W t_W + b_F t_F}$$

where:

Φ : Edge function defined in [1.3.3]

b_E : Width, in m, of the attached shell plating, defined in [1.3.4]

h_{WE} : Effective height, in mm, of the web:

$$h_{WE} = \left(\frac{2,25}{\beta_E} - \frac{1,25}{\beta_E^2}\right) h_W \quad \text{for} \quad \beta_W > 1,25$$

$$h_{WE} = h_W \quad \text{for} \quad \beta_W \le 1,25$$

β_E : Coefficient defined in [1.3.4]

$$\beta_W = 10^3 \frac{h_W}{t_W} \sqrt{\frac{\varepsilon R_{eH}}{E}}$$

ε : Relative strain defined in [1.3.3].

1.3.7 Web local buckling of flat bar ordinary stiffeners

The equation describing the load-end shortening curve σ_{CR4}-ε for the web local buckling of flat bar ordinary stiffeners composing the hull girder transverse section is to be obtained from the following formula (see Fig 6):

$$\sigma_{CR4} = \Phi \frac{10 s t_P \sigma_{CP} + A_S \sigma_{C4}}{A_S + 10 s t_P}$$

where:

Φ : Edge function defined in [1.3.3]

σ_{CP} : Buckling stress of the attached plating, in N/mm², defined in [1.3.5]

σ_{C4} : Critical stress, in N/mm²:

$$\sigma_{C4} = \frac{\sigma_{E4}}{\varepsilon} \quad \text{for} \quad \sigma_{E4} \le \frac{R_{eH}}{2}\varepsilon$$

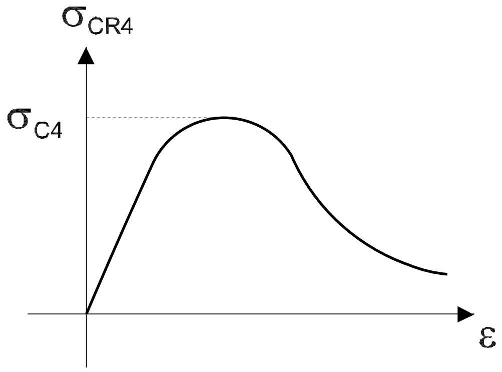
$$\sigma_{C4} = R_{eH}\left(1 - \frac{\Phi R_{eH} \varepsilon}{4 \sigma_{E4}}\right) \quad \text{for} \quad \sigma_{E4} > \frac{R_{eH}}{2}\varepsilon$$

σ_{E4} : Local Euler buckling stress, in N/mm²:

$$\sigma_{E4} = 160000 \left(\frac{t_W}{h_W}\right)^2$$

ε : Relative strain defined in [1.3.3].

Figure 6 : Load-end shortening curve σ_{CR4}-ε for web local buckling of flat bars



1.3.8 Plate buckling

The equation describing the load-end shortening curve σ_{CR5}-ε for the buckling of transversely stiffened panels composing the hull girder transverse section is to be obtained from the following formula:

$$\sigma_{CR5} = R_{eH}\left[\frac{s}{\ell}\left(\frac{2,25}{\beta_E} - \frac{1,25}{\beta_E^2}\right) + 0,1\left(1 - \frac{s}{\ell}\right)\left(1 + \frac{1}{\beta_E^2}\right)^2\right]$$

where:

β_E : Coefficient defined in [1.3.4].

1.3.9 Transversely stiffened curved panels

The equation describing the load-end shortening curve σ_{CR6}-ε for the buckling of transversely stiffened curved panels is to be obtained from the following formulae:

$$\sigma_{CR6} = \frac{\Phi \sigma_{EC}}{\varepsilon} \quad \text{for} \quad \sigma_{EC} \le \frac{R_{eH}}{2}\varepsilon$$

$$\sigma_{CR6} = \Phi R_{eH}\left(1 - \frac{R_{eH}\varepsilon}{4\sigma_{EC}}\right) \quad \text{for} \quad \sigma_{EC} > \frac{R_{eH}}{2}\varepsilon$$

where:

σ_{EC} : Euler buckling stress, to be obtained, in N/mm², from the following formula:

$$\sigma_{EC} = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t}{b}\right)^2 K_3 10^{-6}$$

b : Width of curved panel, in m, measured on arc between two adjacent supports

K_3 : Buckling factor to be taken equal to:

$$K_3 = 2\left\{1 + \sqrt{1 + \frac{12(1-\nu^2)}{\pi^4}\frac{b^4}{r^2 t^2}10^6}\right\}$$

r : Radius of curvature, in m.

CHAPTER 7
HULL SCANTLINGS

Section 1	Plating
Section 2	Ordinary Stiffeners
Section 3	Primary Supporting Members
Section 4	Fatigue Check of Structural Details
Appendix 1	Analyses Based on Three-Dimensional Models
Appendix 2	Analyses of Primary Supporting Members Subjected to Wheeled Loads
Appendix 3	Analyses Based on Complete Ship Models

Symbols used in this Chapter

L_1, L_2 : Lengths, in m, defined in Pt B, Ch 1, Sec 2, [2.1.1]

E : Young's modulus, in N/mm^2, to be taken equal to:

- for steels in general:
  $E = 2{,}06.10^5$ N/mm^2
- for stainless steels:
  $E = 1{,}95.10^5$ N/mm^2
- for aluminium alloys:
  $E = 7{,}0.10^4$ N/mm^2

ν : Poisson's ratio. Unless otherwise specified, a value of 0,3 is to be taken into account

k : Material factor, defined in:

- Pt B, Ch 4, Sec 1, [2.3], for steel
- Pt B, Ch 4, Sec 1, [4.4], for aluminium alloys

R_y : Minimum yield stress, in N/mm^2, of the material to be taken equal to 235/k N/mm^2, unless otherwise specified

t_c : Corrosion addition, in mm, defined in Pt B, Ch 4, Sec 2, Tab 2

I_Y : Net moment of inertia, in m^4, of the hull transverse section around its horizontal neutral axis, to be calculated according to Pt B, Ch 6, Sec 1, [2.4] considering the members contributing to the hull girder longitudinal strength as having their net scantlings

I_Z : Net moment of inertia, in m^4, of the hull transverse section around its vertical neutral axis, to be calculated according to Pt B, Ch 6, Sec 1, [2.4] considering the members contributing to the hull girder longitudinal strength as having their net scantlings

x, y, z : X, Y and Z co-ordinates, in m, of the calculation point with respect to the reference co-ordinate system defined in Pt B, Ch 1, Sec 2, [6]

N : Z co-ordinate, in m, with respect to the reference co-ordinate system defined in Pt B, Ch 1, Sec 2, [6], of the centre of gravity of the hull transverse section constituted by members contributing to the hull girder longitudinal strength considered as having their net scantlings (see Pt B, Ch 6, Sec 1, [2])

$M_{SW,H}$: Design still water bending moment, in kN.m, in hogging condition, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [2.2]

$M_{SW,S}$: Design still water bending moment, in kN.m, in sagging condition, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [2.2]

$M_{SW,Hmin}$: Minimum still water bending moment, in kN.m, in hogging condition, at the hull transverse section considered, without being taken greater than $0{,}3M_{WV,S}$

$M_{WV,H}$: Vertical wave bending moment, in kN.m, in hogging condition, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [3.1]

$M_{WV,S}$: Vertical wave bending moment, in kN.m, in sagging condition, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [3.1]

M_{WH} : Horizontal wave bending moment, in kN.m, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [3.2]

M_{WT} : Wave torque, in kN.m, at the hull transverse section considered, defined in Pt B, Ch 5, Sec 2, [3.3].

Section 1 Plating

Symbols

For symbols not defined in this Section, refer to the list at the beginning of this Chapter.

p_S : Still water pressure, in kN/m² (see [3.2.2]

p_W : Wave pressure and, if necessary, dynamic pressures, according to the criteria in Ch 5, Sec 5, [2] and Ch 5, Sec 6, [2], in kN/m² (see [3.2.2])

p_{SF}, p_{WF} : Still water and wave pressure, in kN/m², in flooding conditions, defined in Ch 5, Sec 6, [7] (see [3.2.3])

F_S : Still water wheeled force, in kN (see [4.2.2]

$F_{W,Z}$: Inertial wheeled force, in kN (see [4.2.2])

σ_{X1} : In-plane hull girder normal stress, in N/mm², defined in:

- [3.2.6] for the strength check of plating subjected to lateral pressure
- [5.2.2] for the buckling check of plating

τ_1 : In-plane hull girder shear stress, in N/mm², defined in [3.2.7]

R_{eH} : Minimum guaranteed yield stress, in N/mm², of the plating material, defined in Ch 4, Sec 1, [2]

ℓ : Length, in m, of the longer side of the plate panel

s : Length, in m, of the shorter side of the plate panel

c_a : Aspect ratio of the plate panel, equal to:

$$c_a = 1{,}21\sqrt{1 + 0{,}33\left(\frac{s}{\ell}\right)^2} - 0{,}69\frac{s}{\ell}$$

to be taken not greater than 1,0

c_r : Coefficient of curvature of the panel, equal to:

$c_r = 1 - 0{,}5\, s / r$

to be taken not less than 0,5

r : Radius of curvature, in m

t_{net} : Net thickness, in mm, of a plate panel.

1 General

1.1 Net thicknesses

1.1.1 As specified in Ch 4, Sec 2, [1], all thicknesses referred to in this Section are net, i.e. they do not include any margin for corrosion.

The gross thicknesses are obtained as specified in Ch 4, Sec 2.

1.2 Partial safety factors

1.2.1 The partial safety factors to be considered for the checking of the plating are specified in Tab 1.

1.3 Elementary plate panel

1.3.1 The elementary plate panel is the smallest unstiffened part of plating.

1.4 Load point

1.4.1 Unless otherwise specified, lateral pressure and hull girder stresses are to be calculated:

- for longitudinal framing, at the lower edge of the elementary plate panel or, in the case of horizontal plating, at the point of minimum y-value among those of the elementary plate panel considered
- for transverse framing, at the lower edge of the strake.

Table 1 : Plating - Partial safety factors

Partial safety factors covering uncertainties regarding	Symbol	Strength check of plating subjected to lateral pressure			Buckling check
		General	Flooding pressure	Testing check	
		(see [3.2], [3.3.1], [3.4.1], [3.5.1] and [4])	(see [3.3.2], [3.4.2] and [3.5.2])	(see [3.3.2], [3.4.2] and [3.5.2])	(see [5])
Still water hull girder loads	γ_{S1}	1,00	1,00	Not applicable	1,00
Wave hull girder loads	γ_{W1}	1,15	1,15	Not applicable	1,15
Still water pressure	γ_{S2}	1,00	1,00	1,00	Not applicable
Wave pressure	γ_{W2}	1,20	1,20	Not applicable	Not applicable
Material	γ_m	1,02	1,02	1,02	1,02
Resistance	γ_R	1,20**(2)**	1,05 **(1)**	1,05**(2)**	1,10

(1) For plating of the collision bulkhead, γ_R = 1,25. This requirement may be disregarded when damage stability considers at least two adjacent compartments flooded.
(2) For plating of decks and side walls of ammunition storage, for assessment under flooding by fire-extinguishing system, γ_R = 1,05. This requirement may be disregarded when the extinguishing system used for ammunition storage is not by flooding of the compartment

2 General requirements

2.1 General

2.1.1 The requirements in [2.2] and [2.3] are to be applied to plating in addition of those in [3] to [5].

2.2 Minimum net thicknesses

2.2.1 As a rule, the net thickness of plating is to be not less than the values given in Tab 2.

The Society may consider lower thicknesses than those in Tab 2, on a case by case basis, when this is deemed appropriate on the basis of scantlings calculations for all types of loading cases.

Table 2 : Minimum net thickness of plating

Plating	Minimum net thickness, in mm
Deck Longitudinal bulkhead Shell	5
Transverse bulkhead	4

2.3 Bilge plating

2.3.1 The net thickness of the longitudinally framed bilge plating, in mm, is to be not less than the greater of the:

- value obtained from [3.3.1]
- value obtained from [5], to be checked as curved panel.

2.3.2 The net thickness of the transversely framed bilge plating, in mm, is to be not less than the greater of:

- $t = 0{,}7\ [\gamma_R\ \gamma_m\ (\gamma_{S2}\ p_S + \gamma_{W2}\ p_W)\ s_b]^{0,4}\ R^{0,6}\ k^{1/2}$

  where:

  R : Bilge radius, in m
- value obtained from [5], to be checked as curved panel.

2.3.3 The net thickness bilge plating is to be not less than the actual thicknesses of the adjacent bottom or side plating, whichever is the greater.

2.4 Sheerstrake

2.4.1 Welded sheerstrake

The net thickness of a welded sheerstrake is to be not less than that of the adjacent side plating, taking into account higher strength steel corrections if needed.

In general, the required net thickness of the adjacent side plating is to be taken as a reference. In specific case, depending on its actual net thickness, this latter may be required to be considered when deemed necessary by the Society.

2.4.2 Rounded sheerstrake

The net thickness of a rounded sheerstrake is to be not less than the actual net thickness of the adjacent deck plating.

2.4.3 Net thickness of the sheerstrake in way of breaks of long superstructures

The net thickness of the sheerstrake is to be increased in way of breaks of long superstructures occurring within 0,5L amidships, over a length of about one sixth of the ship’s breadth on each side of the superstructure end.

This increase in net thickness is to be equal to 40%, but need not exceed 4,5 mm.

Where the breaks of superstructures occur outside 0,5 L amidships, the increase in net thickness may be reduced to 30%, but need not exceed 2,5 mm.

Alternative arrangements justified by direct calculations or compliance with other regulations may be accepted, if deemed equivalent by the Society.

2.4.4 Net thickness of the sheerstrake in way of breaks of short superstructures

The net thickness of the sheerstrake is to be increased in way of breaks of short superstructures occurring within 0,6 L amidships, over a length of about one sixth of the ship’s breadth on each side of the superstructure end.

This increase in net thickness is to be equal to 15%, but need not exceed 4,5 mm.

Alternative arrangements justified by direct calculations or compliance with other regulations may be accepted, if deemed equivalent by the Society.

2.5 Stringer plate

2.5.1 General

The net thickness of the stringer plate is to be not less than the actual net thickness of the adjacent deck plating.

2.5.2 Net thickness of the stringer plate in way of breaks of long superstructures

The net thickness of the stringer plate is to be increased in way of breaks of long superstructures occurring within 0,5L amidships, over a length of about one sixth of the ship’s breadth on each side of the superstructure end.

This increase in net thickness is to be equal to 40%, but need not exceed 4,5 mm.

Where the breaks of superstructures occur outside 0,5L amidships, the increase in net thickness may be reduced to 30%, but need not exceed 2,5 mm.

Alternative arrangements justified by direct calculations or compliance with other regulations may be accepted, if deemed equivalent by the Society.

2.5.3 Net thickness of the stringer plate in way of breaks of short superstructures

The net thickness of the stringer plate is to be increased in way of breaks of short superstructures occurring within 0,6L amidships, over a length of about one sixth of the ship breadth on each side of the superstructure end.

This increase in net thickness is to be equal to 15%, but need not exceed 4,5 mm.

Alternative arrangements justified by direct calculations or compliance with other regulations may be accepted, if deemed equivalent by the Society.

3 Strength check of plating subjected to lateral pressure

3.1 General

3.1.1 The requirements of this Article apply for the yielding check of plating subjected to lateral pressure, wheeled loads or weapon firing dynamic loads and, for plating contributing to the longitudinal strength, to in-plane hull girder normal and shear stresses.

3.2 Load model

3.2.1 General

The still water and wave lateral pressures induced by the sea and the various types of cargoes and ballast in intact conditions are to be considered, depending on the location of the plating under consideration and the type of the compartments adjacent to it, in accordance with Ch 5, Sec 1, [2.4].

The plating located below the deepest equilibrium waterline (excluding side shell plating) which constitute boundaries intended to stop vertical and horizontal flooding is to be subjected to lateral pressure in flooding conditions.

The wave lateral pressures and hull girder loads are to be calculated in the mutually exclusive load cases “a”, “b”, “c” and “d” in Ch 5, Sec 4.

3.2.2 Lateral pressure in intact conditions

The lateral pressure in intact conditions is constituted by still water pressure and wave pressure.

Still water pressure (p_S) includes:

- the still water sea pressure, defined in Ch 5, Sec 5, [1]
- the still water internal pressure, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast.

Wave pressure (p_W) includes:

- the wave pressure, defined in Ch 5, Sec 5, [2] for each load case "a", "b", "c" and "d"
- the inertial pressure, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast, and for each load case "a", "b", "c" and "d"
- the dynamic pressures, according to the criteria in Ch 5, Sec 6, [2].

3.2.3 Lateral pressure in flooding conditions

The lateral pressure in flooding conditions is constituted by the still water pressure p_{SF} and wave pressure p_{WF} defined in Ch 5, Sec 6, [7].

3.2.4 Lateral pressure in testing conditions

The lateral pressure (p_T) in testing conditions is taken equal to:

- $p_{ST} - p_S$ for bottom shell plating and side shell plating
- p_{ST} otherwise,

where:

p_{ST} : Still water pressure defined in Ch 5, Sec 6, Tab 10

p_S : Still water sea pressure defined in Ch 5, Sec 5, [1.1.1] for the draught T_1 at which the testing is carried out.

If the draught T_1 is not defined by the Designer, it may be taken equal to the light ballast draught T_B defined in Ch 5, Sec 1, [2.4.3].

3.2.5 Pressures induced by weapon firing dynamic loads

The following weapon firing dynamic loads are to be considered, depending on the location of the plating under consideration:

- missile blast dynamic pressure
- accidental missile ignition dynamic pressure
- gun blast dynamic pressure.

The lateral pressure p_W induced by the above dynamic loads are to be calculated according to the requirements specified in Ch 5, Sec 6, [9].

3.2.6 In-plane hull girder normal stresses

The in-plane hull girder normal stresses to be considered for the strength check of plating are obtained, in N/mm², from the following formulae:

- for plating contributing to the hull girder longitudinal strength:

  $\sigma_{X1} = \gamma_{S1}\,\sigma_{S1} + \gamma_{W1}\,(C_{FV}\,\sigma_{WV1} + C_{FH}\,\sigma_{WH1})$

- for plating not contributing to the hull girder longitudinal strength:

  $\sigma_{X1} = 0$

where:

σ_{S1}, σ_{WV1}, σ_{WH1} : Hull girder normal stresses, in N/mm², defined in Tab 3

C_{FV}, C_{FH} : Combination factors defined in Tab 4.

Table 3 : Hull girder normal stresses

Condition	σ_{S1}, in N/mm² **(1)**	σ_{WV1}, in N/mm²	σ_{WH1}, in N/mm²
$\dfrac{\lvert\gamma_{S1}M_{SW,S}+0,625\gamma_{W1}C_{FV}M_{WV,S}\rvert}{\gamma_{S1}M_{SW,H}+0,625\gamma_{W1}C_{FV}M_{WV,H}} \geq 1$	$\left\lvert\dfrac{M_{SW,S}}{I_Y}(z-N)\right\rvert 10^{-3}$	$\left\lvert\dfrac{0,625F_D M_{WV,S}}{I_Y}(z-N)\right\rvert 10^{-3}$	$\left\lvert\dfrac{0,625M_{WH}}{I_Z}y\right\rvert 10^{-3}$
$\dfrac{\lvert\gamma_{S1}M_{SW,S}+0,625\gamma_{W1}C_{FV}M_{WV,S}\rvert}{\gamma_{S1}M_{SW,H}+0,625\gamma_{W1}C_{FV}M_{WV,H}} < 1$	$\left\lvert\dfrac{M_{SW,H}}{I_Y}(z-N)\right\rvert 10^{-3}$	$\left\lvert\dfrac{0,625M_{WV,H}}{I_Y}(z-N)\right\rvert 10^{-3}$	

(1) When the ship in still water is always in hogging condition, $M_{SW,S}$ is to be taken equal to 0.
Note 1:
F_D : Coefficient defined in Ch 5, Sec 2, [4].

Table 4 : Combination factors C_{FV}, C_{FH} and $C_{F\Omega}$

Load case	C_{FV}	C_{FH}	$C_{F\Omega}$
"a"	1,0	0	0
"b"	1,0	0	0
"c"	0,4	1,0	1,0
"d"	0,4	1,0	0
Flooding	0,6	0	0

Table 5 : Hull girder shear stresses

Structural element	τ_{S1}, τ_{W1} in N/mm²
Bottom, bilge, inner bottom and decks (excluding possible longitudinal sloping plates)	0
Side, inner side and longitudinal bulkheads (including possible longitudinal sloping plates):	
• $0 \leq z \leq 0,25\ D$	$\tau_0\left(0,5 + 2\dfrac{z}{D}\right)$
• $0,25\ D < z \leq 0,75\ D$	τ_0
• $0,75\ D < z \leq D$	$\tau_0\left(2,5 - 2\dfrac{z}{D}\right)$
Note 1: $\tau_0 = \dfrac{47}{k}\left\{1 - \dfrac{6,3}{\sqrt{L_1}}\right\}$ N/mm²	

3.2.7 In-plane hull girder shear stresses

The in-plane hull girder shear stresses to be considered for the strength check of plating which contributes to the longitudinal strength are obtained, in N/mm², from the following formula:

$$\tau_1 = \gamma_{S1}\ \tau_{S1} + 0,625\ C_{FV}\ \gamma_{W1}\ \tau_{W1}$$

where:

τ_{S1} : Absolute value of the hull girder shear stresses, in N/mm², induced by the maximum still water hull girder vertical shear force

τ_{W1} : Absolute value of the hull girder shear stresses, in N/mm², induced by the maximum wave hull girder vertical shear force

C_{FV} : Combination factor defined in Tab 4.

τ_{S1} and τ_{W1} may be calculated as indicated in Tab 5 where, at a preliminary design stage, the still water hull girder vertical shear force is not defined.

3.3 Longitudinally framed plating contributing to the hull girder longitudinal strength

3.3.1 General

The net thickness of laterally loaded plate panels subjected to in-plane normal stress acting on the shorter sides is to be not less than the value obtained, in mm, from the following formula:

$$t = 14,9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{\lambda_L R_y}}$$

where:

- for bottom, bilge, inner bottom and decks (excluding possible longitudinal sloping plates):

$$\lambda_L = \sqrt{1 - 0,95\left(\gamma_m \frac{\sigma_{x1}}{R_y}\right)^2} - 0,225\gamma_m \frac{\sigma_{x1}}{R_y}$$

- for side, inner side and longitudinal bulkheads (including possible longitudinal sloping plates):

$$\lambda_L = \sqrt{1 - 3\left(\gamma_m \frac{\tau_1}{R_y}\right)^2 - 0,95\left(\gamma_m \frac{\sigma_{x1}}{R_y}\right)^2} - 0,225\gamma_m \frac{\sigma_{x1}}{R_y}$$

3.3.2 Flooding conditions

The plating of structural watertight elements which constitute boundaries intended to stop vertical and horizontal flooding as per Internal Watertight Plan is to be checked in flooding conditions. To this end, its net thickness is to be not less than the value obtained, in mm, from the following formula:

$$t = 14{,}9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_{SF} + \gamma_{W2} p_{WF}}{\lambda_L R_y}}$$

where λ_L is defined in [3.3.1].

3.3.3 Testing conditions

The plating of compartments or structures as defined in Ch 5, Sec 6, Tab 10 is to be checked in testing conditions. To this end, its net thickness is to be not less than the value obtained, in mm, from the following formula:

$$t = 14{,}9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_T}{R_y}}$$

3.4 Transversely framed plating contributing to the hull girder longitudinal strength

3.4.1 General

The net thickness of laterally loaded plate panels subjected to in-plane normal stress acting on the longer sides is to be not less than the value obtained, in mm, from the following formula:

$$t = C_T c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{\lambda_T R_y}}$$

where:

- for bottom, bilge, inner bottom and decks (excluding possible longitudinal sloping plates):

  C_T : Coefficient equal to 17,2

  $$\lambda_T = 1 - 0{,}89 \gamma_m \frac{\sigma_{x1}}{R_y}$$

- for side, inner side and longitudinal bulkheads (including possible longitudinal sloping plates):

  C_T : Coefficient equal to:

  17,2 for side

  14,9 for inner side and longitudinal bulkheads (including possible longitudinal sloping plates)

  $$\lambda_T = \sqrt{1 - 3\left(\gamma_m \frac{\tau_1}{R_y}\right)^2} - 0{,}89 \gamma_m \frac{\sigma_{x1}}{R_y}$$

3.4.2 Flooding conditions

The plating of bulkheads or inner side which constitute the boundary of compartments not intended to carry liquids is to be checked in flooding conditions. To this end, its net thickness is to be not less than the value obtained, in mm, from the following formula:

$$t = 17{,}2 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_{SF} + \gamma_{W2} p_{WF}}{\lambda_T R_y}}$$

where λ_T is defined in [3.4.1].

3.4.3 Testing conditions

The plating of compartments or structures as defined in Ch 5, Sec 6, Tab 10 is to be checked in testing conditions. To this end, its net thickness is to be not less than the value obtained, in mm, from the following formula:

$$t = 14{,}9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_{ST}}{R_y}}$$

3.5 Plating not contributing to the hull girder longitudinal strength

3.5.1 General

The net thickness of plate panels subjected to lateral pressure is to be not less than the value obtained, in mm, from the following formula:

$$t = 14{,}9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y}}$$

3.5.2 Flooding conditions

The plating of bulkheads or inner side which constitute the boundary of compartments not intended to carry liquids is to be checked in flooding conditions. To this end, its net thickness is to be not less than the value obtained, in mm, from the following formula:

$$t = 14{,}9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_{SF} + \gamma_{W2} p_{WF}}{R_y}}$$

3.5.3 Testing conditions

The plating of compartments or structures as defined in Ch 5, Sec 6, Tab 10 is to be checked in testing conditions. To this end, its net thickness is to be not less than the value obtained, in mm, from the following formula:

$$t = 14{,}9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_{ST}}{R_y}}$$

4 Strength check of plating subjected to wheeled loads

4.1 General

4.1.1 The requirements of this Article apply for the strength check of plating subjected to wheeled loads.

4.2 Load model

4.2.1 General

The still water and inertial forces induced by the sea and the various types of wheeled vehicles are to be considered, depending on the location of the plating.

The inertial forces induced by the sea are to be calculated in load case "b", as defined in Ch 5, Sec 4.

4.2.2 Wheeled forces

The wheeled force applied by one wheel is constituted by still water force and inertial force.

Still water force is the vertical force (F_S) defined in Ch 5, Sec 6, [4.1].

Inertial force is the vertical force ($F_{W,Z}$) defined in Ch 5, Sec 6, [4.1], for load case "b", with the acceleration a_{Z1} calculated at x = 0,5L.

4.3 Plating

4.3.1 The net thickness of plate panels subjected to wheeled loads is to be not less than the value obtained, in mm, from the following formula:

$$t = 0{,}9\, C_{WL} \sqrt{\frac{n P_0 k}{\lambda}}$$

where:

C_{WL} : Coefficient to be taken equal to:

$$C_{WL} = 2,15 - 0,05\frac{\ell}{s} + 0{,}02\left(4 - \frac{\ell}{s}\right)\alpha^{0,5} - 1{,}75\alpha^{0,25}$$

where ℓ/s is to be taken not greater than 3

$$\alpha = \frac{A_T}{\ell s}$$

A_T : Tyre print area, in m². In the case of double or triple wheels, A_T is the print area of the group of wheels. A_T is not to be taken greater than the value given in [4.3.2]

ℓ, s : Lengths, in m, of, respectively, the longer and the shorter sides of the plate panel

n : Number of wheels on the plate panel, taken equal to:

- 1 in the case of a single wheel
- the number of wheels in a group of wheels in the case of double or triple wheels

P_0 : Wheeled force, in kN, taken equal to:

$$P_0 = \gamma_{S2} F_S + \gamma_{W2} F_{W,Z}$$

λ : Coefficient taken equal to:

- for longitudinally framed plating:
  $\lambda = \lambda_L$ as defined in [3.3.1]
- for transversely framed plating:
  $\lambda = \lambda_T$ as defined in [3.4.1].

4.3.2 When the tyre print area is not known, it may be taken equal to:

$$A_T = 9,81\frac{nQ_A}{n_W p_T}$$

where:

n : Number of wheels on the plate panel, defined in [4.3.1]

Q_A : Axle load, in t

n_W : Number of wheels for the axle considered

p_T : Tyre pressure, in kN/m². When the tyre pressure is not indicated by the designer, it may be taken as defined in Tab 6.

Table 6 : Tyre pressures p_T for vehicles

Vehicle type	Tyre pressure p_T, in kN/m²	
	Pneumatic tyres	Solid rubber tyres
Private cars	250	not applicable
Trucks and trailers	800	not applicable
Handling machines	1100	1600

4.3.3 For vehicles with the four wheels of the axle located on a plate panel as shown in Fig 1, the net thickness of deck plating is to be not less than the greater of the values obtained, in mm, from the following formulae:

$t = t_1$

$t = t_2\,(1 + \beta_2 + \beta_3 + \beta_4)^{0,5}$

where:

t_1 : Net thickness obtained from [4.3.1] for n = 2, considering one group of two wheels located on the plate panel

t_2 : Net thickness obtained from [4.3.1] for n = 1, considering one wheel located on the plate panel

β_2, β_3, β_4 : Coefficients obtained from the following formula, by replacing i by 2, 3 and 4, respectively (see Fig 1):

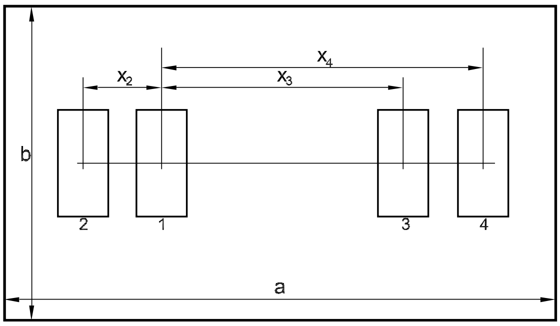
- for $x_i / b < 2$: $\beta_i = 0,8\,(1,2 - 2,02\,\alpha_i + 1,17\,\alpha_i^2 - 0,23\,\alpha_i^3)$
- for $x_i / b \geq 2$: $\beta_i = 0$

x_i : Distance, in m, from the wheel considered to the reference wheel (see Fig 1)

b : Dimension, in m, of the plate panel side perpendicular to the axle

$$\alpha_i = \frac{x_i}{b}$$

Figure 1 : Four wheel axle located on a plate panel



5 Buckling check

5.1 General

5.1.1 Application

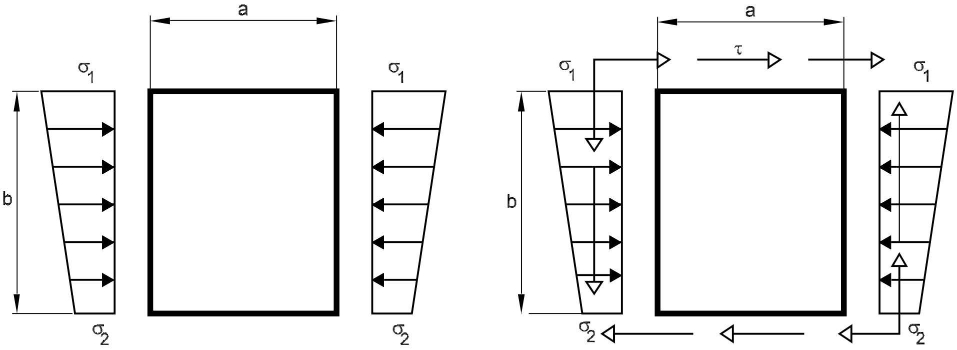
The requirements of this Article apply for the buckling check of plating subjected to in-plane compression stresses, acting on one or two sides, or to shear stress.

Rectangular plate panels are considered as being simply supported. For specific designs, other boundary conditions may be considered, at the Society's discretion, provided that the necessary information is submitted for review.

5.1.2 Compression and bending with or without shear

For plate panels subjected to compression and bending along one side, with or without shear, as shown in Fig 2, side "b" is to be taken as the loaded side. In such case, the compression stress varies linearly from σ_1 to $\sigma_2 = \psi\,\sigma_1$ (with $\psi \leq 1$) along edge "b".

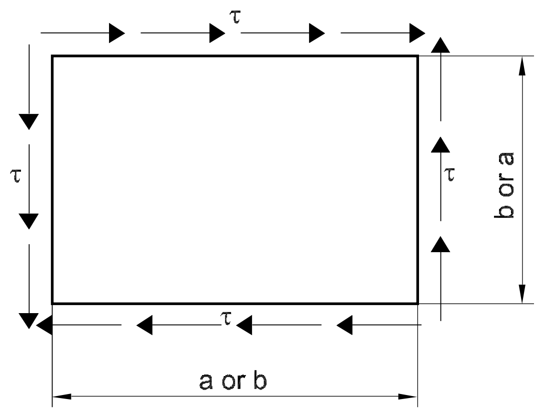
Figure 2 : Buckling of a simply supported rectangular plate panel subjected to compression and bending, with and without shear



5.1.3 Shear

For plate panels subjected to shear, as shown in Fig 3, side "b" may be taken as either the longer or the shorter side of the panel.

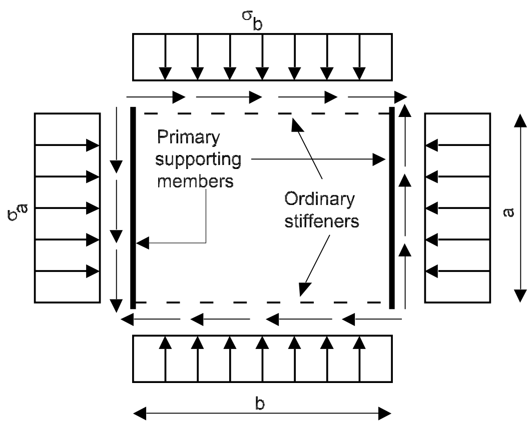
Figure 3 : Buckling of a simply supported rectangular plate panel subjected to shear



5.1.4 Bi-axial compression and shear

For plate panels subjected to bi-axial compression along sides "a" and "b", and to shear, as shown in Fig 4, side "a" is to be taken as the side in the direction of the primary supporting members.

Figure 4 : Buckling of a simply supported rectangular plate panel subjected to bi-axial compression and shear



5.2 Load model

5.2.1 Sign convention for normal stresses

The sign convention for normal stresses is as follows:

- tension: positive
- compression: negative.

5.2.2 In-plane hull girder compression normal stresses

The in-plane hull girder compression normal stresses to be considered for the buckling check of plating contributing to the longitudinal strength are obtained, in N/mm², from the following formula:

$$\sigma_{X1} = \gamma_{S1}\sigma_{S1} + \gamma_{W1}(C_{FV}\sigma_{WV1} + C_{FH}\sigma_{WH1})$$

where:

σ_{S1}, σ_{WV1}, σ_{WH1} : Hull girder normal stresses, in N/mm², defined in Tab 7

C_{FV}, C_{FH} : Combination factors defined in Tab 4.

σ_{X1} is to be taken as the maximum compression stress on the plate panel considered.

When the ship in still water is always in hogging condition, σ_{X1} may be evaluated by means of direct calculations when justified on the basis of the ship's characteristics and intended service. The calculations are to be submitted to the Society for approval.

5.2.3 In-plane hull girder shear stresses

The in-plane hull girder shear stresses to be considered for the buckling check of plating are obtained as specified in [3.2.7] for the strength check of plating subjected to lateral pressure, which contributes to the longitudinal strength.

5.2.4 Combined in-plane hull girder and local compression normal stresses

The combined in-plane compression normal stresses to be considered for the buckling check of plating are to take into account the hull girder stresses and the local stresses resulting from the bending of the primary supporting members. These local stresses are to be obtained from a direct structural analysis using the design loads given in Part B, Chapter 5.

With respect to the reference co-ordinate system defined in Ch 1, Sec 2, [10], the combined stresses in x and y direction are obtained, in N/mm², from the following formulae:

$$\sigma_X = \sigma_{X1} + \gamma_{S2}\sigma_{X2,S} + \gamma_{W2}\sigma_{X2,W}$$

$$\sigma_Y = \gamma_{S2}\sigma_{Y2,S} + \gamma_{W2}\sigma_{Y2,W}$$

where:

σ_{X1} : Compression normal stress, in N/mm², induced by the hull girder still water and wave loads, defined in [5.2.2]

$\sigma_{X2,S}$, $\sigma_{Y2,S}$: Compression normal stress in x and y direction, respectively, in N/mm², induced by the local bending of the primary supporting members and obtained from a direct structural analysis using the still water design loads given in Part B, Chapter 5

$\sigma_{X2,W}$, $\sigma_{Y2,W}$: Compression normal stress in x and y direction, respectively, in N/mm², induced by the local bending of the primary supporting members and obtained from a direct structural analysis using the wave design loads given in Part B, Chapter 5.

5.2.5 Combined in-plane hull girder and local shear stresses

The combined in-plane shear stresses to be considered for the buckling check of plating are to take into account the hull girder stresses and the local stresses resulting from the bending of the primary supporting members. These local stresses are to be obtained from a direct structural analysis using the design loads given in Part B, Chapter 5.

The combined stresses are obtained, in N/mm², from the following formula:

$$\tau = \tau_1 + \gamma_{S2}\tau_{2,S} + \gamma_{W2}\tau_{2,W}$$

where:

τ_1 : Shear stress, in N/mm², induced by the hull girder still water and wave loads, defined in [5.2.3]

$\tau_{2,S}$: Shear stress, in N/mm², induced by the local bending of the primary supporting members and obtained from a direct structural analysis using the still water design loads given in Part B, Chapter 5

$\tau_{2,W}$: Shear stress, in N/mm², induced by the local bending of the primary supporting members and obtained from a direct structural analysis using the wave design loads given in Part B, Chapter 5.

Table 7 : Hull girder normal compression stresses

Condition	σ_{S1} in N/mm² **(1)**	σ_{WV1} in N/mm²	σ_{WH1} in N/mm²
$z \geq N$	$\dfrac{M_{SW,S}}{I_Y}(z-N)10^{-3}$	$\dfrac{0{,}625\,F_D M_{WV,S}}{I_Y}(z-N)10^{-3}$	$-\left\lvert\dfrac{0{,}625\,M_{WH}}{I_Z}y\right\rvert 10^{-3}$
$z < N$	$\dfrac{M_{SW,H}}{I_Y}(z-N)10^{-3}$	$\dfrac{0{,}625\,M_{WV,H}}{I_Y}(z-N)10^{-3}$	

(1) When the ship in still water is always in hogging condition, σ_{S1} for $z \geq N$ is to be obtained, in N/mm², from the following formula, unless σ_{X1} is evaluated by means of direct calculations (see [5.2.2]):

$$\sigma_{S1} = \frac{M_{SW,Hmin}}{I_Y}(z-N)10^{-3}$$

Note 1:

F_D : Coefficient defined in Ch 5, Sec 2, [4].

Table 8 : Buckling factor K_1 for plate panels

Load pattern	Aspect ratio	Buckling factor K_1
$0 \le \psi \le 1$	$\alpha \ge 1$ $\alpha < 1$	$\dfrac{8{,}4}{\psi + 1{,}1}$ $\left(\alpha + \dfrac{1}{\alpha}\right)^2 \dfrac{2{,}1}{\psi + 1{,}1}$
$-1 < \psi < 0$		$(1+\psi)K_1' - \psi K_1'' + 10\psi(1+\psi)$
$\psi \le -1$	$\alpha \dfrac{1-\psi}{2} \ge \dfrac{2}{3}$	$23{,}9\left(\dfrac{1-\psi}{2}\right)^2$
	$\alpha \dfrac{1-\psi}{2} < \dfrac{2}{3}$	$\left(15{,}87 + \dfrac{1{,}87}{\left(\alpha\dfrac{1-\psi}{2}\right)^2} + 8{,}6\left(\alpha\dfrac{1-\psi}{2}\right)^2\right)\left(\dfrac{1-\psi}{2}\right)^2$

Note 1:

$\psi = \dfrac{\sigma_2}{\sigma_1}$

K_1' : Value of K_1 calculated for $\psi = 0$
K_1'' : Value of K_1 calculated for $\psi = -1$

5.3 Critical stresses

5.3.1 Compression and bending for plane panel

The critical buckling stress is to be obtained, in N/mm², from the following formulae:

$$\sigma_c = \sigma_E \quad \text{for } \sigma_E \le \frac{R_{eH}}{2}$$

$$\sigma_c = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_E}\right) \quad \text{for } \sigma_E > \frac{R_{eH}}{2}$$

where:

σ_E : Euler buckling stress, to be obtained, in N/mm², from the following formula:

$$\sigma_E = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_{net}}{b}\right)^2 K_1 \varepsilon 10^{-6}$$

K_1 : Buckling factor defined in Tab 8

ε : Coefficient to be taken equal to:

- $\varepsilon = 1$ for $\alpha \ge 1$
- $\varepsilon = 1{,}05$ for $\alpha < 1$ and side “b” stiffened by flat bar
- $\varepsilon = 1{,}10$ for $\alpha < 1$ and side “b” stiffened by bulb section
- $\varepsilon = 1{,}21$ for $\alpha < 1$ and side “b” stiffened by angle or T-section
- $\varepsilon = 1{,}30$ for $\alpha < 1$ and side “b” stiffened by primary supporting members.

where $\alpha = a / b$

5.3.2 Shear for plane panel

The critical shear buckling stress is to be obtained, in N/mm², from the following formulae:

$$\tau_c = \tau_E \quad \text{for } \tau_E \le \frac{R_{eH}}{2\sqrt{3}}$$

$$\tau_c = \frac{R_{eH}}{\sqrt{3}}\left(1 - \frac{R_{eH}}{4\sqrt{3}\,\tau_E}\right) \quad \text{for } \tau_E > \frac{R_{eH}}{2\sqrt{3}}$$

where:

τ_E : Euler shear buckling stress, to be obtained, in N/mm², from the following formula:

$$\tau_E = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_{net}}{b}\right)^2 K_2 10^{-6}$$

K_2 : Buckling factor to be taken equal to:

$$K_2 = 5,34 + \frac{4}{\alpha^2} \quad \text{for } \alpha > 1$$

$$K_2 = \frac{5,34}{\alpha^2} + 4 \quad \text{for } \alpha \le 1$$

α : Coefficient defined in [5.3.1].

5.3.3 Bi-axial compression and shear for plane panel

The critical buckling stress $\sigma_{c,a}$ for compression on side "a" of the panel is to be obtained, in N/mm², from the following formula:

$$\sigma_{c,a} = \left(\frac{2,25}{\beta} - \frac{1,25}{\beta^2}\right) R_{eH}$$

where:

β : Slenderness of the panel, to be taken equal to:

$$\beta = 10^3 \frac{a}{t_{net}} \sqrt{\frac{R_{eH}}{E}}$$

without being taken less than 1,25.

The critical buckling stress $\sigma_{c,b}$ for compression on side "b" of the panel is to be obtained, in N/mm², from the formulae in [5.3.1].

The critical shear buckling stress is to be obtained, in N/mm², from the formulae in [5.3.2].

5.3.4 Compression and shear for curved panels

The critical buckling stress of curved panels subjected to compression on curved edges is to be obtained, in N/mm², from the following formulae:

$$\sigma_c = \sigma_E \quad \text{for } \sigma_E \le \frac{R_{eH}}{2}$$

$$\sigma_c = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_E}\right) \quad \text{for } \sigma_E > \frac{R_{eH}}{2}$$

where:

σ_E : Euler buckling stress, to be obtained, in N/mm², from the following formula:

$$\sigma_E = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_{net}}{b}\right)^2 K_3$$

b : Width of curved panel, in mm, measured on arc

K_3 : Buckling factor defined in Tab 9.

The critical shear buckling stress is to be obtained, in N/mm², from the following formulae:

$$\tau_c = \tau_E \quad \text{for } \tau_E \le \frac{R_{eH}}{2\sqrt{3}}$$

$$\tau_c = \frac{R_{eH}}{\sqrt{3}}\left(1 - \frac{R_{eH}}{4\sqrt{3}\tau_E}\right) \quad \text{for } \tau_E > \frac{R_{eH}}{2\sqrt{3}}$$

where:

τ_E : Euler shear buckling stress, to be obtained, in N/mm², from the following formula:

$$\tau_E = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_{net}}{b}\right)^2 K_4$$

K_4 : Buckling factor to be taken equal to:

$$K_4 = \frac{12(1-\nu^2)}{\pi^2}\left(5 + 0,1\frac{b^2}{rt_{net}}\right)$$

b, r : Defined above.

Table 9 : Buckling factor K_3 for curved panels

Load	Buckling factor K_3
Compression stress perpendicular to the curved edges	$2\left[1 + \sqrt{1 + \frac{12(1-\nu^2)}{\pi^4} \frac{b^4}{r^2 t_{net}^2}}\right]$
Note 1: r : Radius of curvature, in mm.	

5.3.5 Compression for corrugation flanges

The critical buckling stress is to be obtained, in N/mm², from the following formulae:

$$\sigma_c = \sigma_E \qquad \text{for } \sigma_E \le \frac{R_{eH}}{2}$$

$$\sigma_c = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_E}\right) \quad \text{for } \sigma_E > \frac{R_{eH}}{2}$$

where:

σ_E : Euler buckling stress, to be obtained, in N/mm², from the following formula:

$$\sigma_E = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_f}{V}\right)^2 K_5$$

K_5 : Buckling factor to be taken equal to:

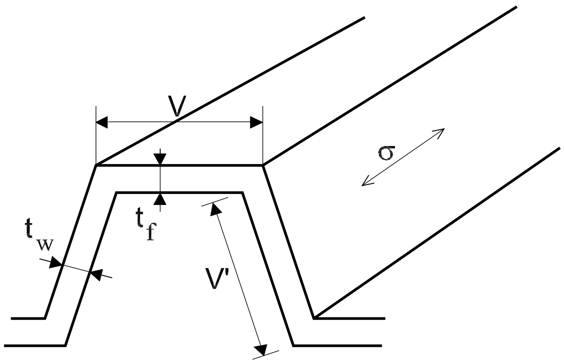
$$K_5 = \left(1 + \frac{t_w}{t_f}\right)\left\{3 + 0{,}5\frac{V'}{V} - 0{,}33\left(\frac{V'}{V}\right)^2\right\}$$

t_f : Net thickness, in mm, of the corrugation flange

t_w : Net thickness, in mm, of the corrugation web

V, V′ : Dimensions of a corrugation, in mm, shown in Fig 5.

Figure 5 : Dimensions of a corrugation



5.4 Checking criteria

5.4.1 Acceptance of results

The net thickness of plate panels is to be such as to satisfy the buckling check, as indicated in [5.4.2] to [5.4.5] depending on the type of stresses acting on the plate panel considered. When the buckling criteria is exceeded, the scantlings may still be considered as acceptable, provided that the stiffeners located on the plate panel satisfy the buckling and the ultimate strength checks as specified in Ch 7, Sec 2, [4] and Ch 7, Sec 2, [5].

5.4.2 Compression and bending

For plate panels subjected to compression and bending on one side, the critical buckling stress is to comply with the following formula:

$$\frac{\sigma_c}{\gamma_R \gamma_m} \ge |\sigma_b|$$

where:

σ_c : Critical buckling stress, in N/mm², defined in [5.3.1], [5.3.4] or [5.3.5], as the case may be

σ_b : Compression stress, in N/mm², acting on side "b" of the plate panel, to be calculated, as specified in [5.2.2] or [5.2.4], as the case may be.

5.4.3 Shear

For plate panels subjected to shear, the critical shear buckling stress is to comply with the following formula:

$$\frac{\tau_c}{\gamma_R \gamma_m} \ge |\tau_b|$$

where:

τ_c : Critical shear buckling stress, in N/mm², defined in [5.3.2] or [5.3.4], as the case may be

τ_b : Shear stress, in N/mm², acting on the plate panel, to be calculated as specified in [5.2.3] or [5.2.5], as the case may be.

5.4.4 Compression, bending and shear

For plate panels subjected to compression, bending and shear, the combined critical stress is to comply with the following formulae:

$$F \le 1 \qquad \text{for } \frac{\sigma_{comb}}{F} \le \frac{R_{eH}}{2\gamma_R\gamma_m}$$

$$F \le \frac{4\sigma_{comb}}{R_{eH}/\gamma_R\gamma_m}\left(1 - \frac{\sigma_{comb}}{R_{eH}/\gamma_R\gamma_m}\right) \qquad \text{for } \frac{\sigma_{comb}}{F} > \frac{R_{eH}}{2\gamma_R\gamma_m}$$

where:

$$\sigma_{comb} = \sqrt{\sigma_1^2 + 3\tau^2}$$

$$F = \gamma_R\gamma_m\left[\frac{1+\psi}{4}\frac{|\sigma_1|}{\sigma_E} + \sqrt{\left(\frac{3-\psi}{4}\right)^2\left(\frac{\sigma_1}{\sigma_E}\right)^2 + \left(\frac{\tau}{\tau_E}\right)^2}\right]$$

σ_E : Euler buckling stress, in N/mm², defined in [5.3.1], [5.3.4] or [5.3.5] as the case may be

τ_E : Euler shear buckling stress, in N/mm², defined in [5.3.2] or [5.3.4], as the case may be

$$\psi = \frac{\sigma_2}{\sigma_1}$$

σ_1, σ_2 and τ are defined in Fig 2 and are to be calculated, in N/mm², as specified in [5.2].

5.4.5 Bi-axial compression, taking account of shear stress

For plate panels subjected to bi-axial compression and shear, the critical buckling stresses are to comply with the following formula:

$$\left|\frac{\sigma_a}{\frac{\sigma_{c,a}}{\gamma_R\gamma_m}R_a}\right|^n + \left|\frac{\sigma_b}{\frac{\sigma_{c,b}}{\gamma_R\gamma_m}R_b}\right|^n \le 1$$

where:

$\sigma_{c,a}$: Critical buckling stress for compression on side “a”, in N/mm², defined in [5.3.3]

$\sigma_{c,b}$: Critical buckling stress for compression on side “b”, in N/mm², defined in [5.3.3]

σ_a : Compression stress acting on side “a”, in N/mm², to be calculated as specified in [5.2.2] or [5.2.4], as the case may be

σ_b : Compression stress acting on side “b”, in N/mm², to be calculated as specified in [5.2.2] or [5.2.4], as the case may be

n : Coefficient to be taken equal to:

$n = 1$ for $\alpha \ge 1/\sqrt{2}$

$n = 2$ for $\alpha < 1/\sqrt{2}$

$\alpha = a / b$

$$R_a = 1 - \left|\frac{\tau}{\tau_c}\right|^{n_a}$$

$$R_b = 1 - \left|\frac{\tau}{\tau_c}\right|^{n_b}$$

τ : Shear stress, in N/mm², to be calculated as specified in [5.2.3] or [5.2.5], as the case may be

τ_c : Critical shear buckling stress, in N/mm², defined in [5.3.2]

n_a : Coefficient to be taken equal to:

$n_a = 1 + 1/\alpha$ for $\alpha \ge 0,5$

$n_a = 3$ for $\alpha < 0,5$

n_b : Coefficient to be taken equal to:

$n_b = 1,9 + 0,1/\alpha$ for $\alpha \ge 0,5$

$n_b = 0,7(1 + 1/\alpha)$ for $\alpha < 0,5$

Section 2 Ordinary Stiffeners

Symbols

For symbols not defined in this Section, refer to the list at the beginning of this Chapter.

p_S : Still water pressure, in kN/m² (see [3.3.2] and [5.3.2]

p_W : Wave pressure and, if necessary, dynamic pressures, according to the criteria in Ch 5, Sec 5, [2] and Ch 5, Sec 6, [2], in kN/m² (see [3.3.2] and [5.3.2])

p_{SF}, p_{WF} : Still water and wave pressures, in kN/m², in flooding conditions, defined in Ch 5, Sec 6, [7]

F_S : Still water wheeled force, in kN (see [3.3.5])

$F_{W,Z}$: Inertial wheeled force, in kN (see [3.3.5]

σ_{X1} : Hull girder normal stress, in N/mm², defined in:

- [3.3.7] for the yielding check of ordinary stiffeners
- [4.2.2] for the buckling check of ordinary stiffeners
- [5.3.3] for the ultimate strength check of ordinary stiffeners

$R_{eH,P}$: Minimum yield stress, in N/mm², of the plating material, defined in Ch 4, Sec 1, [2]

$R_{eH,S}$: Minimum yield stress, in N/mm², of the stiffener material, defined in Ch 4, Sec 1, [2]

s : Spacing, in m, of ordinary stiffeners

ℓ : Span, in m, of ordinary stiffeners, measured between the supporting members (see Ch 4, Sec 3, [3.2]

h_w : Web height, in mm

t_w : Net web thickness, in mm

b_f : Face plate width, in mm

t_f : Net face plate thickness, in mm

b_p : Width, in m, of the plating attached to the stiffener, for the yielding check, defined in Ch 4, Sec 3, [3.3.1]

b_e : Width, in m, of the plating attached to the stiffener, for the buckling check, defined in [4.1]

b_U : Width, in m, of the plating attached to the stiffener, for the ultimate strength check, defined in [5.2]

t_p : Net thickness, in mm, of the attached plating

w : Net section modulus, in cm³, of the stiffener, with an attached plating of width b_p, to be calculated as specified in Ch 4, Sec 3, [3.4]

A_S : Net sectional area, in cm², of the stiffener with attached plating of width s

A_e : Net sectional area, in cm², of the stiffener with attached plating of width b_e

A_U : Net sectional area, in cm², of the stiffener with attached plating of width b_U

A_{Sh} : Net shear sectional area, in cm², of the stiffener, to be calculated as specified in Ch 4, Sec 3, [3.4]

I : Net moment of inertia, in cm⁴, of the stiffener without attached plating, about its neutral axis parallel to the plating (see Ch 4, Sec 3, Fig 4 and Ch 4, Sec 3, Fig 5)

I_S : Net moment of inertia, in cm⁴, of the stiffener with attached shell plating of width s, about its neutral axis parallel to the plating

I_e : Net moment of inertia, in cm⁴, of the stiffener with attached shell plating of width b_e, about its neutral axis parallel to the plating

I_U : Net moment of inertia, in cm⁴, of the stiffener with attached shell plating of width b_U, about its neutral axis parallel to the plating

ρ_S : Radius of gyration, in cm, of the stiffener with attached plating of width s

ρ_U : Radius of gyration, in cm, of the stiffener with attached plating of width b_U.

m : Boundary coefficient, to be taken equal to:

- m = 12 for stiffeners clamped at both ends, whose end connections comply with the requirements in [3.2.2]
- m = 8 for stiffeners clamped at one end and simply supported at the other end, with the clamped end connection complying with the requirements in [3.2.2]
- m = 8 for stiffeners simply supported at both ends.

1 General

1.1 Net scantlings

1.1.1 As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

The gross scantlings are obtained as specified in Ch 4, Sec 2.

1.2 Partial safety factors

1.2.1 The partial safety factors to be considered for the checking of ordinary stiffeners are specified in Tab 1.

1.3 Load point

1.3.1 Lateral pressure

Unless otherwise specified, lateral pressure is to be calculated at mid-span of the ordinary stiffener considered.

1.3.2 Hull girder stresses

For longitudinal ordinary stiffeners contributing to the hull girder longitudinal strength, the hull girder normal stresses are to be calculated in way of the neutral axis of the stiffener considered.

1.4 Net dimensions of ordinary stiffeners

1.4.1 Flat bar

The net dimensions of a flat bar ordinary stiffener (see Fig 1) are to comply with the following requirement:

$$\frac{h_w}{t_w} \leq 20\sqrt{k}$$

Figure 1 : Net dimensions of a flat bar

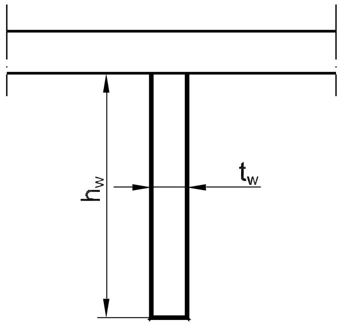


Table 1 : Ordinary stiffeners - Partial safety factors

Partial safety factors covering uncertainties regarding:	Symbol	Yielding check			Buckling check	Ultimate strength check
		General	Flooding pressure	Testing check		
		(see [3.3] to [3.7])	(see [3.8])	(see [3.9])	(see [4])	(see [5])
Still water hull girder loads	γ_{S1}	1,00	1,00	N.A.	1,00	1,00
Wave hull girder loads	γ_{W1}	1,15	1,15	N.A.	1,15	1,30
Still water pressure	γ_{S2}	1,00	1,00	1,00	N.A.	1,00
Wave pressure	γ_{W2}	1,20	1,05	N.A.	N.A.	1,40
Material	γ_m	1,02	1,02	1,02	1,02	1,02
Resistance	γ_R	1,02**(2)**	1,02 **(1)**	1,20**(2)**	1,10	1,02

(1) For ordinary stiffeners of the collision bulkhead, γ_R =1,25. This requirement may be disregarded when damage stability considers at least two adjacent compartments flooded.

(2) For ordinary stiffeners of decks and side walls of ammunition storage, for assessment under flooding by fire-extinguishing system, γ_R = 1,02. This requirement may be disregarded when the extinguishing system used for ammunition storage is not by flooding of the compartment

Note 1: N.A. = Not applicable.

1.4.2 T-section

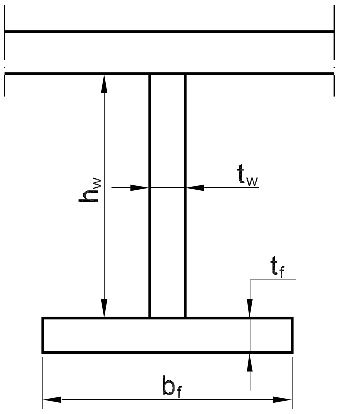
The net dimensions of a T-section ordinary stiffener (see Fig 2) are to comply with the following two requirements:

$$\frac{h_w}{t_w} \le 55\sqrt{k}$$

$$\frac{b_f}{t_f} \le 33\sqrt{k}$$

$$b_f t_f \ge \frac{h_w t_w}{6}$$

Figure 2 : Net dimensions of a T-section



1.4.3 Angle

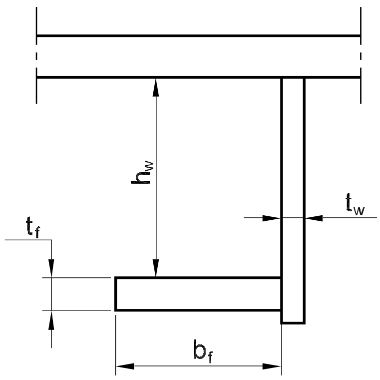
The net dimensions of an angle ordinary stiffener (see Fig 3) are to comply with the following two requirements:

$$\frac{h_w}{t_w} \le 55\sqrt{k}$$

$$\frac{b_f}{t_f} \le 16,5\sqrt{k}$$

$$b_f t_f \ge \frac{h_w t_w}{6}$$

Figure 3 : Net dimensions of an angle



2 General requirements

2.1 General

2.1.1 The requirements in [2.2] are to be applied to ordinary stiffeners in addition to the requirements from Articles [3] to [5].

2.2 Struts of open floors

2.2.1 The sectional area A_{ST}, in cm², and the moment of inertia I_{ST} about the main axes, in cm⁴, of struts of open floors are to be not less than the values obtained from the following formulae:

$$A_{ST} = \frac{p_{ST} s \ell}{20}$$

$$I_{ST} = \frac{0{,}75 s \ell (p_{STB} + p_{STU}) A_{AST} \ell_{ST}^2}{47{,}2 A_{AST} - s \ell (p_{STB} + p_{STU})}$$

where:

p_{ST} : Pressure to be taken equal to the greater of the values obtained, in kN/m², from the following formulae:

$p_{ST} = 0{,}5\ (p_{STB} + p_{STU})$

$p_{ST} = p_{STD}$

p_{STB} : Sea pressure, in kN/m², acting on the bottom in way of the strut, equal to:

$p_{STB} = \gamma_{S2}\ p_S + \gamma_{W2}\ p_W$

p_{STU} : Pressure, in kN/m², acting on the inner bottom in way of the strut due to the load in the tank or hold above, equal to:

$p_{STU} = \gamma_{S2}\ p_S + \gamma_{W2}\ p_W$

p_{STD} : Pressure, in kN/m², in double bottom at mid-span of the strut, equal to:

$p_{STD} = \gamma_{S2}\ p_S + \gamma_{W2}\ p_W$

ℓ : Span, in m, of the transverse ordinary stiffeners constituting the open floor (see Ch 4, Sec 3, [3.2.2])

ℓ_{ST} : Length, in m, of the strut

A_{AST} : Actual net sectional area, in cm², of the strut.

3 Yielding check

3.1 General

3.1.1 The requirements of this Article apply for the yielding check of ordinary stiffeners subjected to lateral pressure, wheeled loads or weapon firing dynamic loads and, for ordinary stiffeners contributing to the hull girder longitudinal strength, to hull girder normal stresses.

3.1.2 The yielding check is also to be carried out for ordinary stiffeners subjected to specific loads, such as concentrated loads.

3.2 Structural model

3.2.1 Boundary conditions

The requirements in [3.4], [3.7.3], [3.7.4], [3.8] and [3.9] apply to stiffeners considered either:

- clamped at both ends, whose end connections comply with the requirements in [3.2.2].
- clamped at one end and simply supported at the other end with the clamped end connection complying with the requirements in [3.2.2]
- simply supported at both ends

The requirements in [3.5] and [3.7.5] and [3.7.6] apply to stiffeners considered as simply supported at both ends. Other boundary conditions may be considered by the Society on a case-by-case basis, depending on the distribution of wheeled loads or weapon firing loads, as the case may be.

For other boundary conditions, the yielding check is to be considered on a case-by-case basis.

3.2.2 Bracket arrangement

The requirements of this Article apply to ordinary stiffeners without end brackets, with a bracket at one end or with two equal end brackets, where the bracket length is not greater than 0,2 ℓ.

In the case of ordinary stiffeners with two different end brackets of length not greater than 0,2 ℓ, the determination of normal and shear stresses due to design loads and the required section modulus and shear sectional area are considered by the Society on a case-by-case basis. In general, an acceptable solution consists in applying the criteria for equal brackets, considering both brackets as having the length of the smaller one.

In the case of ordinary stiffeners with end brackets of length greater than 0,2 ℓ, the determination of normal and shear stresses due to design loads and the required section modulus and shear sectional area are considered by the Society on a case-by-case basis.

3.3 Load model

3.3.1 General

The still water and wave lateral loads induced by the sea and the various types of cargoes and ballast in intact conditions are to be considered, depending on the location of the ordinary stiffener under consideration and the type of compartments adjacent to it, in accordance with Ch 5, Sec 1, [2.4].

Ordinary stiffeners located on platings below the deepest equilibrium waterline (excluding those on side shell platings) which constitute boundaries intended to stop vertical and horizontal flooding are to be subjected to lateral pressure in flooding conditions.

The wave lateral loads and hull girder loads are to be calculated in the mutually exclusive load cases “a”, “b”, “c” and “d” in Ch 5, Sec 4.

3.3.2 Lateral pressure in intact conditions

The lateral pressure in intact conditions is constituted by still water pressure and wave pressure.

Still water pressure p_S includes:

- the still water sea pressure, defined in Ch 5, Sec 5, [1]
- the still water internal pressure, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast.

Wave pressure p_W includes:

- the wave pressure, defined in Ch 5, Sec 5, [2] for each load case “a”, “b”, “c” and “d”
- the inertial pressure, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast, and for each load case “a”, “b”, “c” and “d”
- the dynamic pressures, according to the criteria in Ch 5, Sec 6, [2].

3.3.3 Lateral pressure in flooding conditions

The lateral pressure in flooding conditions is constituted by the still water pressure p_{SF} and wave pressure p_{WF} defined in Ch 5, Sec 6, [7].

3.3.4 Lateral pressure in testing conditions

The lateral pressure p_T in testing conditions is taken equal to:

- $p_{ST} - p_S$ for bottom shell plating and side shell plating
- p_{ST} otherwise,

where:

p_{ST} : Still water pressure defined in Ch 5, Sec 6, Tab 10

p_S : Still water sea pressure defined in Ch 5, Sec 5, [1.1.1] for the draught T_1 at which the testing is carried out.

If the draught T_1 is not defined by the Designer, it may be taken equal to the light ballast draught T_B defined in Ch 5, Sec 1, [2.4.3].

3.3.5 Wheeled forces

The wheeled force applied by one wheel is constituted by still water force and inertial force:

- still water force is the vertical force F_S defined in Ch 5, Sec 6, [4.1]
- inertial force is the vertical force $F_{W,Z}$ defined in Ch 5, Sec 6, [4.1], for load case “b”.

3.3.6 Weapons firing dynamic loads

- missile blast dynamic pressure
- accidental missile ignition dynamic pressure
- gun blast dynamic pressure.

3.3.7 Hull girder normal stresses

The hull girder normal stresses to be considered for the yielding check of ordinary stiffeners are obtained, in N/mm², from the following formulae:

- for longitudinal stiffeners contributing to the hull girder longitudinal strength and subjected to lateral pressure:

  $\sigma_{X1} = \gamma_{S1}\, \sigma_{S1} + \gamma_{W1}\, (C_{FV}\, \sigma_{WV1} + C_{FH}\, \sigma_{WH1} + C_{F\Omega}\, \sigma_{\Omega})$
- for longitudinal stiffeners contributing to the hull girder longitudinal strength and subjected to wheeled loads:

  $\sigma_{X1,Wh} = \text{Max}\, (\sigma_{X1H}\, ;\, \sigma_{X1S})$
- for longitudinal stiffeners not contributing to the hull girder longitudinal strength:

  $\sigma_{X1} = 0$
- for transverse stiffeners:

  $\sigma_{X1} = 0$

where:

σ_{S1} , σ_{WV1} , σ_{WH1} : Hull girder normal stresses, in N/mm², defined in Tab 2

σ_{Ω} : Absolute value of the warping stress, in N/mm², induced by the torque 0,625 M_{WT} and obtained through direct calculation analyses based on a structural model in accordance with Ch 6, Sec 1, [2.6]

σ_{X1H} , σ_{X1S} : Hull girder normal stresses, in N/mm², respectively in hogging and in sagging, defined in Tab 3

C_{FV} , C_{FH} , $C_{F\Omega}$: Combination factors defined in Tab 4.

3.4 Normal and shear stresses due to lateral pressure in intact conditions

3.4.1 General

Normal and shear stresses, induced by lateral pressures, in ordinary stiffeners are to be obtained from the formulae in:

- [3.4.2] in the case of single span longitudinal and transverse stiffeners
- [3.4.3] in the case of single span vertical stiffeners
- [3.4.4] in the case of multispan vertical stiffeners.

Table 2 : Hull girder normal stresses - Ordinary stiffeners subjected to lateral pressure

Condition	σ_{S1} , in N/mm² **(1)**	σ_{WV1} , in N/mm²	σ_{WH1} , in N/mm²
Lateral pressure applied on the side opposite to the ordinary stiffener, with respect to the plating:			
• z ≥ N in general ; z < N for stiffeners simply supported at both ends	$\left\|\dfrac{M_{SW,S}}{I_Y}(z-N)\right\|10^{-3}$	$\left\|\dfrac{0,625F_D M_{WV,S}}{I_Y}(z-N)\right\|10^{-3}$	
• z < N in general ; z ≥ N for stiffeners simply supported at both ends	$\left\|\dfrac{M_{SW,H}}{I_Y}(z-N)\right\|10^{-3}$	$\left\|\dfrac{0,625M_{WV,H}}{I_Y}(z-N)\right\|10^{-3}$	
Lateral pressure applied on the same side as the ordinary stiffener:			$\left\|\dfrac{0,625M_{WH}}{I_Z}y\right\|10^{-3}$
• z ≥ N in general ; z < N for stiffeners simply supported at both ends	$\left\|\dfrac{M_{SW,H}}{I_Y}(z-N)\right\|10^{-3}$	$\left\|\dfrac{0,625M_{WV,H}}{I_Y}(z-N)\right\|10^{-3}$	
• z < N in general ; z ≥ N for stiffeners simply supported at both ends	$\left\|\dfrac{M_{SW,S}}{I_Y}(z-N)\right\|10^{-3}$	$\left\|\dfrac{0,625F_D M_{WV,S}}{I_Y}(z-N)\right\|10^{-3}$	

(1) When the ship in still water is always in hogging condition, $M_{SW,S}$ is to be taken equal to 0.
Note 1:
F_D : Coefficient defined in Ch 5, Sec 2, [4.2].

Table 3 : Hull girder normal stresses - Ordinary stiffeners subjected to wheeled loads

Condition	Hull girder normal stresses, in N/mm²
• Hogging	$\sigma_{X1H} = \left\|\gamma_{S1}\dfrac{M_{SW,H}}{I_Y}(z-N)10^{-3}+\gamma_{W1}\left(C_{FV}\dfrac{0,625M_{WV,H}}{I_Y}(z-N)10^{-3}+C_{FH}\dfrac{0,625M_{WH}}{I_Z}y10^{-3}+C_{F\Omega}\sigma_{\Omega}\right)\right\|$
• Sagging**(1)**	$\sigma_{X1S} = \left\|\gamma_{S1}\dfrac{M_{SW,S}}{I_Y}(z-N)10^{-3}+\gamma_{W1}\left(C_{FV}\dfrac{0,625F_D M_{WV,S}}{I_Y}(z-N)10^{-3}+C_{FH}\dfrac{0,625M_{WH}}{I_Z}y10^{-3}+C_{F\Omega}\sigma_{\Omega}\right)\right\|$

(1) When the ship in still water is always in hogging condition, $M_{SW,S}$ is to be taken equal to 0.
Note 1:
F_D : Coefficient defined in Ch 5, Sec 2, [4.2].

Table 4 : Combination factors C_{FV} , C_{FH} and $C_{F\Omega}$

Load case	C_{FV}	C_{FH}	$C_{F\Omega}$
"a"	1,0	0	0
"b"	1,0	0	0
"c"	0,4	1,0	1,0
"d"	0,4	1,0	0
Flooding	0,6	0	0

Table 5 : Coefficients β_b and β_s

Brackets at ends	Bracket lengths	β_b	β_s
0	–	1	1
1	ℓ_b	$\left(1-\frac{\ell_b}{2\ell}\right)^2$	$1-\frac{\ell_b}{2\ell}$
2	ℓ_{b1} ; ℓ_{b2}	$\left(1-\frac{\ell_{b1}}{2\ell}-\frac{\ell_{b2}}{2\ell}\right)^2$	$1-\frac{\ell_{b1}}{2\ell}-\frac{\ell_{b2}}{2\ell}$

3.4.2 Single span longitudinal and transverse ordinary stiffeners

The maximum normal stress σ and shear stress τ are to be obtained, in N/mm², from the following formulae:

$$\sigma = \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{m w}\left(1-\frac{s}{2\ell}\right) s \ell^2 10^3 + \sigma_{X1}$$

$$\tau = 5\beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{A_{Sh}}\left(1-\frac{s}{2\ell}\right) s \ell$$

where:

β_b , β_s : Coefficients defined in Tab 5.

3.4.3 Single span vertical ordinary stiffeners

The maximum normal stress σ and shear stress τ are to be obtained, in N/mm², from the following formulae:

$$\sigma = \lambda_b \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{m w}\left(1-\frac{s}{2\ell}\right) s \ell^2 10^3$$

$$\tau = 5\lambda_s \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{A_{Sh}}\left(1-\frac{s}{2\ell}\right) s \ell$$

where:

β_b , β_s : Coefficients defined in Tab 5

λ_b : Coefficient taken equal to the greater of the following values:

$$\lambda_b = 1 + 0{,}2\frac{\gamma_{S2}(p_{Sd}-p_{Su}) + \gamma_{W2}(p_{Wd}-p_{Wu})}{\gamma_{S2}(p_{Sd}+p_{Su}) + \gamma_{W2}(p_{Wd}+p_{Wu})}$$

$$\lambda_b = 1 - 0{,}2\frac{\gamma_{S2}(p_{Sd}-p_{Su}) + \gamma_{W2}(p_{Wd}-p_{Wu})}{\gamma_{S2}(p_{Sd}+p_{Su}) + \gamma_{W2}(p_{Wd}+p_{Wu})}$$

λ_s : Coefficient taken equal to the greater of the following values:

$$\lambda_s = 1 + 0{,}4\frac{\gamma_{S2}(p_{Sd}-p_{Su}) + \gamma_{W2}(p_{Wd}-p_{Wu})}{\gamma_{S2}(p_{Sd}+p_{Su}) + \gamma_{W2}(p_{Wd}+p_{Wu})}$$

$$\lambda_s = 1 - 0{,}4\frac{\gamma_{S2}(p_{Sd}-p_{Su}) + \gamma_{W2}(p_{Wd}-p_{Wu})}{\gamma_{S2}(p_{Sd}+p_{Su}) + \gamma_{W2}(p_{Wd}+p_{Wu})}$$

p_{Sd} : Still water pressure, in kN/m², at the lower end of the ordinary stiffener considered

p_{Su} : Still water pressure, in kN/m², at the upper end of the ordinary stiffener considered

p_{Wd} : Wave pressure, in kN/m², at the lower end of the ordinary stiffener considered

p_{Wu} : Wave pressure, in kN/m², at the upper end of the ordinary stiffener considered.

3.4.4 Multispan ordinary stiffeners

The maximum normal stress σ and shear stress τ in a multispan ordinary stiffener are to be determined by a direct calculation taking into account:

- the distribution of still water and wave pressure and forces, to be determined on the basis of the criteria specified in Ch 5, Sec 5 and Ch 5, Sec 6
- the number and position of intermediate supports (decks, girders, etc.)
- the condition of fixity at the ends of the stiffener and at intermediate supports
- the geometrical characteristics of the stiffener on the intermediate spans.

3.5 Normal and shear stresses due to wheeled loads

3.5.1 General

Normal and shear stresses, induced by the wheeled loads, in ordinary stiffeners are to be obtained from the formulae in:

- [3.5.2] in the case of single span longitudinal and transverse stiffeners
- [3.5.3] in the case of multispan stiffeners.

3.5.2 Single span longitudinal and transverse ordinary stiffeners subjected to wheeled loads

The maximum normal stress σ and shear stress τ are to be obtained, in N/mm², from the following formulae:

$$\sigma = \alpha_W K_S \frac{P_0 \ell}{6w} 10^3 + \sigma_{X1,Wh}$$

$$\tau = \alpha_W K_T \frac{10 P_0}{A_{Sh}}$$

where:

P_0 : Wheeled force, in kN, taken equal to: $P_0 = \gamma_{S2} F_S + \gamma_{W2} F_{W,Z}$

α_W : Coefficient taking account of the number of wheels per axle considered as acting on the stiffener, defined in Tab 6

K_S, K_T : Coefficients taking account of the number of axles considered as acting on the stiffener, defined in Tab 7.

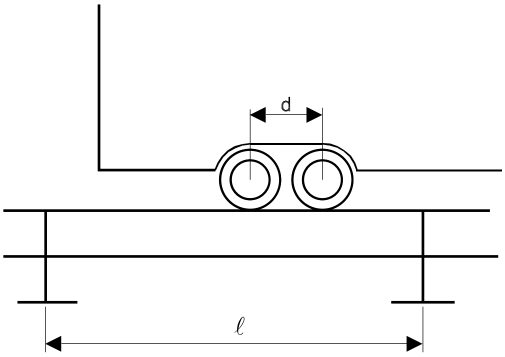
Table 6 : Wheeled loads - Coefficients α_W

Configuration	α_W
Single wheel 	1
Double wheels 	$2\left(1-\frac{y}{s}\right)$
Triple wheels 	$3-2\frac{y}{s}$
Note 1: y : Distance, in m, from the external wheel of a group of wheels to the stiffener under consideration, to be taken equal to the distance from the external wheel to the centre of the group of wheels.	

Table 7 : Wheeled loads - Coefficients K_S and K_T

Coefficient	Configuration	
	Single axle	Double axles
K_S	1	• if $d \le \ell/\sqrt{3}$: $\frac{172}{81}-\frac{4d}{3\ell}-\frac{d^2}{\ell^2}+\frac{d^4}{\ell^4}$ • if $d > \ell/\sqrt{3}$: $\frac{4}{3}-\frac{4d}{3\ell}+\frac{3d^2}{\ell^2}-\frac{8d^3}{3\ell^3}$
K_T	1	$2-\frac{d}{2\ell}-\frac{3d^2}{2\ell^2}+\frac{d^3}{\ell^3}$
Note 1: d : Distance, in m, between two axles (see Fig 4).		

Figure 4 : Wheeled load on stiffeners - Double axles



3.5.3 Multispan ordinary stiffeners subjected to wheeled loads

The maximum normal stress σ and shear stress τ in a multispan ordinary stiffener are to be determined by a direct calculation taking into account:

- the distribution of still water forces and inertial forces applying on the stiffener, to be determined according to [3.3.5]
- the number and position of intermediate supports (girders, bulkheads, etc.)
- the condition of fixity at the ends of the stiffener and at intermediate supports
- the geometrical characteristics of the stiffener on the intermediate spans.

3.6 Checking criteria

3.6.1 General

It is to be checked that the normal stress σ and the shear stress τ, calculated according to [3.4] and [3.5], are in compliance with the following formulae:

$$\frac{R_y}{\gamma_R \gamma_m} \geq \sigma$$

$$0,5\frac{R_y}{\gamma_R \gamma_m} \geq \tau$$

3.7 Net section modulus and net shear sectional area of ordinary stiffeners, complying with the checking criteria

3.7.1 General

The requirements in [3.7.3] and [3.7.4] provide the minimum net section modulus and net shear sectional area of single span ordinary stiffeners subjected to lateral pressure in intact conditions, complying with the checking criteria indicated in [3.6].

The requirements in [3.7.5] provide the minimum net section modulus and net shear sectional area of single span ordinary stiffeners subjected to wheeled loads, complying with the checking criteria indicated in [3.6].

The requirements in [3.7.6] provide the minimum net section modulus and net shear sectional area of single span ordinary stiffeners subjected to weapon firing dynamic loads.

3.7.2 Groups of equal ordinary stiffeners

Where a group of equal ordinary stiffeners is fitted, it is acceptable that the minimum net section modulus in [3.7.1] is calculated as the average of the values required for all the stiffeners of the same group, but this average is to be taken not less than 90% of the maximum required value.

The same applies for the minimum net shear sectional area.

3.7.3 Single span longitudinal and transverse ordinary stiffeners subjected to lateral pressure

The net section modulus w, in cm^3, and the net shear sectional area A_{Sh}, in cm^2, of longitudinal or transverse ordinary stiffeners subjected to lateral pressure are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{m(R_y - \gamma_R \gamma_m \sigma_{X1})}\left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y}\left(1 - \frac{s}{2\ell}\right) s \ell$$

where:

β_b, β_s : Coefficients defined in Tab 5.

3.7.4 Single span vertical ordinary stiffeners subjected to lateral pressure

The net section modulus w, in cm³, and the net shear sectional area A_{Sh}, in cm², of vertical ordinary stiffeners subjected to lateral pressure are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \lambda_b \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{m R_y}\left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \lambda_s \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y}\left(1 - \frac{s}{2\ell}\right) s \ell$$

where:

β_b, β_s : Coefficients defined in Tab 5

λ_b, λ_s : Coefficients defined in [3.4.3].

3.7.5 Single span ordinary stiffeners subjected to wheeled loads

The net section modulus w, in cm³, and the net shear sectional area A_{Sh}, in cm², of ordinary stiffeners subjected to wheeled loads are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \frac{\alpha_W K_S P_0 \ell}{6(R_y - \gamma_R \gamma_m \sigma_{X1,Wh})} 10^3$$

$$A_{Sh} = 20 \gamma_R \gamma_m \frac{\alpha_W K_T P_0}{R_y}$$

where:

P_0 : Wheeled force, in kN, defined in [3.5.2]

α_W, K_S, K_T :Coefficients defined in [3.5.2].

3.7.6 Single span ordinary stiffeners subjected to weapon firing dynamic loads

The net section modulus w, in cm³, and the net shear sectional area A_{Sh}, in cm², of ordinary stiffeners subjected to weapon firing dynamic loads are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{W2} p_W}{8 R_y} s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{W2} p_W}{R_y} s \ell$$

where:

β_b, β_s : Coefficients defined in Tab 5

p_w : Weapon firing dynamic pressure defined in Ch 5, Sec 6, [9].

3.7.7 Multispan ordinary stiffeners

The minimum net section modulus and the net shear sectional area of multispan ordinary stiffeners are to be obtained from [3.4.4] or [3.5.3], as applicable, taking account of the checking criteria indicated in [3.6].

3.8 Net section modulus and net shear sectional area of ordinary stiffeners subjected to lateral pressure in flooding conditions

3.8.1 General

The requirements in [3.8.1] to [3.8.5] provide the minimum net section modulus and net shear sectional area of ordinary stiffeners located on structural watertight elements which constitute boundaries intended to stop vertical and horizontal flooding.

These ordinary stiffeners are to be checked in flooding conditions as specified in [3.8.3] to [3.8.5], depending on the type of stiffener.

3.8.2 Groups of equal ordinary stiffeners

Where a group of equal ordinary stiffeners is fitted, it is acceptable that the minimum net section modulus in [3.8.1] is calculated as the average of the values required for all the stiffeners of the same group, but this average is to be taken not less than 90% of the maximum required value.

The same applies for the minimum net shear sectional area.

3.8.3 Single span longitudinal and transverse ordinary stiffeners

The net section modulus w, in cm³, and the net shear sectional area A_{Sh}, in cm², of longitudinal or transverse ordinary stiffeners are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_{SF} + \gamma_{W2} p_{WF}}{m(R_y - \gamma_R \gamma_m \sigma_{X1})}\left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_{SF} + \gamma_{W2} p_{WF}}{R_y}\left(1 - \frac{s}{2\ell}\right) s \ell$$

where:

β_b, β_s : Coefficients defined in Tab 5.

3.8.4 Single span vertical ordinary stiffeners

The net section modulus w, in cm³, and the net shear sectional area A_{Sh}, in cm², of vertical ordinary stiffeners are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \lambda_b \beta_b \frac{\gamma_{S2} p_{SF} + \gamma_{W2} p_{WF}}{m R_y} \left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \lambda_s \beta_s \frac{\gamma_{S2} p_{SF} + \gamma_{W2} p_{WF}}{R_y} \left(1 - \frac{s}{2\ell}\right) s \ell$$

where:

β_b, β_s : Coefficients defined in Tab 5

λ_b : Coefficient taken equal to the greater of the following values:

$$\lambda_b = 1 + 0,2 \frac{\gamma_{S2}(p_{SFd} - p_{SFu}) + \gamma_{W2}(p_{WFd} - p_{WFu})}{\gamma_{S2}(p_{SFd} + p_{SFu}) + \gamma_{W2}(p_{WFd} + p_{WFu})}$$

$$\lambda_b = 1 - 0,2 \frac{\gamma_{S2}(p_{SFd} - p_{SFu}) + \gamma_{W2}(p_{WFd} - p_{WFu})}{\gamma_{S2}(p_{SFd} + p_{SFu}) + \gamma_{W2}(p_{WFd} + p_{WFu})}$$

λ_s : Coefficient taken equal to the greater of the following values:

$$\lambda_s = 1 + 0,4 \frac{\gamma_{S2}(p_{SFd} - p_{SFu}) + \gamma_{W2}(p_{WFd} - p_{WFu})}{\gamma_{S2}(p_{SFd} + p_{SFu}) + \gamma_{W2}(p_{WFd} + p_{WFu})}$$

$$\lambda_s = 1 - 0,4 \frac{\gamma_{S2}(p_{SFd} - p_{SFu}) + \gamma_{W2}(p_{WFd} - p_{WFu})}{\gamma_{S2}(p_{SFd} + p_{SFu}) + \gamma_{W2}(p_{WFd} + p_{WFu})}$$

p_{SFd} : Still water pressure, in kN/m², in flooding conditions, at the lower end of the ordinary stiffener considered

p_{SFu} : Still water pressure, in kN/m², in flooding conditions, at the upper end of the ordinary stiffener considered

p_{WFd} : Wave pressure, in kN/m², in flooding conditions, at the lower end of the ordinary stiffener considered

p_{WFu} : Wave pressure, in kN/m², in flooding conditions, at the upper end of the ordinary stiffener considered.

3.8.5 Multispan ordinary stiffeners

The minimum net section modulus and the net shear sectional area of multispan ordinary stiffeners are to be obtained from [3.4.4], considering the still water pressure p_{SF} and wave pressure p_{WF} in flooding conditions, and taking account of the checking criteria indicated in [3.6].

3.9 Net section modulus and net shear sectional area of ordinary stiffeners subjected to lateral pressure in testing conditions

3.9.1 General

The requirements in [3.9.3] to [3.9.5] provide the minimum net section modulus and net shear sectional area of ordinary stiffeners of compartments subject to testing conditions.

3.9.2 Groups of equal ordinary stiffeners

Where a group of equal ordinary stiffeners is fitted, it is acceptable that the minimum net section modulus in [3.9.1] is calculated as the average of the values required for all the stiffeners of the same group, but this average is to be taken not less than 90% of the maximum required value.

The same applies for the minimum net shear sectional area.

3.9.3 Single span longitudinal and transverse ordinary stiffeners

The net section modulus w, in cm³, and the net shear sectional area A_{Sh}, in cm², of longitudinal or transverse ordinary stiffeners are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_T}{m R_y} \left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_T}{R_y} \left(1 - \frac{s}{2\ell}\right) s \ell$$

where:

β_b, β_s : Coefficients defined in Tab 5.

3.9.4 Single span vertical ordinary stiffeners

The net section modulus w, in cm^3, and the net shear sectional area A_{Sh}, in cm^2, of vertical ordinary stiffeners are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \lambda_b \beta_b \frac{\gamma_{S2} p_T}{m R_y}\left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \lambda_s \beta_s \frac{\gamma_{S2} p_T}{R_y}\left(1 - \frac{s}{2\ell}\right) s \ell$$

where:

β_b, β_s : Coefficients defined in Tab 5

λ_b : Coefficient taken equal to the greater of the following values:

$$\lambda_b = 1 + 0{,}2 \frac{p_{Td} - p_{Tu}}{p_{Td} + p_{Tu}}$$

$$\lambda_b = 1 - 0{,}2 \frac{p_{Td} - p_{Tu}}{p_{Td} + p_{Tu}}$$

λ_s : Coefficient taken equal to the greater of the following values:

$$\lambda_s = 1 + 0{,}4 \frac{p_{Td} - p_{Tu}}{p_{Td} + p_{Tu}}$$

$$\lambda_s = 1 - 0{,}4 \frac{p_{Td} - p_{Tu}}{p_{Td} + p_{Tu}}$$

p_{Td} : Still water pressure, in kN/m^2, in testing conditions, at the lower end of the ordinary stiffener considered

p_{Tu} : Still water pressure, in kN/m^2, in testing conditions, at the upper end of the ordinary stiffener considered.

3.9.5 Multispan ordinary stiffeners

The minimum net section modulus and the net shear sectional area of multispan ordinary stiffeners are to be obtained from [3.4.4], considering the pressure in testing conditions and taking account of the checking criteria indicated in [3.6].

4 Buckling check

4.1 Width of attached plating

4.1.1 The width of the attached plating to be considered for the buckling check of ordinary stiffeners is to be obtained, in m, from the following formulae:

- where no local buckling occurs on the attached plating (see Ch 7, Sec 1, [5.4.1]):

  $b_e = s$

- where local buckling occurs on the attached plating (see Ch 7, Sec 1, [5.4.1]):

  $$b_e = \left(\frac{2{,}25}{\beta_e} - \frac{1{,}25}{\beta_e^2}\right) s$$

  to be taken not greater than s

where:

$$\beta_e = \frac{s}{t_p}\sqrt{\frac{\sigma_b}{E}} 10^3$$

σ_b : Compression stress σ_X or σ_Y, in N/mm^2, acting on the plate panel, defined in Ch 7, Sec 1, [5.2.4], according to the direction x or y considered.

4.2 Load model

4.2.1 Sign convention for normal stresses

The sign convention for normal stresses is as follows:

- tension: positive
- compression: negative.

4.2.2 Hull girder compression normal stresses

The hull girder compression normal stresses to be considered for the buckling check of ordinary stiffeners contributing to the hull girder longitudinal strength are obtained, in N/mm^2, from the following formula:

$\sigma_{X1} = \gamma_{S1} \sigma_{S1} + \gamma_{W1} (C_{FV} \sigma_{WV1} + C_{FH} \sigma_{WH1} + C_{F\Omega} \sigma_{\Omega})$

where:

σ_{S1}, σ_{WV1}, σ_{WH1} : Hull girder normal stresses, in N/mm^2, defined in Tab 8.

Table 8 : Hull girder normal compression stresses

Condition	σ_{S1} in N/mm² **(1)**	σ_{WV1} in N/mm²	σ_{WH1} in N/mm²
• $z \geq N$	$\frac{M_{SW,S}}{I_Y}(z-N)10^{-3}$	$\frac{0,625F_D M_{WV,S}}{I_Y}(z-N)10^{-3}$	$-\left\lvert\frac{0,625M_{WH}}{I_Z}y\right\rvert 10^{-3}$
• $z < N$	$\frac{M_{SW,H}}{I_Y}(z-N)10^{-3}$	$\frac{0,625M_{WV,H}}{I_Y}(z-N)10^{-3}$	

(1) When the ship in still water is always in hogging condition, σ_{S1} for $z \geq N$ is to be obtained, in N/mm², from the following formula, unless σ_{X1} is evaluated by means of direct calculations (see [4.2.2]):

$$\sigma_{S1} = \frac{M_{SW,Hmin}}{I_Y}(z-N)10^{-3}$$

Note 1:

F_D : Coefficient defined in Ch 5, Sec 2, [4].

σ_Ω : Compression warping stress, in N/mm², induced by the torque 0,625 M_{WT} and obtained through direct calculation analyses based on a structural model in accordance with Ch 6, Sec 1, [2.6]

C_{FV}, C_{FH}, $C_{F\Omega}$: Combination factors defined in Tab 4.

For longitudinal stiffeners, σ_{X1} is to be taken as the maximum compression stress on the stiffener considered.

When the ship in still water is always in hogging condition, σ_{X1} may be evaluated by means of direct calculations when justified on the basis of the ship characteristics and intended service. The calculations are to be submitted to the Society for approval.

4.2.3 Combined hull girder and local compression normal stresses

The combined compression normal stresses to be considered for the buckling check of ordinary stiffeners are to take into account the hull girder stresses and the local stresses resulting from the bending of the primary supporting members. These local stresses are to be obtained from a direct structural analysis using the design loads as given in Part B, Chapter 5.

With respect to the reference co-ordinate system defined in Ch 1, Sec 2, [10.1], the combined stresses in x and y direction are obtained, in N/mm², from the following formulae:

$$\sigma_X = \sigma_{X1} + \gamma_{S2}\sigma_{X2,S} + \gamma_{W2}\sigma_{X2,W}$$

$$\sigma_Y = \gamma_{S2}\sigma_{Y2,S} + \gamma_{W2}\sigma_{Y2,W}$$

where:

σ_{X1} : Compression normal stress, in N/mm², induced by the hull girder still water and wave loads, defined in [4.2.2]

$\sigma_{X2,S}$, $\sigma_{Y2,S}$: Compression normal stress in x and y direction, respectively, in N/mm², induced by the local bending of the primary supporting members and obtained from a direct structural analysis using the still water design loads as given in Part B, Chapter 5

$\sigma_{X2,W}$, $\sigma_{Y2,W}$: Compression normal stress in x and y direction, respectively, in N/mm², induced by the local bending of the primary supporting members and obtained from a direct structural analysis using the wave design loads as given in Part B, Chapter 5.

4.3 Critical stress

4.3.1 General

The critical buckling stress is to be obtained, in N/mm², from the following formulae:

$$\sigma_c = \sigma_E \quad \text{for } \sigma_E \leq \frac{R_{eH,S}}{2}$$

$$\sigma_c = R_{eH,S}\left(1 - \frac{R_{eH,S}}{4\sigma_E}\right) \quad \text{for } \sigma_E > \frac{R_{eH,S}}{2}$$

where:

σ_E = Min (σ_{E1} ; σ_{E2} ; σ_{E3})

σ_{E1} : Euler column buckling stress, in N/mm², given in [4.3.2]

σ_{E2} : Euler torsional buckling stress, in N/mm², given in [4.3.3]

σ_{E3} : Euler web buckling stress, in N/mm², given in [4.3.4].

4.3.2 Column buckling of axially loaded stiffeners

The Euler column buckling stress is obtained, in N/mm², from the following formula:

$$\sigma_E = \pi^2 E \frac{I_e}{A_e \ell^2} 10^{-4}$$

4.3.3 Torsional buckling of axially loaded stiffeners

The Euler torsional buckling stresses is obtained, in N/mm², from the following formula:

$$\sigma_E = \frac{\pi^2 E I_w}{10^4 I_p \ell^2}\left(\frac{K_C}{m^2} + m^2\right) + 0{,}385 E \frac{I_t}{I_p}$$

where:

I_w : Net sectorial moment of inertia, in cm⁶, of the stiffener about its connection to the attached plating:

- for flat bars:

$$I_w = \frac{h_w^3 t_w^3}{36} 10^{-6}$$

- for T-sections:

$$I_w = \frac{t_f b_f^3 h_w^2}{12} 10^{-6}$$

- for angles and bulb sections:

$$I_w = \frac{b_f^3 h_w^2}{12(b_f + h_w)^2}[t_f(b_f^2 + 2b_f h_w + 4h_w^2) + 3t_w b_f h_w]\, 10^{-6}$$

I_p : Net polar moment of inertia, in cm⁴, of the stiffener about its connection to the attached plating:

- for flat bars:

$$I_p = \frac{h_w^3 t_w}{3} 10^{-4}$$

- for stiffeners with face plate:

$$I_p = \left(\frac{h_w^3 t_w}{3} + h_w^2 b_f t_f\right) 10^{-4}$$

I_t : St. Venant's net moment of inertia, in cm⁴, of the stiffener without attached plating:

- for flat bars:

$$I_t = \frac{h_w t_w^3}{3} 10^{-4}$$

- for stiffeners with face plate:

$$I_t = \frac{1}{3}\left[h_w t_w^3 + b_f t_f^3\left(1 - 0{,}63\frac{t_f}{b_f}\right)\right] 10^{-4}$$

m : Number of half waves, to be taken equal to the integer number such that (see also Tab 9):

$$m^2(m-1)^2 \le K_C < m^2(m+1)^2$$

$$K_C = \frac{C_0 \ell^4}{\pi^4 E I_w} 10^6$$

C_0 : Spring stiffness of the attached plating:

$$C_0 = \frac{E t_p^3}{2{,}73 s} 10^{-3}$$

Table 9 : Torsional buckling of axially loaded stiffeners Number m of half waves

K_C	$0 \le K_C < 4$	$4 \le K_C < 36$	$36 \le K_C < 144$
m	1	2	3

4.3.4 Web buckling of axially loaded stiffeners

The Euler buckling stress of the stiffener web is obtained, in N/mm², from the following formulae:

- for flat bars:

$$\sigma_E = 16\left(\frac{t_W}{h_W}\right)^2 10^4$$

- for stiffeners with face plate:

$$\sigma_E = 78\left(\frac{t_W}{h_W}\right)^2 10^4$$

4.4 Checking criteria

4.4.1 Stiffeners parallel to the direction of compression

The critical buckling stress of the ordinary stiffener is to comply with the following formula:

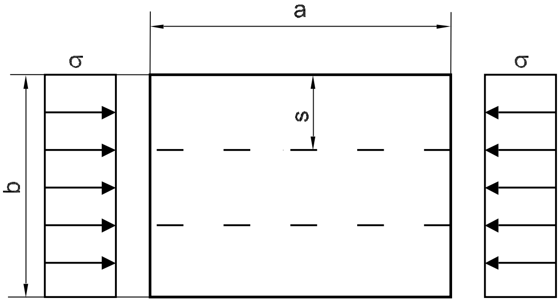
$$\frac{\sigma_c}{\gamma_R \gamma_m} \geq |\sigma_b|$$

where:

σ_c : Critical buckling stress, in N/mm², as calculated in [4.3.1]

σ_b : Compression stress σ_{xb} or σ_{yb}, in N/mm², in the stiffener, as calculated in [4.2.2] or [4.2.3].

Figure 5 : Buckling of stiffeners parallel to the direction of compression



4.4.2 Stiffeners perpendicular to the direction of compression

The net moment of inertia of stiffeners, in cm⁴, is to be not less than the greatest value obtained from the following formulae:

- $I = 360\,\ell^2$
- for $\sigma \leq R_{eH,P} / 2$:

$$I = \frac{s t_p^3}{485}\left[\frac{\left(\frac{\ell}{s}\right)^4 - 4}{\sigma_{E,1} - \sigma_{E,0}}\right](\sigma - \sigma_{E,0})$$

- for $\sigma > R_{eH,P} / 2$:

$$I = \frac{s t_p^3}{485}\left[\frac{\left(\frac{\ell}{s}\right)^4 - 4}{\sigma_{E,1} - \sigma_{E,0}}\right]\left[\frac{R_{eH,P}}{4\left(1 - \frac{\sigma}{R_{eH,P}}\right)} - \sigma_{E,0}\right]$$

where:

ℓ/s : Ratio to be taken not less than 1,41

$\sigma_{E,0}$: Euler buckling stress, in N/mm², of the unstiffened plate taken equal to:

$$\sigma_{E,0} = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_p}{\ell}\right)^2 \varepsilon K_{1,0} 10^{-6}$$

$K_{1,0}$: Coefficient defined in Ch 7, Sec 1, Tab 8 for:
$0 \leq \Psi \leq 1$ and $\alpha = a / \ell$

ε : Coefficient defined in Ch 7, Sec 1, [5.3.1]

$\sigma_{E,1}$: Euler buckling stress, in N/mm², of the plate panel taken equal to:

$$\sigma_{E,1} = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_p}{\ell}\right)^2 \varepsilon K_{1,1} 10^{-6}$$

$K_{1,1}$: Coefficient defined in Ch 7, Sec 1, Tab 8 for:
$0 \leq \Psi \leq 1$ and $\alpha = s/ \ell$

Where intercostal stiffeners are fitted, as shown in Fig 7, the check of the moment of inertia of stiffeners perpendicular to the direction of compression is to be carried out with the equivalent net thickness $t_{eq,net}$, in mm, obtained from the following formula:

$$t_{eq,net} = \frac{1 + \left(\frac{s}{\ell_1}\right)^2}{1 + \left(\frac{s}{\ell}\right)^2} t_{net}$$

where ℓ_1 is to be taken not less than s.

Figure 6 : Buckling of stiffeners perpendicular to the direction of compression

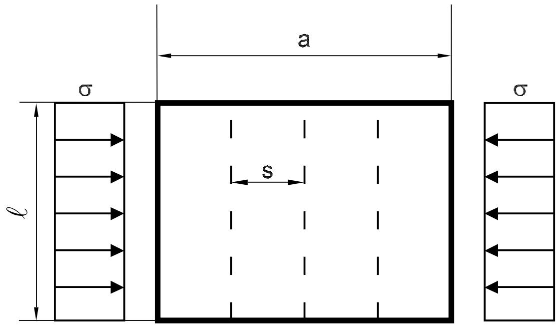


Figure 7 : Buckling of stiffeners perpendicular to the direction of compression (intercostal stiffeners)

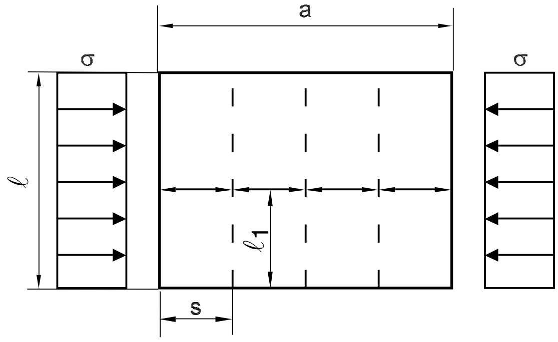

5 Ultimate strength check of ordinary stiffeners contributing to the hull girder longitudinal strength

5.1 Application

5.1.1 The requirements of this Article apply to ships equal to or greater than 90 m in length. For such ships, the ultimate strength of stiffeners subjected to lateral pressure and to hull girder normal stresses is to be checked.

5.2 Width of attached plating

5.2.1 The width of the attached plating to be considered for the ultimate strength check of ordinary stiffeners is to be obtained, in m, from the following formulae:

- if $\beta_U \leq 1{,}25$:

  $b_U = s$

- if $\beta_U > 1{,}25$:

$$b_U = \left(\frac{2{,}25}{\beta_U} - \frac{1{,}25}{\beta_U^2}\right)s$$

where:

$$\beta_U = \frac{s}{t_p}\sqrt{\frac{\sigma_{X1E}}{E}}10^3$$

σ_{X1E} : Stress defined in Tab 10.

5.3 Load model

5.3.1 General

The still water and wave lateral pressures induced by the sea and the various types of weights and ballast in intact conditions are to be considered, depending on the location of the ordinary stiffener under consideration and the type of compartments adjacent to it, in accordance with Ch 5, Sec 1, [2.4].

The wave lateral pressures and hull girder loads are to be calculated in the mutually exclusive load cases "a", "b", "c" and "d" in Ch 5, Sec 4.

Table 10 : Ultimate strength stress

Symbol	Resultant load pressure acting on the side opposite to the ordinary stiffener, with respect to the plating, in N/mm²	Resultant load pressure acting on the same side as the ordinary stiffener, in N/mm²
σ_U	$f\frac{A_U}{A_S}\left(1-\frac{s}{10b_U}\right)R_{eH,P}$	$R_{eH,S}\, f$
f	$\frac{\zeta}{2}-\sqrt{\frac{\zeta^2}{4}-\frac{1-\mu}{(1+\eta_P)\lambda_U^2}}$	
ζ	$\frac{1-\mu}{1+\eta_P}+\frac{1+\eta_P+\eta}{(1+\eta_P)\lambda_U^2}$	
μ	$\frac{125ps\ell^2 d_{P,U}}{R_{eH,P}I_U\left(1-\frac{s}{10b_U}\right)}$	$\frac{41,7ps\ell^2 d_{F,S}}{R_{eH,S}I_S}$
η	$\left(\delta_0+\frac{13ps\ell^4}{E_T I_S}10^4\right)\frac{d_{P,U}}{\rho_U^2}$	$\left(0,577\delta_0+\frac{1,5ps\ell^4}{E_T I_S}10^4\right)\frac{d_{F,S}}{\rho_S^2}$
η_P	$d_P A\left(\frac{1}{A_U}-\frac{1}{A_S}\right)\frac{d_{P,U}}{\rho_U^2}$	0
λ_U	$\frac{31,8\ell}{\rho_U}\sqrt{\frac{R_{eH,P}}{E_T}\left(1-\frac{s}{10b_U}\right)}$	$\frac{18,4\ell}{\rho_S}\sqrt{\frac{R_{eH,S}}{E_T}}$

Note 1:

$d_{P,U}$: Distance, in cm, between the neutral axis of the cross-section of the stiffener with attached plating of width b_U and the fibre at half-thickness of the plating

$d_{F,S}$: Distance, in cm, between the neutral axis of the cross-section of the stiffener with attached plating of width s and the fibre at half-thickness of the face plate of the stiffener

d_P : Distance, in cm, between the neutral axis of the ordinary stiffener without attached plating and the fibre at half-thickness of the attached plating

A : Net sectional area, in cm², of the stiffener without attached plating

p : Lateral pressure acting on the stiffener, equal to: $p = \gamma_{S2}\, p_S + \gamma_{W2U}\, p_W$

δ_0 : Pre-deformation, in cm, of the ordinary stiffener, to be assumed, in the absence of more accurate evaluation: $\delta_0 = 0,2\ \ell$

E_T : Structural tangent modulus, equal to:

$$E_T = 4E\frac{\sigma_{X1E}}{R_{eH,P}}\left(1-\frac{\sigma_{X1E}}{R_{eH,P}}\right) \quad \text{for } \sigma_{X1E} > 0,5R_{eH,P}$$

$$E_T = E \quad \text{for } \sigma_{X1E} \le 0,5R_{eH,P}$$

σ_{X1E} : Stress to be obtained, in N/mm², from the following formulae:

$$\text{if } \alpha > \frac{1,25}{\sqrt{|\sigma_{X1}|}}: \quad \sigma_{X1E} = \left\{\frac{-\frac{22,5st_P}{\alpha}+\sqrt{\left(\frac{22,5st_P}{\alpha}\right)^2+4A\left[(A_S+10st_P)\sigma_{X1}+\frac{12,5st_P}{\alpha^2}\right]}}{2A}\right\}^2$$

$$\text{if } \alpha \le \frac{1,25}{\sqrt{|\sigma_{X1}|}}: \quad \sigma_{X1E} = \sigma_{X1}$$

$$\alpha = 1000\frac{s}{t_P\sqrt{E}}$$

σ_{X1} : Compression stress, in N/mm², acting on the stiffener, as defined in [5.3.3].

5.3.2 Lateral pressure

Lateral pressure is constituted by still water pressure and wave pressure.

Still water pressure p_S includes:

- the still water sea pressure, defined in Ch 5, Sec 5, [1]
- the still water internal pressure, defined in Ch 5, Sec 6 for the various types of cargoes and for minimum operational condition.

Wave induced pressure p_W includes:

- the wave pressure, defined in Ch 5, Sec 5, [2] for each load case "a", "b", "c" and "d"
- the inertial pressure, defined in Ch 5, Sec 6 for the various types of cargoes and for minimum operational condition, and for each load case "a", "b", "c" and "d".

5.3.3 Hull girder compression normal stresses

The hull girder compression normal stresses σ_{X1} to be considered for the ultimate strength check of stiffeners contributing to the longitudinal strength are those given in [4.2.2], where the partial safety factors are those specified in Tab 1 for the ultimate strength check.

5.4 Ultimate strength stress

5.4.1 The ultimate strength stress σ_U is to be obtained, in N/mm², from the formulae in Tab 10, for resultant lateral pressure acting either on the side opposite to the ordinary stiffener, with respect to the plating, or on the same side as the ordinary stiffener.

5.5 Checking criteria

5.5.1 The ultimate strength stress of the ordinary stiffener is to comply with the following formula:

$$\frac{\sigma_U}{\gamma_R \gamma_m} \geq |\sigma_{X1}|$$

where:

σ_U : Ultimate strength stress, in N/mm², as calculated in [5.4.1]

σ_{X1} : Compression stress, in N/mm², as calculated in [5.3.3].

Section 3 Primary Supporting Members

Symbols

For symbols not defined in this Section, refer to the list at the beginning of this Chapter.

p_S : Still water pressure, in kN/m², see [2.4.2] and [2.4.4]

p_W : Wave pressure, in kN/m², see [2.4.2] and [2.4.4]

p_{SF}, p_{WF} : Still water and wave pressures, in kN/m², in flooding conditions, defined in Ch 5, Sec 6, [7]

σ_{X1} : Hull girder normal stress, in N/mm², defined in [2.4.6]

σ_N : Normal stress, in N/mm², defined in [2.4.6]

s : Spacing, in m, of primary supporting members

ℓ : Span, in m, of primary supporting members, measured between the supporting elements, see Ch 4, Sec 3, [4.1]

ℓ_b : Length, in m, of one bracket, see [2.2] and Ch 4, Sec 3, [4.4]

b_p : Width, in m, of the plating attached to the primary supporting member, for the yielding check, defined in Ch 4, Sec 3, [4.2]

w : Net section modulus, in cm³, of the primary supporting member, with an attached plating of width b_p , to be calculated as specified in Ch 4, Sec 3, [4.3]

A_{Sh} : Net shear sectional area, in cm², of the primary supporting member, to be calculated as specified in Ch 4, Sec 3, [4.3]

m : Boundary coefficient, to be taken equal to:

- m = 10 in general
- m = 12 for bottom and side girders

1 General

1.1 Application

1.1.1 Analysis criteria

The requirements of this Section apply for the yielding and buckling checks of primary supporting members.

Depending on their arrangement, primary supporting members are to be analysed through one of the following models:

- an isolated beam structural model
- a three-dimensional structural model
- a complete ship structural model.

1.1.2 Structural models

Depending on the length, primary structural models are to be adopted as specified in Tab 1.

Table 1 : Selection of structural models

Ship length, in m	Calculation model
L < 90	Isolated beam model, or three-dimensional beam model for grillage or complex arrangements
L ≥ 90	Three-dimensional beam model **(1)**
(1) A three-dimensional finite element model or a complete ship model may also be used.	

1.1.3 Yielding check

The yielding check is to be carried out according to:

- [2] for primary supporting members analysed through isolated beam models
- [3] for primary supporting members analysed through three-dimensional models
- [4] for primary supporting members analysed through complete ship models.

1.1.4 Buckling check

The buckling check is to be carried out according to [5], on the basis of the stresses in primary supporting members calculated according to Articles [2], [3] or [4], depending on the structural model adopted.

1.1.5 Normal mode analysis

A normal mode analysis of primary supporting members may be required by the Society to be carried out, when deemed necessary on the basis of the expected frequency of cyclic loads.

1.2 Net scantlings

1.2.1 As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

The gross scantlings are obtained as specified in Ch 4, Sec 2.

1.3 Partial safety factors

1.3.1 The partial safety factors to be considered for checking primary supporting members are specified in:

- Tab 2 for analyses based on isolated beam models
- Tab 3 for analyses based on three-dimensional models
- Tab 4 for analyses based on complete ship models.

Table 2 : Primary supporting members analysed through isolated beam models - Partial safety factors

Partial safety factors covering uncertainties regarding:	Symbol	Yielding check		Buckling check	
		General (see [2.4] to [2.7])	Flooding **(1)** (see [2.8])	Plate panels (see [5.1])	Pillars (see [5.2] and [5.3])
Still water hull girder loads	γ_{S1}	1,00	1,00	1,00	1,00
Wave hull girder loads	γ_{W1}	1,15	1,15	1,15	1,15
Still water pressure	γ_{S2}	1,00	1,00	1,00	1,00
Wave pressure	γ_{W2}	1,20	1,05	1,20	1,20
Material	γ_m	1,02	1,02	1,02	1,02
Resistance	γ_R	• 1,02 in general • 1,15 for bottom and side girders	1,02 **(2)**	1,10	for [5.2]: see Tab 12 for [5.3]: 1,15

(1) Applies only to primary supporting members to be checked in flooding conditions.
(2) For primary supporting members of the collision bulkhead, γ_R = 1,25. This requirement may be disregarded when damaged stability considers at least two adjacent compartments flooded.

Table 3 : Primary supporting members analysed through three-dimensional models - Partial safety factors

Partial safety factors covering uncertainties regarding:	Symbol	Yielding check (see [3])		Buckling check	
		General	Flooding **(1)**	Plate panels (see [5.1])	Pillars (see [5.2] and [5.3])
Still water hull girder loads	γ_{S1}	1,00	1,00	1,00	1,00

2 Yielding check of primary supporting members analysed through an isolated beam structural model

2.1 General

2.1.1 The requirements of this Article apply for the yielding check of primary supporting members subjected to lateral pressure, wheeled loads or weapon firing dynamic loads and, for primary supporting members contributing to the hull girder longitudinal strength, to hull girder normal stresses, which are to be analysed through an isolated beam model, according to [1.1.2].

2.1.2 The yielding check is also to be carried out for primary supporting members subjected to specific loads, such as concentrated loads.

2.2 Bracket arrangement

2.2.1 The requirements of this Article apply to primary supporting members with brackets at both ends of length not greater than 0,2 ℓ.

In the case of a significantly different bracket arrangement, the determination of normal and shear stresses due to design loads and the required section modulus and shear sectional area are considered by the Society on a case-by-case basis.

2.3 Load point

2.3.1 Lateral pressure

Unless otherwise specified, lateral pressure is to be calculated at mid-span of the primary supporting member considered.

2.3.2 Hull girder normal stresses

For longitudinal primary supporting members contributing to the hull girder longitudinal strength, the hull girder normal stresses are to be calculated in way of the face plate of the primary supporting member considered.

2.4 Load model

2.4.1 General

The still water and wave lateral pressures induced by the sea and the various types of cargoes and ballast in intact conditions are to be considered, depending on the location of the primary supporting member under consideration and the type of compartments adjacent to it, in accordance with Ch 5, Sec 1, [2.4].

Primary supporting members of bulkheads or inner side which constitute the boundary of compartments not intended to carry liquids are to be subjected to the lateral pressure in flooding conditions.

The wave lateral pressures and hull girder loads are to be calculated in the mutually exclusive load cases “a”, “b”, “c” and “d” in Ch 5, Sec 4.

2.4.2 Lateral pressure in intact conditions

The lateral pressure in intact conditions is constituted by still water pressure and wave pressure.

Still water pressure p_S includes:

- the still water sea pressure, defined in Ch 5, Sec 5, [1]
- the still water internal pressure, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast.

Wave pressure p_W includes:

- the wave pressure, defined in Ch 5, Sec 5, [2] for each load case “a”, “b”, “c” and “d”
- the inertial pressure, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast, and for each load case “a”, “b”, “c” and “d”.

2.4.3 Lateral pressure in flooding conditions

The lateral pressure in flooding conditions is constituted by the still water pressure p_{SF} and the wave pressure p_{WF} defined in Ch 5, Sec 6, [7].

2.4.4 Wheeled loads

For primary supporting members subjected to wheeled loads, the yielding check may be carried out according to [2.5] to [2.7] considering uniform pressures equivalent to the distribution of vertical concentrated forces, when such forces are closely located.

For the determination of the equivalent uniform pressures, the most unfavourable case, i.e. where the maximum number of axles are located on the same primary supporting member, according to Fig 1 to Fig 3, is to be considered.

The equivalent still water pressure and inertial pressure are indicated in Tab 7.

For arrangements different from those shown in Fig 1 to Fig 3, the yielding check of primary supporting members is to be carried out by a direct calculation, taking into account the distribution of concentrated loads induced by vehicle wheels.

Table 7 : Wheeled loads - Equivalent uniform still water and inertial pressures

Ship condition	Load case	Still water pressure p_S and inertial pressure p_W, in kN/m²
Still water condition		$p_S = 10\ p_{eq}$
Upright condition	“a”	No inertial pressure
	“b”	$p_W = p_{eq}\ a_{Z1}$
Inclined condition	“c”	The inertial pressure may be disregarded
	“d”	$p_W = p_{eq}\ a_{Z2}$
Note 1: $p_{eq} = \frac{n_V Q_A}{\ell s}\left(3 - \frac{X_1 + X_2}{s}\right)$ n_V : Maximum number of vehicles possible located on the primary supporting member Q_A : Maximum axle load, in t, defined in Ch 5, Sec 6, Tab 5 X_1 : Minimum distance, in m, between two consecutive axles (see Fig 2 and Fig 3) X_2 : Minimum distance, in m, between axles of two consecutive vehicles (see Fig 3).		

Figure 1 : Wheeled loads - Distribution of vehicles on a primary supporting member

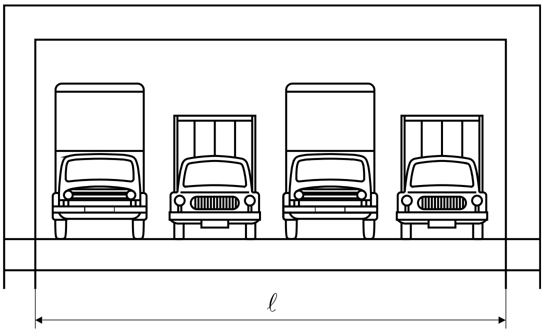

Figure 2 : Wheeled loads - Distance between two consecutive axles

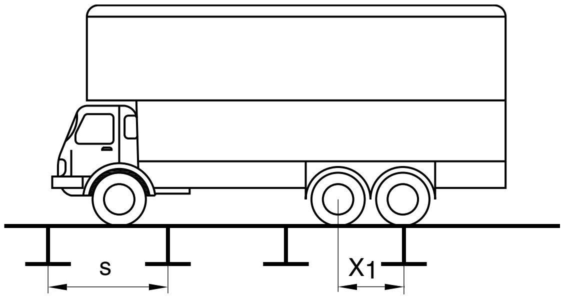

Figure 3 : Wheeled loads - Distance between axles of two consecutive vehicles

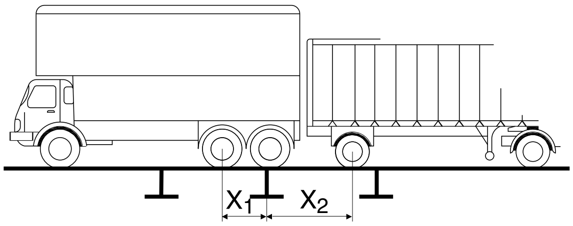

2.4.5 Weapon firing dynamic loads

For primary supporting members subjected to weapon firing dynamic loads, the yielding check may be carried out according to [2.7.4] considering uniform pressure distribution.

The pressure p_W is to be calculated according to the requirements specified in Ch 5, Sec 6, [9] for the following weapon firing dynamic loads:

- missile blast dynamic pressure
- accidental missile ignition dynamic pressure
- gun blast dynamic pressure.

For primary supporting members subjected to the gun recoil dynamic force and, in general, when the weapon firing dynamic loads cannot be considered as uniformly distributed, the yielding check is to be carried out taking into account the actual load distribution.

2.4.6 Normal stresses

The normal stresses to be considered for the yielding check of primary supporting members are obtained, in N/mm², from the following formulae:

- for longitudinal primary supporting members contributing to the hull girder longitudinal strength:

  $\sigma_N = \sigma_{X1} = \gamma_{S1}\sigma_{S1} + \gamma_{W1}(C_{FV}\sigma_{WV1} + C_{FH}\sigma_{WH1})$

- for longitudinal primary supporting members not contributing to the hull girder longitudinal strength and for transverse primary supporting members:

  $\sigma_N = 45/k$ N/mm²

where:

σ_{S1}, σ_{WV1}, σ_{WH1} : Hull girder normal stresses, in N/mm², defined in:

- Tab 8 for primary supporting members subjected to lateral pressure,
- Tab 9 for primary supporting members subjected to wheeled loads

C_{FV}, C_{FH} : Combination factors defined in Tab 10.

Table 8 : Hull girder normal stresses - Primary supporting members subjected to lateral pressure

2.5 Normal and shear stresses due to lateral pressure in intact conditions

2.5.1 General

Normal and shear stresses, induced by lateral pressures, in primary supporting members are to be determined from the formulae given in:

- [2.5.2] in the case of longitudinal and transverse primary supporting members
- [2.5.3] in the case of vertical primary supporting members.

2.5.2 Longitudinal and transverse primary supporting members

The maximum normal stress σ and shear stress τ are to be obtained, in N/mm², from the following formulae:

$$\sigma = \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{m w} s \ell^2 10^3 + \sigma_N$$

$$\tau = 5\beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{A_{Sh}} s \ell$$

where:

$$\beta_b = \left(1 - \frac{\ell_{b1}}{2\ell} - \frac{\ell_{b2}}{2\ell}\right)^2$$

$$\beta_s = 1 - \frac{\ell_{b1}}{2\ell} - \frac{\ell_{b2}}{2\ell}$$

ℓ_{b1} , ℓ_{b2} : Lengths of the brackets at ends, in m.

2.5.3 Vertical primary supporting members

The maximum normal stress σ and shear stress τ are to be obtained, in N/mm², from the following formulae:

$$\sigma = \beta_b \frac{\gamma_{S2}\lambda_{bS}p_S + \gamma_{W2}\lambda_{bW}p_W}{mw} s\ell^2 10^3 + \sigma_A$$

$$\tau = 5\beta_s \frac{\gamma_{S2}\lambda_{sS}p_S + \gamma_{W2}\lambda_{sW}p_W}{A_{Sh}} s\ell$$

where:

β_b, β_s : Coefficients defined in [2.5.2]

$$\lambda_{bS} = 1 + 0{,}2\frac{p_{Sd} - p_{Su}}{p_{Sd} + p_{Su}}$$

$$\lambda_{bW} = 1 + 0{,}2\frac{p_{Wd} - p_{Wu}}{p_{Wd} + p_{Wu}}$$

$$\lambda_{sS} = 1 + 0{,}4\frac{p_{Sd} - p_{Su}}{p_{Sd} + p_{Su}}$$

$$\lambda_{sW} = 1 + 0{,}4\frac{p_{Wd} - p_{Wu}}{p_{Wd} + p_{Wu}}$$

p_{Sd} : Still water pressure, in kN/m², at the lower end of the primary supporting member considered

p_{Su} : Still water pressure, in kN/m², at the upper end of the primary supporting member considered

p_{Wd} : Wave pressure, in kN/m², at the lower end of the primary supporting member considered

p_{Wu} : Wave pressure, in kN/m², at the upper end of the primary supporting member considered

σ_A : Axial stress, to be obtained, in N/mm², from the following formula:

$$\sigma_A = 10\frac{F_A}{A}$$

F_A : Axial load (still water and wave) transmitted to the vertical primary supporting members by the structures above. For multideck ships, the criteria in [5.2.1] for pillars are to be adopted

A : Net sectional area, in cm², of the vertical primary supporting members with attached plating of width b_P.

2.6 Checking criteria

2.6.1 General

It is to be checked that the normal stress σ and the shear stress τ, calculated according to [2.5], are in compliance with the following formulae:

$$\frac{R_y}{\gamma_R\gamma_m} \geq \sigma$$

$$0{,}5\frac{R_y}{\gamma_R\gamma_m} \geq \tau$$

2.7 Net section modulus and net sectional shear area complying with the checking criteria

2.7.1 General

The requirements in [2.7.2] and [2.7.3] provide the minimum net section modulus and net shear sectional area of primary supporting members subjected to lateral pressure in intact conditions, complying with the checking criteria indicated in [2.6].

The requirements in [2.7.4] provide the minimum net section modulus and net shear sectional area of primary supporting members subjected to weapon firing dynamic loads.

2.7.2 Longitudinal and transverse primary supporting members

The net section modulus w, in cm³, and the net shear sectional area A_{Sh}, in cm², of longitudinal or transverse primary supporting members are to be not less than the values obtained from the following formulae:

$$w = \gamma_R\gamma_m\beta_b \frac{\gamma_{S2}p_S + \gamma_{W2}p_W}{m(R_y - \gamma_R\gamma_m\sigma_N)} s\ell^2 10^3$$

$$A_{Sh} = 10\gamma_R\gamma_m\beta_s \frac{\gamma_{S2}p_S + \gamma_{W2}p_W}{R_y} s\ell$$

where β_b and β_s are the coefficients defined in [2.5.2].

2.7.3 Vertical primary supporting members

The net section modulus w, in cm³, and the net shear sectional area A_{Sh} , in cm², of vertical primary supporting members are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2}\lambda_{bS} p_S + \gamma_{W2}\lambda_{bW} p_W}{m(R_y - \gamma_R \gamma_m \sigma_A)} s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2}\lambda_{sS} p_S + \gamma_{W2}\lambda_{sW} p_W}{R_y} s \ell$$

where:

β_b , β_s : Coefficients defined in [2.5.2]

λ_{bs} , λ_{bW} , λ_{sS} , λ_{sW} : Coefficients defined in [2.5.3]

σ_A : Defined in [2.5.3].

2.7.4 Primary supporting members subjected to weapon firing dynamic loads

The net section modulus w, in cm³, and the net shear sectional area A_{Sh} , in cm², of primary supporting members subjected to weapon firing dynamic loads are to be not less than the values obtained from the following formulae:

$$w = c_C \gamma_R \gamma_m \beta_b \frac{\gamma_{W2} p_W s \ell^2}{8 R_y} 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{W2} p_W s \ell^2}{R_y}$$

where:

β_b , β_s : Coefficients defined in [2.5.2]

p_w : Weapon firing dynamic pressure defined in Ch 5, Sec 6, [9].

2.8 Net section modulus and net shear sectional area of primary supporting members subjected to lateral pressure in flooding conditions

2.8.1 General

The requirements in [2.8.1] to [2.8.3] apply to primary supporting members located on structural watertight elements as per Internal Watertight Plan which constitute boundaries intended to stop vertical and horizontal flooding.

These primary supporting members are to be checked in flooding conditions as specified in [2.8.2] and [2.8.3], depending on the type of member.

2.8.2 Longitudinal and transverse primary supporting members

The net section modulus w, in cm³, and the net shear sectional area A_{Sh} , in cm², of longitudinal or transverse primary supporting members are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_{SF} + \gamma_{W2} p_{WF}}{m(R_y - \gamma_R \gamma_m \sigma_N)} s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_{SF} + \gamma_{W2} p_{WF}}{R_y} s \ell$$

where:

β_b , β_s : Coefficients defined in [2.5.2].

2.8.3 Vertical primary supporting members

The net section modulus w, in cm³, and the net shear sectional area A_{Sh} , in cm², of vertical primary supporting members are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2}\lambda_{bS} p_{SF} + \gamma_{W2}\lambda_{bW} p_{WF}}{m R_y} s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2}\lambda_{sS} p_{SF} + \gamma_{W2}\lambda_{sW} p_{WF}}{R_y} s \ell$$

where:

β_b , β_s : Coefficients defined in [2.5.2]

$$\lambda_{bS} = 1 + 0{,}2\frac{p_{SFd} - p_{SFu}}{p_{SFd} + p_{SFu}}$$

$$\lambda_{bW} = 1 + 0{,}2\frac{p_{WFd} - p_{WFu}}{p_{WFd} + p_{WFu}}$$

$$\lambda_{sS} = 1 + 0{,}4\frac{p_{SFd} - p_{SFu}}{p_{SFd} + p_{SFu}}$$

$$\lambda_{sW} = 1 + 0{,}4\frac{p_{WFd} - p_{WFu}}{p_{WFd} + p_{WFu}}$$

p_{SFd} : Still water pressure, in kN/m², in flooding conditions, at the lower end of the primary supporting member considered

p_{SFu} : Still water pressure, in kN/m², in flooding conditions, at the upper end of the primary supporting member considered

p_{WFd} : Wave pressure, in kN/m², in flooding conditions, at the lower end of the primary supporting member considered

p_{WFu} : Wave pressure, in kN/m², in flooding conditions, at the upper end of the primary supporting member considered.

3 Yielding check of primary supporting members analysed through a three-dimensional structural model

3.1 General

3.1.1 The requirements of this Article apply for the yielding check of primary supporting members subjected to lateral pressure, wheeled loads or weapon firing dynamic loads and, for those contributing to the hull girder longitudinal strength, to hull girder normal stresses, which are to be analysed through a three-dimensional structural model, according to [1.1.2].

3.1.2 The yielding check is also to be carried out for primary supporting members subjected to specific loads, such as concentrated loads.

3.2 Analysis criteria

3.2.1 The analysis of primary supporting members based on three-dimensional models is to be carried out according to:

- the requirements in Ch 7, App 1 for primary supporting members subjected to lateral pressure or weapon firing dynamic loads
- the requirements in Ch 7, App 2 for primary supporting members subjected to wheeled loads.

These requirements apply for:

- the structural modelling
- the load modelling
- the stress calculation.

3.3 Checking criteria

3.3.1 General

For all types of analysis (see Ch 7, App 1, [2]), it is to be checked that the equivalent stress σ_{VM}, calculated according to Ch 7, App 1, [5] is in compliance with the following formula:

$$\frac{R_y}{\gamma_R \gamma_m} \geq \sigma_{VM}$$

3.3.2 Additional criteria for analyses based on fine mesh finite element models

Fine mesh finite element models are defined with reference to Ch 7, App 1, [3.4].

For all the elements of the fine mesh models, it is to be checked that the normal stresses σ_1 and σ_2 and the shear stress τ_{12}, calculated according to Ch 7, App 1, [5], are in compliance with the following formulae:

$$\frac{R_y}{\gamma_R \gamma_m} \geq \mathrm{Max}\,(\sigma_1;\sigma_2)$$

$$0{,}5\frac{R_y}{\gamma_R \gamma_m} \geq \tau_{12}$$

3.3.3 Specific case of primary supporting members subjected to wheeled loads

For all types of analysis (see Ch 7, App 2, [2]), it is to be checked that the equivalent stress σ_{VM}, calculated according to Ch 7, App 2, [5] is in compliance with the following formula:

$$\frac{R_y}{\gamma_R \gamma_m} \geq \sigma_{VM}$$

4 Yielding check of primary supporting members analysed through a complete ship structural model

4.1 General

4.1.1 The requirements of this Article apply for the yielding check of primary supporting members which are to be analysed through a complete ship structural model.

4.1.2 A complete ship structural model is to be carried out, when deemed necessary by the Society, to analyse primary supporting members of ships with one or more of the following characteristics:

- ships having large deck openings
- ships having large space arrangements
- multideck ships having series of openings in side or longitudinal bulkheads, when the stresses due to the different contribution of each deck to the hull girder strength are to be taken into account.

4.2 Analysis criteria

4.2.1 The analysis of primary supporting members based on complete ship models is to be carried out according to Ch 7, App 3.

These requirements apply for:

- the structural modelling
- the load modelling
- the stress calculation.

4.3 Checking criteria

4.3.1 General

It is to be checked that the equivalent stress σ_{VM}, calculated according to Ch 7, App 3, [4] is in compliance with the following formula:

$$\frac{R_y}{\gamma_R \gamma_m} \geq \sigma_{VM}$$

4.3.2 Additional criteria for elements modelled with fine meshes

Fine meshes are defined with reference to Ch 7, App 3, [2.4].

For all the elements modelled with fine meshes, it is to be checked that the normal stresses σ_1 and σ_2 and the shear stress τ_{12}, calculated according to Ch 7, App 3, [4], are in compliance with the following formulae:

$$\frac{R_y}{\gamma_R \gamma_m} \geq \mathrm{Max}\,(\sigma_1;\sigma_2)$$

$$0{,}5\frac{R_y}{\gamma_R \gamma_m} \geq \tau_{12}$$

5 Buckling check

5.1 Local buckling of plate panels

5.1.1 A local buckling check is to be carried out, according to Ch 7, Sec 1, [5], for plate panels which constitute primary supporting members.

In carrying out this check, the stresses in the plate panels are to be calculated according to [2], [3] or [4], depending on the structural model adopted for the analysis of primary supporting members.

5.2 Buckling of pillars subjected to compression axial load

5.2.1 Compression axial load

The compression axial load in the pillar is to be obtained, in kN, from the following formula:

$$F_A = A_D(\gamma_{S2} p_S + \gamma_{W2} p_W) + \sum_i r(\gamma_{S2} Q_{i,S} + \gamma_{W2} Q_{i,W})$$

where:

A_D : Area, in m², of the portion of the deck or the platform supported by the pillar considered

r : Coefficient which depends on the relative position of each pillar above the one considered, to be taken equal to:
- $r = 1,0$ for the pillar considered
- $r = 0,9$ for the pillar immediately above that considered
- $r = 0,9^{i}$ for the i^{th} pillar of the line above the pillar considered, to be taken not less than 0,478

$Q_{i,S}$, $Q_{i,W}$: Still water and wave load, respectively, in kN, from the i^{th} pillar of the line above the pillar considered, if any.

5.2.2 Critical column buckling stress of pillars

The critical column buckling stress of pillars is to be obtained, in N/mm², from the following formulae:

$$\sigma_{cB} = \sigma_{E1} \qquad \text{for} \quad \sigma_{E1} \le \frac{R_{eH}}{2}$$

$$\sigma_{cB} = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_{E1}}\right) \qquad \text{for} \quad \sigma_{E1} > \frac{R_{eH}}{2}$$

where:

σ_{E1} : Euler column buckling stress, to be obtained, in N/mm², from the following formula:

$$\sigma_{E1} = \pi^2 E \frac{I}{A(f\ell)^2} 10^{-4}$$

I : Minimum net moment of inertia, in cm⁴, of the pillar

A : Net cross-sectional area, in cm², of the pillar

ℓ : Span, in m, of the pillar

f : Coefficient, to be obtained from Tab 11.

Table 11 : Coefficient f

	Both ends fixed	One end fixed, one end pinned	Both ends pinned
Boundary conditions of the pillar			Coefficient f	$f = 0,5$	$f = \frac{\sqrt{2}}{2}$	$f = 1,0$

5.2.3 Critical torsional buckling stress of built-up pillars

The critical torsional buckling stress of built-up pillars is to be obtained, in N/mm², from the following formulae:

$$\sigma_{cT} = \sigma_{E2} \qquad \text{for} \quad \sigma_{E2} \le \frac{R_{eH}}{2}$$

$$\sigma_{cT} = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_{E2}}\right) \qquad \text{for} \quad \sigma_{E2} > \frac{R_{eH}}{2}$$

where:

σ_{E2} : Euler torsional buckling stress, to be obtained, in N/mm², from the following formula:

$$\sigma_{E2} = \frac{\pi^2 E I_w}{10^4 I_p \ell^2} + 0,41 E \frac{I_t}{I_p}$$

I_w : Net sectorial moment of inertia of the pillar, to be obtained, in cm⁶, from the following formula:

$$I_w = \frac{t_f b_f^3 h_w^2}{24} 10^{-6}$$

h_W : Web height of built-up section, in mm

t_W : Net web thickness of built-up section, in mm

b_F : Face plate width of built-up section, in mm

t_F : Net face plate thickness of built-up section, in mm

I_p : Net polar moment of inertia of the pillar, to be obtained, in cm⁴, from the following formula:

$I_P = I_{XX} + I_{YY}$

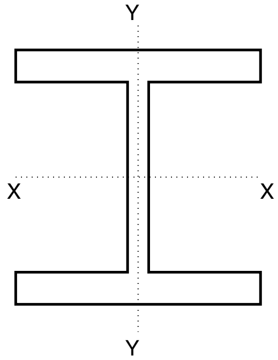
I_{XX} : Net moment of inertia about the XX axis of the pillar section (see Fig 4)

I_{YY} : Net moment of inertia about the YY axis of the pillar section (see Fig 4)

I_t : St. Venant's net moment of inertia of the pillar, to be obtained, in cm^4, from the following formula:

$$I_t = \frac{1}{3}[h_w t_w^3 + 2 b_f t_f^3] 10^{-4}$$

Figure 4 : Reference axes for the calculationof the moments of inertia of a built-up section



5.2.4 Critical local buckling stress of built-up pillars

The critical local buckling stress of built-up pillars is to be obtained, in N/mm^2, from the following formulae:

$$\sigma_{cL} = \sigma_{E3} \qquad \text{for} \quad \sigma_{E3} \le \frac{R_{eH}}{2}$$

$$\sigma_{cL} = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_{E3}}\right) \qquad \text{for} \quad \sigma_{E3} > \frac{R_{eH}}{2}$$

where:

σ_{E3} : Euler local buckling stress, to be taken equal to the lesser of the values obtained, in N/mm^2, from the following formulae:

$$\sigma_{E3} = 78\left(\frac{E}{206000}\right)\left(\frac{t_W}{h_W}\right)^2 10^4$$

$$\sigma_{E3} = 32\left(\frac{E}{206000}\right)\left(\frac{t_F}{b_F}\right)^2 10^4$$

t_W, h_W, t_F, b_F : Dimensions, in mm, of the built-up section, defined in [5.2.3].

5.2.5 Critical local buckling stress of pillars having hollow rectangular section

The critical local buckling stress of pillars having hollow rectangular section is to be obtained, in N/mm^2, from the following formulae:

$$\sigma_{cL} = \sigma_{E4} \qquad \text{for} \quad \sigma_{E4} \le \frac{R_{eH}}{2}$$

$$\sigma_{cL} = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_{E4}}\right) \qquad \text{for} \quad \sigma_{E4} > \frac{R_{eH}}{2}$$

where:

σ_{E4} : Euler local buckling stress, to be taken equal to the lesser of the values obtained, in N/mm^2, from the following formulae:

$$\sigma_{E4} = 78\left(\frac{E}{206000}\right)\left(\frac{t_2}{b}\right)^2 10^4$$

$$\sigma_{E4} = 78\left(\frac{E}{206000}\right)\left(\frac{t_1}{h}\right)^2 10^4$$

b : Length, in mm, of the shorter side of the section

t_2 : Net web thickness, in mm, of the shorter side of the section

h : Length, in mm, of the longer side of the section

t_1 : Net web thickness, in mm, of the longer side of the section.

5.2.6 Checking criteria

The net scantlings of the pillar loaded by the compression axial stress F_A defined in [5.2.1] are to comply with the formulae in Tab 12.

Table 12 : Buckling check of pillars subject to compression axial load

Pillar cross-section	Column buckling check	Torsional buckling check	Local buckling check	Geometric condition
Built-up 	$\frac{\sigma_{cB}}{\gamma_R\gamma_m} \geq 10\frac{F_A}{A}$	$\frac{\sigma_{cT}}{\gamma_R\gamma_m} \geq 10\frac{F_A}{A}$	$\frac{\sigma_{cL}}{\gamma_R\gamma_m} \geq 10\frac{F_A}{A}$	$\frac{b_F}{t_F} \leq 40$
Hollow tubular 	$\frac{\sigma_{cB}}{\gamma_R\gamma_m} \geq 10\frac{F_A}{A}$	Not required	Not required	$\frac{d}{t} \leq 55$ $t \geq 5{,}5$ mm
Hollow rectangular 	$\frac{\sigma_{cB}}{\gamma_R\gamma_m} \geq 10\frac{F_A}{A}$	Not required	$\frac{\sigma_{cL}}{\gamma_R\gamma_m} \geq 10\frac{F_A}{A}$	$\frac{b}{t_2} \leq 55$ $\frac{h}{t_1} \leq 55$ $t_1 \geq 5{,}5$ mm $t_2 \geq 5{,}5$ mm

Note 1:

σ_{cB} : Critical column buckling stress, in N/mm², defined in [5.2.2]
σ_{cT} : Critical torsional buckling stress, in N/mm², defined in [5.2.3]
σ_{cL} : Critical local buckling stress, in N/mm², defined in [5.2.4] for built-up section or in [5.2.5] for hollow rectangular section
γ_R : Resistance partial safety factor, to be taken equal to:
- 1,15 for column buckling
- 1,05 for torsional and local buckling

F_A : compression axial load in the pillar, in kN, defined in [5.2.1]
A : Net sectional area, in cm², of the pillar.

5.2.7 Contact pressure

At connections between pillars and decks, it is to be checked that the contact pressure σ_C, in N/mm2, complies with the following criteria:

$\sigma_c \leq 0{,}8\ R_{eH}$

where:

$\sigma_c = 10F_A/A_C$

with:

F_A : Compression axial load in the pillar, in kN
A_C : Contact area between the pillar and the deck structural members, in cm²
R_{eH} : Smallest of the assembled elements yield stress, in N/mm².

5.3 Buckling of pillars subjected to compression axial load and bending moments

5.3.1 Checking criteria

In addition to the requirements in [5.2], the net scantlings of the pillar loaded by the compression axial load and bending moments are to comply with the following formula:

$$10F\left(\frac{1}{A} + \frac{\Phi e}{w_P}\right) + \left(10^3\frac{M_{max}}{w_P}\right) \leq \frac{R_{eH}}{\gamma_R\gamma_m}$$

where:

F : Compression load, in kN, acting on the pillar

A : Net cross-sectional area, in cm², of the pillar

e : Eccentricity, in cm, of the compression load with respect to the centre of gravity of the cross-section

$$\Phi = \frac{1}{1 - \frac{F}{\sigma_{E1} A}}$$

σ_{E1} : Euler column buckling stress, in N/mm², defined in [5.2.2]

w_P : Minimum net section modulus, in cm³, of the cross-section of the pillar

$M_{max} = Max\ (M_1\ ;\ M_2\ ;\ M_0)$

M_1 : Bending moment, in kN.m, at the upper end of the pillar

M_2 : Bending moment, in kN.m, at the lower end of the pillar

$$M_0 = \frac{0{,}5(\sqrt{1 + t^2})(M_1 + M_2)}{\cos(u)}$$

$$u = 0{,}5\pi\sqrt{\frac{F}{\sigma_{E1} A}}$$

$$t = \frac{1}{\tan(u)}\left(\frac{M_2 - M_1}{M_2 + M_1}\right)$$

6 Dynamic analysis of main weapon mount supporting structure

6.1 Application

6.1.1 The requirements of this Article apply for the dynamic analysis of main weapon mount supporting structure subjected to dynamic loads.

6.2 Dynamic analysis

6.2.1 Analysis criteria

The dynamic analysis of main weapon mount supporting structure is to be based on direct calculations performed through three-dimensional models.

The criteria adopted for structural modelling are to comply with the requirements specified in Ch 7, App 1.

In any case, the mesh accuracy is to be such that the stiffness and the mass distribution of the model elements of the mount supporting structure and of the surrounding hull structure properly represent those of the actual structure.

Dynamic analysis of special weapons, such as vertical missile launching system (VLS) and rocket or missile launching system with elevation and slewing capabilities, are to be considered by the Society on a case-by-case basis. When deemed necessary, the Society may also require that finite element model transient analyses be performed.

6.2.2 Normal mode analysis

It is to be checked that each normal mode frequency f_{Ni}, in Hz, of the weapon mount supporting structure is in compliance with one of the following formulae:

$f_{Ni} < 0{,}8\ f_{E,MIN}$

$f_{Ni} > 1{,}2\ f_{E,MAX}$

where:

$F_{E,MIN}$, $F_{E,MAX}$: The lesser and the greater values, in Hz, respectively, among the possible excitations frequencies due to the weapon (e.g. hail) or the propulsion system.

The normal mode calculation method and the number of normal modes to be taken into account are considered by the Society on a case-by-case basis.

When at least one of the normal mode frequencies does not comply with the above formulae, a dynamic analysis is to be carried out according to the requirements in [6.2.3].

6.2.3 Dynamic analysis

It is to be checked that the dynamic effects induced in the weapon mounting supporting structure by the weapon or the propulsion system are within allowable limits, when this is required according to [6.2.2].

The dynamic effects are to be calculated by means of a dynamic analysis aiming at evaluating:

- the response of the weapon system in the time domain to possible excitations due to the weapon (e.g. hail)
- the response amplitude operators (RAOs) of the weapon system versus possible excitations due to the propulsion system.

When the dynamic analysis is based on normal models, their number is, in general, to be such that the modal effective mass is not less than 95% of the mass of the system constituted by the weapon and its mounting supporting structure.

The modal effective mass is defined as:

$$\sum_{i=1}^{N} \gamma_i^2$$

where γ_i is the i^{th} modal participation factor and N is the number of the considered normal modes.

The dynamic analysis criteria and the relevant allowable limits are considered by the Society on a case-by-case basis.

Section 4 Fatigue Check of Structural Details

Symbols

For symbols not defined in this Section, refer to the list at the beginning of this Chapter.

p_W : Wave pressure, in kN/m² (see [2.2])

s : Spacing, in m, of ordinary stiffeners

ℓ : Span, in m, of ordinary stiffeners, measured between the supporting members, see Ch 4, Sec 3, [3.2]

w : Net section modulus, in cm³, of the stiffener, with an attached plating of width b_p, to be calculated as specified in Ch 4, Sec 3, [3.4]

K_h, $K\ell$: Stress concentration factors, defined in Ch 11, Sec 2 for the special structural details there specified

K_F : Fatigue notch factor, defined in [4.3.1]

K_m : Stress concentration factor, taking account of misalignment, defined in [4.3.1]

$\Delta\sigma_{P0}$: Allowable stress range, defined in Article [4].

T_1 : Draught, in m, corresponding to the loading condition considered.

1 General

1.1 Net scantlings

1.1.1 As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

The gross scantlings are obtained as specified in Ch 4, Sec 2.

1.2 Application

1.2.1 Structural details to be checked

The requirements of this Section apply for the fatigue check of special structural details, according to Ch 11, Sec 2.

The Society may require other details to be checked, when deemed necessary on the basis of the detail geometry, tolerances and stress level, in agreement with the Designer.

1.2.2 Categorisation of details

With respect to the method to be adopted to calculate the stresses acting on structural members, the details for which the fatigue check is to be carried out may be grouped as follows:

- details where the stresses are to be calculated through a three-dimensional structural model (e.g. connections between primary supporting members)
- details located at ends of ordinary stiffeners, for which an isolated structural model can be adopted.

1.2.3 Details where the stresses are to be calculated through a three-dimensional structural model

The requirements of Ch 7, App 1, [6] apply, in addition to those from Articles [1] to [5] of this Section.

1.2.4 Details located at ends of ordinary stiffeners

The requirements from Articles [1] to [6] of this Section apply.

1.2.5 Other details

In general, for details other than those in [1.2.2], the stresses are to be calculated through a method agreed by the Society on a case-by-case basis, using the load model defined in Article [2].

The checking criterion in Article [5] is generally to be applied.

1.3 Definitions

1.3.1 Hot spots

Hot spots are the locations where fatigue cracking may occur. They are indicated in the relevant figures of special structural details in Ch 11, Sec 2.

1.3.2 Nominal stress

Nominal stress is the stress in a structural component taking into account macro-geometric effects but disregarding the stress concentration due to structural discontinuities and to the presence of welds (see Fig 1).

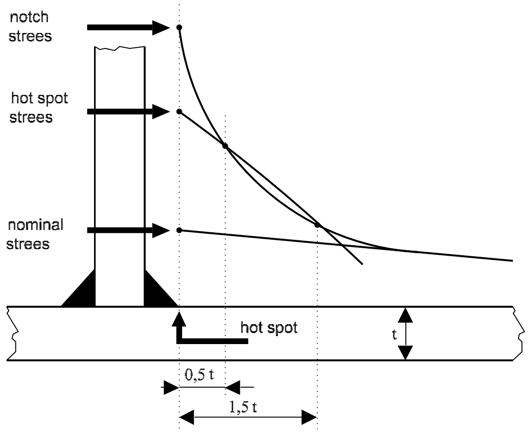
1.3.3 Hot spot stress

Hot spot stress is a local stress at the hot spot taking into account the influence of structural discontinuities due to the geometry of the detail, but excluding the effects of welds (see Fig 1).

1.3.4 Notch stress

Notch stress is a peak stress in a notch such as the root of a weld or the edge of a cut-out. This peak stress takes into account the stress concentrations due to the presence of notches (see Fig 1).

Figure 1 : Nominal, hot spot and notch stresses



1.3.5 Elementary stress range

Elementary stress range is the stress range determined for one of the load cases "a", "b", "c" or "d" (see Ch 5, Sec 4, [2]) and for either of the loading conditions (see Ch 5, Sec 1, [2.4] and Ch 5, Sec 1, [2.5]).

1.3.6 Equivalent stress range

Equivalent stress range is a stress range obtained from a combination of elementary stress ranges, as indicated in [4.3.1] for notch stress and [2.3.1] for hull girder nominal stress.

1.4 Partial safety factors

1.4.1 The partial safety factors to be considered for the fatigue check of structural details are specified in Tab 1.

Table 1 : Fatigue check - Partial safety factors

Partial safety factors covering uncertainties regarding:	Symbol	Value	
		General	Details at ends of ordinary stiffeners
Still water hull girder loads	γ_{S1}	1,00	1,00
Wave hull girder loads	γ_{W1}	1,05	1,15
Still water pressure	γ_{S2}	1,00	1,00
Wave pressure	γ_{W2}	1,10	1,20
Resistance	γ_R	1,02	1,02

2 Load model

2.1 General

2.1.1 Load point

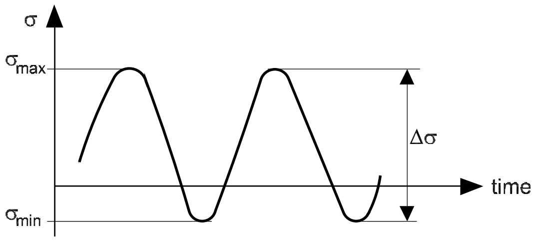
Unless otherwise specified, design loads are to be determined at points defined in:

- Ch 7, Sec 2, [1.3] for ordinary stiffeners
- Ch 7, Sec 3, [1] for primary supporting members.

2.1.2 Local and hull girder loads

The fatigue check is based on the stress range induced at the hot spot by the time variation of local and hull girder loads in each load case "a", "b", "c" and "d" defined in [2.2] for the loading conditions defined in [2.1.4] and [2.1.3] (see Fig 2).

Figure 2 : Stress range



2.1.3 Loading conditions for details where the stresses are to be calculated through a three-dimensional structural model

The most severe full load and operational load conditions for the detail concerned are to be considered in accordance with Ch 5, Sec 1, [2.5].

2.1.4 Loading conditions for details located at ends of ordinary stiffeners

The load distribution is to be considered in accordance with Ch 5, Sec 1, [2.4].

2.1.5 Spectral fatigue analysis

For ships with non-conventional shapes or with restricted navigation, the Society may require a spectral fatigue analysis to be carried out.

In this analysis, the loads and stresses are to be evaluated through long-term stochastic analysis taking into account the characteristics of the ship and the navigation notation.

The load calculations and fatigue analysis are to be submitted to the Society for approval.

2.2 Local lateral pressures

2.2.1 General

The still water and wave lateral pressures induced by the sea, various types of loads and ballast are to be considered.

Lateral pressure is constituted by still water pressure and wave pressure.

2.2.2 Load cases “a-max” and “a-min”, in upright ship condition

The still water sea pressure (p_S) is defined in Ch 5, Sec 5, [1.1.1].

The wave pressure p_W is defined in Tab 2.

No internal inertial pressures are considered.

2.2.3 Load cases “b-max” and “b-min”, in upright ship condition

Still water pressures p_S includes:

- the still water sea pressure defined in Ch 5, Sec 5, [1]
- the still water internal pressure, defined in Ch 5, Sec 6 for the various types of loads and for ballast.

Dynamic pressure p_W is constituted by internal inertial pressures defined in Tab 4.

No sea wave dynamic pressures are considered.

2.2.4 Load cases “c-max” and “c-min”, in inclined ship condition

Still water pressures p_S includes:

- the still water sea pressure defined in Ch 5, Sec 5, [1]
- the still water internal pressure, defined in Ch 5, Sec 6 for the various types of loads and for ballast.

Wave pressure p_W includes:

- the wave pressure obtained from Tab 3
- the inertial pressure obtained from Tab 4 for the various types of loads and ballast.

2.2.5 Load cases “d-max” and “d-min”, in inclined ship condition

Still water pressures p_S includes:

- the still water sea pressure defined in Ch 5, Sec 5, [1]
- the still water internal pressure, defined in Ch 5, Sec 6 for the various types of loads and for ballast.

Wave pressure p_W includes:

- the wave pressure obtained from Tab 3
- the inertial pressure obtained from Tab 4 for the various types of loads and ballast.

Table 2 : Wave pressure in load case "a"

Location	Wave pressure p_W, in kN/m²	
	a-max	a-min
Bottom and sides below the waterline ($z \le T_1$)	$\alpha^{1/4}\rho g\frac{h_1}{2}\left[\frac{T_1+z}{T_1}\right]$	$-\alpha^{1/4}\rho g\frac{h_1}{2}\left[\frac{T_1+z}{T_1}\right]$ without being taken less than $\frac{\gamma_S}{\gamma_W}\rho g(z-T_1)$
Sides above the waterline ($z > T_1$)	$\rho g(T_1+\alpha^{1/4}h_1-z)$	0,0

Note 1:
α : Coefficient equal to T_1/T, but not to be taken greater than 1

Table 3 : Wave pressure in inclined ship conditions (load cases "c" and "d")

Location		Wave pressure p_W, in kN/m² **(1)**	
		c-max / d-max	c-min / d-min
Bottom and sides below the waterline ($z \le T_1$)	$y \ge 0$	$C_{F2}\alpha^{1/4}\rho g h_2\frac{\lvert y\rvert}{B_W}\left[\frac{T_1+z}{T_1}\right]$	$-C_{F2}\alpha^{1/4}\rho g h_2\frac{\lvert y\rvert}{B_W}\left[\frac{T_1+z}{T_1}\right]$ without being taken less than $\frac{\gamma_S}{\gamma_W}\rho g(z-T_1)$
	$y < 0$	$-C_{F2}\alpha^{1/4}\rho g h_2\frac{\lvert y\rvert}{B_W}\left[\frac{T_1+z}{T_1}\right]$ without being taken less than $\frac{\gamma_S}{\gamma_W}\rho g(z-T_1)$	$C_{F2}\alpha^{1/4}\rho g h_2\frac{\lvert y\rvert}{B_W}\left[\frac{T_1+z}{T_1}\right]$
Sides above the waterline ($z > T_1$)	$y \ge 0$	$\rho g\left[T_1+2C_{F2}\alpha^{1/4}\frac{\lvert y\rvert}{B_W}h_2-z\right]$	0,0
	$y < 0$	0,0	$\rho g\left[T_1+2C_{F2}\alpha^{1/4}\frac{\lvert y\rvert}{B_W}h_2-z\right]$

(1) In the formulae giving the wave pressure p_W, the ratio $|y| / B_W$ is not to be taken greater than 0,5.
Note 1:
α : Coefficient equal to T_1/T, but not to be taken greater than 1
C_{F2} : Combination factor, to be taken equal to:
- C_{F2} = 1,0 for load case "c"
- C_{F2} = 0,5 for load case "d"

B_W : Moulded breadth, in m, measured at the waterline at draught T_1, at the hull transverse section considered
h_2 : Reference value, in m, of the relative motion in the inclined ship condition, defined in Ch 5, Sec 3, [3.3.2] and not to be taken greater than the minimum of T_1 and (D – 0,9 T_1).

Table 4 : Inertial pressures

Loads	Load case	Inertial pressures, in kN/m² **(1)**
Liquids	b-max	$p_W = \rho_L[-0,5a_{X1}\ell_B - a_{Z1}(z_{TOP}-z)]$
	b-min	$p_W = \rho_L[0,5a_{X1}\ell_B + a_{Z1}(z_{TOP}-z)]$
	c-max d-max	$p_W = \rho_L[0,7C_{FA}a_{Y2}(y-y_H)+(-0,7C_{FA}a_{Z2}-g)(z-z_H)+g(z-z_{TOP})]$
	c-min d-min	$p_W = \rho_L[-0,7C_{FA}a_{Y2}(y-y_H)+(0,7C_{FA}a_{Z2}-g)+g(z-z_{TOP})]$

(1) The symbols used in the formulae of inertial pressures are defined in Ch 5, Sec 6.
Note 1:
C_{FA} : Combination factor, to be taken equal to:
C_{FA} = 0,7 for load case "c"
C_{FA} = 1,0 for load case "d"

2.3 Nominal hull girder normal stresses

2.3.1 The nominal hull girder normal stresses are obtained, in N/mm², from the following formulae:

- for members contributing to the hull girder longitudinal strength:

$$\sigma_h = \gamma_{S1}\sigma_{SW} + \gamma_{W1}(C_{FV}\sigma_{WV} + C_{FH}\sigma_{WH})$$

- for members not contributing to the hull girder longitudinal strength:

$\sigma_h = 0$

where:

σ_{SW} : Still water hull girder normal stresses, in N/mm², taken equal to:

$$\sigma_{SW} = \frac{M_{SW}}{I_Y}(z-N)10^{-3}$$

M_{SW} : Still water bending moment for the loading condition considered

σ_{WV}, σ_{WH}: Hull girder normal stresses, in N/mm², defined in Tab 5

C_{FV}, C_{FH} : Combination factors defined in Tab 6.

Table 5 : Nominal hull girder normal stresses

Load case	σ_{WV}, in N/mm²	σ_{WH}, in N/mm²
a-max	$\frac{0,625 M_{WV,H}}{I_Y}(z-N)10^{-3}$	0
a-min	$\frac{0,625 M_{WV,S}}{I_Y}(z-N)10^{-3}$	0
b-max b-min	0	0
c-max d-max	0	$-\frac{0,625 M_{WH}}{I_Z}y10^{-3}$
c-min d-min	0	$\frac{0,625 M_{WH}}{I_Z}y10^{-3}$

Table 6 : Combination factors C_{FV}, C_{FH} and $C_{F\Omega}$

Load case	C_{FV}	C_{FH}	$C_{F\Omega}$
"a"	1,0	0	0
"b"	1,0	0	0
"c"	0,4	1,0	1,0
"d"	0,4	1,0	0

3 Fatigue damage ratio

3.1 General

3.1.1 Elementary fatigue damage ratio

The elementary fatigue damage ratio is to be obtained from the following formula:

$$D_{ij} = \frac{N_t}{K_p}\frac{(\Delta\sigma_{N,ij})^3}{(-\ln p_R)^{3/\xi}}\mu_{ij}\,\Gamma_C\left[\frac{3}{\xi}+1\right]$$

where:

$\Delta\sigma_{N,ij}$: Elementary notch stress range, in N/mm², defined in [4.3.1]

$$\mu_{ij} = 1 - \frac{\Gamma_N\frac{3}{\xi}+1, \nu_{ij} - \Gamma_N\frac{5}{\xi}+1, \nu_{ij}\nu_{ij}^{-2/\xi}}{\Gamma_C\frac{3}{\xi}+1}$$

$\xi = \xi_0 K_2$

$\xi_0 = \frac{73 - 0,07L}{60}$ without being less than 0,85

K_2 : For fatigue calculation in way of connection of longitudinals on transverses, K_2 is given below, without being taken less than 0,9:

$$K_2 = 1,04 - 0,14\frac{|z - T_1|}{D - T_1}$$

K_2 is to be taken equal to 1 for all other fatigue calculations

T_1 : Draught, in m, corresponding to the loading condition "Full load" or "Operational load"

$$\nu_{ij} = -\left(\frac{S_q}{\Delta\sigma_{N,ij}}\right)^{\xi}\ln p_R$$

$$S_q = (K_p 10^{-7})^{1/3}$$

$$K_p = 5,802\left(\frac{22}{t}\right)^{0,9}10^{12}$$

t : Net thickness, in mm, of the element under consideration not being taken less than 22 mm

N_t : Number of cycles corresponding to the design fatigue life T_{FL}, to be taken equal to:

$$N_t = \frac{31,55 \cdot \alpha_0 \cdot T_{FL}}{T_A}10^6$$

α_0 : Sailing factor, taken equal to 0,80, except if otherwise specified

T_A : Average period, in seconds, to be taken equal to: $T_A = 4 \log L$

T_{FL} : Increased design fatigue life, in years, having a value between 30 and 40

$p_R = 10^{-5}$

$\Gamma_N[X+1,\nu_{ij}]$: Incomplete Gamma function, calculated for $X = 3 / \xi$ or $X = 5 / \xi$ and equal to:

$$\Gamma_N[X+1,\nu_{ij}] = \int_0^{\nu_{ij}} t^X e^{-t} dt$$

Values of $\Gamma_N[X+1,\nu_{ij}]$ are also indicated in Tab 7. For intermediate values of X and ν_{ij}, Γ_N may be obtained by linear interpolation

$\Gamma_C[X+1]$: Complete Gamma function, calculated for $X = 3/\xi$, equal to:

$$\Gamma_C[X+1] = \int_0^{\infty} t^X e^{-t} dt$$

Values of $\Gamma_C[X+1]$ are also indicated in Tab 8. For intermediate values of X, Γ_C may be obtained by linear interpolation.

3.1.2 Cumulative damage ratio

The cumulative damage ratio is to be obtained from the following formula:

$D = K_{cor} [\alpha D_F + (1 - \alpha) D_B]$

where:

K_{cor} : Corrosion factor, taken equal to:

- $K_{cor} = 1,0$ for dry compartments
- $K_{cor} = 1,1$ for ballast tanks having an effective coating protection
- $K_{cor} = 1,5$ for cargo oil tanks

α : coefficient to be taken equal to 0,75

D_F : Cumulative damage ratio for ship in "Full load" condition, taken equal to:

$$D_F = \frac{1}{6}D_{aF} + \frac{1}{6}D_{bF} + \frac{1}{3}D_{cF} + \frac{1}{3}D_{dF}$$

D_B : Cumulative damage ratio for ship in "Operational load" condition, taken equal to:

$$D_B = \frac{1}{3}D_{aB} + \frac{1}{3}D_{bB} + \frac{1}{3}D_{cB}$$

D_{aF}, D_{bF}, D_{cF}, D_{dF} : Elementary damage ratios for load cases "a", "b", "c" and "d", respectively, in "Full load" condition, defined in [3.1.1]

D_{aB}, D_{bB}, D_{cB} : Elementary damage ratios for load cases "a", "b", and "c", respectively, in "Operational load" condition, defined in [3.1.1].

Table 7 : Function Γ_N [X+1, ν_{ij}]

X	ν_{ij} = 1,5	ν_{ij} = 2,0	ν_{ij} = 2,5	ν_{ij} = 3,0	ν_{ij} = 3,5	ν_{ij} = 4,0	ν_{ij} = 4,5

4 Stress range

4.1 General

4.1.1 Calculation point

Unless otherwise specified, stresses are to be determined at the hot spots indicated, for each detail, in the relevant figures in Ch 11, Sec 2.

4.1.2 Stress components

For the details in [1.2.2], the stresses to be used in the fatigue check are the normal stresses in the directions indicated, for each detail, in the relevant figures in Ch 11, Sec 2.

Where the fatigue check is required for details other than those in [1.2.2], the stresses to be used are the principal stresses at the hot spots which form the smallest angle with the crack rising surface.

4.2 Hot spot stress range

4.2.1 Elementary hot spot stress range

The elementary hot spot stress range $\Delta\sigma_{G,ij}$ is to be obtained, in N/mm^2, in accordance with:

- Ch 7, App 1, [6] for details where the stresses are to be calculated through a three-dimensional structural models
- [6.2] for details located at ends of ordinary stiffeners.

4.3 Notch stress range

4.3.1 Elementary notch stress range

The elementary notch stress range is to be obtained, in N/mm^2, from the following formula:

$\Delta\sigma_{N,ij} = K_{C,ij}\ \Delta\sigma_{N0,ij}$

with:

$\Delta\sigma_{N0,ij} = 0{,}7\ K_F\ K_m\ \Delta\sigma_{G,ij}$

Table 9 : Weld coefficient λ

Weld configuration	Coefficient λ	
	Grind welds	Other cases
Butt joints:		
• Stresses parallel to weld axis		
- full penetration	1,85	2,10
- partial penetration	1,85	2,10
• Stresses perpendicular to weld axis		
- full penetration	2,10	2,40
- partial penetration	3,95	4,50
T joints:		
• Stresses parallel to weld axis; fillet weld and partial penetration	1,60	1,80
• Stresses perpendicular to weld axis and in plane of continuous element **(1)**; fillet weld and partial penetration	1,90	2,15
• Stresses perpendicular to weld axis and in plane of welded element; fillet weld and partial penetration	3,95	4,50
Cruciform joints:		
• Full penetration	1,85	2,10
• Partial penetration	2,05	2,35
(1) This case includes the hot spots indicated in the sheets of special structural details in Ch 11, Sec 2 relevant to the connections of longitudinal ordinary stiffeners with transverse primary supporting members.		

where:

K_F : Fatigue notch factor, equal to:

$$K_F = \lambda \sqrt{\frac{\theta}{30}}$$

for flame-cut edges, K_F may be taken equal to 2,0

λ : Coefficient depending on the weld configuration, and given in Tab 9

θ : Mean weld toe angle, in degrees, without being taken less than 30°. Unless otherwise specified, θ may be taken equal to:

- 30° for butt joints
- 45° for T joints or cruciform joints

K_m : Stress concentration factor, taking account of misalignment, defined in Tab 10, and to be taken not less than 1

$\Delta\sigma_{G,ij}$: Elementary hot spot stress range, defined in [4.2.1]

$$K_{C,ij} = \frac{0,4R_{eH}}{\Delta\sigma_{N0,ij}} + 0,6 \quad \text{with} \quad 0,8 \le K_{C,ij} \le 1$$

Table 10 : Stress concentration factor K_m for misalignment

Geometry	K_m **(1)**
Axial misalignment between flat plates 	$1 + \frac{3(m - m_0)}{t}$
Axial misalignment between flat plates of different thicknesses 	$1 + \frac{6(m - m_0)}{t_1} \frac{t_1^{3/2}}{t_1^{3/2} + t_2^{3/2}}$
Axial misalignment in fillet welded cruciform joints 	$1 + \frac{m - m_0}{t + h}$

(1) When the actual misalignment m is lower than the permissible misalignment m_0, K_m is to be taken equal to 1.

Note 1:

m : Actual misalignment between two abutting members

m_0 : Permissible misalignment for the detail considered, given in Ch 11, Sec 2, or any other agreed document according to [1.2.1].

5 Checking criterion

5.1 Damage ratio

5.1.1 The cumulative damage ratio D, calculated according to [3.1.2], is to comply with the following criterion:

$$D \le \frac{1}{\gamma_R}$$

6 Structural details located at ends of ordinary stiffeners

6.1 General

6.1.1 For the fatigue check of connections located at ends of ordinary stiffeners, the elementary hot spot stress range $\Delta\sigma_{G,ij}$ may be calculated as indicated in [6.2].

6.2 Determination of elementary hot spot stress range

6.2.1 Nominal local stress

For each load case "a", "b", "c" and "d", "-max" and "-min", the nominal local stress $\sigma\ell$ applied to the ordinary stiffener, is to be obtained, in N/mm², from the following formula:

$$\sigma_\ell = \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{12 w}\left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$$

where:

w : Net section modulus, in cm³, of the stiffener, with an attached plating of width b_p, to be calculated as specified in Ch 4, Sec 3, [3.4]

s : Spacing, in m, of ordinary stiffeners

ℓ : Span, in m, of ordinary stiffeners, measured between the supporting members, see Ch 4, Sec 3, [3.2]

β_b : Coefficient to be taken as follows:

- $\beta_b = 1,0$ in the case of an ordinary stiffener without brackets at ends
- $\beta_b = \beta_{b1}$ defined in Ch 7, Sec 2, [3.4.3], in the case of an ordinary stiffener with a bracket of length not greater than 0,2 ℓ at one end
- $\beta_b = \beta_{b2}$ defined in Ch 7, Sec 2, [3.4.4], in the case of an ordinary stiffener with equal brackets of length not greater than 0,2 ℓ at ends.

6.2.2 Elementary hot spot stress range

For each load case "a", "b", "c" and "d", the elementary hot spot stress range $\Delta\sigma_{G,ij}$ is to be obtained, in N/mm², from the following formula:

$$\Delta\sigma_{G,\,ij} = |\sigma_{G\,(i\text{-}max)} - \sigma_{G\,(i\text{-}min)}| + K\ell\ \Delta\sigma_{DEF,\,ij}$$

where:

$$\sigma_{G\,(i\text{-}max)} = K_N\,(K_h\,\sigma_h + K\ell\,K_S\,\sigma\ell)_{(i\text{-}max)}$$

$$\sigma_{G\,(i\text{-}min)} = K_N\,(K_h\,\sigma_h + K\ell\,K_S\,\sigma\ell)_{(i\text{-}min)}$$

$\Delta\sigma_{DEF,\,ij}$: Nominal stress range due to the local deflection of the ordinary stiffener to be obtained, in N/mm², from the following formula:

$$\Delta\sigma_{DEF,ij} = \frac{4(\Delta\delta)EI}{w\ell^2}10^{-5}$$

σ_h : Nominal hull girder stress for the load case "i-max" or "i-min" considered, to be determined as indicated in [2.3.1]

$\sigma\ell$: Nominal local stress for the load case "i-max" or "i-min" considered, to be determined as indicated in [6.2.1]

K_N : Coefficient taking account of North Atlantic navigation, taken equal to 1

K_h , $K\ell$: Geometrical stress concentration factors for overall hull girder stress and local stress, as given in Pt B, Ch 11, App 2

K_S : Coefficient taking account of the stiffener section geometry, equal to:

$$K_S = 1 + \left[\frac{t_f(a^2 - b^2)}{2 w_B}\right]\left[1 - \frac{b}{a+b}\left(1 + \frac{w_B}{w_A}\right)\right]10^{-3}$$

a, b : Eccentricities of the stiffener, in mm, defined in Fig 3

Bulb sections may be taken as equivalent to an angle profile, as defined in Ch 4, Sec 3, [3.1.2] with:

$a = 0,75\ b_f$

$b = 0,25\ b_f$

t_f : Face plate net thickness, in mm

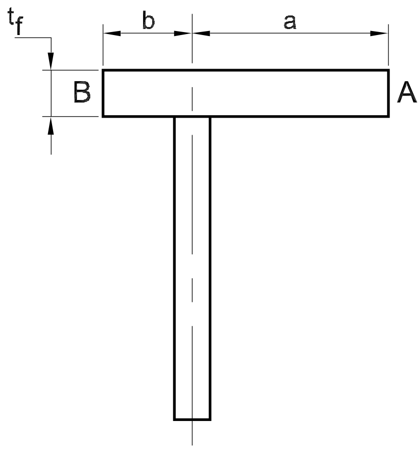
b_f : Face plate width, in mm

w_A, w_B : Net section moduli of the stiffener, in cm^3, in A and B, respectively, about its vertical axis and without attached plating

$\Delta\delta$: Local range of deflection, in mm, of the ordinary stiffener (total amplitude of vertical deflection between the two adjacent primary members supporting the ordinary stiffener under consideration)

I : Net moment of inertia, in cm^4, of the ordinary stiffener with an attached plating of width b_p, to be calculated as specified in Ch 4, Sec 3, [3.4].

Figure 3 : Geometry of a stiffener section



Appendix 1 Analyses Based on Three-Dimensional Models

Symbols

For symbols not defined in this Appendix, refer to the list at the beginning of this Chapter.

ρ : Sea water density, taken equal to 1,025 t/m^3

g : Gravity acceleration, in m/s^2: g = 9,81 m/s^2

h_1 : Reference values of the ship relative motions in the upright ship condition, defined in Ch 5, Sec 3, [3.3]

h_2 : Reference values of the ship relative motions in the inclined ship conditions, defined in Ch 5, Sec 3, [3.3]

$\alpha = \frac{T_1}{T}$

T_1 : draught, in m, corresponding to the loading condition considered

M_{SW} : Still water bending moment, in kN.m, at the hull transverse section considered

M_{WV} : Vertical wave bending moment, in kN.m, at the hull transverse section considered, defined in Ch 5, Sec 2, [3.1], having the same sign as M_{SW}

Q_{SW} : Still water shear force, in kN, at the hull transverse section considered

Q_{WV} : Vertical wave shear force, in kN, at the hull transverse section considered, defined in Ch 5, Sec 2, [3.4], having:

- where M_{WV} is positive (hogging condition):
  - a positive sign for $x < 0,5L$
  - a negative sign for $x \geq 0,5L$
- where M_{WV} is negative (sagging condition):
  - a negative sign for $x < 0,5L$
  - a positive sign for $x \geq 0,5L$

γ_{S1} , γ_{W1} : Partial safety factors, defined in Ch 7, Sec 3.

1 General

1.1 Application

1.1.1 The requirements of this Appendix apply for the analysis criteria, structural modelling, load modelling and stress calculation of primary supporting members which are to be analysed through three-dimensional structural models, according to Ch 7, Sec 3.

The analysis application procedure is shown graphically in Fig 1.

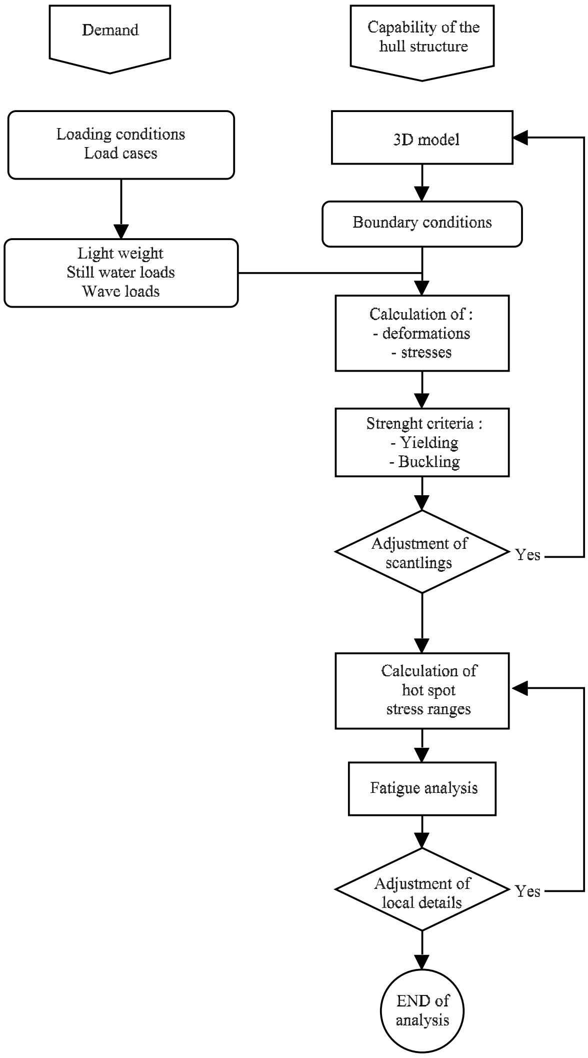
1.1.2 This Appendix deals with that part of the structural analysis which aims at calculating:

- the stresses in the primary supporting members in the midship area and, when necessary, in other areas, which are to be used in the yielding and buckling checks
- the hot spot stress ranges in the structural details which are to be used in the fatigue check.

1.1.3 The yielding and buckling checks of primary supporting members are to be carried out according to Ch 7, Sec 3.

The fatigue check of structural details is to be carried out according to Ch 7, Sec 4.

Figure 1 : Application procedure of the analyses based on three-dimensional models



1.2 Information required

1.2.1 The following information is necessary to perform these structural analyses:

- general arrangement
- capacity plan
- structural plans of the areas involved in the analysis
- longitudinal sections and decks.

2 Analysis criteria

2.1 General

2.1.1 All primary supporting members in the midship regions are normally to be included in the three-dimensional model, with the purpose of calculating their stress level and verifying their scantlings.

When the primary supporting member arrangement is such that the Society can accept that the results obtained for the midship region are extrapolated to other regions, no additional analyses are required. Otherwise, analyses of the other regions are to be carried out.

2.2 Finite element model analysis

2.2.1 For ships more than 150 m in length, finite element models, built according to [3.2] and [3.4], are generally to be adopted.

The analysis of primary supporting members is to be carried out on fine mesh models, as defined in [3.4.3].

2.3 Beam model analysis

2.3.1 Beam models may be adopted in lieu of the finite element models for cases specified in Ch 7, Sec 3, [1.1.2] provided that:

- primary supporting members are not so stout that the beam theory is deemed inapplicable by the Society
- their behaviour is not substantially influenced by the transmission of shear stresses through the shell plating.

In any case, finite element models may need to be adopted when deemed necessary by the Society on the basis of the ship structural arrangement.

2.4 Structural detail analysis

2.4.1 Structural details in Ch 7, Sec 4, [1.2.3], for which a fatigue analysis is to be carried out, are to be modelled as specified in [6].

3 Structural modelling of primary supporting members

3.1 Model construction

3.1.1 Elements

The structural model is to represent the primary supporting members with the plating to which they are connected.

Ordinary stiffeners are also to be represented in the model in order to reproduce the stiffness and inertia of the actual hull girder structure. The way ordinary stiffeners are represented in the model depends on the type of model (beam or finite element), as specified in [3.4] and [3.5].

3.1.2 Net scantlings

All the elements in [3.1.1] are to be modelled with their net scantlings according to Ch 4, Sec 2, [1]. Therefore, also the hull girder stiffness and inertia to be reproduced by the model are those obtained by considering the net scantlings of the hull structures.

3.2 Model extension

3.2.1 The longitudinal extension of the structural model is to be such that:

- the hull girder stresses in the area to be analysed are properly taken into account in the structural analysis
- the results in the areas to be analysed are not influenced by the unavoidable inaccuracy in the modelling of the boundary conditions.

3.2.2 In the case of structural symmetry with respect to the ship centreline longitudinal plane, the hull structures may be modelled over half the ship breadth.

3.3 Finite element modelling criteria

3.3.1 Modelling of primary supporting members

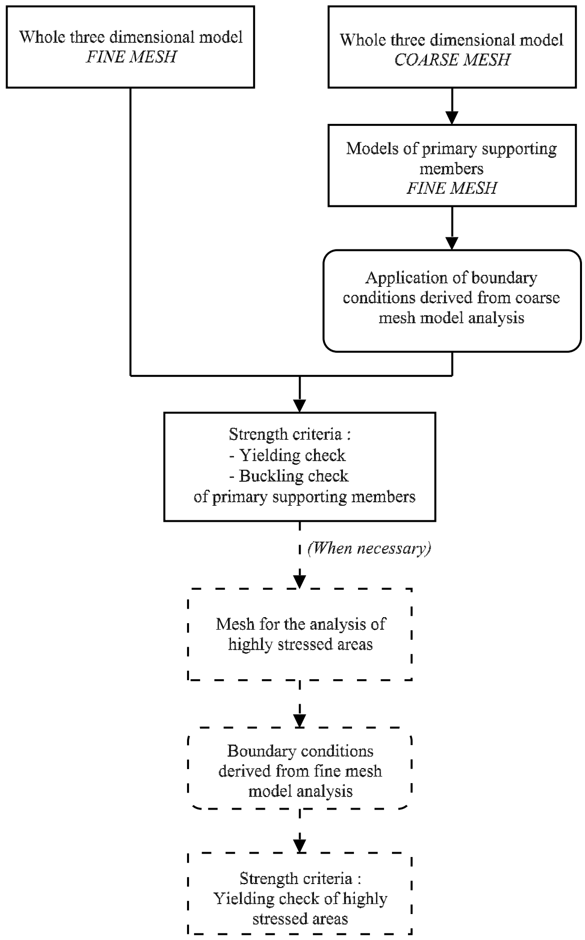
The analysis of primary supporting members based on fine mesh models, as defined in [3.4.3], is to be carried out by applying one of the following procedures (see Fig 2), depending on the computer resources:

- an analysis of the whole three-dimensional model based on a fine mesh
- an analysis of the whole three-dimensional model based on a coarse mesh, as defined in [3.4.2], from which the nodal displacements or forces are obtained to be used as boundary conditions for analyses based on fine mesh models of primary supporting members, e.g.:
  - transverse rings
  - double bottom girders
  - side girders
  - deck girders
  - primary supporting members of transverse bulkheads
  - primary supporting members which appear from the analysis of the whole model to be highly stressed.

3.3.2 Modelling of the most highly stressed areas

The areas which appear from the analyses based on fine mesh models to be highly stressed may be required to be further analysed, using the mesh accuracy specified in [3.4.4].

Figure 2 : Finite element modelling criteria



3.4 Finite element models

3.4.1 General

Finite element models are generally to be based on linear assumptions. The mesh is to be executed using membrane or shell elements, with or without mid-side nodes.

Meshing is to be carried out following uniformity criteria among the different elements.

In general, for some of the most common elements, the quadrilateral elements are to be such that the ratio between the longer side length and the shorter side length does not exceed 4 and, in any case, is less than 2 for most elements. Their angles are to be greater than 60° and less than 120°. The triangular element angles are to be greater than 30° and less than 120°.

Further modelling criteria depend on the accuracy level of the mesh, as specified in [3.4.2] to [3.4.4].

3.4.2 Coarse mesh

The number of nodes and elements is to be such that the stiffness and inertia of the model properly represent those of the actual hull girder structure, and the distribution of loads among the various load carrying members is correctly taken into account.

To this end, the structural model is to be built on the basis of the following criteria:

- ordinary stiffeners contributing to the hull girder longitudinal strength and which are not individually represented in the model are to be modelled by rod elements and grouped at regular intervals
- webs of primary supporting members may be modelled with only one element on their height
- face plates may be simulated with bars having the same cross-section
- the plating between two primary supporting members may be modelled with one element stripe
- holes for the passage of ordinary stiffeners or small pipes may be disregarded
- manholes (and similar discontinuities) in the webs of primary supporting members may be disregarded, but the element thickness is to be reduced in proportion to the hole height and the web height ratio.

In some specific cases, some of the above simplifications may not be deemed acceptable by the Society in relation to the type of structural model and the analysis performed.

3.4.3 Fine mesh

The ship structure may be considered as finely meshed when each longitudinal ordinary stiffener is modelled; as a consequence, the standard size of finite elements used is based on the spacing of ordinary stiffeners.

The structural model is to be built on the basis of the following criteria:

- webs of primary members are to be modelled with at least three elements on their height
- the plating between two primary supporting members is to be modelled with at least two element stripes
- the ratio between the longer side and the shorter side of elements is to be less than 3 in the areas expected to be highly stressed
- the holes for the passage of ordinary stiffeners may be disregarded.

In some specific cases, some of the above simplifications may not be deemed acceptable by the Society in relation to the type of structural model and the analysis performed.

3.4.4 Mesh for the analysis of structural details

The structural modelling is to be accurate; the mesh dimensions are to be such as to enable a faithful representation of the stress gradients. The use of membrane elements is only allowed when significant bending effects are not present; in other cases, elements with general behaviour are to be used.

3.5 Beam models

3.5.1 Beams representing primary supporting members

Primary supporting members are to be modelled by beam elements with shear strain, positioned on their neutral axes, whose inertia characteristics are to be calculated as specified in Ch 4, Sec 3, [4].

3.5.2 Torsional moments of inertia

Whenever the torsional effects of the modelling beams are to be taken into account (e.g. for modelling the double bottom, hopper tanks and lower stools), their net torsional moments of inertia are obtained, in cm^4, from the following formulae:

- for open section beams (see Fig 3):

$$I_T = \frac{1}{3}\sum_i (t_i^3 \ell_i) 10^{-4}$$

- for beams of double skin structures (see Fig 4):

$$I_T = \frac{t_1 t_2 (b_1 + b_2) H_D^2}{2(t_1 + t_2)} 10^{-4}$$

where:

Σi	:	Sum of all the profile segments that constitute the beam section
t_i, ℓ_i	:	Net thickness and length, respectively, in mm, of the i-th profile segment of the beam section
t_1, t_2	:	Net thickness, in mm, of the inner and outer plating, respectively
b_1, b_2	:	Distances, in mm, from the beam considered to the two adjacent beams
H_D	:	Height, in mm, of the double skin.

Figure 3 : Open section beams

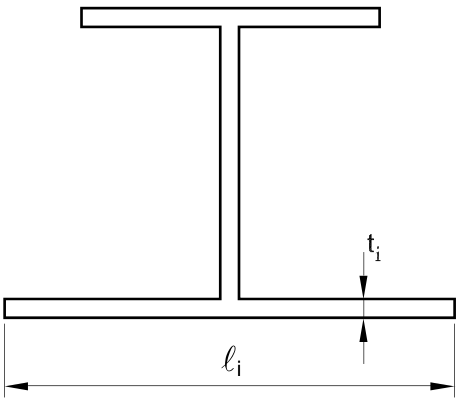


Figure 4 : Beams of double skin structures

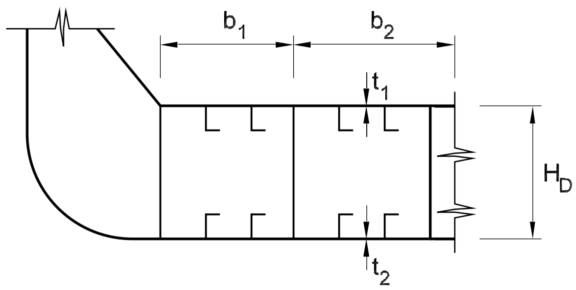


3.5.3 Primary supporting members with variable cross-section

In the case of primary supporting members with variable cross-section, the inertia characteristics of the modelling beams may be assumed as a constant and equal to their average value along the length of the elements themselves.

3.5.4 Modelling of primary supporting member ends

The presence of end brackets may be disregarded; in such case their presence is also to be neglected for the evaluation of the beam inertia characteristics.

Rigid end beams are generally to be used to connect ends of the various primary supporting members, such as:

- floors and side vertical primary supporting members
- bottom girders and vertical primary supporting members of transverse bulkheads
- cross ties and side/longitudinal bulkhead primary supporting members.

3.5.5 Beams representing hull girder characteristics

The stiffness and inertia of the hull girder are to be taken into account by longitudinal beams positioned as follows:

- on deck and bottom in way of side shell and longitudinal bulkheads, if any, for modelling the hull girder bending strength
- on deck, side shell, longitudinal bulkheads, if any, and bottom for modelling the hull girder shear strength.

3.6 Boundary conditions of the whole three-dimensional model

3.6.1 Structural model extended over at least three cargo tank/hold lengths

The whole three-dimensional model is assumed to be fixed at its aft end, while shear forces and bending moments are applied at its fore end to ensure equilibrium (see Article [4]).

At the fore end section, rigid constraint conditions are to be applied to all nodes located on longitudinal members, in such a way that the transverse section remains plane after deformation.

When the hull structure is modelled over half the ship's breadth (see [3.2.2]), in way of the ship centreline longitudinal plane, symmetry or anti-symmetry boundary conditions as specified in Tab 1 are to be applied, depending on the loads applied to the model (symmetrical or anti-symmetrical, respectively).

Table 1 : Symmetry and anti-symmetry conditions in way of the ship centreline longitudinal plane

Boundary conditions	DISPLACEMENTS in directions **(1)**		
	X	Y	Z
Symmetry	free	fixed	free
Anti-symmetry	fixed	free	fixed

Boundary conditions	ROTATION around axes **(1)**		
	X	Y	Z
Symmetry	fixed	free	fixed
Anti-symmetry	free	fixed	free

(1) X, Y and Z directions and axes are defined with respect to the reference co-ordinate system in Ch 1, Sec 2, [10].

4 Load models of primary supporting members

4.1 General

4.1.1 Loading conditions and load cases in intact conditions

The still water and wave loads are to be calculated for the most severe loading conditions as given in the loading manual, with a view to maximizing the stresses in the longitudinal structure and primary supporting members.

The following loading conditions are generally to be considered:

- homogeneous loading conditions at draught T
- non-homogeneous loading conditions at draught T, when applicable
- partial loading conditions at the relevant draught
- ballast conditions at the relevant draught.

The wave local and hull girder loads are to be calculated in the mutually exclusive load cases “a”, “b”, “c” and “d” in Ch 5, Sec 4.

4.1.2 Loading conditions and load cases in flooding conditions

When applicable, the pressures in flooding conditions are to be calculated according to Ch 5, Sec 6, [7].

4.1.3 Lightweight

The lightweight of the modelled portion of the hull is to be uniformly distributed over the length of the model in order to obtain the actual longitudinal distribution of the still water bending moment.

4.1.4 Models extended over half breadth of ship

When the ship is symmetrical with respect to her centreline longitudinal plane and the hull structure is modelled over half the ship breadth, non-symmetrical loads are to be broken down into symmetrical and anti-symmetrical loads and applied separately to the model with symmetry and anti-symmetry boundary conditions in way of the ship centreline longitudinal plane (see [3.6]).

4.2 Local loads

4.2.1 General

Still water loads include:

- the still water sea pressure, defined in Ch 5, Sec 5, [1]
- the still water internal loads, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast.

Wave loads include:

- the wave pressure, defined in [4.2.2] for each load case “a”, “b”, “c” and “d”
- the inertial loads, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast, and for each load case “a”, “b”, “c” and “d”.

4.2.2 Wave loads

The wave pressure at any point of the model is obtained from the formulae in Tab 2 for upright ship conditions (load cases “a” and “b”) and in Tab 3 for inclined ship conditions (load cases “c” and “d”).

4.2.3 Distributed loads

Distributed loads are to be applied to the plating panels.

In the analyses carried out on the basis of membrane finite element models or beam models, the loads distributed perpendicularly to the plating panels are to be applied on the ordinary stiffeners proportionally to their areas of influence. When ordinary stiffeners are not modelled or are modelled with rod elements (see [3.4]), the distributed loads are to be applied to the primary supporting members actually supporting the ordinary stiffeners.

4.2.4 Concentrated loads

When the elements directly supporting the concentrated loads are not represented in the structural model, the loads are to be distributed on the adjacent structures according to the actual stiffness of the structures which transmit them.

In the analyses carried out on the basis of coarse mesh finite element models or beam models, concentrated loads applied in five or more points almost equally spaced inside the same span may be applied as equivalent linearly distributed loads.

Table 2 : Wave pressure in upright ship conditions (load cases "a" and "b")

Location	Wave pressure p_W, in kN/m²	C_1	
		crest	trough **(1)**
Bottom and sides below the waterline with: $z \le T_1 - h$	$C_1 \rho g h e^{\frac{-2\pi(T_1 - z)}{\alpha L}}$	1,0	– 1,0
Sides below the waterline with: $T_1 - h < z \le T_1$	$C_1 \rho g h e^{\frac{-2\pi(T_1 - z)}{\alpha L}}$	1,0	$\frac{z - T_1}{h}$
Sides above the waterline: $z > T_1$	$C_1 \rho g (T_1 + h - z)$	1,0	0,0

(1) The wave pressure for load case "b, trough" is to be used only for the fatigue check of structural details.

Note 1:

$h = \alpha^{1/4} C_{F1} h_1$

C_{F1} : Combination factor, to be taken equal to:
- $C_{F1} = 1,0$ for load case "a"
- $C_{F1} = 0,5$ for load case "b".

Table 3 : Wave pressure in inclined ship conditions (load cases "c" and "d")

Location	Wave pressure p_W, in kN/m²	C_2 (negative roll angle)	
		$y \ge 0$	$y < 0$
Bottom and sides below the waterline with: $z \le T_1 - h$	$C_2 C_{F2} \alpha^{1/4} \rho g \left[\frac{y}{B_W} h_1 e^{\frac{-2\pi(T_1 - z)}{\alpha L}} + A_R y e^{\frac{-\pi(T_1 - z)}{\alpha L}}\right]$	1,0	1,0
Sides below the waterline with: $T_1 - h < z \le T_1$	$C_2 C_{F2} \alpha^{1/4} \rho g \left[\frac{y}{B_W} h_1 e^{\frac{-2\pi(T_1 - z)}{\alpha L}} + A_R y e^{\frac{-\pi(T_1 - z)}{\alpha L}}\right]$	1,0	$\frac{T_1 - z}{h}$
Sides above the waterline: $z > T_1$	$C_2 \rho g \left[T_1 + C_{F2} \alpha^{1/4}\left(\frac{y}{B_W} h_1 + A_R y\right) - z\right]$	1,0	0,0

Note 1:

$h = \alpha^{1/4} C_{F2} h_2$

C_{F2} : Combination factor, to be taken equal to:
- $C_{F2} = 1,0$ for load case "c"
- $C_{F2} = 0,5$ for load case "d"

B_W : Moulded breadth, in m, measured at the waterline at draught T_1, at the hull transverse section considered

A_R : Roll amplitude, defined in Ch 5, Sec 3, [2.4.1].

4.2.5 Cargo in sacks, bales and similar packages

The vertical loads are comparable to distributed loads. The loads on vertical walls may be disregarded.

4.2.6 Other cargoes

The modelling of cargoes other than those mentioned under [4.2.3] to [4.2.5] will be considered by the Society on a case-by-case basis.

4.3 Hull girder loads

4.3.1 The hull girder loads are constituted by:

- the still water and wave vertical bending moments
- the horizontal wave bending moment
- the still water and wave vertical shear forces,

and are to be applied at the model fore end section. The shear forces are to be distributed on the plating according to the theory of bidimensional flow of shear stresses.

These loads are to be applied separately for the following two conditions:

- maximal bending moments at the middle of the central tank/hold: the hull girder loads applied at the fore end section are to be such that the values of the hull girder loads in Tab 4 are obtained
- maximal shear forces in way of the aft transverse bulkhead of the central tank/hold: the hull girder loads applied at the fore end section are to be such that the values of the hull girder loads in Tab 5 are obtained.

Table 4 : Hull girder loads - Maximal bending moments at the middle of the model

Ship condition	Load case	Vertical bending moments at the middle of the model		Horizontal wave bending moment at the middle of the model	Vertical shear forces at the middle of the model	
		Still water	Wave		Still water	Wave
Upright	"a" crest	$\gamma_{S1}\, M_{SW}$	$0,625\, \gamma_{W1}\, M_{WV,H}$	0	0	0
	"a" trough	$\gamma_{S1}\, M_{SW}$	$0,625\, \gamma_{W1}\, M_{WV,S}$	0	0	0
	"b"	$\gamma_{S1}\, M_{SW}$	$0,625\, \gamma_{W1}\, M_{WV,S}$	0	0	0
Inclined	"c"	$\gamma_{S1}\, M_{SW}$	$0,25\, \gamma_{W1}\, M_{WV}$	$0,625\, \gamma_{W1}\, M_{WH}$	$\gamma_{S1}\, Q_{SW}$	$0,25\, \gamma_{W1}\, Q_{WV}$
	"d"	$\gamma_{S1}\, M_{SW}$	$0,25\, \gamma_{W1}\, M_{WV}$	$0,625\, \gamma_{W1}\, M_{WH}$	$\gamma_{S1}\, Q_{SW}$	$0,25\, \gamma_{W1}\, Q_{WV}$
Note 1: Hull girder loads are to be calculated at the middle of the model.						

Table 5 : Hull girder loads - Maximal shear forces in way of the aft bulkhead of the model

Ship condition	Load case	Vertical bending moments in way of the aft bulkhead of the model		Vertical shear forces in way of the aft bulkhead of the model	
		Still water	Wave	Still water	Wave
Upright	"a" crest	$\gamma_{S1}\, M_{SW}$	$0,4\, \gamma_{W1}\, M_{WV}$	$\gamma_{S1}\, Q_{SW}$	$0,625\, \gamma_{W1}\, Q_{WV}$
	"a" trough	$\gamma_{S1}\, M_{SW}$	$0,4\, \gamma_{W1}\, M_{WV}$	$\gamma_{S1}\, Q_{SW}$	$0,625\, \gamma_{W1}\, Q_{WV}$
	"b"	$\gamma_{S1}\, M_{SW}$	$0,4\, \gamma_{W1}\, M_{WV}$	$\gamma_{S1}\, Q_{SW}$	$0,625\, \gamma_{W1}\, Q_{WV}$
Inclined	"c"	$\gamma_{S1}\, M_{SW}$	$0,4\, \gamma_{W1}\, M_{WV}$	$\gamma_{S1}\, Q_{SW}$	$0,25\, \gamma_{W1}\, Q_{WV}$
	"d"	$\gamma_{S1}\, M_{SW}$	$0,4\, \gamma_{W1}\, M_{WV}$	$\gamma_{S1}\, Q_{SW}$	$0,25\, \gamma_{W1}\, Q_{WV}$
Note 1: Hull girder loads are to be calculated in way of the aft bulkhead of the model.					

5 Stress calculation

5.1 Analysis based on finite element models

5.1.1 Stresses induced by local and hull girder loads

Both local and hull girder loads are to be directly applied to the model, as specified in [4.3.1] so that the stresses calculated by the finite element program include the contribution of both local and hull girder loads.

5.1.2 Stress components

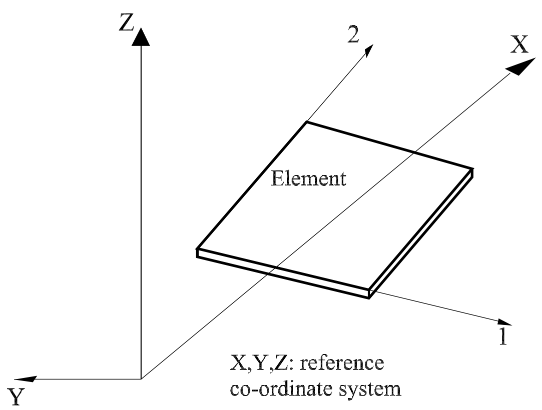
Stress components are generally identified with respect to the element co-ordinate system, as shown, by way of example, in Fig 5. The orientation of the element co-ordinate system may or may not coincide with that of the reference co-ordinate system in Ch 1, Sec 2, [10].

The following stress components are to be calculated at the centroid of each element:

- the normal stresses σ_1 and σ_2 in the directions of the element co-ordinate system axes
- the shear stress τ_{12} with respect to the element co-ordinate system axes
- the Von Mises equivalent stress, obtained from the following formula:

$$\sigma_{VM} = \sqrt{\sigma_1^2 + \sigma_2^2 - \sigma_1 \sigma_2 + 3\tau_{12}^2}$$

Figure 5 : Reference and element co-ordinate systems



5.1.3 Stress calculation points

Stresses are generally calculated by the computer programs for each element. The values of these stresses are to be used for carrying out the checks required.

5.2 Analysis based on beam models

5.2.1 Stresses induced by local and hull girder loads

Since beam models generally have limited extension compared with the ship length, only local loads are directly applied to the structural model, as specified in [4.2]. Therefore, the stresses calculated by the beam program include the contribution of local loads only. Hull girder stresses are to be calculated separately and added to the stresses induced by local loads.

5.2.2 Stress components

The following stress components are to be calculated:

- the normal stress σ_1 in the direction of the beam axis
- the shear stress τ_{12} in the direction of the local loads applied to the beam
- the Von Mises equivalent stress, obtained from the following formula:

$$\sigma_{VM} = \sqrt{\sigma_1^{\ 2} + 3\tau_{12}^{\ 2}}$$

5.2.3 Stress calculation points

Stresses are to be calculated at least in the following points of each primary supporting member:

- in the primary supporting member span where the maximum bending moment occurs
- at the connection of the primary supporting member with other structures, assuming as resistant section that formed by the member, the bracket (if any and if represented in the model) and the attached plating
- at the toe of the bracket (if any and if represented in the model) assuming as resistant section that formed by the member and the attached plating.

The values of the stresses are to be used for carrying out the checks required.

6 Fatigue analysis

6.1 Elementary hot spot stress range calculation

6.1.1 General

The requirements of this Article apply for calculating the elementary hot spot stress range for the fatigue check of structural details at the connections of primary supporting members analysed through a three-dimensional structural model. The fatigue check of these details is to be carried out in accordance with the general requirements of Ch 7, Sec 4, [1] to Ch 7, Sec 4, [5].

The definitions in Ch 7, Sec 4, [1.3] apply.

6.1.2 Net scantlings

The three-dimensional structural model is to be built considering all the structures with their net scantlings according to Ch 4, Sec 2, [1].

6.1.3 Hot spot stresses directly obtained through finite element analysis

Where the structural detail is analysed through a finite element analysis based on a very fine mesh, the elementary hot spot stress range may be obtained as the difference between the maximum and minimum stresses induced by the wave loads in the hot spot considered.

The requirements for:

- the finite element modelling, and
- the calculation of the hot spot stresses and the hot spot stress range

are specified in [6.2].

6.1.4 Hot spot stresses directly obtained through the calculation of nominal stresses

Where the structural detail is analysed through a finite element analysis based on a mesh less fine than that in [6.1.3], the elementary hot spot stress range may be obtained by multiplying the nominal stress range, obtained as the difference between the maximum and minimum nominal stresses induced by the wave loads in the vicinity of the hot spot considered, by the appropriate stress concentration factors.

The requirements for:

- the finite element modelling
- the calculation of the nominal stresses and the nominal stress range
- the stress concentration factors
- the calculation of the hot spot stresses and the hot spot stress range

are specified in [6.3].

6.2 Hot spot stresses directly obtained through finite element analysis

6.2.1 Finite element model

In general, the determination of hot spot stresses necessitates carrying out a very fine mesh finite element analysis, further to a coarser mesh finite element analysis. The boundary nodal displacements or forces obtained from the coarser mesh model are applied to the very fine mesh model as boundary conditions.

The model extension is to be such as to enable a faithful representation of the stress gradient in the vicinity of the hot spot and to avoid it being incorrectly affected by the application of the boundary conditions.

6.2.2 Finite element modelling criteria

The finite element model is to be built according to the following requirements:

- the detail may be considered as being realised with no misalignment
- the size of finite elements located in the vicinity of the hot spot is to be about twice to three times the thickness of the structural member. Where the details is the connection between two or more members of different thickness, the thickness to be considered is that of the thinnest member
- the centre of the first element adjacent to a weld toe is to be located between the weld toe and 0,4 times the thickness of the thinnest structural member connected by the weld
- plating, webs and face plates of primary and secondary members are to be modelled by 4-node thin shell or 8-node solid elements. In the case of a steep stress gradient, 8-node thin shell elements or 20-node solid elements are recommended
- when thin shell elements are used, the structure is to be modelled at mid-face of the plates
- the aspect ratio of elements is to be not greater than 3.

6.2.3 Calculation of hot spot stresses

The hot spot stresses are to be calculated at the centroid of the first element adjacent to the hot spot.

The stress components to be considered are those specified in Ch 7, Sec 4, [3.1.2]. They are to be calculated at the surface of the plate in order to take into account the plate bending moment, where relevant.

Where the detail is the free edge of an opening (e.g. a cutout for the passage of an ordinary stiffener through a primary supporting member), fictitious truss elements with minimal stiffness may needed to be fitted along the edge to calculate the hot spot stresses.

6.2.4 Calculation of the elementary hot spot stress range

The elementary hot spot stress range is to be obtained, in N/mm², from the following formula:

$$\Delta\sigma_{S,ij} = |\sigma_{S,ij,max} - \sigma_{S,ij,min}|$$

where:

$\sigma_{S,ij,max}$, $\sigma_{S,ij,min}$: Maximum and minimum values of the hot spot stress, induced by the maximum and minimum loads, defined in Ch 7, Sec 4, [2.2] and Ch 7, Sec 4, [2.3]

i : Denotes the load case

j : Denotes the loading condition.

6.3 Hot spot stresses directly obtained through calculation of nominal stresses

6.3.1 Finite element model

A finite element is to be adopted, to be built according to the requirements in [3.3] and [3.4]. The areas in the vicinity of the structural details are to be modelled with fine mesh models, as defined in [3.4.3].

6.3.2 Calculation of the elementary nominal stress range

The elementary nominal stress range is to be obtained, in N/mm², from the following formula:

$$\Delta\sigma_{n,ij} = |\sigma_{n,ij,max} - \sigma_{n,ij,min}|$$

where:

$\sigma_{n,ij,max}$, $\sigma_{n,ij,min}$: Maximum and minimum values of the nominal stress, induced by the maximum and minimum loads, defined in Ch 7, Sec 4, [2.2] and Ch 7, Sec 4, [2.3]

i : Denotes the load case

j : Denotes the loading condition.

6.3.3 Calculation of the elementary hot spot stress range

The elementary hot spot stress range is to be obtained, in N/mm², from the following formula:

$\Delta\sigma_{S,ij} = K_S \, \Delta\sigma_{n,ij}$

where:

K_S : Stress concentration factor, defined in Ch 11, Sec 2, [2] for the relevant detail configuration

$\Delta\sigma_{n,ij}$: Elementary nominal stress range, defined in [6.3.2].

Appendix 2 Analyses of Primary Supporting Members Subjected to Wheeled Loads

1 General

1.1 Scope

1.1.1 The requirements of this Appendix apply for the analysis criteria, structural modelling, load modelling and stress calculation of primary supporting members subjected to wheeled loads which are to be analysed through three-dimensional structural models, according to Ch 7, Sec 3.

1.1.2 The purpose of these structural analyses is to determine:

- the distribution of the forces induced by the vertical acceleration acting on wheeled cargoes, among the various primary supporting members of decks, sides and possible bulkheads
- the behaviour of the above primary supporting members under the racking effects due to the transverse forces induced by the transverse acceleration acting on wheeled cargoes, when the number or location of transverse bulkheads are not sufficient to avoid such effects,

and to calculate the stresses in primary supporting members.

The above calculated stresses are to be used in the yielding and buckling checks.

In addition, the results of these analyses may be used, where deemed necessary by the Society, to determine the boundary conditions for finer mesh analyses of the most highly stressed areas.

1.1.3 When the behaviour of primary supporting members under the racking effects, due to the transverse forces induced by the transverse acceleration, is not to be determined, the stresses in deck primary supporting members may be calculated according to the simplified analysis in [6], provided that the conditions for its application are fulfilled (see [6.1]).

1.1.4 The yielding and buckling checks of primary supporting members are to be carried out according to Ch 7, Sec 3.

1.2 Application

1.2.1 The requirements of this Appendix apply to ships whose structural arrangement is such that the following assumptions may be considered as being applicable:

- primary supporting members of side and possible bulkheads may be considered fixed in way of the double bottom (this is generally the case when the stiffness of floors is at least three times that of the side primary supporting members)
- under transverse inertial forces, decks behave as beams loaded in their plane and supported at the ship ends; their effect on the ship transverse rings (side primary supporting members and deck beams) may therefore be simulated by means of elastic supports in the transverse direction or transverse displacements assigned at the central point of each deck beam.

1.2.2 When the assumptions in [1.2.1] are considered by the Society as not being applicable, the analysis criteria are defined on a case-by-case basis, taking into account the ship structural arrangement and loading conditions. In such cases, the analysis is generally to be carried out on the basis of a finite element model of the whole ship, built according to the requirements in Ch 7, App 1, as far as applicable.

1.3 Information required

1.3.1 The following information is necessary to perform these structural analyses:

- general arrangement
- structural plans of the areas involved in the analysis
- longitudinal sections and decks
- characteristics of vehicles loaded: load per axles, arrangement of wheels on axles, tyre dimensions.

1.4 Lashing of vehicles

1.4.1 The presence of lashing for vehicles is generally to be disregarded, but may be given consideration by the Society, on a case-by-case basis, at the request of the interested parties.

2 Analysis criteria

2.1 Finite element model analysis

2.1.1 For ships greater than 200 m in length, finite element models, built according to Ch 7, App 1, [3.4], are generally to be adopted.

The analysis of primary supporting members is to be carried out on fine mesh models, as defined in Ch 7, App 1, [3.4.3].

2.1.2 Areas which appear, from the primary supporting member analysis, to be highly stressed may be required to be further analysed through appropriately meshed structural models, as defined in Ch 7, App 1, [3.4.4].

2.2 Beam model analysis

2.2.1 For ships less than 200 m in length, beam models, built according to Ch 7, App 1, [3.5], may be adopted in lieu of the finite element models in [2.1], provided that:

- primary supporting members are not so stout that the beam theory is deemed inapplicable by the Society
- their behaviour is not substantially influenced by the transmission of shear stresses through the shell plating.

2.2.2 In any case, finite element models may need to be adopted when deemed necessary by the Society on the basis of the ship structural arrangement.

3 Structural modelling of primary supporting members

3.1 Model construction

3.1.1 Elements

The structural model is to represent the primary supporting members with the plating to which they are connected. In particular, the following primary supporting members are to be included in the model:

- deck beams
- side primary supporting members
- primary supporting members of longitudinal and transverse bulkheads, if any
- pillars
- deck beams, deck girders and pillars supporting ramps and deck openings, if any.

3.1.2 Net scantlings

All the elements in [3.1.1] are to be modelled with their net scantlings according to Ch 4, Sec 2, [1].

3.2 Model extension

3.2.1 The structural model is to represent a hull portion which includes the zone under examination and which is repeated along the hull. The non-modelled hull parts are to be considered through boundary conditions as specified in [3.3].

In addition, the longitudinal extension of the structural model is to be such that the results in the areas to be analysed are not influenced by the unavoidable inaccuracy in the modelling of the boundary conditions.

3.2.2 Double bottom structures are not required to be included in the model, based on the assumptions in [1.2.1].

3.3 Boundary conditions of the three-dimensional model

3.3.1 Boundary conditions at the lower ends of the model

The lower ends of the model (i.e. the lower ends of primary supporting members of side and possible bulkheads) are to be considered as being clamped in way of the inner bottom.

3.3.2 Boundary conditions at the fore and aft ends of the model

Symmetry conditions are to be applied at the fore and aft ends of the model, as specified in Tab 1.

Table 1 : Symmetry conditions at the model fore and aft ends

DISPLACEMENTS in directions **(1)**			ROTATION around axes **(1)**		
X	Y	Z	X	Y	Z
fixed	free	free	free	fixed	fixed
(1) X, Y and Z directions and axes are defined with respect to the reference co-ordinate system in Ch 1, Sec 2, [10].					

3.3.3 Additional boundary conditions at the fore and aft ends of models subjected to transverse loads

When the model is subjected to transverse loads, i.e. when the loads in inclined ship conditions (as defined in Ch 5, Sec 4) are applied to the model, the transverse displacements of the deck beams are to be obtained by means of a racking analysis and applied at the fore and aft ends of the model, in way of each deck beam.

For ships with a traditional arrangement of fore and aft parts, a simplified approximation may be adopted, when deemed acceptable by the Society, defining the boundary conditions without taking into account the racking calculation and introducing springs, acting in the transverse direction, at the fore and aft ends of the model, in way of each deck beam (see Fig 1). Each spring, which simulates the effects of the deck in way of which it is modelled, has a stiffness obtained, in kN/m, from the following formula:

$$R_D = \frac{24EJ_Ds_a10^3}{2x^4 - 4L_Dx^3 + L_D^2\left(x^2 + 15{,}6\frac{J_D}{A_D}\right) + L_D^3x}$$

where:

J_D : Net moment of inertia, in m^4, of the average cross-section of the deck, with the attached side shell plating

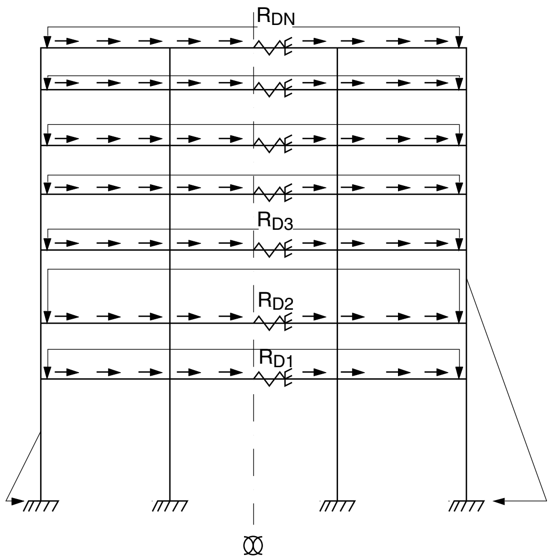
A_D : Net area, in m^2, of the average cross-section of deck plating

s_a : Spacing of side vertical primary supporting members, in m

x : Longitudinal distance, in m, measured from the transverse section at mid-length of the model to any deck end

L_D : Length of the deck, in m, to be taken equal to the ship length. Special cases in which such value may be reduced will be considered by the Society on a case-by-case basis.

Figure 1 : Springs at the fore and aft ends of models subjected to transverse loads



4 Load model

4.1 General

4.1.1 Hull girder and local loads

Only local loads are to be directly applied to the structural model.

The stresses induced by hull girder loads are to be calculated separately and added to the stresses induced by local loads.

4.1.2 Loading conditions and load cases: wheeled cargoes

The still water and wave loads are to be calculated for the most severe loading conditions as given in the loading manual, with a view to maximizing the stresses in primary supporting members.

The loads transmitted by vehicles are to be applied taking into account the most severe axle positions for the ship structures.

The wave local loads and hull girder loads are to be calculated in the mutually exclusive load cases “b” and “d” in Ch 5, Sec 4. Load cases “a” and “c” may be disregarded for the purposes of the structural analyses dealt with in this Appendix.

4.1.3 Loading conditions and load cases: dry uniform cargoes

When the ship decks are also designed to carry dry uniform cargoes, the loading conditions which envisage the transportation of such cargoes are also to be considered. The still water and wave loads induced by these cargoes are to be calculated for the most severe loading conditions, with a view to maximizing the stresses in primary supporting members.

The wave local loads and hull girder loads are to be calculated in the mutually exclusive load cases “b” and “d” in Ch 5, Sec 4. Load cases “a” and “c” may be disregarded for the purposes of the structural analyses dealt with in this Appendix.

4.2 Local loads

4.2.1 General

Still water loads include:

- the still water sea pressure, defined in Ch 5, Sec 5, [1]
- the still water forces induced by wheeled cargoes, defined in Ch 5, Sec 6, Tab 5.

Wave induced loads include:

- the wave pressure, defined in Ch 5, Sec 5, [2] for load cases “b” and “d”
- the inertial forces defined in Ch 5, Sec 6, Tab 5 for load cases “b” and “d”.

When the ship decks are also designed to carry dry uniform cargoes, local loads also include the still water and inertial pressures defined in Ch 5, Sec 6, [4]. Inertial pressures are to be calculated for load cases “b” and “d”.

4.2.2 Tyred vehicles

For the purpose of primary supporting members analyses, the forces transmitted through the tyres may be considered as concentrated loads in the tyre print centre.

The forces acting on primary supporting members are to be determined taking into account the area of influence of each member and the way ordinary stiffeners transfer the forces transmitted through the tyres.

4.2.3 Non-tyred vehicles

The requirements in [4.2.2] also apply to tracked vehicles. In this case, the print to be considered is that below each wheel or wheelwork.

For vehicles on rails, the loads transmitted are to be applied as concentrated loads.

4.2.4 Distributed loads

In the analyses carried out on the basis of beam models or membrane finite element models, the loads distributed perpendicularly to the plating panels are to be applied on the primary supporting members proportionally to their areas of influence.

4.3 Hull girder loads

4.3.1 The normal stresses induced by the hull girder loads in Tab 2 are to be added to the stresses induced in the primary supporting members by local loads.

Table 2 : Hull girder loads

Ship condition	Load case	Vertical bending moments at the middle of the model		Horizontal wave bending moment at the middle of the model
		Still water	Wave	
Upright	“b”	M_{SW}	0,625 $M_{WV,S}$	0
Inclined	“d”	M_{SW}	0,25 M_{WV}	0,625 M_{WH}

Note 1:
M_{SW} : Still water bending moment at the middle of the model, for the loading condition considered
$M_{WV,S}$: Sagging wave bending moments at the middle of the model, defined in Ch 5, Sec 2
M_{WV} : Wave bending moment at the middle of the model, defined in Ch 5, Sec 2, having the same sign as M_{SW}
M_{WH} : Horizontal wave bending moment at the middle of the model, defined in Ch 5, Sec 2.
Note 2: Lower values of wave bending moments may be considered on case-by-case basis, for wheeled loads applied only in specified limited sea states.

5 Stress calculation

5.1 Stresses induced by local and hull girder loads

5.1.1 Only local loads are directly applied to the structural model, as specified in [4.1.1]. Therefore, the stresses calculated by the program include the contribution of local loads only. Hull girder stresses are to be calculated separately and added to the stresses induced by local loads.

5.2 Analysis based on finite element models

5.2.1 Stress components

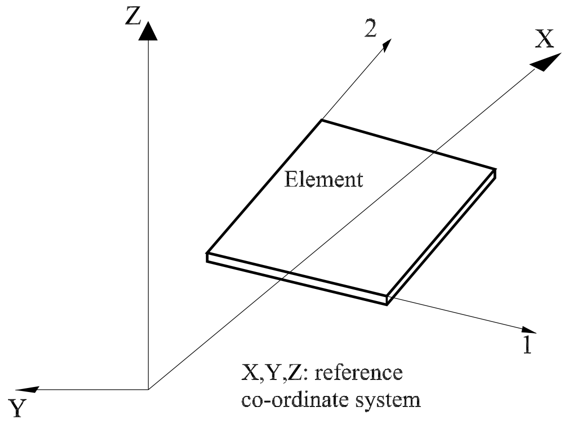
Stress components are generally identified with respect to the element co-ordinate system, as shown, by way of example, in Fig 2. The orientation of the element co-ordinate system may or may not coincide with that of the reference co-ordinate system in Ch 1, Sec 2, [10].

The following stress components are to be calculated at the centroid of each element:

- the normal stresses σ_1 and σ_2 in the directions of element co-ordinate system axes
- the shear stress τ_{12} with respect to the element co-ordinate system axes
- the Von Mises equivalent stress, obtained from the following formula:

$$\sigma_{VM} = \sqrt{\sigma_1^2 + \sigma_2^2 - \sigma_1\sigma_2 + 3\tau_{12}^2}$$

Figure 2 : Reference and element co-ordinate systems



5.2.2 Stress calculation points

Stresses are generally calculated by the computer programs for each element. The values of these stresses are to be used for carrying out the checks required.

5.3 Analysis based on beam models

5.3.1 Stress components

The following stress components are to be calculated:

- the normal stress σ_1 in the direction of the beam axis
- the shear stress τ_{12} in the direction of the local loads applied to the beam
- the Von Mises equivalent stress, obtained from the following formula:

$$\sigma_{VM} = \sqrt{\sigma_1^2 + 3\tau_{12}^2}$$

5.3.2 Stress calculation points

Stresses are to be calculated at least in the following points of each primary supporting member:

- in the primary supporting member span where the maximum bending moment occurs
- at the connection of the primary supporting member with other structures, assuming as resistant section that formed by the member, the bracket (if any and if represented in the model) and the attached plating
- at the toe of the bracket (if any and if represented in the model) assuming as resistant section that formed by the member and the attached plating.

The values of the stresses calculated in the above points are to be used for carrying out the checks required.

6 Grillage analysis of deck primary supporting members

6.1 Application

6.1.1 For the sole purpose of calculating the stresses in deck primary supporting members, due to the forces induced by the vertical accelerations acting on wheeled cargoes, these members may be subjected to the simplified two-dimensional analysis described in [6.2].

This analysis is generally considered as being acceptable for usual structural typology, where there are neither pillar lines, nor longitudinal bulkheads.

6.2 Analysis criteria

6.2.1 Structural model

The structural model used to represent the deck primary supporting members is a beam grillage model.

6.2.2 Model extension

The structural model is to represent a hull portion which includes the zone under examination and which is repeated along the hull. The non-modelled hull parts are to be considered through boundary conditions as specified in [3.3].

6.3 Boundary conditions

6.3.1 Boundary conditions at the fore and aft ends of the model

Symmetry conditions are to be applied at the fore and aft ends of the model, as specified in Tab 1.

6.3.2 Boundary conditions at the connections of deck beams with side vertical primary supporting members

Vertical supports are to be fitted at the nodes positioned in way of the connection of deck beams with side primary supporting members.

The contribution of flexural stiffness supplied by the side primary supporting members to the deck beams is to be simulated by springs, applied at their connections, having rotational stiffness, in the plane of the deck beam webs, obtained, in kN.m/rad, from the following formulae:

- for intermediate decks:

$$R_F = \frac{3E(J_1 + J_2)(\ell_1 + \ell_2)}{\ell_1^2 + \ell_2^2 - \ell_1 \ell_2} 10^{-5}$$

- for the uppermost deck:

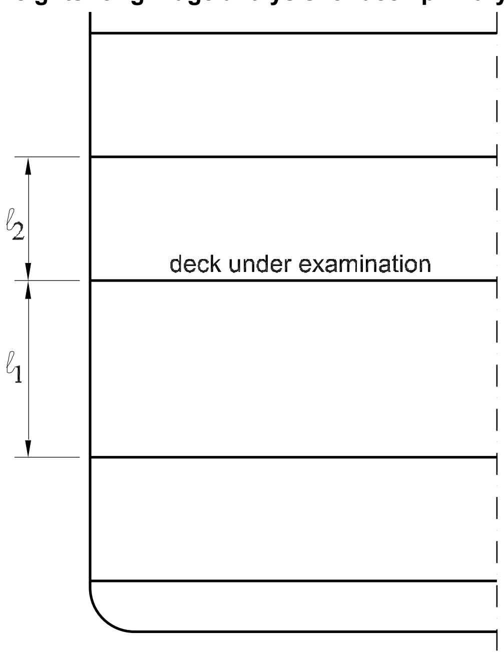
$$R_F = \frac{6EJ_1}{\ell_1} 10^{-5}$$

where:

ℓ_1 , ℓ_2 : Heights of the 'tweendecks, in m, respectively below and above the deck under examination (see Fig 3)

J_1 , J_2 : Net moments of inertia, in cm^4, of side primary supporting members with attached shell plating, relevant to the 'tweendecks, respectively below and above the deck under examination.

Figure 3 : 'Tweendeck heights for grillage analysis of deck primary supporting members



6.4 Load model

6.4.1 Hull girder and local loads are to be calculated and applied to the model according to Article [4].

Wave loads are to be calculated considering load case "b" only.

6.5 Stress calculation

6.5.1 Stress components are to be calculated according to [5.1] and [5.3].

Appendix 3 Analyses Based on Complete Ship Models

Symbols

g : Gravity acceleration, equal to 9,81 m/s^2

Δ : Moulded displacement in seawater, in t

B_{WS} : Breadth at full load waterline, in m, defined in Ch 1, Sec 2, [4.4]

L : Rule length, in m

T_R : Roll period, in s, defined in Ch 5, Sec 3, [2.4.1]

F : Froude's number, defined in Part B, Chapter 5, calculated at the maximum service speed

γ_{S1} , γ_{W1} , γ_{S2} , γ_{W2} : Partial safety factors defined in Ch 7, Sec 3

λ : Wave length, in m.

1 General

1.1 Application

1.1.1 The requirements of this Appendix apply for the analysis criteria, structural modelling, load modelling and stress calculation of primary supporting members which are to be analysed through a complete ship model, according to Ch 7, Sec 3.

1.1.2 This Appendix deals with that part of the structural analysis which aims at calculating the stresses in the primary supporting members and more generally in the hull plating, to be used for yielding and buckling checks.

1.1.3 The yielding and buckling checks of primary supporting members are to be carried out according to Ch 7, Sec 3.

2 Structural modelling

2.1 Model construction

2.1.1 Elements

The structural model is to represent the primary supporting members with the plating to which they are connected.

Ordinary stiffeners are also to be represented in the model in order to reproduce the stiffness and the inertia of the actual hull girder structure.

2.1.2 Net scantlings

All the elements in [2.1.1] are to be modelled with their net scantlings according to Ch 4, Sec 2. Therefore, also the hull girder stiffness and inertia to be reproduced by the model are those obtained by considering the net scantlings of the hull structures.

2.2 Model extension

2.2.1 Superstructures are to be modelled in order to reproduce the correct lightweight distribution.

Long superstructures are to be modelled in order to also reproduce the correct hull global strength, in particular the contribution of each superstructure deck to the hull girder longitudinal strength.

2.2.2 In the case of structural symmetry with respect to the ship centreline longitudinal plane, the hull structures may be modelled over half the ship breadth.

2.3 Finite element modelling criteria

2.3.1 Modelling of primary supporting members

The analyses of primary supporting members are to be based on fine mesh models, as defined in [2.4.2].

Such analyses may be carried out deriving the nodal displacements or forces, to be used as boundary conditions, from analyses of the complete ships based on coarse meshes, as defined in Ch 7, App 1, [3.4.2].

The areas for which analyses based on fine mesh models are to be carried out are the following:

- typical reinforced transverse rings
- typical deck girders
- areas of structural discontinuity (e.g. ramp areas)
- areas in way of typical side and deck openings
- areas of significant discontinuity in primary supporting, member arrangements (e.g. in way of large spaces).

Other areas may be required to be analysed through fine mesh models, where deemed necessary by the Society, depending on the ship structural arrangement and loading conditions as well as the results of the coarse mesh analysis.

2.3.2 Modelling of the most highly stressed areas

The areas which appear from the analyses based on fine mesh models to be highly stressed may be required to be further analysed, using the mesh accuracy specified in Ch 7, App 1, [3.4.4].

2.4 Finite element models

2.4.1 General

Finite element models are generally to be based on linear assumptions. The mesh is to be executed using membrane or shell elements, with or without mid-side nodes.

Meshing is to be carried out following uniformity criteria among the different elements.

In general, for some of the most common elements, the quadrilateral elements are to be such that the ratio between the longer side length and the shorter side length does not exceed 4 and, in any case, is less than 2 for most elements. Their angles are to be greater than 60° and less than 120°. The triangular element angles are to be greater than 30° and less than 120°.

Further modelling criteria depend on the accuracy level of the mesh, as specified from [2.4.2] to [2.4.4].

2.4.2 Coarse mesh

The number of nodes and elements is to be such that the stiffness and the inertia of the model represent properly those of the actual hull girder structure, and the distribution of loads among the various load carrying members is correctly taken into account.

To this end, the structural model is to be built on the basis of the following criteria:

- ordinary stiffeners contributing to the hull girder longitudinal strength and which are not individually represented in the model are to be modelled by rod elements and grouped at regular intervals
- webs of primary supporting members may be modelled with only one element on their height
- face plates may be simulated with bars having the same cross-section
- the plating between two primary supporting members may be modelled with one element stripe
- holes for the passage of ordinary stiffeners or small pipes may be disregarded
- manholes (and similar discontinuities) in the webs of primary supporting members may be disregarded, but the element thickness is to be reduced in proportion to the hole height and the web height ratio.

In some specific cases, some of the above simplifications may not be deemed acceptable by the Society in relation to the type of structural model and the analysis performed.

2.4.3 Fine mesh

The ship structure may be considered as finely meshed when each longitudinal secondary stiffener is modelled; as a consequence, the standard size of finite elements used is based on the spacing of ordinary stiffeners.

The structural model is to be built on the basis of the following criteria:

- webs of primary members are to be modelled with at least three elements on their height
- the plating between two primary supporting members is to be modelled with at least two element stripes
- the ratio between the longer side and the shorter side of elements is to be less than 3 in the areas expected to be highly stressed
- holes for the passage of ordinary stiffeners may be disregarded.

In some specific cases, some of the above simplifications may not be deemed acceptable by the Society in relation to the type of structural model and the analysis performed.

2.4.4 Mesh for the analysis of structural details

The structural modelling is to be accurate; the mesh dimensions are to be such as to enable a faithful representation of the stress gradients. The use of membrane elements is only allowed when significant bending effects are not present; in other cases, elements with general behaviour are to be used.

2.5 Boundary conditions of the model

2.5.1 In order to prevent rigid body motions of the overall model, the constraints specified in Tab 1 are to be applied.

Table 1 : Boundary conditions to prevent rigid body motion of the model

Boundary conditions	DISPLACEMENTS in directions**(1)**		
	X	Y	Z
One node on the fore end of the ship	free	fixed	fixed
One node on the port side shell at aft end of the ship**(2)**	fixed	free	fixed
One node on the starboard side shell at aft end of the ship**(2)**	free	fixed	fixed

Boundary conditions	ROTATION around axes **(1)**		
	X	Y	Z
One node on the fore end of the ship	free	free	free
One node on the port side shell at aft end of the ship**(2)**	free	free	free
One node on the starboard side shell at aft end of the ship**(2)**	free	free	free

(1) X, Y and Z directions and axes are defined with respect to the reference co-ordinate system in Ch 1, Sec 2, [10].
(2) The nodes on the port side shell and that on the starboard side shell are to be symmetrical with respect to the ship longitudinal plane of symmetry.

Table 2 : Symmetry and anti-symmetry conditions in way of the ship centreline longitudinal plane

Boundary conditions	DISPLACEMENTS in directions**(1)**		
	X	Y	Z
Symmetry	free	fixed	free
Anti-symmetry	fixed	free	fixed

Boundary conditions	ROTATION around axes**(1)**		
	X	Y	Z
Symmetry	fixed	free	fixed
Anti-symmetry	free	fixed	free

(1) X, Y and Z directions and axes are defined with respect to the reference co-ordinate system in Ch 1, Sec 2, [10].

2.5.2 When the hull structure is modelled over half the ship's breadth (see [2.2.2]), in way of the ship centreline longitudinal plane, symmetry or anti-symmetry boundary conditions as specified in Tab 2 are to be applied, depending on the loads applied to the model (respectively symmetrical or anti-symmetrical).

3 Load model

3.1 General

3.1.1 Design wave method

The various load components which occur simultaneously may be combined by setting the characteristics of regular waves that maximize the dominant load parameters given in Part B, Chapter 5.

Any other method may be used provided that relevant documentation is submitted to the Society for review.

A recommended procedure to compute the characteristics of the design wave is provided in [3.2].

3.1.2 Loads

Still water loads include:

- the still water sea pressure, defined in Ch 5, Sec 5, [1]
- the still water internal loads, defined in Ch 5, Sec 6 for the various types of cargoes and for ballast.

Wave loads, determined by mean of hydrodynamic calculations according to [3.2], include:

- the wave pressure
- the inertial loads.

3.1.3 Lightweight

The lightweight of the ship is to be uniformly distributed over the model length, in order to obtain the actual longitudinal distribution of the still water bending moment.

3.1.4 Models extended over half breadth of ship

When the ship is symmetrical with respect to her centreline longitudinal plane and the hull structure is modelled over half the ship breadth, non-symmetrical loads are to be broken down into symmetrical and anti-symmetrical loads and applied separately to the model with symmetry and anti-symmetry boundary conditions in way of the ship centreline longitudinal plane (see [2.5.2]).

3.2 Procedure for the selection of design waves

3.2.1 Summary of the loading procedure

Applicable cargo loading conditions given in Part D are analysed through:

- the computation of the characteristics of the finite element model under still water loads (see [3.3.1])
- the election of the load cases critical for the strength of the resistant structural members (see [3.3.2]).

The determination of the design wave characteristics for each load case includes the following steps:

- computation of the response operators (amplitude and phase) of the dominant load effect
- selection of the wave length and heading according to the guidelines in [3.3]
- computation of the wave amplitude corresponding to the design value of the dominant load effect
- determination of the wave phase such that the dominant load effect reaches its maximum.

3.2.2 Dominant load effects

Each critical load case maximizes the value of one of the following load effects having a dominant influence on the strength of some parts of the structure:

- vertical wave bending moment in hogging condition at midship section
- vertical wave bending moment in sagging condition at midship section
- vertical wave shear force on transverse bulkheads
- horizontal wave bending moment at midship section
- vertical acceleration at centreline in midship and fore body sections
- transverse acceleration at deck at sides at midship section
- vertical relative motion at sides in upright ship condition, at midship section
- vertical relative motion at sides in inclined ship condition, at midship section.

3.2.3 Response Amplitude Operators

The Response Amplitude Operators (RAO's) and associated phase characteristics are to be computed for wave periods between 4 and 22 seconds, using a seakeeping program, for the following motions and load effects:

- heave, pitch, roll and yaw motions
- vertical wave bending moment at 0,50 L
- vertical wave shear force at 0,25 L and 0,50 L
- horizontal wave bending moment at 0,50 L
- wave torque at 0,25 L, 0,50 L and 0,75 L (for ships with large deck openings).

The response amplitude operators are to be calculated for wave headings ranging from following seas (0 degree) to head seas (180 degrees) by increment of 15 degrees, using a ship speed of 60% of the maximum service speed.

The amplitude and phase of other dominant load effects may be computed at relevant wave period, using the RAO's listed above.

3.2.4 Design waves

For each load case, the ship is considered to encounter a regular wave, defined by its parameters (see Fig 1):

- wave length λ or period T
- heading angle α
- wave height (double amplitude)
- wave phase.

The wave length λ and the wave period T are linked by the following relation:

$\lambda = g\,T^2 / 2\,\pi$

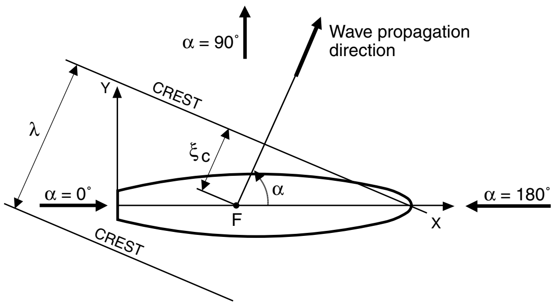
The range of variation of design wave period is between T1 and 22 seconds, where T1 is equal to:

$$T1 = 2\sqrt{\frac{\pi B_{WS}}{g}}$$

The possible wave height H, in m, is limited by the maximum wave steepness according to the relation (see Fig 2):

$H = 0{,}02\,g\,T^2$

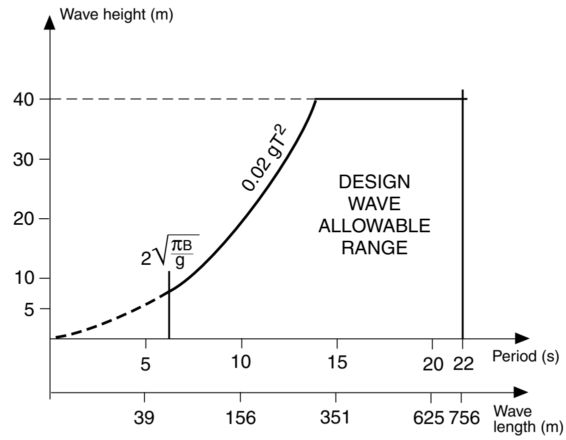
Figure 1 : Wave heading



Phase angle = 360 ξ_C / λ (in degrees)

F : Centre of rotation.

Figure 2 : Allowable range of design waves



3.2.5 Design wave amplitude

The amplitude of the design wave is obtained by dividing the design value of the dominant load effect by the value of the response amplitude operator of this effect computed for the relevant heading and wave length.

The design values of load effect, heading and wave length are given for each load case in [3.3.2].

When positioning the finite element model of the ship on the design wave, the amplitude of the wave is to be corrected to obtain the design value of the dominant load effect in order to take into account the non linear effects due to the hull shape and to the pressure distribution above the mean waterline given in [3.2.7].

The design wave phase is the phase of the dominant load effect.

3.2.6 Combined load cases

For the wave characteristics and crest position selected according to [3.2.5], the value of the wave-induced motions, accelerations and other load effects is obtained by the following formula:

$E_i = RAO_i \, a \cos(\varphi_d - \varphi_i)$

where:

- E_i : Value of amplitude of the load component i
- RAO_i : Response amplitude operator of the load component i computed for the design heading and wave length
- a : Design wave amplitude
- φ_d : Phase of the dominant load effect
- φ_i : Phase of the load component i.

As a rule, the amplitude of the load components computed above are not to exceed their rule reference value by a factor C_{max} given in Tab 3.

3.2.7 Finite element model loading

The loads are applied to the finite element model according to the following indications:

a) For fatigue analysis of structural members located in the vicinity of the mean waterline, the sum of the wave and hydrostatic parts of the pressure is zero above the deformed wave profile and varies linearly between the mean waterline and the wave crest levels.

b) The fluid pressure in tanks is affected by the change of direction of the total acceleration vector defined in Ch 5, Sec 6, [1.2.2].

c) For dry unit cargoes, the inertial forces are computed at the centre of mass, taking into account the mass moment of inertia.

d) Inertial loads for structure weight and dry uniform cargo are computed using local accelerations calculated at their location.

Table 3 : Values of factor C_{max}

Load component	C_{max}
Wave bending moments (see Ch 5, Sec 2, [3])	1,10
Wave shear forces (see Ch 5, Sec 2, [3])	1,40
Absolute motions and accelerations (see Ch 5, Sec 3, [2])	1,10
Relative vertical motions (see Ch 5, Sec 3, [3])	1,20

Table 4 : Load cases and load effect values

Load case	Dominant load effect	Wave parameters **(1)**		Location(s)
		Wave length λ, in m	Heading angle α	
1	Vertical wave bending moment in hogging condition	peak value of vertical wave bending moment RAO without being taken less than 0,9 L	180°	Midship section
2	Vertical wave bending moment in sagging condition	same as load case 1	180°	Midship section
3	Vertical wave shear force	peak value of vertical wave shear force RAO: • at 0,50 L for 0,35 L < x < 0,65 L • at 0,25 L elsewhere	0° or 180°	Each transverse bulkhead
4	Horizontal wave bending moment	peak value of horizontal wave bending moment RAO or 0,5 L	120° or 135° **(2)**	Midship section
5	Vertical acceleration in inclined ship condition	$\lambda = \dfrac{12{,}3 C_\beta \Delta}{B_{WS} L C_W}$ where: C_β = 1,00 for 90° heading C_β = 1,15 for 105° heading C_W : Waterplane coefficient at load waterline	90° or 105°	Midship section
6	Vertical acceleration in upright ship condition	$\lambda = 1{,}6\ L\ (0{,}575 + 0{,}8\ F)^2$	180°	from forward end of cargo area to F.P.
7	Transverse acceleration	$\lambda = 1{,}35\ g\ T_R^2 / (2\ \pi)$ without being taken greater than 756	90°	Midship section
8	Vertical relative motion at sides in upright ship condition	0,7 L **(3)**	180° or 0°	Midship section
9	Vertical relative motion at sides in inclined ship condition	$\lambda = 0{,}35\ g\ T_R^2 / (2\ \pi)$ without being taken less than 2,0 B_{WS}	90°	Midship section

(1) The forward ship speed is to be taken equal to 0,6 V_{max}.
(2) Select the heading such that the value of C_{max} for vertical wave bending moment is not exceeded.
(3) λ may have to be increased to keep the wave steepness below wave breaking limit.

3.2.8 Equilibrium check

The finite element model is to be in equilibrium condition with all the still water and wave loads applied.

The unbalanced forces in the three axes are not to exceed 2% of the displacement.

The unbalanced moments are not to exceed 2% of $\Delta.B_{WS}$ around Y and Z axes and 0,2% of $\Delta.B_{WS}$ around X axis.

3.3 Load cases

3.3.1 Hydrostatic calculation

For each cargo loading condition given in the relevant chapter of Part D, the longitudinal distribution of still water shear force and bending moment is to be computed and checked by reference to the approved loading manual (see Ch 11, Sec 2).

The convergence of the displacement, trim and vertical bending moment is deemed satisfactory if within the following tolerances:

- 2% of the displacement
- 0,1 degrees of the trim angle
- 10% of the still water wave bending moment.

Table 5 : Dominant load effect values

Dominant load effect	Design value	Combined load components	References
Vertical wave bending moment in hogging condition	$0{,}625\ \gamma_{W1}\ M_{WV,\ H}$	vertical relative motion at sides at F.P.	$M_{WV,\ H}$ defined in Ch 5, Sec 2, [3.1.1]
Vertical wave bending moment in sagging condition	$0{,}625\ \gamma_{W1}\ F_D\ M_{WV,\ S}$		$M_{WV,\ S}$ defined in Ch 5, Sec 2, [3.1.1] F_D defined in Ch 5, Sec 2, [4.2.2]
Vertical wave shear force	$0{,}625\ \gamma_{W1}\ Q_{WV}$	–	Q_{WV} defined in Ch 5, Sec 2, [3.4]
Horizontal wave bending moment	$0{,}625\ \gamma_{W1}\ M_{WH}$	–	M_{WH} defined in Ch 5, Sec 2, [3.2.1]
Vertical acceleration at centreline in upright ship condition	γ_{W2} AZ1	–	AZ1 defined in Ch 5, Sec 3, [3.4.1]
Vertical acceleration at centreline in inclined ship condition	γ_{W2} AZ2	–	AZ2 defined in Ch 5, Sec 3, [3.4.1]
Transverse acceleration at deck at sides	γ_{W2} AY2	roll angle	AY2 defined in Ch 5, Sec 3, [3.4.1]
Vertical relative motion at sides in upright ship condition	$\gamma_{W2}\ h_1$	wave pressure on bottom	h_1 defined in Ch 5, Sec 3, [3.3.1]
Vertical relative motion at sides in inclined ship condition	$\gamma_{W2}\ h_2$	–	h_2 defined in Ch 5, Sec 3, [3.3.2]

3.3.2 Value of load effects

The wave length and heading which maximize each dominant load effect are specified in Tab 4. Where two values of heading angle are indicated in the table, the angle which corresponds to the highest peak value of the load effect's RAO is to be considered.

The design value of dominant load effects is specified in Tab 5.

4 Stress calculation

4.1 Stress components

4.1.1 Stress components are generally identified with respect to the element co-ordinate system, as shown, by way of example, in Fig 3. The orientation of the element co-ordinate system may or may not coincide with that of the reference co-ordinate system in Ch 1, Sec 2, [10].

The following stress components are to be calculated at the centroid of each element:

- the normal stresses σ_1 and σ_2 in the directions of element co-ordinate system axes
- the shear stress τ_{12} with respect to the element co-ordinate system axes
- the Von Mises equivalent stress, obtained from the following formula:

$$\sigma_{VM} = \sqrt{\sigma_1^2 + \sigma_2^2 - \sigma_1\sigma_2 + 3\tau_{12}^2}$$

Figure 3 : Reference and element co-ordinate systems

Section 1 Fore Part

Symbols

L_1 , L_2 : Lengths, in m, defined in Ch 1, Sec 2, [2.1.1]

h_1 : Reference value of the ship relative motion, defined in Ch 5, Sec 3, [3.3]

a_{Z1} : Reference value of the vertical acceleration, defined in Ch 5, Sec 3, [3.4]

ρ_L : Density, in t/m^3, of the liquid carried

g : Gravity acceleration, in m/s^2:

$g = 9,81$ m/s^2

x, y, z : X, Y and Z co-ordinates, in m, of the calculation point with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [10]

p_S , p_W : Still water pressure and wave pressure defined in [2.3]

p_{BI} : Bottom impact pressure, defined in [3.2]

p_{FI} : Bow impact pressure, defined in [4.2]

k : Material factor, defined in Ch 4, Sec 1, [2.3]

R_y : Minimum yield stress, in N/mm^2, of the material, to be taken equal to 235/k, unless otherwise specified

s : Spacing, in m, of ordinary stiffeners or primary supporting members, as applicable

ℓ : Span, in m, of ordinary stiffeners or primary supporting members, as applicable

c_a : Aspect ratio of the plate panel, equal to:

$$c_a = 1,21\sqrt{1 + 0,33\left(\frac{s}{\ell}\right)^2} - 0,69\frac{s}{\ell}$$

to be taken not greater than 1,0

c_r : Coefficient of curvature of the panel, equal to:

$c_r = 1 - 0,5\ s / r$

to be taken not less than 0,75

r : Radius of curvature, in m

β_b , β_s : Coefficients defined in Ch 7, Sec 2, [3.7.3]

λ_{bS} , λ_{bW} , λ_{sS} , λ_{sW} : Coefficients defined in Ch 7, Sec 2, [3.4.3]

c_E : Coefficient to be taken equal to:

$c_E = 1$ for $L \leq 65$ m

$c_E = 3 - L / 32,5$ for $65\text{ m} < L < 90$ m

$c_E = 0$ for $L \geq 90$ m

c_F : Coefficient to be taken equal to:

$c_F = 0,9$ for forecastle sides

$c_F = 1,0$ in the other cases

m : Boundary coefficient, to be taken equal to:

- m = 12 in general, for stiffeners considered as clamped
- m = 8 for stiffeners considered as simply supported
- other values of m may be considered, on a case-by-case basis, for other boundary conditions.

1 General

1.1 Application

1.1.1 The requirements of this Section apply for the scantling of structures located forward of the collision bulkhead, i.e.:

- fore peak structures
- stem.

In addition, the requirements of this Section apply to structure subjected to impact loads, i.e.:

- flat bottom forward area, according to Article [3]
- bow flare area, according to Article [4].

1.1.2 Fore peak structures which form the boundary of spaces not intended to carry liquids, and which do not belong to the outer shell, are to be subjected to lateral pressure in flooding conditions. Their scantlings are to be determined according to the relevant criteria in Part B, Chapter 6 or Part B, Chapter 7, as applicable.

1.2 Connections of the fore part with structures located aft of the collision bulkhead

1.2.1 Tapering

Adequate tapering is to be ensured between the scantlings in the fore part and those aft of the collision bulkhead. The tapering is to be such that the scantling requirements for both areas are fulfilled.

1.2.2 Supports of fore peak structures

Aft of the collision bulkhead, side girders are to be fitted as specified in Ch 4, Sec 5, [2.2] or Ch 4, Sec 5, [3.2], as applicable.

1.3 Net scantlings

1.3.1 As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

Gross scantlings are obtained as specified in Ch 4, Sec 2.

2 Fore peak

2.1 Partial safety factors

2.1.1 The partial safety factors to be considered for the checking of fore peak structures are specified in Tab 1.

2.2 Load point

2.2.1 Unless otherwise specified, lateral pressure is to be calculated at:

- the lower edge of the elementary plate panel considered, for plating
- mid-span, for stiffeners.

2.3 Load model

2.3.1 General

The still water and wave lateral pressures in intact conditions are to be considered. They are to be calculated as specified in [2.3.2] for the elements of the outer shell and in [2.3.3] for the other elements.

Still water pressure p_S includes:

- the still water sea pressure, defined in Tab 2
- the still water internal pressure due to liquids or ballast, defined in Tab 4
- for decks, the still water internal pressure due to uniform loads, defined in Tab 5.

Wave pressure p_W includes:

- the wave pressure, defined in Tab 2
- the inertial internal pressure due to liquids or ballast, defined in Tab 4
- for decks, the inertial internal pressure due to uniform loads, defined in Tab 5.

2.3.2 Lateral pressures for the elements of the outer shell

The still water and wave lateral pressures are to be calculated considering separately:

- the still water and wave external sea pressures
- the still water and wave internal pressures, considering the compartment adjacent to the outer shell as being loaded.

If the compartment adjacent to the outer shell is not intended to carry liquids, only the external sea pressures are to be considered.

Table 1 : Fore peak structures - Partial safety factors

Partial safety factors covering uncertainties regarding:	Partial safety factors			
	Symbol	Plating	Ordinary stiffeners	Primary supporting members
Still water pressure	γ_{S2}	1,00	1,00	1,00
Wave induced pressure	γ_{W2}	1,20	1,20	1,20
Material	γ_m	1,02	1,02	1,02
Resistance	γ_R	1,20	1,40	1,60

Table 2 : Still water and wave pressures

Location	Still water sea pressure p_S, in kN/m²	Wave pressure p_W, in kN/m²
Bottom and side below the waterline: $z \le T$	$\rho g (T - z)$	$\rho g h_1 e^{\frac{-2\pi(T-z)}{L}}$
Side above the waterline: $z > T$	0	$\rho g (T + h_1 - z)$ without being taken less than $0,15\,\varphi_1\,\varphi_2\,L$
Exposed deck	Pressure due to the load carried**(1)**	$19,6\varphi_1\varphi_2\sqrt{H}$

(1) The pressure due to the load carried is to be defined by the Designer and, in any case, it may not be taken less than 10 φ_1 φ_2 kN/m², where φ_1 ανδ φ_2 are defined hereafter.
The Society may accept pressure values lower than 10 φ_1 φ_2 kN/m² when considered appropriate on the basis of the intended use of the deck.

Note 1:

φ_1 : Coefficient defined in Tab 3

φ_2 = Min (L / 90 ; 1,0) without being taken less than 0,42

$$H = \left[2,66\left(\frac{x}{L} - 0,7\right)^2 + 0,14\right]\sqrt{\frac{VL}{C_B}} - (z - T)$$

without being taken less than 0,8

V : Maximum ahead service speed, in knots, to be taken not less than 13 knots.

Table 3 : Coefficient φ_1 for pressure on exposed deck

Exposed deck location	φ_1
Watertight deck	1,00
Superstructure deck	0,75
1st tier of deckhouse	0,56
2nd tier of deckhouse	0,42
3rd tier of deckhouse	0,32
4th tier of deckhouse and above	0,25

Table 4 : Still water and inertial internal pressures due to liquids

Still water pressure p_S, in kN/m²	Inertial pressure p_W, in kN/m²
$\rho_L g(z_L - z)$	$\rho_L a_{Z1}(z_{TOP} - z)$

Note 1:

z_{TOP} : Z co-ordinate, in m, of the highest point of the tank

z_L : Z co-ordinate, in m, of the highest point of the liquid:
$z_L = z_{TOP} + 0,5\,(z_{AP} - z_{TOP})$

z_{AP} : Z co-ordinate, in m, of the moulded deck line of the deck to which the air pipes extend, to be taken not less than z_{TOP}.

Table 5 : Still water and inertial internal pressures due to uniform loads

Still water pressure p_S, in kN/m²	Inertial pressure p_W, in kN/m²
The value of p_S is, in general, defined by the Designer; in any case it may not be taken less than 10 kN/m². When the value of p_S is not defined by the Designer, it may be taken, in kN/m², equal to 6,9 h_{TD}, where h_{TD} is the compartment 'tweendeck height at side, in m.	$p_S \frac{a_{Z1}}{g}$

2.3.3 Lateral pressures for elements other than those of the outer shell

The still water and wave lateral pressures to be considered as acting on an element which separates two adjacent compartments are those obtained considering the two compartments individually loaded.

2.4 Longitudinally framed bottom

2.4.1 Plating and ordinary stiffeners

The net scantlings of plating and ordinary stiffeners are to be not less than the values obtained from the formulae in Tab 6 and the minimum values in the same Table.

Table 6 : Scantling of bottom plating and ordinary stiffeners

Element	Formula	Minimum value
Plating	Net thickness, in mm: $t = 14{,}9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y}}$	Minimum net thickness, in mm **(1)**: • in general: $t = c_F (0{,}03 L + 5{,}5) k^{1/2} - c_E$ • for inner bottom: $t = 2 + 0{,}017 L k^{1/2} + 4{,}5 s$
Ordinary stiffeners	Net section modulus, in cm³: $w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{m(R_y - \gamma_R \gamma_m \sigma_{X1})} \left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$	Web minimum net thickness, in mm, to be not less than the lesser of: • $t = 1{,}5 L_2^{1/3} k^{1/6}$ • the thickness of the attached plating.
	Net shear sectional area, in cm²: $A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y} \left(1 - \frac{s}{2\ell}\right) s \ell$	
(1) L need not be taken greater than 300 m. **Note 1:** σ_{X1} : Hull girder normal stress, taken equal to: • the value defined in Ch 7, Sec 2, [3.3.7], for stiffeners contributing to the hull girder longitudinal stress • $\sigma_{X1} = 0$, for stiffeners not contributing to the hull girder longitudinal stress.		

2.4.2 Floors

Floors are to be fitted at every four frame spacings and generally spaced no more than 2,5 m apart.

The floor dimensions and scantlings are to be not less than those specified in Tab 7.

In no case may the above scantlings be lower than those of the corresponding side transverses, as defined in [2.6.2].

2.4.3 Centre girder

Where no centreline bulkhead is to be fitted (see [2.10]), a centre bottom girder having the same dimensions and scantlings required in [2.4.2] for floors is to be provided.

The centre bottom girder is to be connected to the collision bulkhead by means of a large end bracket.

2.4.4 Side girders

Side girders, having the same dimensions and scantlings required in [2.4.2] for floors, are generally to be fitted every two longitudinals, in line with bottom longitudinals located aft of the collision bulkhead. Their extension is to be compatible in each case with the shape of the bottom.

2.5 Transversely framed bottom

2.5.1 Plating

The net scantling of plating is to be not less than the value obtained from the formulae in Tab 6 and the minimum values in the same Table.

2.5.2 Floors

Solid floors are to be fitted at every frame spacing.

The solid floor dimensions and scantlings are to be not less than those specified in Tab 8.

Table 7 : Longitudinally framed bottom - Floor dimensions and scantlings

Dimension or scantling	Specified value
Web height, in m	$h_M = 0{,}085\ D + 0{,}15$
Web net thickness, in mm	To be not less than that required for double bottom floors aft of the collision bulkhead; in any case, it may be taken not greater than 10 mm.
Floor face plate net sectional area, in cm²	$A_P = 3{,}15\ D$
Floor face plate net thickness, in mm	$t_P = 0{,}4\ D + 5$ May be assumed not greater than 14 mm.

Table 8 : Transversely framed bottom - Floor dimensions and scantlings

Dimension or scantling	Specified value
Web height, in m	$h_M = 0,085\ D + 0,15$
Web net thickness, in mm	To be not less than that required for double bottom floors aft of the collision bulkhead; in any case, it may be taken not greater than 10 mm.
Floor face plate net sectional area, in cm^2	$A_P = 1,67\ D$

2.5.3 Centre girder

Where no centreline bulkhead is to be fitted (see [2.10]), a centre bottom girder is to be fitted according to [2.4.3].

2.6 Longitudinally framed side

2.6.1 Plating and ordinary stiffeners

The net scantlings of plating and ordinary stiffeners are to be not less than the values obtained from the formulae in Tab 9 and the minimum values in the same Table.

2.6.2 Side transverses

Side transverses are to be located in way of bottom transverse and are to extend to the upper deck. Their ends are to be amply faired in way of bottom and deck transverses.

Their net section modulus w, in cm^3, and net shear sectional area A_{Sh}, in cm^2, are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2}\lambda_{bS} p_S + \gamma_{W2}\lambda_{bW} p_W}{8 R_y} s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2}\lambda_{sS} p_S + \gamma_{W2}\lambda_{sW} p_W}{R_y} s \ell$$

2.7 Transversely framed side

2.7.1 Plating and ordinary stiffeners (side frames)

Side frames fitted at every frame space are to have the same vertical extension as the collision bulkhead.

The net scantlings of plating and side frames are to be not less than the values obtained from the formulae in Tab 9 and the minimum values in the same Table.

The value of the side frame section modulus is generally to be maintained for the full extension of the side frame.

Table 9 : Scantling of side plating and ordinary stiffeners

Element	Formula	Minimum value
Plating	Net thickness, in mm: $t = 14,9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y}}$	Minimum net thickness, in mm **(1)**: $t = c_F (0,03 L + 5,5) k^{1/2} - c_E$
Ordinary stiffeners	Net section modulus, in cm^3: $w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{m(R_y - \gamma_R \gamma_m \sigma_{X1})}\left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$	Web minimum net thickness, in mm, to be not less than the lesser of: • $t = 1,5 L_2^{1/3} k^{1/6}$ • the thickness of the attached plating
	Net shear sectional area, in cm^2: $A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y}\left(1 - \frac{s}{2\ell}\right) s \ell$	

(1) L need not be taken greater than 300 m.
Note 1:
σ_{X1} : Hull girder normal stress, taken equal to:
- the value defined in Ch 7, Sec 2, [3.3.7], for stiffeners contributing to the hull girder longitudinal stress
- $\sigma_{X1} = 0$, for stiffeners not contributing to the hull girder longitudinal stress.

2.7.2 Side girders

Depending on the hull body shape and structure aft of the collision bulkhead, one or more adequately spaced side girders per side are to be fitted.

Their net section modulus w, in cm³, and net shear sectional area A_{Sh}, in cm², are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{8 R_y} s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y} s \ell$$

Moreover, the depth b_A, in mm, and the net thickness t_A, in mm, of the side girder web are generally to be not less than the values obtained from the following formulae:

$b_A = 2,5\ (180 + L)$

$t_A = (6 + 0,018\ L)\ k^{1/2}$

2.7.3 Panting structures

In order to withstand the panting loads, horizontal structures are to be provided. These structures are to be fitted at a spacing generally not exceeding 2 m and consist of side girders supported by panting beams or side transverses whose ends are connected to deck transverses, located under the tank top, so as to form a strengthened ring structure.

Panting beams, which generally consist of sections having the greater side vertically arranged, are to be fitted every two frames.

2.7.4 Connection between panting beams, side frames and side girders

Each panting beam is to be connected to the side transverses by means of brackets whose arms are generally to be not less than twice the panting beam depth.

2.7.5 Connection between side frames and side girders

Side transverses not supporting panting beams are to be connected to side girders by means of brackets having the same thickness as that of the side girder and arms which are to be not less than one half of the depth of the side girder.

2.7.6 Panting beam scantlings

The net area A_B, in cm², and the net inertia J_B, in cm⁴, of the panting beam section are to be not less than the values obtained from the following formulae:

$A_B = 0,5\ L - 18$

$J_B = 0,34\ (0,5\ L - 18)\ b_B^2$

where:

b_B : Beam length, in m, measured between the internal edges of side girders or the internal edge of the side girder and any effective central or lateral support.

Where side girder spacing is other than 2 m, the values A_B and J_B are to be modified according to the relation between the actual spacing and 2 m.

2.7.7 Panting beams of considerable length

Panting beams of considerable length are generally to be supported at the centreline by a wash bulkhead or pillars arranged both horizontally and vertically.

2.7.8 Non-tight platforms

Non-tight platforms may be fitted in lieu of side girders and panting beams. Their openings and scantlings are to be in accordance with [2.9.1].

Their spacing is to be not greater than 2,5 m.

If the peak exceeds 10 m in depth, a non-tight platform is to be arranged at approximately mid-depth.

2.7.9 Additional transverse bulkheads

Where the peak exceeds 10 m in length and the frames are supported by panting beams or non-tight platforms, additional transverse wash bulkheads or side transverses are to be fitted.

2.8 Decks

2.8.1 Plating and ordinary stiffeners

The net scantlings of plating and ordinary stiffeners are to be not less than the values obtained from the formulae in Tab 10 and the minimum values in the same Table.

2.8.2 Primary supporting members

Scantlings of primary supporting members are to be in accordance with Ch 7, Sec 3, considering the loads in [2.3].

Table 10 : Scantling of deck plating and ordinary stiffeners

Element	Formula	Minimum value
Plating	Net thickness, in mm: $t = 14{,}9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y}}$	Minimum net thickness, in mm **(1)**: $t = 2{,}1 + 0{,}013 L k^{1/2} + 4{,}5 s$
Ordinary stiffeners	Net section modulus, in cm³: $w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{m(R_y - \gamma_R \gamma_m \sigma_{X1})} \left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$	Web minimum net thickness, in mm, to be not less than the lesser of: • $t = 1{,}5 L_2^{1/3} k^{1/6}$ • the thickness of the attached plating.
	Net shear sectional area, in cm²: $A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y} \left(1 - \frac{s}{2\ell}\right) s \ell$	

(1) L need not be taken greater than 300 m.
Note 1:
σ_{X1} : Hull girder normal stress, taken equal to:
- the value defined in Ch 7, Sec 2, [3.3.7], for stiffeners contributing to the hull girder longitudinal stress
- $\sigma_{X1} = 0$, for stiffeners not contributing to the hull girder longitudinal stress.

2.9 Platforms

2.9.1 Non-tight platforms

Non-tight platforms located inside the peak are to be provided with openings having a total area not less than 10% of that of the platforms. Moreover, the thickness of the plating and the section modulus of ordinary stiffeners are to be not less than those required in [2.10] for the non-tight central longitudinal bulkhead.

The number and depth of non-tight platforms within the peak is considered by the Society on a case-by-case basis.

The platforms may be replaced by equivalent horizontal structures whose scantlings are to be supported by direct calculations.

2.9.2 Platform transverses

The net sectional area of platform transverses, calculated considering a width of attached plating whose net sectional area is equal to that of the transverse flange, is to be not less than the value obtained, in cm², from the following formula:

$$A = 10 \gamma_R \gamma_m \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{C_P R_y} d_S h_S$$

where:

p_S , p_W : Still water pressure and wave pressure, defined in [2.9.1], acting at the ends of the platform transverse in the direction of its axis

d_S : Half of the longitudinal distance, in m, between the two transverses longitudinally adjacent to that under consideration

h_S : Half of the vertical distance, in m, between the two transverses vertically adjacent to that under consideration

C_P : Coefficient, to be taken equal to:

$$C_P = 1 \quad \text{for } \frac{d_P}{r_P} \le 70$$

$$C_P = 1{,}7 - 0{,}01 \frac{d_P}{r_P} \quad \text{for } 70 < \frac{d_P}{r_P} \le 140$$

When $d_P / r_P > 140$, the scantlings of the struts are considered by the Society on a case-by-case basis

d_P : Distance, in cm, from the face plate of the side transverse and that of the bulkhead vertical web, connected by the strut, measured at the level of the platform transverse

r_P : Radius of gyration of the strut, to be obtained, in cm, from the following formula:

$$r_P = \sqrt{\frac{J}{A_E}}$$

J : Minimum net moment of inertia, in cm⁴, of the strut considered

A_E : Actual net sectional area, in cm², of the transverse section of the strut considered.

2.9.3 Breasthooks

Breasthooks are to have the same thickness of that required for platforms. They are to be arranged on the stem, in way of every side longitudinal, or at equivalent spacing in the case of transverse framing, extending aft for a length equal to approximately twice the breasthook spacing.

Other dispositions may be accepted by the Society if deemed equivalent.

2.10 Central longitudinal bulkhead

2.10.1 General

Unless otherwise agreed by the Society on a case-by-case basis, a centreline non-tight longitudinal bulkhead is not to be fitted. In case such a bulkhead is fitted, the following requirements apply.

2.10.2 Extension

In the case of a bulbous bow, such bulkhead is generally to extend for the whole length and depth of the fore peak.

Where hull structures are flared, such as those situated above the bulb and in the fore part of the peak, the bulkhead may be locally omitted.

Similarly, the extension of the bulkhead may be limited for bows without a bulb, depending on the shape of the hull. However, the bulkhead is to be fitted in the higher part of the peak.

2.10.3 Plating thickness

The net plating thickness of the lower part of the longitudinal bulkhead over a height at least equal to h_M defined in [2.4.2] is to be not less than that required for the centre girder in [2.4.3].

Elsewhere, the net thickness of the longitudinal bulkhead plating is to be not less than the value obtained, in mm, from the following formula:

$$t = 6,5 + 0,013\ L_1$$

2.10.4 Ordinary stiffeners

The net section modulus of ordinary stiffeners is to be not less than the value obtained, in cm^3, from the following formula:

$$w = 3,5\ s\ \ell^2\ k\ (z_{TOP} - z_M)$$

where:

z_{TOP} : Z co-ordinate, in m, of the highest point of the tank

z_M : Z co-ordinate, in m, of the stiffener mid-span.

2.10.5 Primary supporting members

Vertical and longitudinal primary supporting members, to be made preferably with symmetrical type sections, are to have a section modulus not less than 50% of that required for the corresponding side or longitudinal webs.

The vertical and longitudinal webs are to be provided with adequate fairing end brackets and to be securely connected to the struts, if any.

2.10.6 Openings

Bulkhead openings are to be limited in the zone corresponding to the centre girder to approximately 2% of the area, and, in the zone above, to not less than 10% of the area. Openings are to be located such as to affect as little as possible the plating sections adjacent to primary supporting members.

2.11 Bulbous bow

2.11.1 General

Where a bulbous bow is fitted, fore peak structures are to effectively support the bulb and are to be adequately connected to its structures.

When the bulbous bow is intended to contain a sonar device, the requirements in [2.11.7] apply.

2.11.2 Shell plating

The thickness of the shell plating of the fore end of the bulb and the first strake above the keel is generally to be not less than that required in [5.2.1] for plate stems. This thickness is to be extended to the bulbous zone, which, depending on its shape, may be damaged by anchors and chains during handling.

2.11.3 Connection with the fore peak

Fore peak structures are to be extended inside the bulb as far as permitted by the size and shape of the latter.

2.11.4 Floors

Solid floors are to be part of reinforced transverse rings generally arranged not more than 3 frame spaces apart.

2.11.5 Longitudinal centreline wash bulkhead

For a bulb of considerable width, a longitudinal centreline wash bulkhead may be required by the Society in certain cases.

2.11.6 Transverse wash bulkhead

In way of a long bulb, transverse wash bulkheads or side transverses of adequate strength arranged not more than 5 frame spaces apart may be required by the Society in certain cases.

2.11.7 Bulbous bow intended to contain a sonar device

The fore part of the bulbous bow is generally constituted by a GRP dome bolted to the fore structures. The aft part of the bulbous bow, of metallic construction, is to be connected with the fore structures according to [2.11.3] to [2.11.6] as far as practicable.

The sonar space is generally filled with water and is provided with a system for filling and emptying it. The hull watertightness is to be ensured by means of an horizontal flat and a transverse watertight floor, which contour the sonar dome. The scantlings of these watertight elements are to be checked considering them as being part of the outer shell.

If the access, in floating condition, to the sonar dome is to be ensured, for inspection and maintenance, two watertight hatches are, in general, to be fitted. For small domes, one hatch only may be accepted provided that its clear opening is such to allow contemporary easy access and ventilation. For the scantlings of these hatches, the sea pressures acting on the outer shell are to be considered.

3 Reinforcements of the flat bottom forward area

3.1 Area to be reinforced

3.1.1 In addition to the requirements in Article [2], the structures of the flat bottom forward area are to be able to sustain the dynamic pressures due to the bottom impact. The flat bottom forward area is:

- longitudinally, over the bottom located between ξL and 0,05L aft of the fore end, where the coefficient ξ is obtained from the following formula:

  $\xi = 0,25\ (1,6 - C_B)$

  without being taken less than 0,20 or greater than 0,25
- transversely, over the whole flat bottom and the adjacent zones up to a height, from the base line, not less than 2 L, in mm. In any case, it is not necessary that such height is greater than 300 mm.

3.1.2 The bottom dynamic impact pressure is to be considered if:

$T_F < \text{Min}\ (0,04\ L\ ;\ 8,6)$

where T_F is the minimum forward draught, in m, among those foreseen in operation in ballast conditions or conditions of partial loading.

3.1.3 The value of the minimum forward draught T_F adopted for the calculations is to be specified in the loading manual.

3.1.4 An alternative arrangement and extension of strengthening with respect to the above may also be required where the minimum forward draught exceeds 0,04 L, depending on the shape of the forward hull body and the ship length and service speed.

3.2 Bottom impact pressure

3.2.1 The bottom impact pressure p_{BI} is to be obtained, in kN/m², from the following formula:

$$p_{BI} = 25\left[0,004 - \left(\frac{T_F}{L}\right)^2\right]\frac{L_1 L}{T_F}$$

where T_F is the draught defined in [3.1.2].

3.3 Partial safety factors

3.3.1 The partial safety factors to be considered for checking the reinforcements of the flat bottom forward area are specified in Tab 11.

Table 11 : Reinforcements of the flat bottom forward area - Partial safety factors

Partial safety factors covering uncertainties regarding:	Partial safety factors		
	Symbol	Plating	Ordinary stiffeners
Still water pressure	γ_{S2}	1,00	1,00
Wave pressure	γ_{W2}	1,10	1,10
Material	γ_m	1,02	1,02
Resistance	γ_R	1,30	1,15

3.4 Scantlings

3.4.1 Plating and ordinary stiffeners

In addition to the requirements in [2.4.1] and [2.5.1], the net scantlings of plating and ordinary stiffeners of the flat bottom forward area, defined in [3.1], are to be not less than the values obtained from the formulae in Tab 12 and the minimum values in the same Table.

3.4.2 Tapering

Outside the flat bottom forward area, scantlings are to be gradually tapered so as to reach the values required for the areas considered.

Table 12 : Reinforcements of plating and ordinary stiffeners of the flat bottom forward area

Element	Formula	Minimum value
Plating	Net thickness, in mm: $t = 13{,}9 c_a c_r s \sqrt{\gamma_R \gamma_m \dfrac{\gamma_{W2} p_{BI}}{R_y}}$	Minimum net thickness, in mm **(1)**: $t = c_F(0{,}03L + 5{,}5)k^{1/2} - c_E$
Ordinary stiffeners	Net section modulus, in cm³: $w = \gamma_R \gamma_m \beta_b \dfrac{\gamma_{W2} p_{BI}}{16 c_P R_y}\left(1 - \dfrac{s}{2\ell}\right) s \ell^2 10^3$	Web minimum net thickness, in mm, to be not less than the lesser of: • $t = 1{,}5 L_2^{1/3} k^{1/6}$ • the thickness of the attached plating
	Net shear sectional area, in cm²: $A_{Sh} = 10 \gamma_R \gamma_m \beta_s \dfrac{\gamma_{W2} p_{BI}}{R_y}\left(1 - \dfrac{s}{2\ell}\right) s \ell$	
(1) L need not be taken greater than 300 m.		
Note 1:		
c_P : Ratio of the plastic section modulus to the elastic section modulus of the ordinary stiffeners with attached shell plating, to be taken equal to 1,16 in the absence of more precise evaluation.		

3.5 Arrangement of primary supporting members and ordinary stiffeners: longitudinally framed bottom

3.5.1 The requirements in [3.5.2] to [3.5.4] apply to the structures of the flat bottom forward area, defined in [3.1], in addition to the requirements of [2.4].

3.5.2 Bottom longitudinals and side girders, if any, are to extend as far forward as practicable, and their spacing may not exceed that adopted aft of the collision bulkhead.

3.5.3 The spacing of solid floors in a single or double bottom is to be not greater than:

- either the spacing required in Ch 4, Sec 4 for the midship section, or
- (1,35 + 0,007 L) m,

whichever is the lesser.

However, where the minimum forward draught T_F is less than 0,02 L, the spacing of floors forward of 0,2 L from the stem is to be not greater than (0,9 + 0,0045 L) m.

3.5.4 The Society may require adequately spaced side girders having a depth equal to that of the floors. As an alternative to the above, girders with increased scantlings may be fitted.

3.6 Arrangement of primary supporting members and ordinary stiffeners: transversely framed double bottom

3.6.1 The requirements from [3.6.2] to [3.6.4] apply to the structures of the flat bottom forward area, defined in [3.1], in addition to the requirements of [2.5].

3.6.2 Solid floors are to be fitted:

- at every second frame between 0,75 L and 0,80 L from the aft end
- at every frame space forward of 0,80 L from the aft end.

3.6.3 Side girders with a depth equal to that of the floors are to be fitted at a spacing generally not exceeding 2,4 m. In addition, the Society may require intermediate half height girders, half the depth of the side girders, or other equivalent stiffeners.

3.6.4 Intercostal longitudinal ordinary stiffeners are to be fitted at a spacing generally not exceeding 1,2 m. Their section modulus is to be not less than 250 cm³.

4 Reinforcements of the bow flare area

4.1 Area to be reinforced

4.1.1 In addition to the requirements in [2], the structures of the bow flare area are to be able to sustain the dynamic pressures due to the bow impact pressure.

4.1.2 The bow area to be reinforced is that extending forward of 0,9 L from the aft end of L and above the full load waterline up to the level at which a knuckle with an angle greater than 15° is located on the side shell.

4.2 Bow impact pressure

4.2.1 The bow impact pressure p_{FI} is to be obtained, in kN/m², from the following formula:

$$p_{FI} = C_S C_L C_Z (0{,}22 + 0{,}15 \tan\alpha)(0{,}4 V \sin\beta + 0{,}6\sqrt{L})^2$$

where:

C_S : Coefficient depending on the type of structures on which the bow impact pressure is considered to be acting:

- $C_S = 1{,}8$ for plating and ordinary stiffeners
- $C_S = 0{,}5$ for primary supporting members

C_L : Coefficient depending on the ship length:

- $C_L = 0{,}0125\ L$ for $L < 80$ m
- $C_L = 1{,}0$ for $L \geq 80$ m

C_Z : Coefficient depending on the distance between the full load waterline and the calculation point:

- $C_Z = C - 0{,}5\ (z - T)$ for $z \geq 2\ C + T - 11$
- $C_Z = 5{,}5$ for $z < 2\ C + T - 11$

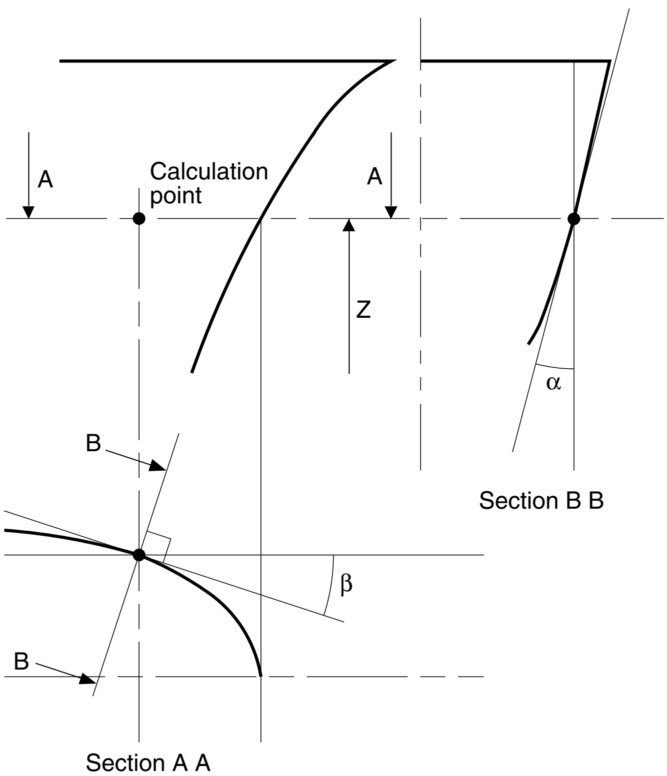
C : Wave parameter, defined in Ch 5, Sec 2

α : Flare angle at the calculation point, defined as the angle between a vertical line and the tangent to the side plating, measured in a vertical plane normal to the horizontal tangent to the shell plating (see Fig 1)

β : Entry angle at the calculation point, defined as the angle between a longitudinal line parallel to the centreline and the tangent to the shell plating in a horizontal plane (see Fig 1)

V : Maximum service speed, in knots.

Figure 1 : Definition of angles α and β



4.3 Partial safety factors

4.3.1 The partial safety factors to be considered to check the reinforcements of the bow flare area are specified in Tab 13.

4.4 Scantlings

4.4.1 Plating and ordinary stiffeners

In addition to the requirements in [2.6.1] and [2.7.1], the net scantlings of plating and ordinary stiffeners of the bow flare area, defined in [4.1], are to be not less than the values obtained from the formulae in Tab 14 and the minimum values in the same Table.

4.4.2 Tapering

Outside the bow flare area, scantlings are to be gradually tapered so as to reach the values required for the areas considered.

4.4.3 Intercostal stiffeners

Intercostal stiffeners are to be fitted at mid-span where the angle between the stiffener web and the attached plating is less than 70°.

4.4.4 Primary supporting members

In addition to the requirements in [2.6] and [2.7], primary supporting members are generally to be verified through direct calculations carried out according to Ch 7, Sec 3, considering the bow impact pressures defined in [4.2].

Table 13 : Reinforcements of the bow flare area - Partial safety factors

Partial safety factors covering uncertainties regarding:	Partial safety factors		
	Symbol	Plating	Ordinary stiffeners
Still water pressure	γ_{S2}	1,00	1,00
Wave pressure	γ_{W2}	1,10	1,10
Material	γ_m	1,02	1,02
Resistance	γ_R	1,30	1,02

Table 14 : Reinforcements of plating and ordinary stiffeners of the bow flare area

Element	Formula	Minimum value
Plating	Net thickness, in mm: $t = 11 c_a c_r s \sqrt{\gamma_R \gamma_m \dfrac{\gamma_{W2} p_{FI}}{R_y}}$	Minimum net thickness, in mm **(1)**: $t = c_F(0{,}03L + 5{,}5)k^{1/2} - c_E$
Ordinary stiffeners	Net section modulus, in cm³: $w = \gamma_R \gamma_m \beta_b \dfrac{\gamma_{W2} p_{FI}}{18 c_P R_y}\left(1 - \dfrac{s}{2\ell}\right) s \ell^2 10^3$	Web minimum net thickness, in mm, to be not less than the lesser of: • $t = 1{,}5 L_2^{1/3} k^{1/6}$ • the thickness of the attached plating.
	Net shear sectional area, in cm²: $A_{Sh} = 10 \gamma_R \gamma_m \beta_s \dfrac{\gamma_{W2} p_{FI}}{R_y}\left(1 - \dfrac{s}{2\ell}\right) s \ell$	

(1) L need not be taken greater than 300 m.

Note 1:

c_P : Ratio of the plastic section modulus to the elastic section modulus of the ordinary stiffeners with attached shell plating, to be taken equal to 1,16 in the absence of more precise evaluation.

5 Stems

5.1 General

5.1.1 Arrangement

Adequate continuity of strength is to be ensured at the connection of stems to the surrounding structure.

Abrupt changes in sections are to be avoided.

5.1.2 Gross scantlings

With reference to Ch 4, Sec 2, [1], all scantlings and dimensions referred to in [5.2] and [5.3] are gross, i.e. they include the margins for corrosion.

5.2 Plate stems

5.2.1 Where the stem is constructed of shaped plates, the gross thickness of the plates below the load waterline is to be not less than the value obtained, in mm, from the following formula:

$$t_S = 1{,}37(0{,}95 + \sqrt{L_3})\sqrt{k}$$

where:

L_3 : Ship length L, in m, but to be taken not greater than 300.

Above the load waterline this thickness may be gradually tapered towards the stem head, where it is to be not less than that required for side plating at ends.

5.2.2 The plating forming the stems is to be supported by horizontal diaphragms spaced not more than 1200 mm apart and connected, as far as practicable, to the adjacent frames and side stringers.

5.2.3 If considered necessary, and particularly where the stem radius is large, a centreline stiffener or web of suitable scantlings is to be fitted.

5.3 Bar stems

5.3.1 The gross area of bar stems constructed of forged or rolled steel is to be not less than the value obtained, in cm^2, from the following formulae:

$$A_P = \left(0{,}40 + \frac{10T}{L}\right)(0{,}009L^2 + 20)\sqrt{k} \quad \text{for } L \le 90$$

$$A_P = \left(0{,}40 + \frac{10T}{L}\right)(1{,}8L - 69)\sqrt{k} \quad \text{for } 90 < L \le 200$$

where the ratio T/L in the above formulae is to be taken neither less than 0,050 nor greater than 0,075.

5.3.2 The gross thickness t_B of the bar stem is to be not less than the value obtained, in mm, from the following formula:

$$t_B = (0{,}4L + 13)\sqrt{k}$$

5.3.3 The cross-sectional area of the stem may be gradually tapered from the load waterline to the upper end, where it may be equal to the two thirds of the value as calculated above.

5.3.4 The lower part of the stem may be constructed of cast steel subject to the examination by the Society; where necessary, a vertical web is to be fitted for welding of the centre keelson.

5.3.5 Welding of the bar stem with the bar keel and the shell plating is to be in accordance with Ch 11, Sec 1, [3.4].

6 Transverse thrusters

6.1 Scantlings of the thruster tunnel and connection with the hull

6.1.1 The thickness of the tunnel is to be not less than the thickness of the adjacent hull plating.

6.1.2 When the tunnel is not welded to the hull, the connection devices are examined by the Society on a case-by-case basis.

Section 2 Aft Part

Symbols

L_1 , L_2 : Lengths, in m, defined in Ch 1, Sec 2, [2.1.1]

h_1 : Reference value of the ship relative motion, defined in Ch 5, Sec 3, [3.3]

a_{Z1} : Reference value of the vertical acceleration, defined in Ch 5, Sec 3, [3.4]

ρ : Sea water density, in t/m^3

g : Gravity acceleration, in m/s^2:

$g = 9,81$ m/s^2

x, y, z : X, Y and Z co-ordinates, in m, of the calculation point with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [10]

p_S , p_W : Still water pressure and wave pressure defined in [2.3]

k : Material factor, defined in Ch 4, Sec 1, [2.3]

R_y : Minimum yield stress, in N/mm^2, of the material, to be taken equal to 235/k, unless otherwise specified

s : Spacing, in m, of ordinary stiffeners or primary supporting members, as applicable

ℓ : Span, in m, of ordinary stiffeners or primary supporting members, as applicable

c_a : Aspect ratio of the plate panel, equal to:

$$c_a = 1,21\sqrt{1+0,33\left(\frac{s}{\ell}\right)^2} - 0,69\frac{s}{\ell}$$

to be taken not greater than 1,0

c_r : Coefficient of curvature of the panel, equal to:

$c_r = 1 - 0,5\ s / r$

to be taken not less than 0,75

r : Radius of curvature, in m

β_b , β_s : Coefficients defined in Ch 7, Sec 2, [3.7.3]

λ_{bS} , λ_{bW} , λ_{sS} , λ_{sW} : Coefficients defined in Ch 7, Sec 2, [3.4.3]

c_E : Coefficient to be taken equal to:

$c_E = 1$ for $L \leq 65$ m

$c_E = 3 - L/30$ for $65\text{ m} < L < 90$ m

$c_E = 0$ for $L \geq 90$ m

c_F : Coefficient:

$c_F = 0,8$ for poop sides

$c_F = 1,0$ in the other cases

m : Boundary coefficient, to be taken equal to:

- m = 12 in general, for stiffeners considered as clamped
- m = 8 for stiffeners considered as simply supported
- other values of m may be considered, on a case-by-case basis, for other boundary conditions.

1 General

1.1 Application

1.1.1 The requirements of this Section apply for the scantlings of structures located aft of the after peak bulkhead and for the reinforcements of the flat bottom aft area.

1.1.2 Aft peak structures which form the boundary of spaces not intended to carry liquids, and which do not belong to the outer shell, are to be subjected to lateral pressure in flooding conditions. Their scantlings are to be determined according to the relevant criteria in Part B, Chapter 7, as applicable.

1.2 Connections of the aft part with structures located fore of the after peak bulkhead

1.2.1 Tapering

Adequate tapering is to be ensured between the scantlings in the aft part and those fore of the after peak bulkhead. The tapering is to be such that the scantling requirements for both areas are fulfilled.

1.3 Net scantlings

1.3.1 As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

Gross scantlings are obtained as specified in Ch 4, Sec 2.

2 Aft peak

2.1 Partial safety factors

2.1.1 The partial safety factors to be considered for the checking of aft peak structures are specified in Tab 1.

Table 1 : Aft peak structures - Partial safety factors

Partial safety factors covering uncertainties regarding:	Partial safety factors			
	Symbol	Plating	Ordinary stiffeners	Primary supporting members
Still water pressure	γ_{S2}	1,00	1,00	1,00
Wave pressure	γ_{W2}	1,20	1,20	1,20
Material	γ_m	1,02	1,02	1,02
Resistance	γ_R	1,20	1,40	1,60

2.2 Load point

2.2.1 Unless otherwise specified, lateral pressure is to be calculated at:

- the lower edge of the elementary load panel considered, for plating
- mid-span, for stiffeners.

2.3 Load model

2.3.1 General

The still water and wave lateral pressures in intact conditions are to be considered. They are to be calculated as specified in [2.3.2] for the elements of the outer shell and in [2.3.3] for the other elements.

Still water pressure p_S includes:

- the still water sea pressure, defined in Tab 2
- the still water internal pressure due to liquid or ballast, defined in Tab 4
- for decks, the still water internal pressure due to dry uniform weights, defined in Tab 5.

Wave pressure p_W includes:

- the wave pressure, defined in Tab 2
- the inertial pressure due to liquids or ballast, defined in Tab 4
- for decks, the inertial pressure due to uniform loads, defined in Tab 5.

2.3.2 Lateral pressures for the elements of the outer shell

The still water and wave lateral pressures are to be calculated considering separately:

- the still water and wave external sea pressures
- the still water and wave internal pressure, considering the compartment adjacent to the outer shell as being loaded.

If the compartment adjacent to the outer shell is not intended to carry liquids, only the external sea pressures are to be considered.

2.3.3 Lateral pressures for elements other than those of the outer shell

The still water and wave lateral pressures to be considered as acting on an element which separates two adjacent compartments are those obtained considering the two compartments individually loaded.

Table 2 : Still water and wave pressures

Location	Still water sea pressure p, in kN/m²	Wave pressure p_W, in kN/m²
Bottom and side below the waterline: $z \le T$	$\rho\, g\, (T - z)$	$\rho g h_1 e^{\frac{-2\pi(T-z)}{L}}$
Side above the waterline: $z > T$	0	$\rho\, g\, (T + h_1 - z)$ without being taken less than $0{,}15\, \varphi_1\, \varphi_2\, L$
Exposed deck	Pressure due to the load carried **(1)**	$17{,}5\, \varphi_1\, \varphi_2$

(1) The pressure due to the load carried is to be defined by the Designer and, in any case, it may not be taken less than $10\, \varphi_1\, \varphi_2$ kN/m², where φ_1 ανδ φ_2 are defined hereafter.
The Society may accept pressure values lower than $10\, \varphi_1\, \varphi_2$ kN/m² when considered appropriate on the basis of the intended use of the deck.

Note 1:

φ_1 : Coefficient defined in Tab 3

φ_2 = Min (L / 90 ; 1,0) without being taken less than 0,42.

Table 3 : Coefficient φ_1 for pressure on exposed deck

Exposed deck location	φ_1
Watertight deck	1,00
Superstructure deck	0,75
1st tier of deckhouse	0,56
2nd tier of deckhouse	0,42
3rd tier of deckhouse	0,32
4th tier of deckhouse	0,25
5th tier of deckhouse	0,20
6th tier of deckhouse	0,15
7th tier of deckhouse and above	0,10

Table 4 : Still water and wave internal pressures due to liquids

Still water pressure p_S, in kN/m²	Inertial pressure p_W, in kN/m²
$\rho\, g\, (z_L - z)$	$\rho\, a_{Z1}\, (z_{TOP} - z)$

Note 1:

z_{TOP} : Z co-ordinate, in m, of the highest point of the tank

z_L : Z co-ordinate, in m, of the highest point of the liquid:
$z_L = z_{TOP} + 0{,}5\, (z_{AP} - z_{TOP})$

z_{AP} : Z co-ordinate, in m, of the moulded deck line of the deck to which the air pipes extend, to be taken not less than z_{TOP}.

Table 5 : Still water and inertial internal pressures due to uniform loads

Still water pressure p_S, in kN/m²	Inertial pressure p_W, in kN/m²
The value of p_S is, in general, defined by the Designer: in any case it may not be taken less than 10 kN/m². When the value of p_S is not defined by the Designer, it may be taken, in kN/m², equal to 6,9 h_{TD}, where h_{TD} is the compartment 'tweendeck height at side, in m.	$p_S \dfrac{a_{Z1}}{g}$

3 After peak

3.1 Arrangement

3.1.1 General

The provisions of this sub-article apply to transversely framed after peak structure.

3.1.2 Floors

Solid floors are to be fitted at every frame spacing.

The floor height is to be adequate in relation to the shape of the hull. Where a sterntube is fitted, the floor height is to extend at least above the sterntube. Where the hull lines do not allow such extension, plates of suitable height with upper and lower edges stiffened and securely fastened to the frames are to be fitted above the sterntube.

In way of and near the rudder post, propeller post and rudder horn, floors are to be extended up to the peak tank top and are to be increased in thickness; the increase will be considered by the Society on a case-by-case basis, depending on the arrangement proposed.

Floors are to be fitted with stiffeners having spacing not greater than 800 mm.

3.1.3 Side frames

Side frames are to be extended up to a deck located above the full load waterline.

Side frames are to be supported by one of the following types of structure:

- non-tight platforms, to be fitted with openings having a total area not less than 10% of the area of the platforms
- side girders supported by side primary supporting members connected to deck transverses.

The distance between the above side frame supports is to be not greater than 2,5 m.

3.1.4 Platforms and side girders

Platforms and side girders within the peak are to be arranged in line with those located in the area immediately forward.

Where this arrangement is not possible due to the shape of the hull and access needs, structural continuity between the peak and the structures of the area immediately forward is to be ensured by adopting wide tapering brackets.

Where the after peak is adjacent to a machinery space whose side is longitudinally framed, the side girders in the after peak are to be fitted with tapering brackets.

3.1.5 Longitudinal bulkheads

A longitudinal non-tight bulkhead is to be fitted on the centreline of the ship, in general in the upper part of the peak, and stiffened at each frame spacing.

Where either the stern overhang is very large or the maximum breadth of the peak is greater than 20 m, additional longitudinal wash bulkheads may be required.

3.2 Scantlings

3.2.1 Plating and ordinary stiffeners (side frames)

The net scantlings of plating and ordinary stiffeners are to be not less than those obtained from the formulae in:

- Tab 6 for plating
- Tab 7 for ordinary stiffeners,

and not less than the minimum values in the same Tables.

3.2.2 Floors

The net thickness of floors is to be not less than that obtained, in mm, from the following formula:

$t_M = 6,5 + 0,02\ L_2\ k^{1/2}$

3.2.3 Side transverses

The net section modulus w, in cm^3, and the net shear sectional area A_{Sh} , in cm^2, of side transverses are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \lambda_b \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{8 R_y} s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \lambda_s \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y} s \ell$$

Table 6 : Net thickness of plating

Plating location	Net thickness, in mm	Minimum net thickness, in mm**(1)**
Bottom and side	$14,9 c_a c_r s \sqrt{\gamma_R \gamma_m \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y}}$	$c_F\ (0,03\ L + 5,5)\ k^{1/2} - c_E$
Inner bottom		$2 + 0,017\ L\ k^{1/2} + 4,5\ s$
Deck		For strength deck: $2,1 + 0,013\ L\ k^{1/2} + 4,5\ s$
Platform and wash bulkhead		$1,3 + 0,004\ L\ k^{1/2} + 4,5\ s$ for $L < 120$ m $2,1 + 2,2\ k^{1/2} + s$ for $L \geq 120$ m
(1) L need not be taken greater than 300 m.		

Table 7 : Net scantlings of ordinary stiffeners

Ordinary stiffener location	Formulae	Minimum value
Bottom, side and deck	Net section modulus, in cm³: $w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{m(R_y - \gamma_R \gamma_m \sigma_{X1})} \left(1 - \frac{s}{2\ell}\right) s \ell^2 10^3$	Web minimum net thickness, in mm, to be not less than the lesser of: • $t = 1,5 \, L_2^{1/3} \, k^{1/6}$ • the net thickness of the attached plating.
	Net shear sectional area, in cm²: $A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y} \left(1 - \frac{s}{2\ell}\right) s \ell$	
Platform and wash bulkhead	Net section modulus, in cm³: $w = 3{,}5 \, s \, \ell^2 \, k \, (z_{TOP} - z_M)$	

Note 1:

σ_{X1} : Hull girder normal stress, taken equal to:
- the value defined in Ch 7, Sec 2, [3.3.7], for stiffeners contributing to the hull girder longitudinal stress
- $\sigma_{X1} = 0$, for stiffeners not contributing to the hull girder longitudinal stress

Z_{TOP} : Z co-ordinate, in m, of the highest point of the peak tank

Z_M : Z co-ordinate, in m, of the stiffener mid-span.

3.2.4 Side girders

The net section modulus w, in cm³, and the net shear sectional area A_{Sh}, in cm², of side girders are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \beta_b \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{8 R_y} s \ell^2 10^3$$

$$A_{Sh} = 10 \gamma_R \gamma_m \beta_s \frac{\gamma_{S2} p_S + \gamma_{W2} p_W}{R_y} s \ell$$

3.2.5 Deck primary supporting members

Scantlings of deck primary supporting members are to be in accordance with Ch 7, Sec 3, as applicable, considering the loads in [2.3].

4 Reinforcements of the flat area of the bottom aft

4.1 General

4.1.1 In the flat area of the bottom aft, if any, increased bottom plating thickness as well as additional bottom stiffeners may be considered by the Society on a case-by-case basis.

5 Connection of hull structures with the rudder horn

5.1 Connection of after peak structures with the rudder horn

5.1.1 General

The requirement of this sub-article apply to the connection between peak structure and rudder horn where the sternframe is of an open type and is fitted with the rudder horn.

5.1.2 Rudder horn

Horn design is to be such as to enable sufficient access for welding and inspection.

The scantlings of the rudder horn, which are to comply with Ch 9, Sec 1, [9.2], may be gradually tapered inside the hull.

Connections by slot welds are not acceptable.

5.1.3 Hull structures

Direct calculations are to be performed to check the connection of the rudder horn to the structure of the vessel, taking into account of the reactions induced by the rudder on the rudder horn.

In general, between the horn intersection with the shell and the peak tank top, the vertical extension of the hull structures is to be not less than the horn height, defined as the distance from the horn intersection with the shell to the mid-point of the lower horn gudgeon.

The thickness of the structures adjacent to the rudder horn, such as shell plating, floors, platforms and side girders, the centreline bulkhead and any other structures, is to be adequately increased in relation to the horn scantlings.

5.2 Structural arrangement above the after peak

5.2.1 Side transverses

Where a rudder horn is fitted, side transverses, connected to deck beams, are to be arranged between the platform forming the peak tank top and the weather deck.

The side transverse spacing is to be not greater than:

- 2 frame spacings in way of the horn
- 4 frame spacings for and aft of the rudder horn
- 6 frame spacings in the area close to the after peak bulkhead.

The side transverses are to be fitted with end brackets and located within the poop. Where there is no poop, the scantlings of side transverses below the weather deck are to be adequately increased.

5.2.2 Side girders

Where the depth from the peak tank top to the weather deck is greater than 2,6 m and the side is transversely framed, one or more side girders are to be fitted, preferably in line with similar structures existing forward.

6 Sternframes

6.1 General

6.1.1 Sternframes may be made of cast or forged steel, with a hollow section, or fabricated from plate.

6.1.2 Cast steel and fabricated sternframes are to be strengthened by adequately spaced horizontal plates.

Abrupt changes of section are to be avoided in castings; all sections are to have adequate tapering radius.

6.2 Connections

6.2.1 Connection with hull structure

The requirements below are applicable to single screw ships.

Sternframes are to be effectively attached to the aft structure and the lower part of the sternframe is to be extended forward of the propeller post to a length not less than (1500 + 6 L) mm, in order to provide an effective connection with the keel. However, the sternframe need not extend beyond the after peak bulkhead.

The net thickness of shell plating connected with the sternframe is to be not less than that obtained, in mm, from the following formula:

$t = 0{,}045\ L\ k^{1/2} + 8{,}5$

6.2.2 Connection with the keel

The requirements below are applicable to single screw ships.

The thickness of the lower part of the sternframes is to be gradually tapered to that of the solid bar keel or keel plate.

Where a keel plate is fitted, the lower part of the sternframe is to be so designed as to ensure an effective connection with the keel.

6.2.3 Connection with transom floors

The requirements below are applicable to single screw ships.

Rudder posts and, in the case of ships greater than 90 m in length, propeller posts are to be connected with transom floors having height not less than that of the double bottom and net thickness not less than that obtained, in mm, from the following formula:

$t = 9 + 0{,}023\ L_1\ k^{1/2}$

6.2.4 Connection with centre keelson

The requirements below are applicable to single screw ships.

Where the sternframe is made of cast steel, the lower part of the sternframe is to be fitted, as far as practicable, with a longitudinal web for connection with the centre keelson.

6.3 Propeller posts

6.3.1 Gross scantlings

With reference to Ch 4, Sec 2, [1], all scantlings and dimensions referred to in [6.3.2] to [6.3.4] are gross, i.e. they include the margins for corrosion.

6.3.2 Gross scantlings of propeller posts

The gross scantlings of propeller posts are to be not less than those obtained from the formulae in Tab 8 for single screw ships and Tab 9 for twin screw ships.

Scantlings and proportions of the propeller post which differ from those above may be considered acceptable provided that the section modulus of the propeller post section about its longitudinal axis is not less than that calculated with the propeller post scantlings in Tab 8 or Tab 9, as applicable.

Table 8 : Single screw ships - Gross scantlings of propeller posts

Gross scantlings of propeller posts, in mm	**Fabricated propeller post** 	**Cast propeller post** 	**Bar propeller post, cast or forged, having rectangular section** a	$50\ L^{1/2}$	$33\ L^{1/2}$	$10\sqrt{2,5(L+10)}$ for $L \le 60$ $10\sqrt{7,2L-256}$ for $L > 60$
b	$35\ L^{1/2}$	$23\ L^{1/2}$	$10\sqrt{1,6(L+10)}$ for $L \le 60$ $10\sqrt{4,6L-164}$ for $L > 60$
t_1 **(1)**	$2,5\ L^{1/2}$	$3,2\ L^{1/2}$ to be taken not less than 19 mm	N.A.
t_2 **(1)**	N.A.	$4,4\ L^{1/2}$ to be taken not less than 19 mm	N.A.
t_D	$1,3\ L^{1/2}$	$2,0\ L^{1/2}$	N.A.
R	N.A.	$50\ L^{1/2}$	N.A.

(1) Propeller post thicknesses t_1 and t_2 are, in any case, to be not less than (0,05 L + 9,5) mm.
Note 1: N.A. = not applicable.

Table 9 : Twin screw ships - Gross scantlings of propeller posts

Gross scantlings of propeller posts, in mm	**Fabricated propeller post** 	**Cast propeller post** 	**Bar propeller post, cast or forged, having rectangular section** a	$25\ L^{1/2}$	$12,5\ L^{1/2}$	0,72 L + 90 for $L \le 50$ 2,40 L + 6 for $L > 50$
b	$25\ L^{1/2}$	$25\ L^{1/2}$	0,24 L + 30 for $L \le 50$ 0,80 L + 2 for $L > 50$
t_1 **(1)**	$2,5\ L^{1/2}$	$2,5\ L^{1/2}$	N.A.
t_2 **(1)**	$3,2\ L^{1/2}$	$3,2\ L^{1/2}$	N.A.
t_3 **(1)**	N.A.	$4,4\ L^{1/2}$	N.A.
t_D	$1,3\ L^{1/2}$	$2,0\ L^{1/2}$	N.A.

(1) Propeller post thicknesses t_1 , t_2 and t_3 are, in any case, to be not less than (0,05 L + 9,5) mm.
Note 1: N.A. = not applicable.

6.3.3 Section modulus below the propeller shaft bossing

In the case of a propeller post without a sole piece, the section modulus of the propeller post may be gradually reduced below the propeller shaft bossing down to 85% of the value calculated with the scantlings in Tab 8 or Tab 9, as applicable.

In any case, the thicknesses of the propeller posts are to be not less than those obtained from the formulae in the Tables.

6.3.4 Welding of fabricated propeller post with the propeller shaft bossing

Welding of a fabricated propeller post with the propeller shaft bossing is to be in accordance with Ch 11, Sec 1, [3.3].

6.4 Integral rudder posts

6.4.1 Net section modulus of integral rudder post

The net section modulus around the horizontal axis X (see Fig 1) of an integral rudder post is to be not less than that obtained, in cm^3, from the following formula:

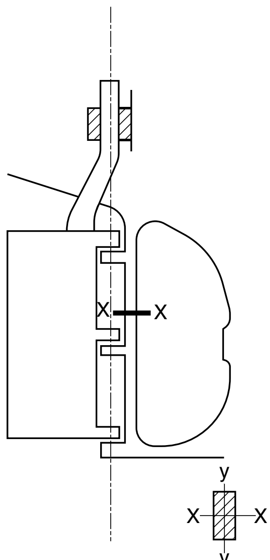
$w_{RP} = 14{,}4\ C_R\ L_D\ 10^{-6}$

where:

C_R : Rudder force, in N, acting on the rudder blade, defined in Ch 9, Sec 1, [2.1.2] and Ch 9, Sec 1, [2.2.2], as the case may be

L_D : Length of rudder post, in m.

Figure 1 : Integral rudder post



6.5 Propeller shaft bossing

6.5.1 In single screw ships, the thickness of the propeller shaft bossing, included in the propeller post, is to be not less than 60% of the dimension "b" required in [6.3.2] for bar propeller posts with a rectangular section.

6.6 Rudder gudgeon

6.6.1 Rudder gudgeons

In general, gudgeons are to be solidly forged or cast with the sternframe.

The height of the gudgeon is to be not greater than 1,2 times the pintle diameter. In any case, the height and diameter of the gudgeons are to be suitable to house the rudder pintle.

The thickness of the metal around the finished bore of the gudgeons is to be not less than half the diameter of the pintle.

6.7 Sterntubes

6.7.1 The sterntube thickness is considered by the Society on a case-by-case basis. In no case, however, may it be less than the thickness of the side plating adjacent to the sternframe.

Where the materials adopted for the sterntube and the plating adjacent to the sternframe are different, the sterntube thickness is to be at least equivalent to that of the plating.

Section 3 Machinery Space

Symbols

L_2 : Length, in m, defined in Ch 1, Sec 2, [2.1.1]

k : Material factor, defined in Ch 4, Sec 1, [2.3]

s : Spacing, in m, of ordinary stiffeners

P : Maximum power, in kW, of the engine

n_r : Number of revolutions per minute of the engine shaft at power equal to P

L_E : Effective length, in m, of the engine foundation plate required for bolting the engine to the seating, as specified by the engine manufacturer.

1 General

1.1 Application

1.1.1 The requirements of this Section apply for the arrangement and scantling of machinery space structures as regards general strength. It is no substitute to machinery manufacturer's requirements which have to be dealt with at Shipyard diligence.

1.2 Scantlings

1.2.1 Net scantlings

As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

The gross scantlings are obtained as specified in Ch 4, Sec 2.

1.2.2 General

Unless otherwise specified in this Section, the scantlings of plating, ordinary stiffeners and primary supporting members in the machinery space are to be determined according to the relevant criteria in Part B, Chapter 7 as applicable. In addition, the minimum thickness requirements specified in this Section apply.

1.2.3 Primary supporting members

The Designer may propose arrangements and scantlings alternative to the requirements of this Section, on the basis of direct calculations which are to be submitted to the Society for examination on a case-by-case basis.

The Society may also require such direct calculations to be carried out whenever deemed necessary.

1.3 Connections of the machinery space with structures located aft and forward

1.3.1 Tapering

Adequate tapering is to be ensured between the scantlings in the machinery space and those aft and forward. The tapering is to be such that the scantling requirements for all areas are fulfilled.

1.3.2 Deck discontinuities

Decks which are interrupted in the machinery space are to be tapered on the side by means of horizontal brackets.

2 Double bottom

2.1 Arrangement

2.1.1 General

Where the machinery space is immediately forward of the after peak, the double bottom is generally to be transversely framed. In all other cases it may be transversely or longitudinally framed.

2.1.2 Double bottom height

The double bottom height at the centreline, irrespective of the location of the machinery space, is to be not less than the value defined in Ch 4, Sec 4, [4.2.1]. This depth may need to be considerably increased in relation to the type and depth of main machinery seatings.

The above height is to be increased by the Shipyard where the machinery space is very large and where there is a considerable variation in draught between light ballast and full load conditions.

Where the double bottom height in the machinery space differs from that in adjacent spaces, structural continuity of longitudinal members is to be ensured by sloping the inner bottom over an adequate longitudinal extent. The knuckles in the sloped inner bottom are to be located close to the floors.

2.1.3 Centre bottom girder

In general, the centre bottom girder may not be provided with holes. In any case, in way of any openings for manholes on the centre girder, permitted only where absolutely necessary for double bottom access and maintenance, local strengthening is to be arranged.

2.1.4 Side bottom girders

In the machinery space the number of side bottom girders is to be adequately increased, with respect to the adjacent areas, to ensure adequate rigidity of the structure.

The side bottom girders are to be a continuation of any bottom longitudinals in the areas adjacent to the machinery space and are generally to have a spacing not greater than 3 times that of longitudinals and in no case greater than 3 m.

2.1.5 Side bottom girders in way of machinery seatings

Additional side bottom girders are to be fitted in way of machinery seatings.

Side bottom girders arranged in way of main machinery seatings are to extend for the full length of the machinery space.

Where the machinery space is situated amidships, the bottom girders are to extend aft of the after bulkhead of such space for at least three frame spaces, and beyond to be connected to the hull structure by tapering.

Where the machinery space is situated aft, the bottom girders are to extend as far aft as practicable in relation to the shape of the bottom and to be supported by floors and side primary supporting members at the ends.

Forward of the machinery space forward bulkhead, the bottom girders are to be tapered for at least three frame spaces and are to be effectively connected to the hull structure.

2.1.6 Floors in longitudinally framed double bottom

Where the double bottom is longitudinally framed, the floor spacing is to be not greater than:

- 1 frame spacing in way of the main engine and thrust bearing
- 2 frame spacings in other areas of the machinery space.

Additional floors are to be fitted in way of other important machinery.

2.1.7 Floors in transversely framed double bottom

Where the double bottom in the machinery space is transversely framed, floors are to be arranged at every frame.

Furthermore, additional floors are to be fitted in way of boiler foundations or other important machinery.

2.1.8 Floors stiffeners

In addition to the requirements in Ch 4, Sec 3, [4.7], floors are to have web stiffeners sniped at the ends and spaced not more than approximately 1 m apart.

The section modulus of web stiffeners is to be not less than 1,2 times that required in Ch 4, Sec 3, [4.7].

2.1.9 Manholes and wells

The number and size of manholes in floors located in way of seatings and adjacent areas are to be kept to the minimum necessary for double bottom access and maintenance.

The depth of manholes is generally to be not greater than 40% of the floor local depth, and in no case greater than 750 mm, and their width is to be equal to approximately 400 mm.

In general, manhole edges are to be stiffened with flanges; failing this, the floor plate is to be adequately stiffened with flat bars at manhole sides.

Manholes with perforated portable plates are to be fitted in the inner bottom in the vicinity of wells arranged close to the aft bulkhead of the engine room.

Drainage of the tunnel is to be arranged through a well located at the aft end of the tunnel.

2.2 Minimum thicknesses

2.2.1 The net thicknesses of inner bottom, floor and girder webs are to be not less than the values given in Tab 1.

The Society may consider lower thicknesses than those in Tab 1, on a case-by-case basis, when this is deemed appropriate on the basis of scantling calculations for all type s of loading cases.

Table 1 : Double bottom - Minimum net thicknesses of inner bottom, floors and girder webs

Element	Minimum net thickness, in mm	
	Machinery space within 0,4L amidships	Machinery space outside 0,4L amidships
Inner bottom	$[0,75\ L^{1/2} + 1,35 + 4,5\ (s - 0,23\ L^{1/4})]\ k^{1/2}$ The Society may require the thickness of the inner bottom in way of the main machinery seatings and on the main thrust blocks to be increased, on a case-by-case basis	
Margin plate	$L^{1/2}\ k^{1/4} + 1$	$0,9\ L^{1/2}\ k^{1/4} + 1$
Centre girder	$1,8\ L^{1/3}\ k^{1/6} + 4$	$1,55\ L^{1/3}\ k^{1/6} + 3,5$
Floors and side girders	$1,7\ L^{1/3}\ k^{1/6} + 1$	
Girder bounding a duct keel	$0,8\ L^{1/2}\ k^{1/4} + 2,5$ to be taken not less than that required for the centre girder	

3 Single bottom

3.1 Arrangement

3.1.1 Bottom girder

For single bottom girder arrangement, the requirements of Ch 4, Sec 4, [2.1] and Ch 4, Sec 4, [3.1] apply for longitudinally framed and transversely framed single bottoms respectively.

3.1.2 Floors in longitudinally framed single bottom

Where the single bottom is longitudinally framed, the floor spacing is to be not greater than:

- 1 frame spacing in way of the main engine and thrust bearing
- 2 frame spacings in other areas of the machinery spaces.

Additional floors are to be fitted in way of other important machinery.

3.1.3 Floors in transversely framed single bottom

Where the single bottom is transversely framed, the floors are to be arranged at every frame.

Furthermore, additional floors are to be fitted in way of boiler foundations or other important machinery.

3.1.4 Floor height

The height of floors in way of machinery spaces located amidships is to be not less than B/14,5. Where the top of the floors is recessed in way of main machinery, the height of the floors in way of this recess is generally to be not less than B/16. Lower values will be considered by the Society on a case-by-case basis.

Where the machinery space is situated aft or where there is considerable rise of floor, the depth of the floors will be considered by the Society on a case-by-case basis.

3.1.5 Floor flanging

Floors are to be fitted with welded face plates in way of:

- engine bed plates
- thrust blocks
- auxiliary seatings.

3.2 Minimum thicknesses

3.2.1 The net thicknesses of floor and girder webs are to be not less than the values given in Tab 2.

The Society may consider lower thicknesses than those in Tab 2, on a case-by-case basis, when this is deemed appropriate on the basis of scantling calculations for all types of loading cases.

Table 2 : Single bottom Minimum net thicknesses of floors and girder webs

Element	Minimum net thickness, in mm	
	Machinery space within 0,4L amidships	Machinery space outside 0,4L amidships
Centre girder	$7 + 0,05\ L_2\ k^{1/2}$	$6 + 0,05\ L_2\ k^{1/2}$
Floors and side girders	$6,5 + 0,05\ L_2\ k^{1/2}$	$5 + 0,05\ L_2\ k^{1/2}$

4 Side

4.1 Arrangement

4.1.1 General

The type of side framing in machinery spaces is generally to be the same as that adopted in the adjacent areas.

4.1.2 Extension of the hull longitudinal structure within the machinery space

In ships where the machinery space is located aft and where the side is longitudinally framed, the longitudinal structure is preferably to extend for the full length of the machinery space.

In any event, the longitudinal structure is to be maintained for at least 0,3 times the length of the machinery space, calculated from the forward bulkhead of the latter, and abrupt structural discontinuities between longitudinally and transversely framed structures are to be avoided.

4.1.3 Side transverses

Side transverses are to be aligned with floors. One is preferably to be located in way of the forward end and another in way of the after end of the machinery casing.

For a longitudinally framed side, the side transverse spacing is to be not greater than 4 frame spacings.

For a transversely framed side, the side transverse spacing is to be not greater than 5 frame spaces. The web height is to be not less than twice that of adjacent frames and the section modulus is to be not less than four times that of adjacent frames.

Side transverse spacing greater than that above may be accepted provided that the scantlings of ordinary frames are increased, according to the Society's requirements to be defined on a case-by-case basis.

5 Platforms

5.1 Arrangement

5.1.1 General

The location and extension of platforms in machinery spaces are to be arranged so as to be a continuation of the structure of side longitudinals, as well as of platforms and side girders located in the adjacent hull areas.

5.1.2 Platform transverses

In general, platform transverses are to be arranged in way of side or longitudinal bulkhead transverses.

For longitudinally framed platforms, the spacing of platform transverses is to be not greater than 4 frame spacings.

5.2 Minimum thicknesses

5.2.1 The net thickness of platforms is to be not less than that obtained, in mm, from the following formula:

$t = 0{,}018\ L_2\ k^{1/2} + 4{,}5$

The Society may consider lower thicknesses, on a case-by-case basis, based on scantling calculations with appropriate loadings.

6 Pillaring

6.1 Arrangement

6.1.1 General

The pillaring arrangement in machinery spaces is to account both for the concentrated loads transmitted by machinery and superstructures and for the position of main machinery and auxiliary engines.

6.1.2 Pillars

Pillars are generally to be arranged in the following positions:

- in way of machinery casing corners and corners of large openings on platforms; alternatively, two pillars may be fitted on the centreline (one at each end of the opening)
- in way of the intersection of platform transverses and girders
- in way of transverse and longitudinal bulkheads of the superstructure.

In general, pillars are to be fitted with brackets at their ends.

6.1.3 Pillar bulkheads

In general, pillar bulkheads, fitted 'tweendecks below the upper deck, are to be located in way of load-bearing bulkheads in the superstructures.

Longitudinal pillar bulkheads are to be a continuation of main longitudinal hull structures in the adjacent spaces forward and aft of the machinery space.

Pillar bulkhead scantlings are to be not less than those required in [7.3] for machinery casing bulkheads.

7 Machinery casing

7.1 Arrangement

7.1.1 Ordinary stiffener spacing

Ordinary stiffeners are to be located:

- at each frame, in longitudinal bulkheads
- at a distance of about 750 mm, in transverse bulkheads.

The ordinary stiffener spacing in portions of casings which are particularly exposed to wave action is considered by the Society on a case-by-case basis.

7.2 Openings

7.2.1 General

All machinery space openings, which are to comply with the requirements in Ch 8, Sec 9, [6], are to be enclosed in a steel casing leading to the highest open deck. Lower parts of casings are to be reinforced at the ends by deck beams and girders associated to pillars.

In the case of large openings, the arrangement of cross-ties as a continuation of deck beams may be required.

7.2.2 Access doors

Access doors to casings are to comply with Ch 8, Sec 9, [6.2].

7.3 Scantlings

7.3.1 Plating and ordinary stiffeners

The net scantlings of plating and ordinary stiffeners are to be not less than those obtained according to the applicable requirements in Ch 8, Sec 4.

7.3.2 Minimum thicknesses

The net thickness of bulkheads is to be not less than:

- 5,5 mm for bulkheads in way of cargo holds
- 4,0 mm for bulkheads in way of accommodation spaces.

The Society may consider lower thicknesses, on a case-by-case basis, based on scantling calculations with appropriate loadings.

8 Main machinery seatings

8.1 Arrangement

8.1.1 General

The scantlings of main machinery seatings and thrust bearings are to be adequate in relation to the weight and power of engines and the static and dynamic forces transmitted by the propulsive installation.

8.1.2 Seating supporting structure

Transverse and longitudinal members supporting the seatings are to be located in line with floors and double or single bottom girders, respectively.

They are to be so arranged as to avoid discontinuity and ensure sufficient accessibility for welding of joints and for surveys and maintenance.

8.1.3 Seatings included in the double bottom structure

Where high-power internal combustion engines or turbines are fitted, seatings are to be integral with the double bottom structure. Girders supporting the bedplates in way of seatings are to be aligned with double bottom girders and are to be extended aft in order to form girders for thrust blocks.

The girders in way of seatings are to be continuous from the bedplates to the bottom shell.

8.1.4 Seatings above the double bottom plating

Where the seatings are situated above the double bottom plating, the girders in way of seatings are to be fitted with flanged brackets, generally located at each frame and extending towards both the centre of the ship and the sides.

The extension of the seatings above the double bottom plating is to be limited as far as practicable while ensuring adequate spaces for the fitting of bedplate bolts. Bolt holes are to be located such that they do not interfere with seating structures.

8.1.5 Seatings in a single bottom structure

For ships having a single bottom structure within the machinery space, seatings are to be located above the floors and to be adequately connected to the latter and to the girders located below.

8.1.6 Number of girders in way of machinery seatings

In general, at least two girders are to be fitted in way of main machinery seatings.

One girder may be fitted only where the following three formulae are complied with:

$L < 150$ m

$P < 7100$ kW

$P < 2{,}3\ n_r\ L_E$

8.2 Minimum scantlings

8.2.1 The net scantlings of the structural elements in way of the internal combustion engine seatings are to be not less than those obtained from the formulae in Tab 3.

Table 3 : Minimum scantlings of structural elements in way of engine seatings

Scantling	Minimum value
Net cross-sectional area, in cm², of each bedplate of the seatings	$40 + 70\dfrac{P}{n_r L_E}$
Net thickness, in mm, of each bedplate of the seatings	• Bedplate supported by two or more longitudinal members: $\sqrt{240 + 175\dfrac{P}{n_r L_E}}$ • Bedplate supported by one longitudinal member: $5 + \sqrt{240 + 175\dfrac{P}{n_r L_E}}$
Web net thickness, in mm, of longitudinal members fitted in way of each bedplate of the seatings	• Bedplate supported by two or more longitudinal members: $\dfrac{1}{n_G}\sqrt{320 + 215\dfrac{P}{n_r L_E}}$ where n_G is the number of longitudinal members in way of the bedplate considered • Bedplate supported by one longitudinal member: $\sqrt{95 + 65\dfrac{P}{n_r L_E}}$
Web net thickness, in mm, of transverse members fitted in way of bedplates of the seating**(1)**	$\sqrt{55 + 40\dfrac{P}{n_r L_E}}$
(1) When intermediate transverse members welded to the bedplate are fitted, the web minimum net thickness may be reduced on a case-by-case basis.	

Section 4 Superstructures and Deckhouses

Symbols

x, y, z : X, Y and Z co-ordinates, in m, of the calculation point with respect to the reference co-ordinate system defined in Ch 1, Sec 2, [10]

s : Spacing, in m, of ordinary stiffeners

k : Material factor, defined in:
- Ch 4, Sec 1, [2.3], for steel
- Ch 4, Sec 1, [4.4], for aluminium alloys

t_c : Corrosion addition, in mm, defined in Ch 4, Sec 2, Tab 2.

1 General

1.1 Application

1.1.1 The requirements of this Section apply for the scantling of plating and associated structures of front, side and aft bulkheads and decks of superstructures and deckhouses, which may or may not contribute to the longitudinal strength.

1.1.2 The requirements of this Section comply with the applicable regulations of the 1966 International Convention on Load Lines, with regard to the strength of enclosed superstructures.

1.2 Net scantlings

1.2.1 As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

The gross scantlings are obtained as specified in Ch 4, Sec 2.

1.3 Definitions

1.3.1 Superstructures and deckhouses contributing to the longitudinal strength

Superstructures and deckhouses contributing to the longitudinal strength are defined in Ch 6, Sec 1, [2.2].

1.3.2 Tiers of superstructures and deckhouses

The lowest tier is normally that which is directly situated above the main watertight deck.

Where the difference of height between the deepest subdivision loadline and the watertight deck exceeds the value given, in m, by the following formula:

1,80 + 0,01 (L – 75) to be taken neither less than 1,80 m, nor greater than 2,30 m, the lowest tier may be considered as an upper tier when calculating the scantlings of superstructures and deckhouses.

The second tier is that located immediately above the lowest tier, and so on.

1.4 Connections of superstructures and deckhouses with the hull structure

1.4.1 Superstructure and deckhouse frames are to be fitted as far as practicable as extensions of those underlying and are to be effectively connected to both the latter and the deck beams above.

Ends of superstructures and deckhouses are to be efficiently supported by bulkheads, diaphragms, webs or pillars.

Where hatchways are fitted close to the ends of superstructures, additional strengthening may be required.

1.4.2 Connection to the deck of corners of superstructures and deckhouses is considered by the Society on a case-by-case basis. Where necessary, doublers or reinforced welding may be required.

1.4.3 As a rule, the frames of sides of superstructures and deckhouses are to have the same spacing as the beams of the supporting deck.

Web frames are to be arranged to support the sides and ends of superstructures and deckhouses.

1.4.4 The side plating at ends of superstructures is to be tapered into the bulwark or sheerstrake of the strength deck.

Where a raised deck is fitted, this arrangement is to extend over at least 3 frame spacings.

1.5 Structural arrangement of superstructures and deckhouses

1.5.1 Strengthening in way of superstructures and deckhouses

Web frames, transverse partial bulkheads or other equivalent strengthening are to be fitted inside deckhouses of at least 0,5 B in breadth extending more than 0,15 L in length within 0,4 L amidships. These transverse strengthening reinforcements are to be spaced approximately 9 m apart and are to be arranged, where practicable, in line with the transverse bulkheads below.

Web frames are also to be arranged in way of large openings, boats davits and other areas subjected to point loads.

Web frames, pillars, partial bulkheads and similar strengthening are to be arranged, in conjunction with deck transverses, at ends of superstructures and deckhouses.

1.5.2 Strengthening of the raised quarter deck stringer plate

When a superstructure is located above a raised quarter deck, the thickness of the raised quarter deck stringer plate is to be increased by 30% and is to be extended within the superstructure.

The increase above may be reduced when the raised quarter deck terminates outside 0,5 L amidships.

1.5.3 Openings

Openings are to be in accordance with Ch 6, Sec 1.

Continuous coamings are to be fitted above and below doors or similar openings.

1.5.4 Access and doors

Access openings cut in sides of enclosed superstructures are to be fitted with doors made of steel or other equivalent material, and permanently attached.

Special consideration is to be given to the connection of doors to the surrounding structure.

Securing devices which ensure watertightness are to include tight gaskets, clamping dogs or other similar appliances, and are to be permanently attached to the bulkheads and doors. These doors are to be operable from both sides.

1.5.5 Strengthening of deckhouses in way of lifeboats and rescue boats

Stiffening of sides of deckhouses in way of lifeboats and rescue boats is to be compatible with the launching operation. Deckhouses in way of launching appliances are to be adequately strengthened.

1.5.6 Constructional details

Lower tier stiffeners are to be welded to the decks at their ends.

Brackets are to be fitted at the upper and preferably also the lower ends of vertical stiffeners of exposed front bulkheads of engine casings and superstructures or deckhouses protecting pump room openings.

1.5.7 Use of aluminium alloys

Unprotected front bulkheads of first tier superstructures or deckhouses are generally to be built of steel and not of aluminium alloy.

Aluminium alloys may be adopted for front bulkheads of superstructures or deckhouses above the first tier.

2 Design loads

2.1 Sides contributing to the longitudinal strength

2.1.1 Load point

Lateral pressure is to be calculated at:

- the lower edge of the elementary plate panel, for plating
- mid-span, for stiffeners.

2.1.2 Lateral pressure

The lateral pressure is constituted by the still water sea pressure p_S and the wave pressure p_W, defined in Ch 5, Sec 5.

Moreover, when the side is a tank boundary, the lateral pressure constituted by the still water internal pressure p_S and the inertial pressure p_W, defined in Ch 5, Sec 6, [1] is also to be considered.

2.2 Front, side and aft bulkheads not contributing to the longitudinal strength

2.2.1 Load point

Lateral pressure is to be calculated at:

- mid-height of the bulkhead, for plating
- mid-span, for stiffeners.

2.2.2 Lateral pressure

The lateral pressure to be used for the determination of scantlings of the structure of front, side and aft bulkheads of superstructures and deckhouses is to be obtained, in kN/m², from the following formula:

$p = 10\ a\ c\ [b\ f - (z - T)]$

without being less than p_{min}

where:

a : Coefficient defined in Tab 1

c : Coefficient taken equal to:

$$c = 0{,}3 + 0{,}7\frac{b_1}{B_1}$$

For exposed parts of machinery casings, c is to be taken equal to 1

b_1 : Breadth of deckhouse, in m, at the position considered, to be taken not less than 0,25 B_1

B_1 : Actual maximum breadth of ship on the exposed weather deck, in m, at the position considered

b : Coefficient defined in Tab 2

f : Coefficient defined in Tab 3

p_{min} : Minimum lateral pressure defined in Tab 4.

2.3 Decks

2.3.1 The lateral pressure for decks which may or may not contribute to the longitudinal strength is constituted by the still water internal pressure p_S and the inertial pressure p_W, defined in Ch 5, Sec 6, [5] or Ch 5, Sec 6, [6] as applicable.

Moreover, when the deck is a tank boundary, the lateral pressure constituted by the still water internal pressure p_S and the inertial pressure p_W, defined in Ch 5, Sec 6, [1] is also to be considered.

Table 1 : Lateral pressure for superstructures and deckhouses - Coefficient a

Type of bulkhead	Location	a	a maximum
Unprotected front	Lowest tier	$2 + \frac{L}{120}$	4,5
	Second tier	$1 + \frac{L}{120}$	3,5
	Third tier	$0{,}5 + \frac{L}{150}$	2,5
	Fourth tier	$0{,}9\left(0{,}5 + \frac{L}{150}\right)$	2,25
	Fifth tier and above	$0{,}8\left(0{,}5 + \frac{L}{150}\right)$	2,0
Protected front	Lowest, second and third tiers	$0{,}5 + \frac{L}{150}$	2,5
	Fourth tier	$0{,}9\left(0{,}5 + \frac{L}{150}\right)$	2,25
	Fifth tier and above	$0{,}8\left(0{,}5 + \frac{L}{150}\right)$	2,0
Side	Lowest, second and third tiers	$0{,}5 + \frac{L}{150}$	2,5
	Fourth tier	$0{,}9\left(0{,}5 + \frac{L}{150}\right)$	2,25
	Fifth tier and above	$0{,}8\left(0{,}5 + \frac{L}{150}\right)$	2,0
Aft end	All tiers, when: $x/L \leq 0{,}5$	$0{,}7 + \frac{L}{1000} - 0{,}8\frac{x}{L}$	$1 - 0{,}8\frac{x}{L}$
	All tiers, when: $x/L > 0{,}5$	$0{,}5 + \frac{L}{1000} - 0{,}4\frac{x}{L}$	$0{,}8 - 0{,}4\frac{x}{L}$

Table 2 : Lateral pressure for superstructures and deckhouses - Coefficient b

Location of bulkhead **(1)**	b
$\frac{x}{L} \le 0{,}45$	$1 + \left(\frac{\frac{x}{L} - 0{,}45}{C_B + 0{,}2}\right)^2$
$\frac{x}{L} > 0{,}45$	$1 + 1{,}5\left(\frac{\frac{x}{L} - 0{,}45}{C_B + 0{,}2}\right)^2$

(1) For deckhouse sides, the deckhouse is to be subdivided into parts of approximately equal length, not exceeding 0,15 L each, and x is to be taken as the co-ordinate of the centre of each part considered.

Note 1:

C_B : Block coefficient, with $0{,}6 \le C_B \le 0{,}8$

Table 3 : Lateral pressure for superstructures and deckhouses - Coefficient f

Length L of ship, in m	f
$L < 150$	$\frac{L}{10}e^{-L/300} - \left[1 - \left(\frac{L}{150}\right)^2\right]$
$150 \le L < 300$	$\frac{L}{10}e^{-L/300}$
$L \ge 300$	11,03

Table 4 : Minimum lateral pressurefor superstructures and deckhouses

Location and type of bulkhead	p_{min}, in kN/m²
Lowest tier of unprotected fronts	$30 \le 25{,}0 + 0{,}10L \le 50$
Elsewhere:	
• if $z \le T + 0{,}5\ B\ A_R + 0{,}5\ h_w$	$15 \le 12{,}5 + 0{,}05\ L \le 25$
• if $T + 0{,}5\ B\ A_R + 0{,}5\ h_w < z$ and $z \le T + 0{,}5\ B\ A_R + h_w$	linear interpolation
• if $z > T + 0{,}5\ B\ A_R + h_w$	2,5

Note 1:

A_R : Roll amplitude, in rad, defined in Ch 5, Sec 3, [2.4] or taken equal to 0,35 for ships less than 65 m in length

h_w : Wave parameter, in m, defined in Ch 5, Sec 3.

3 Plating

3.1 Front, side and aft bulkheads

3.1.1 Plating contributing to the longitudinal strength

The net thickness of side plate panels contributing to the longitudinal strength is to be determined in accordance with the applicable requirements of Ch 7, Sec 1, as applicable, considering the lateral pressure defined in [2.1.2].

3.1.2 Plating not contributing to the longitudinal strength

The net thickness of plating of front, side and aft bulkheads not contributing to the longitudinal strength is to be not less than the value obtained, in mm, from the following formula:

$$t = 0{,}95s\sqrt{kp} - t_c$$

without being less than the values indicated in Tab 5, where p is the lateral pressure, in kN/m², defined in [2.2].

The Society may consider lower thicknesses than those in Tab 5, on a case-by-case basis, when this is deemed appropriate on the basis of scantling calculations for all types of loading cases.

For plating which forms tank boundaries, the net thickness is to be determined in accordance with [3.1.1], considering the hull girder stress equal to 0.

Table 5 : Superstructures and deckhouses - Minimum thicknesses

Location	Minimum thickness, in mm
Lowest tier	$k_1\ (5 + 0{,}01\ L)\ k^{1/2} - t_C$
Second tier and above	$k_1\ (4 + 0{,}01\ L)\ k^{1/2} - t_C$
Note 1: L is to be taken not less than 100 m and not greater than 300 m. k_1 : • for steel: $k_1 = 1{,}00$ • for aluminium: $k_1 = 0{,}65$	

3.2 Decks

3.2.1 The net thickness of plate panels of decks which may or may not contribute to the longitudinal strength is to be determined in accordance with the applicable requirements of Ch 7, Sec 1 or Ch 8, Sec 3, as applicable.

3.2.2 For decks sheathed with wood, the net thickness obtained from [3.2.1] may be reduced by 10 percent.

4 Ordinary stiffeners

4.1 Front, side and aft bulkheads

4.1.1 Ordinary stiffeners of plating contributing to the longitudinal strength

The net scantlings of ordinary stiffeners of plating contributing to the longitudinal strength are to be determined in accordance with the applicable requirements of Ch 7, Sec 2.

4.1.2 Ordinary stiffeners of plating not contributing to the longitudinal strength

The net section modulus w of ordinary stiffeners of plating not contributing to the longitudinal strength is to be not less than the value obtained, in cm^3, from the following formula:

$$w = 0{,}35\ \varphi\ k\ s\ \ell^2\ p\ (1 - \alpha\ t_c) - \beta\ t_c$$

where:

ℓ : Span of the ordinary stiffener, in m, equal to the ‘tweendeck height and to be taken not less than 2 m

p : Lateral pressure, in kN/m^2, defined in [2.2.2]

φ : Coefficient depending on the stiffener end connections, and taken equal to:

- 1 for lower tier stiffeners
- value defined in Tab 6 for stiffeners of upper tiers

α, β : Parameters defined in Ch 4, Sec 2, Tab 1.

The section modulus of side ordinary stiffeners need not be greater than that of the side ordinary stiffeners of the tier situated directly below taking account of spacing and span.

For ordinary stiffeners of plating forming tank boundaries, the net scantlings are to be determined in accordance with [4.1.1], considering the hull girder stress equal to 0.

In addition, the net section modulus, in cm^3, of ordinary stiffeners is not to be less than the values given in Tab 7.

4.2 Decks

4.2.1 The net scantlings of ordinary stiffeners of decks which may or may not contribute to the longitudinal strength are to be determined in accordance with the applicable requirements of Ch 7, Sec 2.

Table 6 : Stiffeners of superstructures and deckhouses - Coefficient φ for end connections

Coefficient φ	Upper end welded to deck	Bracketed upper end	Sniped upper end
Lower end welded to deck	1,00	0,85	1,15
Bracketed lower end	0,85	0,85	1,00
Sniped lower end	1,15	1,00	1,15

Table 7 : Minimum ordinary stiffener section modulus (cm^3)

	Lowest tier	Second tier	Third tier	Fourth tier and above
Unprotected front	30 $k^{0.25}$	21 $k^{0.25}$	15 $k^{0.25}$	10 $k^{0.25}$
Side	20 $k^{0.25}$	14 $k^{0.25}$	10 $k^{0.25}$	
Aft end and protected front	27 $k^{0.25}$	19 $k^{0.25}$	13 $k^{0.25}$	

5 Primary supporting members

5.1 Front, side and aft bulkheads

5.1.1 Primary supporting members of plating contributing to the longitudinal strength

The net scantlings of side primary supporting members of plating contributing to the longitudinal strength are to be determined in accordance with the applicable requirements of Ch 7, Sec 3, as applicable.

5.1.2 Primary supporting members of plating not contributing to the longitudinal strength

The net scantlings of side primary supporting members of plating not contributing to the longitudinal strength are to be determined in accordance with the applicable requirements of Ch 7, Sec 3, as applicable, using the lateral pressure defined in [2.2.2].

5.2 Decks

5.2.1 The net scantlings of primary supporting members of decks which may or may not contribute to the longitudinal strength are to be determined in accordance with the applicable requirements of Ch 7, Sec 3.

Section 5 Bow Doors and Inner Doors

Symbols

L_1 : Length, in m, defined in Ch 1, Sec 2, [2.1.1].

1 General

1.1 Application

1.1.1 The requirements of this Section apply to the arrangement, strength and securing of bow doors and inner doors leading to a complete or long forward enclosed superstructure.

1.1.2 Two types of bow doors are provided for:

- visor doors opened by rotating upwards and outwards about a horizontal axis through two or more hinges located near the top of the door and connected to the primary supporting members of the door by longitudinally arranged lifting arms
- side-opening doors opened either by rotating outwards about a vertical axis through two or more hinges located near the outboard edges or by horizontal translation by means of linking arms arranged with pivoted attachments to the door and the ship. It is anticipated that side-opening bow doors are arranged in pairs.

Other types of bow door are considered by the Society on a case-by-case basis in association with the applicable requirements of this Section.

1.2 Gross scantlings

1.2.1 With reference to Ch 4, Sec 2, [1], all scantlings and dimensions referred to in this Section are gross, i.e. they include the margins for corrosion.

1.3 Arrangement

1.3.1 Bow doors are to be situated above the watertight deck. A watertight recess in the watertight deck located forward of the collision bulkhead and above the deepest waterline fitted for arrangement of ramps or other related mechanical devices may be regarded as a part of the watertight deck for the purpose of this requirement.

1.3.2 An inner door is to be fitted as part of the collision bulkhead. The inner door need not be fitted directly above the bulkhead below, provided it is located within the limits specified for the position of the collision bulkhead, as per Ch 2, Sec 1, [3.1].

A vehicle ramp may be arranged for this purpose, provided its position complies with Ch 2, Sec 1, [3.1].

If this is not possible, a separate inner weathertight door is to be installed, as far as practicable within the limits specified for the position of the collision bulkhead.

1.3.3 Bow doors are to be so fitted as to ensure tightness consistent with operational conditions and to give effective protection to inner doors.

Inner doors forming part of the collision bulkhead are to be weathertight over the full height of the cargo space and arranged with fixed sealing supports on the aft side of the doors.

1.3.4 Bow doors and inner doors are to be arranged so as to preclude the possibility of the bow door causing structural damage to the inner door or to the collision bulkhead in the case of damage to or detachment of the bow door. If this is not possible, a separate inner weathertight door is to be installed, as indicated in [1.3.2].

1.3.5 The requirements for inner doors are based on the assumption that vehicles are effectively lashed and secured against movement in stowed position.

1.4 Definitions

1.4.1 Securing device

A securing device is a device used to keep the door closed by preventing it from rotating about its hinges.

1.4.2 Supporting device

A supporting device is a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, which transmits loads from the door to the ship structure.

1.4.3 Locking device

A locking device is a device that locks a securing device in the closed position.

2 Design loads

2.1 Bow doors

2.1.1 Design external pressure

The design external pressure to be considered for the scantlings of primary supporting members and securing and supporting devices of bow doors is to be not less than that obtained, in kN/m², from the following formula:

$$p_E = 0,5 C_L C_Z (0,22 + 0,15 \tan\alpha)(0,4 V \sin\beta + 0,6\sqrt{L_1})^2$$

where:

V : Maximum ahead service speed, in knots

C_L : Coefficient depending on the ship length:

$C_L = 0,0125\ L$ for $L < 80$ m

$C_L = 1,0$ for $L \geq 80$ m

C_Z : Coefficient defined in Ch 8, Sec 1, [4.2.1], to be taken equal to 5,5

α : Flare angle at the calculation point, defined as the angle between a vertical line and the tangent to the side plating, measured in a vertical plane normal to the horizontal tangent to the shell plating (see Fig 1)

β : Entry angle at the calculation point, defined as the angle between a longitudinal line parallel to the centreline and the tangent to the shell plating in a horizontal plane (see Fig 1).

2.1.2 Design external forces

The design external forces F_X, F_Y, F_Z to be considered for the scantlings of securing and supporting devices of bow doors are to be not less than those obtained, in kN, from the following formulae:

$F_X = p_E A_X$

$F_Y = p_E A_Y$

$F_Z = p_E A_Z$

where:

p_E : External pressure, in kN/m², to be calculated according to [2.1.1], assuming the angles α and β measured at the point on the bow door located $\ell/2$ aft of the stem line on the plane h/2 above the bottom of the door, as shown in Fig 1

h : Height, in m, to be taken as the lesser of h_1 and h_2

h_1 : Height, in m, of the door between the levels of its bottom and the upper deck

h_2 : Height, in m, of the door between its bottom and top

ℓ : Length, in m, of the door at a height h/2 above the bottom of the door

A_X : Area, in m², to be taken as the lesser of A_{X1} and A_{X2}

A_Y : Area, in m², to be taken as the lesser of A_{Y1} and A_{Y2}

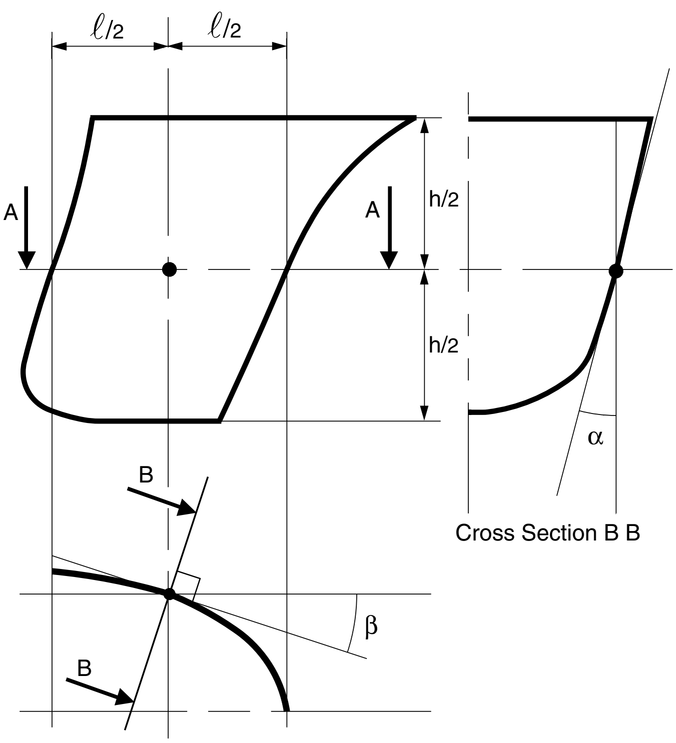
A_Z : Area, in m², to be taken as the lesser of A_{Z1} and A_{Z2}

A_{X1}, A_{Y1}, A_{Z1} : Areas, in m², of the vertical transverse, vertical longitudinal and horizontal projections, respectively, of the door between the levels of its bottom and the upper deck

A_{X2}, A_{Y2}, A_{Z2} : Areas, in m², of the vertical transverse, vertical longitudinal and horizontal projections, respectively, of the door between the levels of its bottom and top.

For bow doors, including bulwark, of unusual form or proportions, e.g. ships with a rounded nose and large stem angles, the areas and angles used for determination of the design values of external forces will be considered on a case-by-case basis.

Figure 1 : Definition of angles α and β



2.1.3 Closing moment

For visor doors, the closing moment under external loads is to be obtained, in kN·m, from the following formula:

$M_Y = F_X\ a + 10\ W\ c - F_Z\ b$

where:

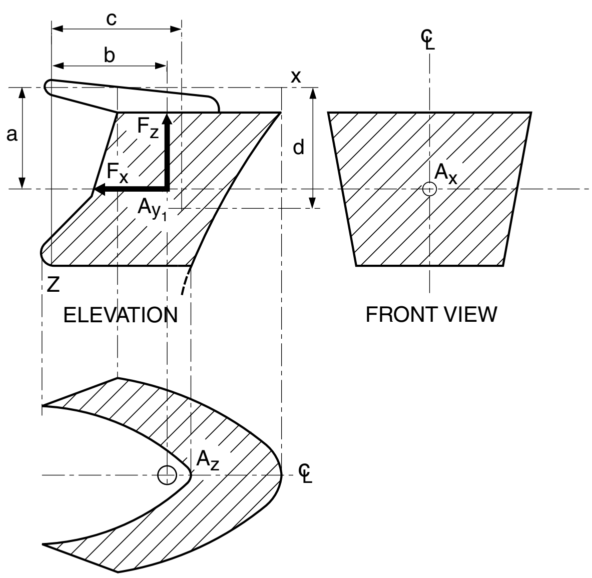
W : Mass of the visor door, in t

a : Vertical distance, in m, from visor pivot to the centroid of the transverse vertical projected area of the visor door, as shown in Fig 2

b : Horizontal distance, in m, from visor pivot to the centroid of the horizontal projected area of the visor door, as shown in Fig 2

c : Horizontal distance, in m, from visor pivot to the centre of gravity of visor mass, as shown in Fig 2.

Figure 2 : Bow doors of visor type



2.1.4 Forces acting on the lifting arms

The lifting arms of a visor door and its supports are to be dimensioned for the static and dynamic forces applied during the lifting and lowering operations, and a minimum wind pressure of 1,5 kN/m^2 is to be taken into account.

2.2 Inner doors

2.2.1 Design external pressure

The design external pressure to be considered for the scantlings of primary supporting members, securing and supporting devices and surrounding structure of inner doors is to be taken as the greater of the values obtained, in kN/m^2, from the following formulae:

$p_E = 0,45\ L_1$

$p_E = 10\ h$

where:

h : Distance, in m, from the calculation point to the top of the cargo space.

2.2.2 Design internal pressure

The design internal pressure p_I to be considered for the scantlings of securing devices of inner doors is to be not less than 25 kN/m^2.

3 Scantlings of bow doors

3.1 General

3.1.1 The strength of bow doors is to be commensurate with that of the surrounding structure.

3.1.2 Bow doors are to be adequately stiffened and means are to be provided to prevent lateral or vertical movement of the doors when closed.

For visor doors, adequate strength for opening and closing operations is to be provided in the connections of the lifting arms to the door structure and to the ship structure.

3.2 Plating and ordinary stiffeners

3.2.1 Plating

The thickness of the bow door plating is to be not less than that obtained according to the requirements in Ch 8, Sec 1 for the fore part, using the bow door stiffener spacing. In no case may it be less than the minimum required thickness of fore part shell plating.

3.2.2 Ordinary stiffeners

The section modulus of bow door ordinary stiffeners is to be not less than that obtained according to the requirements in Ch 8, Sec 1 for the fore part, using the bow door stiffener spacing.

Consideration is to be given, where necessary, to differences in conditions of fixity between the ends of ordinary stiffeners of bow doors and those of the fore part shell.

3.3 Primary supporting members

3.3.1 Bow door ordinary stiffeners are to be supported by primary supporting members constituting the main stiffening of the door.

3.3.2 The primary supporting members of the bow door and the hull structure in way are to have sufficient stiffness to ensure integrity of the boundary support of the door.

3.3.3 Scantlings of primary supporting members are generally to be verified through direct calculations on the basis of the external pressure p_E in [2.1.1] and the strength criteria in [6.1.1] and [6.1.2].

In general, isolated beam models may be used to calculate the loads and stresses in primary supporting members.

4 Scantlings of inner doors

4.1 General

4.1.1 The gross scantlings of the primary supporting members are generally to be verified through direct calculations on the basis of the external pressure p_E in [2.1.1] and the strength criteria in [6.1.1] and [6.1.2].

In general, isolated beam models may be used to calculate the loads and stresses in primary supporting members.

4.1.2 Where inner doors also serve as vehicle ramps, their scantlings are to be not less than those obtained according to Ch 8, Sec 8.

4.1.3 The distribution of the forces acting on the securing and supporting devices is generally to be supported by direct calculations taking into account the flexibility of the structure and the actual position and stiffness of the supports.

5 Securing and supporting of bow doors

5.1 General

5.1.1 Bow doors are to be fitted with adequate means of securing and supporting so as to be commensurate with the strength and stiffness of the surrounding structure.

The hull supporting structure in way of the bow doors is to be suitable for the same design loads and design stresses as the securing and supporting devices.

Where packing is required, the packing material is to be of a comparatively soft type, and the supporting forces are to be carried by the steel structure only. Other types of packing may be considered by the Society on a case-by-case basis.

The maximum design clearance between securing and supporting devices is generally not to exceed 3 mm.

A means is to be provided for mechanically fixing the door in the open position.

5.1.2 Only the active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered to calculate the reaction forces acting on the devices. Small and/or flexible devices such as cleats intended to provide local compression of the packing material may generally not be included in the calculation in [5.2.5].

The number of securing and supporting devices is generally to be the minimum practical while taking into account the requirements for redundant provision given in [5.2.6] and [5.2.7]and the available space for adequate support in the hull structure.

5.1.3 For visor doors which open outwards, the pivot arrangement is generally to be such that the visor is self-closing under external loads, i.e. it is to be checked that the closing moment M_Y, defined in [2.1.3], is in compliance with the following formula:

$M_Y > 0$

Moreover, the closing moment M_Y is to be not less than the value M_{Y0} , in kN.m, obtained from the following formula:

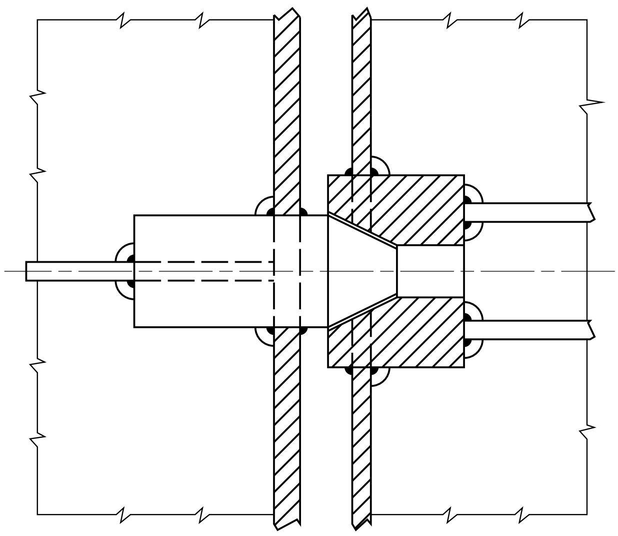
$$M_{Y0} = 10Wc + 0{,}1\sqrt{a^2+b^2}\sqrt{F_X^2+F_Z^2}$$

5.1.4 For side-opening doors, a thrust bearing is to be provided in way of girder ends at the closing of the two leaves to prevent one leaf from shifting towards the other under the effect of unsymmetrical pressure (see example in Fig 3).

The parts of the thrust bearing are to be kept secured to each other by means of securing devices.

The Society may consider any other arrangement serving the same purpose.

Figure 3 : Thrust bearing



5.2 Scantlings

5.2.1 Securing and supporting devices are to be adequately designed so that they can withstand the reaction forces within the allowable stresses defined in [6.1.1].

5.2.2 For visor doors, the reaction forces applied on the effective securing and supporting devices assuming the door as a rigid body are determined for the following combination of external loads acting simultaneously together with the self weight of the door:

- Case 1: F_X and F_Z
- Case 2: 0,7 F_Y acting on each side separately together with 0,7 F_X and 0,7 F_Z ,

where F_X, F_Y and F_Z are to be calculated as indicated in [2.1.2] and applied at the centroid of projected areas.

5.2.3 For side-opening doors, the reaction forces applied on the effective securing and supporting devices assuming the door as a rigid body are determined for the following combination of external loads acting simultaneously together with the self weight of the door:

- Case 1: F_X , F_Y and F_Z acting on both doors
- Case 2: 0,7 F_X and 0,7 F_Z acting on both doors and 0,7 F_Y acting on each door separately,

where F_X , F_Y and F_Z are to be calculated as indicated in [2.1.2] and applied at the centroid of projected areas.

5.2.4 The support forces as calculated according to Case 1 in [5.2.2] and Case 1 in [5.2.3] are to generally give rise to a zero moment about the transverse axis through the centroid of the area A_X .

For visor doors, longitudinal reaction forces of pin and/or wedge supports at the door base contributing to this moment are not to be in the forward direction.

5.2.5 The distribution of the reaction forces acting on the securing and supporting devices may need to be supported by direct calculations taking into account the flexibility of the hull structure and the actual position and stiffness of the supports.

5.2.6 The arrangement of securing and supporting devices in way of these securing devices is to be designed with redundancy so that, in the event of failure of any single securing or supporting device, the remaining devices are capable of withstanding the reaction forces without exceeding by more than 20% the allowable stresses defined in [6.1.1].

5.2.7 For visor doors, two securing devices are to be provided at the lower part of the door, each capable of providing the full reaction force required to prevent opening of the door within the allowable stresses defined in [6.1.1].

The opening moment M_0 to be balanced by this reaction force is to be taken not less than that obtained, in kN.m, from the following formula:

$M_0 = 10\ W\ d + 5\ A_X\ a$

where:

d : Vertical distance, in m, from the hinge axis to the centre of gravity of the door, as shown in Fig 2

a : Vertical distance, in m, defined in [2.1.3].

5.2.8 For visor doors, the securing and supporting devices excluding the hinges are to be capable of resisting the vertical design force (F_Z – 10 W), in kN, within the allowable stresses defined in [6.1.1].

5.2.9 All load transmitting elements in the design load path, from the door through securing and supporting devices into the ship structure, including welded connections, are to be of the same strength standard as required for the securing and supporting devices.

6 Strength criteria

6.1 Primary supporting members and securing and supporting devices

6.1.1 Yielding check

It is to be checked that the normal stresses σ, the shear stress τ and the equivalent stress σ_{VM}, induced in the primary supporting members and in the securing and supporting devices of bow doors by the design load defined in [2], are in compliance with the following formulae:

$\sigma \le \sigma_{ALL}$

$\tau \le \tau_{ALL}$

$\sigma_{VM} = (\sigma^2 + 3\ \tau^2)^{0,5} \le \sigma_{VM,ALL}$

where:

σ_{ALL} : Allowable normal stress, in N/mm², equal to: $\sigma_{ALL} = 120 / k$

τ_{ALL} : Allowable shear stress, in N/mm², equal to: $\tau_{ALL} = 80 / k$

$\sigma_{VM,ALL}$: Allowable equivalent stress, in N/mm^2, equal to: $\sigma_{VM,ALL} = 150 / k$

k : Material factor, defined in Ch 4, Sec 1, [2.3], but to be taken not less than 0,72 unless a fatigue analysis is carried out.

6.1.2 Buckling check

The buckling check of primary supporting members is to be carried out according to Ch 7, Sec 3, [5].

6.1.3 Bearings

For steel to steel bearings in securing and supporting devices, it is to be checked that the nominal bearing pressure σ_B, in N/mm^2, is in compliance with the following formula:

$\sigma_B \leq 0,8\ R_{e,HB}$

where:

$$\sigma_B = 10\frac{F}{A_B}$$

F : Design force, in kN, defined in [2.1.2]

A_B : Projected bearing area, in cm^2

$R_{e,HB}$: Yield stress, in N/mm^2, of the bearing material.

For other bearing materials, the allowable bearing pressure is to be determined according to the manufacturer's specification.

6.1.4 Bolts

The arrangement of securing and supporting devices is to be such that threaded bolts do not carry support forces.

It is to be checked that the tension σ_T in way of threads of bolts not carrying support forces is in compliance with the following formula:

$\sigma_T \leq \sigma_{T,ALL}$

where:

$\sigma_{T,ALL}$: Allowable tension in way of threads of bolts, in N/mm^2, equal to: $\sigma_{T,ALL} = 125 / k$

k : Material coefficient defined in [6.1.1].

7 Securing and locking arrangement

7.1 Systems for operation

7.1.1 Securing devices are to be simple to operate and easily accessible.

Securing devices are to be equipped with mechanical locking arrangement (self-locking or separate arrangement), or to be of the gravity type.

The opening and closing systems as well as securing and locking devices are to be interlocked in such a way that they can only operate in the proper sequence.

7.1.2 Bow doors and inner doors giving access to vehicle decks are to be provided with an arrangement for remote control, from a position above the main watertight deck, of:

- the closing and opening of the doors, and
- associated securing and locking devices for every door.

Indication of the open/closed position of every door and every securing and locking device is to be provided at the remote control stations.

The operating panels for operation of doors are to be inaccessible to unauthorized persons.

A notice plate, giving instructions to the effect that all securing devices are to be closed and locked before leaving harbour, is to be placed at each operating panel and is to be supplemented by warning indicator lights.

7.1.3 Where hydraulic securing devices are applied, the system is to be mechanically lockable in closed position. This means that, in the event of loss of hydraulic fluid, the securing devices remain locked.

The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits, when in closed position.

7.2 Systems for indication/monitoring

7.2.1 Separate indicator lights and audible alarms are to be provided on the navigation bridge and on the operating panel to show that the bow door and inner door are closed and that their securing and locking devices are properly positioned.

The indication panel is to be provided with a lamp test function. It is not to be possible to turn off the indicator light.

7.2.2 The indicator system is to be designed on the fail safe principle and is to show by visual alarms if the door is not fully closed and not fully locked and by audible alarms if securing devices become open or locking devices become unsecured.

The power supply for the indicator system is to be independent of the power supply for operating and closing the doors.

The sensors of the indicator system are to be protected from water, ice formation and mechanical damage.

7.2.3 The indication panel on the navigation bridge is to be equipped with a mode selection function “harbour/sea voyage”, so arranged that an audible alarm is given if the ship leaves harbour with the bow door or inner door not closed and with any of the securing devices not in the correct position.

7.2.4 A water leakage detection system with an audible alarm and television surveillance is to be arranged to provide an indication to the navigation bridge and to the engine control room of leakage through the inner door.

7.2.5 Between the bow door and the inner door a television surveillance system is to be fitted with a monitor on the navigation bridge and in the engine control room.

The system is to monitor the position of doors and a sufficient number of their securing devices.

Special consideration is to be given to the lighting and contrasting colour of the objects under surveillance.

7.2.6 The indicator system for the closure of the doors and the television surveillance systems for the doors and water leakage detection, and for special category and ro-ro spaces are to be suitable to operate correctly in the ambient conditions on board and to be type approved on the basis of the applicable tests.

7.2.7 A drainage system is to be arranged in the area between bow door and ramp, as well as in the area between the ramp and inner door, where fitted.

The system is to be equipped with an audible alarm providing an indication on the navigation bridge when the water level in these areas exceeds 0,5 m above the car deck level.

8 Operating and maintenance manual

8.1 General

8.1.1 An Operating and Maintenance Manual (OMM) for the bow door and inner door is to be provided on board and is to contain the necessary information on:

a) main particulars and design drawings:
   - special safety precautions
   - details of ship
   - equipment and design loading (for ramps)
   - key plan of equipment (doors and ramps)
   - manufacturer’s recommended testing for equipment
   - description of equipment:
     - bow doors
     - inner bow doors
     - bow ramp/doors
     - central power pack
     - control panels.

b) service conditions:
   - limiting heel and trim of ship for loading/unloading
   - limiting heel and trim for door operations
   - doors/ramps operating instructions
   - doors/ramps emergency operating instructions.

c) maintenance:
   - schedule and extent of maintenance
   - trouble shooting and acceptable clearances
   - manufacturer’s maintenance procedures.

d) register of inspections, including inspection of locking, securing and supporting devices, repairs and renewals.

This manual is to be submitted to the Society for approval. It is to be checked that the above mentioned items are contained in the OMM and that the maintenance part includes the necessary information with regard to inspections, trouble-shooting and acceptance/rejection criteria.

Note 1: It is recommended that inspections of the doors and supporting and securing devices be carried out by ship’s personnel at monthly intervals or following any incidents which could result in damage, including heavy weather or contact in the region of the shell doors. A record is to be kept and any damage found during such inspections is to be reported to the Society.

8.1.2 Documented operating procedures for closing and securing the bow door and inner door are to be kept on board and posted at an appropriate place.

Section 6 Side Doors and Stern Doors

Symbols

L_1 : Length, in m, defined in Ch 1, Sec 2, [2.1.1].

1 General

1.1 Application

1.1.1 The requirements of this Section apply to the arrangement, strength and securing of side doors, located below the bulkhead deck and abaft the collision bulkhead, and to stern doors located below the bulkhead deck.

1.2 Gross scantlings

1.2.1 With reference to Ch 4, Sec 2, [1], all scantlings and dimensions referred to in this Section are gross, i.e. they include the margins for corrosion.

1.3 Arrangement

1.3.1 Side doors and stern doors are to be so fitted as to ensure tightness and structural integrity commensurate with their location and the surrounding structure.

1.3.2 Where the sill of any side door is below the uppermost load line, the arrangement is considered by the Society on a case-by-case basis.

1.3.3 Doors are preferably to open outwards.

1.4 Definitions

1.4.1 Securing device

A securing device is a device used to keep the door closed by preventing it from rotating about its hinges or about pivoted attachments to the ship.

1.4.2 Supporting device

A supporting device is a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, which transmits loads from the door to the ship structure.

1.4.3 Locking device

A locking device is a device that locks a securing device in the closed position.

2 Design loads

2.1 Side and stern doors

2.1.1 Design forces

The design external forces F_E and the design internal forces F_I to be considered for the scantlings of primary supporting members and securing and supporting devices of side doors and stern doors are to be obtained, in kN, from the formulae in Tab 1.

Table 1 : Design forces

Structural elements	External force F_E, in kN	Internal force F_I, in kN
Securing and supporting devices of doors opening inwards	$A\ p_E + F_P$	$F_0 + 10\ W$
Securing and supporting devices of doors opening outwards	$A\ p_E$	$F_0 + 10\ W + F_P$
Primary supporting members **(1)**	$A\ p_E$	$F_0 + 10\ W$

(1) The design force to be considered for the scantlings of the primary supporting members is the greater of F_E and F_I.

Note 1:

- A : Area, in m², of the door opening
- W : Mass of the door, in t
- F_P : Total packing force, in kN; the packing line pressure is normally to be taken not less than 5 N/mm
- F_0 : The greater of F_C and 5 A, in kN
- F_C : Accidental force, in kN, due to loose cargoes etc., to be uniformly distributed over the area A and to be taken not less than 300 kN. For small doors such as bunker doors and pilot doors, the value of F_C may be appropriately reduced. However, the value of F_C may be taken as zero, provided an additional structure such as an inner ramp is fitted, which is capable of protecting the door from accidental forces due to loose cargoes
- p_E : External design pressure determined at the centre of gravity of the door opening and to be taken not less than that obtained, in kN/m², from the following formulae:

  $p_E = 10\ (T - Z_G) + 25$ for $Z_G < T$

  $p_E = 25$ for $Z_G \geq T$

  Moreover, for stern doors of ships fitted with bow doors, p_E is to be taken not less than that obtained, in kN/m², from the following formula:

  $$p_E = 0{,}6 C_L (0{,}8 + 0{,}6\sqrt{L_1})^2$$
- T : Draught, in m, at the highest subdivision load line
- Z_G : Height of the centre of the area of the door, in m, above the baseline
- C_L : Coefficient depending on the ship length:

  $C_L = 0{,}0125\ L$ for $L < 80$ m

  $C_L = 1{,}0$ for $L \geq 80$ m.

3 Scantlings of side doors and stern doors

3.1 General

3.1.1 The strength of side doors and stern doors is to be commensurate with that of the surrounding structure.

3.1.2 Side doors and stern doors are to be adequately stiffened and means are to be provided to prevent any lateral or vertical movement of the doors when closed.

Adequate strength is to be provided in the connections of the lifting/manoeuvring arms and hinges to the door structure and to the ship structure.

3.1.3 Where doors also serve as vehicle ramps, the design of the hinges is to take into account the ship angle of trim and heel which may result in uneven loading on the hinges.

3.1.4 Shell door openings are to have well rounded corners and adequate compensation is to be arranged with web frames at sides and stringers or equivalent above and below.

3.2 Plating and ordinary stiffeners

3.2.1 Plating

The thickness of the door plating is to be not less than that obtained according to the requirements in Ch 7, Sec 1 for side plating, using the door stiffener spacing. In no case may it be less than the minimum required thickness of side plating.

Where doors also serve as vehicle ramps, the thickness of the door plating is to be not less than that obtained according to Ch 8, Sec 8.

3.2.2 Ordinary stiffeners

The scantling of door ordinary stiffeners is to be not less than that obtained according to the requirements in Ch 7, Sec 2 for the side, using the door stiffener spacing.

Consideration is to be given, where necessary, to differences in conditions of fixity between the ends of ordinary stiffeners of doors and those of the side.

Where doors also serve as vehicle ramps, the scantling of ordinary stiffeners is to be not less than that obtained according to Ch 8, Sec 8.

3.3 Primary supporting members

3.3.1 The door ordinary stiffeners are to be supported by primary supporting members constituting the main stiffening of the door.

3.3.2 The primary supporting members and the hull structure in way are to have sufficient stiffness to ensure structural integrity of the boundary of the door.

3.3.3 Scantlings of primary supporting members are generally to be verified through direct calculations on the basis of the design forces in [2.1.1] and the strength criteria in [5.1.1] and [5.1.2].

In general, isolated beam models may be used to calculate the loads and stresses in primary supporting members.

4 Securing and supporting of doors

4.1 General

4.1.1 Side doors and stern doors are to be fitted with adequate means of securing and supporting so as to be commensurate with the strength and stiffness of the surrounding structure.

The hull supporting structure in way of the doors is to be suitable for the same design loads and design stresses as the securing and supporting devices.

Where packing is required, the packing material is to be of a comparatively soft type, and the supporting forces are to be carried by the steel structure only. Other types of packing may be considered by the Society on a case-by-case basis.

The maximum design clearance between securing and supporting devices is generally not to exceed 3 mm.

A means is to be provided for mechanically fixing the door in the open position.

4.1.2 Only the active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered to calculate the reaction forces acting on the devices. Small and/or flexible devices such as cleats intended to provide local compression of the packing material may generally not be included in the calculation in [4.2.2].

The number of securing and supporting devices is generally to be the minimum practical while taking into account the requirements for redundant provision given in [4.2.3] and the available space for adequate support in the hull structure.

4.2 Scantlings

4.2.1 Securing and supporting devices are to be adequately designed so that they can withstand the reaction forces within the allowable stresses defined in [5.1.1].

4.2.2 The distribution of the reaction forces acting on the securing and supporting devices may need to be supported by direct calculations taking into account the flexibility of the hull structure and the actual position of the supports.

4.2.3 The arrangement of securing and supporting devices in way of these securing devices is to be designed with redundancy so that, in the event of failure of any single securing or supporting device, the remaining devices are capable of withstanding the reaction forces without exceeding by more than 20% the allowable stresses defined in [5.1.1].

4.2.4 All load transmitting elements in the design load path, from the door through securing and supporting devices into the ship structure, including welded connections, are to be of the same strength standard as required for the securing and supporting devices.

5 Strength criteria

5.1 Primary supporting members and securing and supporting devices

5.1.1 Yielding check

It is to be checked that the normal stress σ, the shear stress τ and the equivalent stress σ_{VM}, induced in the primary supporting members and in the securing and supporting devices of doors by the design load defined in [2], are in compliance with the following formulae:

$\sigma \le \sigma_{ALL}$

$\tau \le \tau_{ALL}$

$\sigma_{VM} = (\sigma^2 + 3\ \tau^2)^{0,5} \le \sigma_{VM,ALL}$

where:

σ_{ALL}	:	Allowable normal stress, in N/mm²: $\sigma_{ALL} = 120 / k$
τ_{ALL}	:	Allowable shear stress, in N/mm²: $\tau_{ALL} = 80 / k$
$\sigma_{VM,ALL}$	:	Allowable equivalent stress, in N/mm²: $\sigma_{VM,ALL} = 150 / k$
k	:	Material factor, defined in Ch 4, Sec 1, [2.3], but to be taken not less than 0,72 unless a fatigue analysis is carried out.

5.1.2 Buckling check

The buckling check of primary supporting members is to be carried out according to Ch 7, Sec 3, [5].

5.1.3 Bearings

For steel to steel bearings in securing and supporting devices, it is to be checked that the nominal bearing pressure σ_B, in N/mm², is in compliance with the following formula:

$\sigma_B \leq 0,8\ R_{eH,B}$

where:

$$\sigma_B = 10\frac{F}{A_B}$$

with:

F : Design force, in KN, defined in [2.1.1]

A_B : Projected bearing area, in cm²

$R_{eH,B}$: Yield stress, in N/mm², of the bearing material.

For other bearing materials, the allowable bearing pressure is to be determined according to the manufacturer's specification.

5.1.4 Bolts

The arrangement of securing and supporting devices is to be such that threaded bolts do not carry support forces.

It is to be checked that the tension σ_T in way of threads of bolts not carrying support forces is in compliance with the following formula:

$\sigma_T \leq \sigma_{T,ALL}$

where:

$\sigma_{T,ALL}$: Allowable tension in way of threads of bolts, in N/mm²: $\sigma_{T,ALL} = 125 / k$

k : Material factor, defined in [5.1.1].

6 Securing and locking arrangement

6.1 Systems for operation

6.1.1 Securing devices are to be simple to operate and easily accessible.

Securing devices are to be equipped with mechanical locking arrangement (self-locking or separate arrangement), or to be of the gravity type.

The opening and closing systems as well as securing and locking devices are to be interlocked in such a way that they can only operate in the proper sequence.

6.1.2 Doors which are located partly or totally below the watertight deck with a clear opening area greater than 6 m² are to be provided with an arrangement for remote control, from a position above the main watertight deck, of:

- the closing and opening of the doors
- associated securing and locking devices.

For doors which are required to be equipped with a remote control arrangement, indication of the open/closed position of the door and the securing and locking device is to be provided at the remote control stations.

The operating panels for operation of doors are to be inaccessible to unauthorized persons.

A notice plate, giving instructions to the effect that all securing devices are to be closed and locked before leaving harbour, is to be placed at each operating panel and is to be supplemented by warning indicator lights.

6.1.3 Where hydraulic securing devices are applied, the system is to be mechanically lockable in closed position. This means that, in the event of loss of hydraulic fluid, the securing devices remain locked.

The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits, when in closed position.

7 Operating and maintenance manual

7.1 General

7.1.1 An Operating and Maintenance Manual (OMM) for the side doors and stern doors is to be provided on board and is to contain the necessary information on:

a) main particulars and design drawings:
   - special safety precautions
   - details of ship
   - equipment and design loading (for ramps)
   - key plan of equipment (doors and ramps)
   - manufacturer's recommended testing for equipment
   - description of equipment:
     - side doors
     - stern doors
     - central power pack
     - control panels.

b) service conditions:
   - limiting heel and trim of ship for loading / unloading
   - limiting heel and trim for door operations
   - doors / ramps operating instructions
   - doors / ramps emergency operating instructions.

c) maintenance:
   - schedule and extend of maintenance
   - trouble shooting and acceptable clearances
   - manufacturer's maintenance procedures.

d) register of inspections, including inspection of locking, securing and supporting devices, repairs and renewals.

This manual is to be submitted to the Society for approval. It is to be checked that the above mentioned items are contained in the OMM and that the maintenance part includes the necessary information with regard to inspections, trouble-shooting and acceptance / rejection criteria.

Note 1: It is recommended that inspections of the door and supporting and securing devices be carried out by ship's personnel at monthly intervals or following any incidents which could result in damage, including heavy weather or contact in the region of the shell doors. A record is to be kept and any damage recorded during such inspections is to be reported to the Society.

7.1.2 Documented operating procedures for closing and securing the side and stern doors are to be kept on board and posted at an appropriate place.

Section 7 Hatch Covers

Symbols

p_S : Still water pressure, in kN/m² (see [5.1])

p_{SF} : Still water pressure for flooding, in kN/m², defined in Ch 5, Sec 6, Tab 9

p_W : Wave pressure, in kN/m² (see [5.1])

p_{WF} : Wave pressure for flooding, in kN/m², defined in Ch 5, Sec 6, Tab 9

p_T : Test pressure, in kN/m²

s : Length, in m, of the shorter side of the plate panel

ℓ : Length, in m, of the longer side of the plate panel

b_P : Width, in m, of the plating attached to the ordinary stiffener or primary supporting member, defined in [4]

w : Net section modulus, in cm³, of the ordinary stiffener or primary supporting member, with an attached plating of width b_p

A_{Sh} : Net shear sectional area, in cm², of the ordinary stiffener or primary supporting member, to be calculated as specified in Ch 4, Sec 3, [3.4], for ordinary stiffeners, and Ch 4, Sec 3, [4.3], for primary supporting members

m : Boundary coefficient for ordinary stiffeners and primary supporting members, taken equal to:

- m = 8 in the case of ordinary stiffeners and primary supporting members simply supported at both ends or supported at one end and clamped at the other
- m = 12 in the case of ordinary stiffeners and primary supporting members clamped at both ends

t_C : Corrosion additions, in mm, defined in [1.6]

R_{eH} : Minimum yield stress, in N/mm², of the material, defined in Ch 4, Sec 1, [2]

R_m : Minimum ultimate tensile strength, in N/mm², of the material, defined in Ch 4, Sec 1, [2]

R_y : Yield stress, in N/mm², of the material, to be taken equal to 235/k N/mm², unless otherwise specified

k : Material factor, defined in Ch 4, Sec 1, [2.3]

c_S : Coefficient, taken equal to:

- $c_S = 1 - (s / 2\ell)$ for ordinary stiffeners
- $c_S = 1{,}0$ for primary supporting members

g : Gravity acceleration, in m/s²: g = 9,81 m/s².

1 General

1.1 Application

1.1.1 The requirements of this Section apply to steel hatch covers in positions 1 and 2 on weather decks, defined in Ch 1, Sec 2, [9.1] as well as hatches installed in watertight boundaries and in emergency escape routes.

1.2 Definitions

1.2.1 Large hatches

Large hatches are hatches with openings greater than 2,5 m².

1.2.2 Small hatches

Small hatches are hatches designed for access to spaces below the deck and are capable to be closed weathertight or watertight, as applicable. Their opening is generally equal to or less than 2,5 m².

1.3 Materials

1.3.1 Steel

The formulae for scantlings given in the requirements in Article [6] are applicable to steel hatch covers.

Materials used for the construction of steel hatch covers are to comply with the applicable requirements of NR216 Materials and Welding, Chapter 2.

1.3.2 Other materials

The use of materials other than steel is considered by the Society on a case-by-case basis, by checking that criteria adopted for scantlings are such as to ensure strength and stiffness equivalent to those of steel hatch covers.

1.4 Net scantlings

1.4.1 As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

The gross scantlings are obtained as specified in Ch 4, Sec 2.

1.5 Partial safety factors

1.5.1 The partial safety factors to be considered for checking hatch cover structures are specified in Tab 1.

Table 1 : Hatch covers - Partial safety factors

Partial safety factors covering uncertainties regarding:	Partial safety factors		
	Symbol	Plating	Ordinary stiffeners and primary supporting members
Still water pressure	γ_{S2}	1,00	1,00
Wave pressure	γ_{W2}	1,20	1,20
Material	γ_m	1,02	1,02
Resistance	γ_R	1,20	1,02

1.6 Corrosion additions

1.6.1 General

The requirements of Ch 4, Sec 2, [1] and Ch 4, Sec 2, [2] apply.

1.6.2 Corrosion additions for hatch covers on exposed decks

In general, for steel other than stainless steel the corrosion addition to be considered for the plating and internal members of hatch covers on exposed decks is the value specified in Tab 2 for the total thickness of the member under consideration.

Table 2 : Corrosion additions t_C for steel hatch covers on exposed decks

Steel hatch covers	t_C, in mm
Plating and stiffeners of single skin hatch cover	2,0
Top and bottom plating of pontoon hatch cover	2,0
Internal structures of pontoon hatch cover	1,5

1.6.3 Corrosion addition for hatch covers on non-exposed decks

For hatch covers on non-exposed decks, the corrosion addition t_C is to be taken equal to that of the adjacent deck.

1.6.4 Corrosion additions for stainless steel

For structural members made of stainless steel, the corrosion addition t_C is to be taken equal to 0.

1.6.5 Corrosion additions for aluminium alloys

For structural members made of aluminium alloys, the corrosion addition t_C is to be taken equal to 0.

2 Arrangement of large hatches

2.1 Height of hatch coamings

2.1.1 The height above the deck of hatch coamings for large hatches is to be not less than:

- 600 mm in position 1
- 450 mm in position 2.

2.1.2 The height of hatch coamings in positions 1 and 2 closed by steel covers provided with gaskets and securing devices may be reduced with respect to the above values or the coamings may be omitted entirely, on condition that the Society is satisfied that the safety of the ship is not thereby impaired in any sea conditions.

In such cases the scantlings of the covers, their gasketing, their securing arrangements and the drainage of recesses in the deck are considered by the Society on a case-by-case basis.

2.1.3 Regardless of the type of closing arrangement adopted, the coamings may have reduced height or be omitted in way of openings in closed superstructures or decks below the main watertight deck.

2.2 Hatch covers

2.2.1 Hatch covers on exposed decks are to be weathertight.

Hatch covers in closed superstructures need not be weathertight.

However, hatch covers fitted in way of ballast tanks, fuel oil tanks or other tanks are to be watertight.

2.2.2 The covers used in 'tweendecks are to be fitted with an appropriate system ensuring an efficient stowing when the ship is sailing with open 'tweendecks.

2.2.3 The ends of hatch covers are normally to be protected by efficiently secured galvanized steel strips.

2.2.4 The width of each bearing surface for hatch covers is to be at least 65 mm.

2.3 Hatch coamings

2.3.1 Coamings, stiffeners and brackets are to be capable of withstanding the local forces in way of the clamping devices and handling facilities necessary for securing and moving the hatch covers as well as those due to cargo stowed on the latter.

2.3.2 Special attention is to be paid to the strength of the fore transverse coaming of the forward hatch and to the scantlings of the closing devices of the hatch cover on this coaming.

2.3.3 Longitudinal coamings are to be extended at least to the lower edge of deck beams.

Where they are not part of continuous deck girders, longitudinal coamings are to extend for at least two frame spaces beyond the end of the openings.

Where longitudinal coamings are part of deck girders, their scantlings are to be as required in Ch 7, Sec 3.

2.3.4 Transverse coamings are to extend below the deck at least to the lower edge of longitudinals.

Transverse coamings not in line with ordinary deck beams below are to extend below the deck at least three longitudinal frame spaces beyond the side coamings.

3 Arrangement of small hatches

3.1 General

3.1.1 Hatchways of special design are considered by the Society on a case-by-case basis.

3.2 Height of hatch coamings

3.2.1 The height above the deck of hatch coamings for small hatches is to be not less than:

- 600 mm in position 1
- 450 mm in position 2.

3.2.2 Where the closing appliances are in the form of hinged steel covers secured weathertight by gaskets and swing bolts, the height of the coamings may be reduced or the coamings may be omitted altogether.

3.2.3 The height of coamings for hatches in escape routes are to be determined considering the rules in Pt C, Ch 4, Sec 8, [4.1].

3.3 Hatch covers fitted on exposed decks

3.3.1 Small hatch covers on exposed decks are to be weathertight.

3.3.2 Hold accesses located on the weather deck are to be provided with watertight metallic hatch covers, unless they are protected by a closed superstructure. The same applies to accesses located on the forecastle deck and leading directly to a dry cargo hold through a trunk.

3.4 Hatch covers fitted on non-exposed decks

3.4.1 Small hatch covers on non-exposed decks need not be weathertight.

3.4.2 Small hatch covers fitted on non-exposed decks are to have a level of tightness equivalent to that required for adjacent compartment(s).

3.5 Watertight hatch covers

3.5.1 Hatches defined as per the Internal Watertight Plan which constitute boundaries intended to stop vertical and horizontal flooding shall have the same level of tightness as the structure in which they are installed.

3.5.2 Accesses to cofferdams and ballast tanks are to be manholes fitted with watertight covers fixed with bolts which are sufficiently closely spaced (refer to Ch 3, Sec 3, [2.2.2], c)).

4 Width of attached plating

4.1 Ordinary stiffeners

4.1.1 The width of the attached plating to be considered for the check of ordinary stiffeners is to be obtained, in m, from the following formulae:

- where the attached plating extends on both sides of the stiffener:

  $b_P = s$

- where the attached plating extends on one side of the stiffener:

  $b_P = 0{,}5\ s$

4.2 Primary supporting members

4.2.1 Primary supporting members parallel to ordinary stiffeners

The width of the attached plating to be considered for the check of primary supporting members parallel to ordinary stiffeners is to be obtained, in m, from the following formulae:

- if $\beta \le 1{,}0$:

  $b_P = S_P$

- if $\beta > 1{,}0$:

$$b_P = \left(\frac{1,8}{\beta} - \frac{0,8}{\beta^2}\right) S_P$$

where:

$$\beta = 10^3 \frac{s}{t} \sqrt{\frac{R_{eH}}{E}}$$

E : Young's modulus, in N/mm², to be taken equal to $2{,}06 \cdot 10^5$ N/mm² for steels in general

S_P : Spacing, in m, of primary supporting members.

Where the attached plating extends on one side of the primary supporting member, the width b_P calculated as required above is to be multiplied by 0,5.

4.2.2 Primary supporting members perpendicular to ordinary stiffeners

The width of the attached plating to be considered for the check of primary supporting members perpendicular to ordinary stiffeners is to be obtained, in m, from the following formula:

$$b_P = \left[b_{P,L}\frac{s}{\ell} + 0,115\left(1 - \frac{s}{\ell}\right)\left(1 + \frac{1}{\beta^2}\right)^2\right]\ell$$

to be taken not greater than ℓ

where:

$$b_{P,L} = \frac{1,8}{\beta} - \frac{0,8}{\beta^2} \qquad \text{for } \beta > 1,0$$

$$b_{P,L} = 1,0 \qquad \text{for } \beta \le 1,0$$

β : Defined in [4.2.1].

Where the attached plating extends on one side of the primary supporting member, the width b_P calculated as required above is to be multiplied by 0,5.

5 Load model

5.1 Lateral pressures and concentrated loads

5.1.1 General

The still water and wave lateral pressures p_S and p_W and the concentrated loads, to be considered as acting on hatch covers are those in [5.1.2] to [5.1.9].

All hatch covers are to be subject to the still water and wave lateral pressures in either [5.1.2] or [5.1.3], according to their position in exposed or non-exposed decks. In addition to this, the requirements in [5.1.4] to [5.1.9] are to be applied where applicable, depending upon the intended use and location of each cover. The applicable checks in [5.1.2] to [5.1.9] are to be conducted separately. Multiple checks as defined in [5.1.4] to [5.1.9] may apply to any individual hatch.

5.1.2 Hatch covers on exposed decks

The still water and wave lateral pressures p_S and p_W to be considered and are defined in Ch 5, Sec 5, [3].

5.1.3 Hatch covers on non-exposed decks

The still water and wave pressures p_S and p_W to be considered are those applicable to the adjacent deck structure, determined as per Ch 5, Sec 6, [5].

When a hatch cover is installed with a coaming in an emergency escape route on a non-exposed deck, a still water pressure of 3 kN/m² may be considered in lieu of the value applicable to the adjacent deck structure. In this case, a warning notice must be applied to ensure that the hatch cover remains unloaded and clear of obstacles as per Pt C, Ch 4, Sec 8, [2.1.1].

5.1.4 Additional lateral pressures for hatch covers in way of liquid cargo or ballast tanks

Additional checks shall be conducted for the still water and wave lateral pressures p_S and p_W defined in Ch 5, Sec 6, [1].

5.1.5 Additional lateral pressures for hatch covers carrying uniform cargoes

Additional checks shall be conducted for the still water and wave lateral pressures p_S and p_W defined in Ch 5, Sec 6, [2].

5.1.6 Additional loads for hatch covers carrying containers

Additional checks shall be conducted for the still water and wave loads defined in Ch 5, Sec 6, [3].

5.1.7 Additional loads for hatch covers carrying wheeled loads

Additional checks shall be conducted for the still water and wave loads defined in Ch 5, Sec 6, [4].

5.1.8 Additional lateral pressures for hatch covers carrying special cargoes

In the case of carriage on the hatch covers of special cargoes (e.g. pipes, etc.) which may temporarily retain water during navigation, the lateral pressure to be applied is considered by the Society on a case-by-case basis.

5.1.9 Additional lateral pressures for hatch covers in ammunition magazines

Attention is to be given to hatches in ammunition magazines which are subject to fire-extinguishing by flooding. In this case, additional checks are to be conducted for the still water and wave lateral pressures p_S and p_W determined as per Ch 5, Sec 6, [5.1.4].

5.2 Conventional pressure for hatch covers on exposed decks

5.2.1 The conventional pressure p_0 is defined in Tab 3 according to the hatch cover position.

Table 3 : Conventional pressure on hatch covers

Conventional pressure p_0, in kN/m²	
Position 1	Position 2
$g\left(\frac{58+0{,}75L}{76}\right)$	$g\left(\frac{43{,}8+0{,}55L}{76}\right)$
Note 1: L is to be taken not greater than 100 m.	

5.3 Load point

5.3.1 Wave lateral pressure for hatch covers on exposed decks

The wave lateral pressure to be considered as acting on each hatch cover is to be calculated at a point located:

- longitudinally, at the hatch cover mid-length
- transversely, on the longitudinal plane of symmetry of the ship
- vertically, at the top of the hatch coaming.

5.3.2 Lateral pressures other than the wave pressure

The lateral pressure is to be calculated:

- in way of the geometrical centre of gravity of the plate panel, for plating
- at mid-span, for ordinary stiffeners and primary supporting members.

6 Strength check

6.1 General

6.1.1 Application

The strength check is applicable to rectangular hatch covers with primary supporting members arranged in one direction and subjected to a uniform pressure.

In the case of hatch covers with primary supporting members with arrangement of a grillage type or of non-rectangular hatch covers, the scantlings are to be determined by direct calculations. It is to be checked that stresses induced by concentrated loads are in accordance with the criteria in [6.3.4].

6.1.2 Hatch covers supporting wheeled loads

The scantlings of hatch covers supporting wheeled loads are to be obtained in accordance with:

- the applicable requirements of Ch 7, Sec 1 for plating
- the applicable requirements of Ch 7, Sec 2 for ordinary stiffeners
- the applicable requirements of Ch 7, Sec 3 for primary supporting members.

6.1.3 Hatch covers subjected to concentrated loads

For hatch covers supporting concentrated loads, ordinary stiffeners and primary supporting members are generally to be checked by direct calculations, taking into account the stiffener arrangements and their relative inertia. It is to be checked that stresses induced by concentrated loads are in accordance with the criteria in [6.3.4].

6.2 Plating

6.2.1 Net thickness

The net thickness of steel hatch cover plating is to be not less than the value obtained, in mm, from the following formula:

$$t = 14{,}9s\sqrt{\gamma_R\gamma_m\frac{\gamma_{S2}p_S + \gamma_{W2}p_W}{R_y}}$$

where p_S and p_W are the lateral pressures, in kN/m^2, defined in [5.1].

6.2.2 Flooding

For watertight hatches defined as per the Internal Watertight Plan which constitute boundaries intended to stop vertical and horizontal flooding, the net thickness of steel hatch cover plating is to be not less than the value obtained, in mm, from the following formula:

$$t = 14{,}9s\sqrt{\gamma_R\gamma_m\frac{\gamma_{S2}p_{SF} + \gamma_{W2}p_{WF}}{R_y}}$$

where p_{SF} and p_{WF} are the lateral pressures, in kN/m2, defined in Ch 5, Sec 6, Tab 9.

6.2.3 Minimum net thickness of small hatch cover plating

The minimum net thickness of plating of small hatch covers fitted on exposed decks shall be no less than 6 mm.

The minimum net thickness of plating of small hatch covers fitted on non-exposed decks shall be no less than 5 mm.

This thickness is to be increased or an efficient stiffening fitted to the Society's satisfaction where the greatest horizontal dimension of the cover exceeds 1,20 m.

6.2.4 Minimum net thickness of large hatch cover plating

In addition to the requirements in [6.2.1] to [6.2.3], the net thickness, in mm, of large hatch cover plating is to be not less than the values indicated in Tab 4.

Table 4 : Minimum net thicknesses for steel hatch covers

Type of hatch covers	Minimum net thickness, in mm		
	Single skin hatch cover	Double skin hatch cover	
	Plating and stiffeners	Top and bottom plating	Internal structure
Cargo tank hatch cover	6,0	6,0	6,5
Ballast tank hatch cover and fuel oil tank hatch cover	5,0	5,0	5,5
Dry cargo hold hatch cover	4,0	4,0	4,5

6.3 Ordinary stiffeners and primary supporting members

6.3.1 General

Ordinary stiffeners and primary supporting members of hatch covers located on exposed decks are also to fulfil the requirements in [6.4].

6.3.2 Application

The requirements in [6.3.3] to [6.3.9] apply to:

- ordinary stiffeners
- primary supporting members which may be analysed through isolated beam models.

Primary supporting members whose arrangement is of a grillage type and which cannot be analysed through isolated beam models are to be checked by direct calculations, using the checking criteria in [6.3.4].

6.3.3 Normal and shear stress

The maximum normal stress σ and shear stress τ are to be obtained, in N/mm^2, from the following formulae:

$$\sigma = \frac{\gamma_{S2}p_S + \gamma_{W2}p_W}{mw} c_S s \ell^2 10^3$$

$$\tau = 5\frac{\gamma_{S2}p_S + \gamma_{W2}p_W}{A_{Sh}} c_S s \ell$$

6.3.4 Checking criteria

It is to be checked that the normal stress σ and the shear stress τ, calculated according to [6.3.3], are in compliance with the following formulae:

$$\frac{R_y}{\gamma_R \gamma_m} \geq \sigma$$

$$0,5\frac{R_y}{\gamma_R \gamma_m} \geq \tau$$

6.3.5 Net section modulus and net shear sectional area

This requirement provides the minimum net section modulus and net shear sectional area of an ordinary stiffener or a primary supporting member subjected to lateral pressure, complying with the checking criteria indicated in [6.3.4].

The net section modulus w, in cm^3, and the net shear sectional area A_{Sh} , in cm^2, of an ordinary stiffener or a primary supporting member subjected to lateral pressure are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \frac{\gamma_{S2}p_S + \gamma_{W2}p_W}{mR_y} c_S s \ell^2 10^3$$

$$A_{Sh} = 10\gamma_R \gamma_m \frac{\gamma_{S2}p_S + \gamma_{W2}p_W}{R_y} c_S s \ell$$

6.3.6 Net section modulus and net shear sectional area for lateral pressure in flooding conditions

For watertight hatches defined as per the Internal Watertight Plan which constitute boundaries intended to stop vertical and horizontal flooding, the net section modulus w, in cm^3, and the net shear sectional area A_{Sh} , in cm^2, of ordinary stiffeners and primary supporting members are to be not less than the values obtained from the following formulae:

$$w = \gamma_R \gamma_m \frac{\gamma_{S2}p_S + \gamma_{W2}p_W}{mR_y} c_S s \ell^2 10^3$$

$$A_{Sh} = 10\gamma_R \gamma_m \frac{\gamma_{S2}p_{SF} + \gamma_{W2}p_{WF}}{R_y} c_S s \ell$$

where p_{SF} and p_{WF} are the lateral pressures, in kN/m^2, defined in Ch 5, Sec 6, Tab 9.

6.3.7 Minimum net thickness of webs for small hatch covers

Minimum net web thickness of ordinary stiffeners and primary supporting members for small hatch covers is not to be less than the net thickness of the attached plating.

6.3.8 Minimum net thickness of webs for large hatch covers

The net thickness of the ordinary stiffeners and primary supporting members, in mm, is to be not less than the minimum values given in Tab 4.

6.3.9 Ordinary stiffeners and primary supporting members of variable cross-section

The section modulus of ordinary stiffeners and primary supporting members with a variable cross-section is to be not less than the greater of the values obtained, in cm³, from the following formulae:

$$w = w_{CS}$$

$$w = \left(1 + \frac{3,2\alpha - \psi - 0,8}{7\psi + 0,4}\right) w_{CS}$$

where:

w_{CS} : Section modulus, in cm³, for a constant cross-section, obtained according to [6.3.5] or, where applicable, according to [6.3.6] or [6.4.5].

$$\alpha = \frac{\ell_1}{\ell_0}$$

$$\psi = \frac{w_1}{w_0}$$

ℓ_1 : Length of the variable section part, in m (see Fig 1)

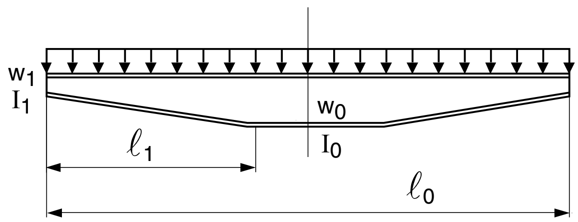
ℓ_0 : Span measured, in m, between end supports (see Fig 1)

w_1 : Section modulus at end, in cm³ (see Fig 1)

w_0 : Section modulus at mid-span, in cm³ (see Fig 1).

The use of this formula is limited to the determination of the strength of ordinary stiffeners and primary supporting members in which abrupt changes in the cross-section do not occur along their length.

Figure 1 : Variable cross-section stiffener



6.4 Additional requirements for ordinary stiffeners and primary supporting members of hatch covers on exposed decks

6.4.1 General

In addition to those in [6.3], ordinary stiffeners and primary supporting members of hatch covers on exposed decks are also to fulfil the requirements in [6.4.2] to [6.4.7].

6.4.2 Application

The requirements in [6.4.3] to [6.4.7] apply to:

- ordinary stiffeners
- primary supporting members which may be analysed through isolated beam models.

Primary supporting members whose arrangement is of a grillage type and which cannot be analysed through isolated beam models are to be checked by direct calculations, using the checking criteria in [6.4.4].

6.4.3 Normal and shear stress

The maximum normal stress σ and shear stress τ are to be obtained, in N/mm², from the following formulae:

$$\sigma = \frac{p_0}{mw} c_S s \ell^2 10^3$$

$$\tau = 5 \frac{p_0}{A_{Sh}} c_S s \ell$$

where p_0 is the conventional pressure, in kN/m², defined in [5.2].

6.4.4 Checking criteria

It is to be checked that the normal stress σ and the shear stress τ, calculated according to [6.4.3], are in compliance with the following formulae:

$$\frac{R_m}{\gamma_{LL}} \geq \sigma$$

$$0,57 \frac{R_m}{\gamma_{LL}} \geq \tau$$

where γ_{LL} is a safety factor, taken equal to:

- 4,25 for hatch covers
- 5,00 for pontoon hatch covers and portable hatch covers.

6.4.5 Net section modulus and net shear sectional area

This requirement provides the minimum net section modulus and net shear sectional area of an ordinary stiffener or a primary supporting member subjected to conventional pressure, complying with the checking criteria indicated in [6.4.4].

The net section modulus w, in cm^3, and the net shear sectional area A_{Sh}, in cm^2, of an ordinary stiffener or a primary supporting member subjected to conventional pressure are to be not less than the values obtained from the following formulae:

$$w = \frac{\gamma_{LL} p_0}{m R_m} c_S s \ell^2 10^3$$

$$A_{Sh} = 8{,}8 \frac{\gamma_{LL} p_0}{R_m} c_S s \ell$$

where γ_{LL} is as defined in [6.4.4].

6.4.6 Moment of inertia of ordinary stiffeners and primary supporting members

The moment of inertia I_{CS} of an ordinary stiffener or a primary supporting member, calculated for the conventional pressure p_0, is to be such that the deflection does not exceed $\mu\ell$, where μ is defined in Tab 5.

Table 5 : Hatch covers - Deflection coefficient for ordinary stiffeners and primary supporting members

	μ
Weathertight hatch cover	0,0028
Pontoon hatch cover Portable beam	0,0022

6.4.7 Ordinary stiffeners and primary supporting members of variable cross-section

The section modulus of ordinary stiffeners and primary supporting members with a variable cross-section is to be not less than the value obtained according to [6.3.9], where w_{CS} is the section modulus for a constant cross-section obtained according to [6.4.5].

Moreover, the moment of inertia of ordinary stiffeners and primary supporting members with a variable cross-section is to be not less than the greater of the values obtained, in cm^4, from the following formulae:

$$I = I_{CS}$$

$$I = \left[1 + 8\alpha^3\left(\frac{1-\varphi}{0{,}2 + 3\sqrt{\varphi}}\right)\right] I_{CS}$$

where:

I_{CS} : Moment of inertia with a constant cross-section, in cm^4, obtained according to [6.4.6]

α : Coefficient defined in [6.3.9]

$$\varphi = \frac{I_1}{I_0}$$

I_1 : Moment of inertia at end, in cm^4 (see Fig 1)

I_0 : Moment of inertia at mid-span, in cm^4 (see Fig 1).

The use of this formula is limited to the determination of the strength of ordinary stiffeners and primary supporting members in which abrupt changes in the cross-section do not occur along their length.

7 Hatch coamings

7.1 Stiffening

7.1.1 Coamings are to be stiffened on their upper edges with a stiffener suitably shaped to fit the hatch cover closing appliances.

Moreover, when covers are fitted with tarpaulins, an angle or a bulb section is to be fitted all around coamings of more than 3 m in length or 600 mm in height; this stiffener is to be fitted at approximately 250 mm below the upper edge. The width of the horizontal flange of the angle is not to be less than 180 mm.

7.1.2 Where hatch covers are fitted with tarpaulins, coamings are to be strengthened by brackets or stays with a spacing not greater than 3 m.

Where the height of the coaming exceeds 900 mm, additional strengthening may be required.

However, reductions may be granted for transverse coamings in protected areas.

7.1.3 When two hatches are close to each other, underdeck stiffeners are to be fitted to connect the longitudinal coamings with a view to maintaining the continuity of their strength.

Similar stiffening is to be provided over 2 frame spacings at ends of hatches exceeding 9 frame spacings in length.

In some cases, the Society may require the continuity of coamings to be maintained above the deck.

7.1.4 Where watertight metallic hatch covers are fitted, other arrangements of equivalent strength may be adopted.

7.2 Scantlings

7.2.1 General

The scantlings of continuous side coamings are considered by the Society on a case-by-case basis.

7.2.2 Plating

The plate thickness of hatch coamings on the weather deck is generally to be not less than 11 mm.

In ships intended for the carriage of liquid cargoes, the plate thickness of coamings is also to be checked under liquid internal pressures.

7.2.3 Coamings of small hatchways

As a Rule, the coaming plate thickness is to be not less than the lesser of the following values:

- the thickness for the deck inside line of openings calculated for that position, assuming as spacing of stiffeners the lesser of the values of the height of the coaming and the distance between its stiffeners, if any, or
- 10 mm.

Coamings are to be suitably strengthened where their height exceeds 0,80 m or their greatest horizontal dimension exceeds 1,20 m, unless their shape ensures an adequate rigidity.

8 Weathertightness, closing arrangement and securing devices of large hatches

8.1 Weathertightness

8.1.1 Where the hatchway is exposed and closed with a single panel, the weathertightness is to be ensured by gaskets and clamping devices sufficient in number and quality.

Weathertightness may also be ensured means of tarpaulins.

8.1.2 The mean spacing of swing bolts or equivalent devices is, in general, to be not greater than:

- 2,0 m for dry cargo holds
- 1,5 m for ballast compartments
- 1,0 m for liquid cargo holds.

8.2 Gaskets

8.2.1 The weight of hatch covers and any cargo stowed thereon, together with inertia forces generated by ship motions, are to be transmitted to the ship structure through steel to steel contact.

This may be achieved by continuous steel to steel contact of the hatch cover skirt plate with the ship structure or by means of defined bearing pads.

8.2.2 The sealing is to be obtained by a continuous gasket of relatively soft elastic material compressed to achieve the necessary weathertightness. Similar sealing is to be arranged between cross-joint elements.

Where fitted, compression flat bars or angles are to be well rounded where in contact with the gasket and to be made of a corrosion-resistant material.

8.2.3 The gasket and the securing arrangements are to maintain their efficiency when subjected to large relative movements between the hatch cover and the ship structure or between hatch cover elements.

If necessary, suitable devices are to be fitted to limit such movements.

8.2.4 The gasket material is to be of a quality suitable for all environmental conditions likely to be encountered by the ship, and is to be compatible with the cargoes transported.

The material and form of gasket selected are to be considered in conjunction with the type of hatch cover, the securing arrangement and the expected relative movement between the hatch cover and the ship structure.

The gasket is to be effectively secured to the hatch cover.

8.2.5 Coamings and steel parts of hatch covers in contact with gaskets are to have no sharp edges.

8.2.6 Metallic contact is required for an earthing connection between the hatch cover and the hull structures. If necessary, this is to be achieved by means of a special connection for the purpose.

8.3 Closing arrangement and securing devices

8.3.1 General

Panel hatch covers are to be secured by appropriate devices (bolts, wedges or similar) suitably spaced alongside the coamings and between cover elements.

The securing and stop arrangements are to be fitted using appropriate means which cannot be easily removed.

In addition to the requirements above, all hatch covers, and in particular those carrying deck cargo, are to be effectively secured against horizontal shifting due to the horizontal forces resulting from ship motions.

Towards the ends of the ship, vertical acceleration forces may exceed the gravity force. The resulting lifting forces are to be considered when dimensioning the securing devices according to [8.3.5] to [8.3.7] Lifting forces from cargo secured on the hatch cover during rolling are also to be taken into account.

Hatch coamings and supporting structure are to be adequately stiffened to accommodate the loading from hatch covers.

Hatch covers provided with special sealing devices, insulated hatch covers, flush hatch covers and those having coamings of a reduced height (see [2.1]) are considered by the Society on a case-by-case basis.

In the case of hatch covers carrying containers, the scantlings of the closing devices are to take into account the possible upward vertical forces transmitted by the containers.

8.3.2 Arrangements

The securing and stopping devices are to be arranged so as to ensure sufficient compression on gaskets between hatch covers and coamings and between adjacent hatch covers.

Arrangement and spacing are to be determined with due attention to the effectiveness for weathertightness, depending on the type and the size of the hatch cover, as well as on the stiffness of the hatch cover edges between the securing devices.

At cross-joints of multipanel covers, (male/female) vertical guides are to be fitted to prevent excessive relative vertical deflections between loaded/unloaded panels.

The location of stoppers is to be compatible with the relative movements between hatch covers and the ship structure in order to prevent damage to them. The number of stoppers is to be as small as possible.

8.3.3 Spacing

The spacing of the securing arrangements is to be generally not greater than 6 m.

The spacing of securing arrangements of tank hatch covers in ‘tweendecks is to be not greater than 600 mm.

8.3.4 Construction

Securing arrangements with reduced scantlings may be accepted provided it can be demonstrated that the possibility of water reaching the deck is negligible.

Securing devices are to be of reliable construction and securely attached to the hatchway coamings, decks or hatch covers.

Individual securing devices on each hatch cover are to have approximately the same stiffness characteristics.

8.3.5 Area of securing devices

The net cross area of each securing device is to be not less than the value obtained, in cm², from the following formula:

$$A = 1{,}4 S_S \left(\frac{235}{R_{eH}}\right)^f$$

where:

S_S : Spacing, in m, of securing devices

f : Coefficient taken equal to:

- 0,75 for $R_{eH} > 235$ N/mm²
- 1,00 for $R_{eH} \leq 235$ N/mm².

In the above calculations, R_{eH} may not be taken greater than 0,7 R_m.

Between hatch cover and coaming and at cross-joints, a packing line pressure sufficient to obtain weathertightness is to be maintained by securing devices. For packing line pressures exceeding 5 N/mm, the net cross area A is to be increased in direct proportion. The packing line pressure is to be specified.

In the case of securing arrangements which are particularly stressed due to the unusual width of the hatchway, the net cross area A of the above securing arrangements is to be determined through direct calculations.

8.3.6 Inertia of edges elements

The hatch cover edge stiffness is to be sufficient to maintain adequate sealing pressure between securing devices.

The moment of inertia of edge elements is to be not less than the value obtained, in cm⁴, from the following formula:

$$I = 6\, p_L\, S_S^4$$

where:

p_L : Packing line pressure, in N/mm, to be taken not less than 5 N/mm

S_S : Spacing, in m, of securing devices.

8.3.7 Diameter of rods or bolts

Rods or bolts are to have a net diameter not less than 19 mm for hatchways exceeding 5 m^2 in area.

8.4 Tarpaulins

8.4.1 Where weathertightness of hatch covers is ensured by means of tarpaulins, at least two layers of tarpaulins are to be fitted.

Tarpaulins are to be free from jute and waterproof and are to have adequate characteristics of strength and resistance to atmospheric agents and high and low temperatures.

The mass per unit surface of tarpaulins made of vegetable fibres, before the waterproofing treatment, is to be not less than:

- 0,65 kg/m^2 for waterproofing by tarring
- 0,60 kg/m^2 for waterproofing by chemical dressing
- 0,55 kg/m^2 for waterproofing by dressing with black oil.

In addition to tarpaulins made of vegetable fibres, those of synthetic fabrics or plastic laminates may be accepted by the Society provided their qualities, as regards strength, waterproofing and resistance to high and low temperatures, are equivalent to those of tarpaulins made of vegetable fibres.

8.5 Cleats

8.5.1 The arrangements for securing the tarpaulins to hatch coamings are to incorporate cleats of a suitable pattern giving support to battens and wedges and with edges rounded so as to minimise damage to the wedges.

8.5.2 Cleats are to be spaced not more than 600 mm from centre to centre and are to be not more than 150 mm from the hatch corners.

8.5.3 The thickness of cleats is to be not less than 9,5 mm for angle cleats and 11 mm for forged cleats.

8.5.4 Where rod cleats are fitted, resilient washers or cushions are to be incorporated.

8.5.5 Where hydraulic cleating is adopted, a positive means is to be provided to ensure that it remains mechanically locked in the closed position in the event of failure of the hydraulic system.

8.6 Wedges, battens and locking bars

8.6.1 Wedges

Wedges are to be of tough wood, generally not more than 200 mm in length and 50 mm in width.

They are generally to be tapered not more than 1 in 6 and their thickness is to be not less than 13 mm.

8.6.2 Battens and locking bars

For all hatchways in exposed positions, battens or transverse bars in steel or other equivalent means are to be provided in order to efficiently secure the portable covers after the tarpaulins are battened down.

Portable covers of more than 1,5 m in length are to be secured by at least two such securing appliances.

9 Tightness, closing arrangement and securing devices of small hatches

9.1 Tightness and gaskets

9.1.1 The seal for weathertight or watertight hatches is to be obtained by a continuous gasket of relatively soft elastic material compressed to achieve the necessary tightness.

9.1.2 Coamings and steel parts of hatch covers in contact with gaskets are to have no sharp edges.

9.1.3 For non-bolted hatch covers, metal-to-metal contacts are to be provided in order to prevent over compression of the gasket. Gasket sealing arrangements are to be designed in order to withstand the bearing force induced by any relevant lateral load on the hatch cover.

9.2 Closing arrangement and securing devices

9.2.1 At least one securing device is to be fitted at each side. The hinges of scuttles and round hatch covers are considered equivalent to securing devices.

9.2.2 Securing arrangements and stiffening of hatch cover edges are to be such that the required degree of tightness can be maintained in any sea condition, for all loads acting on the hatch cover.

9.2.3 Towards the ends of the ship, vertical acceleration forces may exceed the gravity force. The resulting lifting forces are to be considered when dimensioning the securing devices.

9.2.4 The primary securing method is to be designed and manufactured such that the designed compression pressure is achieved by one person without the need of any tools.

9.2.5 Small hatches located on exposed fore deck are to be fitted with primary securing devices such that their hatch covers can be secured in place and made weathertight by means of a mechanism employing any one of the following methods:

a) butterfly nuts tightening onto forks (clamps)

b) quick acting cleats

c) central locking device.

Dogs (twist tightening handles) with wedges are not acceptable.

9.2.6 For a primary securing method using butterfly nuts, the forks (clamps) are to be of robust design. They are to be designed to minimize the risk of butterfly nuts being dislodged while in use by means of curving the forks upwards, a raised surface on the free end, or a similar method. The plate thickness of unstiffened steel forks is to be not less than 16 mm. An example arrangement is shown in Fig 2.

9.2.7 Small hatches on the fore deck are to be fitted with an independent secondary securing device, e.g. by means of a sliding bolt, a hasp or a backing bar of slack fit, which is capable of keeping the hatch cover in place, even in the event that the primary securing device became loosened or dislodged. It is to be fitted on the side opposite to the hatch cover hinges.

9.2.8 For small hatch covers located on the exposed deck forward of the foremost cargo hatch, the hinges are to be fitted such that the predominant direction of green seas is to cause the cover to close, which means that the hinges are normally to be located on the fore edge.

9.2.9 On small hatches located between the main hatches, for example between Nos. 1 and 2, the hinges are to be placed on the fore edge or outboard edge, whichever is practicable for protection from green water in beam sea and bow quartering conditions.

9.2.10 Securing devices of hatches designed for emergency escape shall, in general, be operable from both sides of the hatch cover.

9.2.11 Where wear of securing elements may eventually lead to degraded hatch tightness, the design of the securing arrangements shall permit the necessary periodic adjustment or renewal of elements in order to ensure the continued performance of the seal and hatch tightness.

9.2.12 The metal-to-metal contacts are to be arranged close to each securing device and shall be of a sufficient capacity to withstand the bearing force. Where stiffeners are fitted, they shall be aligned with the metal-to-metal contact points.

10 Testing

10.1 Initial test of watertight hatches

10.1.1 Watertight hatches are to be tested by water pressure to at least a test pressure p_T, in kN/m², equal to the sum of p_{SF} and p_{WF}, as defined in Ch 5, Sec 6, Tab 9 at the location in which the hatch is to be installed.

10.2 Prototype test

10.2.1 Testing of individual hatches may be replaced by a prototype pressure test of each type and size of hatch with a test pressure corresponding at least to the head required for the individual location. The prototype test is to be carried out before the hatch is fitted. The installation method and procedure for fitting the hatch on board is to correspond to that of the prototype test. When fitted on board, each hatch is to be checked for proper seating between the deck, the coaming and the hatch cover.

11 Drainage

11.1 Arrangement

11.1.1 If drain channels are provided inside the line of the gasket by means of a gutter bar or vertical extension of the hatch side and end coaming, drain openings are to be provided at appropriate positions in the drain channels.

11.1.2 Drain openings in hatch coamings are to be arranged with sufficient distance to areas of stress concentration (e.g. hatch corners).

11.1.3 Drain openings are to be arranged at the ends of drain channels and are to be provided with efficient means for preventing ingress of water from outside, such as non-return valves or equivalent.

11.1.4 Cross-joints of multipanel hatch covers are to be arranged with drainage of water from the space above the gasket and a drainage channel below the gasket.

11.1.5 If a continuous outer steel contact is arranged between the cover and the ship structure, drainage from the space between the steel contact and the gasket is also to be provided.

11.1.6 Requirements [11.1.1] to [11.1.5] are not applicable to hatches of less than 0,6 m^2 and hatches on non-exposed decks.

Section 8 Movable Decks and Inner Ramps - External Ramps

1 Movable decks and inner ramps

1.1 Materials

1.1.1 The decks and inner ramps are to be made of steel or aluminium alloys complying with the requirements of NR216 Materials and Welding. Other materials of equivalent strength may be used, subject to a case-by-case examination by the Society.

1.2 Net scantlings

1.2.1 As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

The gross scantlings are obtained as specified in Ch 4, Sec 2.

1.3 Plating

1.3.1 The net thickness of plate panels subjected to wheeled loads is to be not less than the value obtained from Ch 7, Sec 1, [4.3], where ($n\ P_0$) is not to be taken less than 50 kN.

1.4 Supporting structure

1.4.1 General

The supporting structure of movable decks and inner ramps is to be verified through direct calculation, considering the following cases:

- movable deck stowed in upper position, empty and locked, at sea
- movable deck in service, loaded, in lower position, resting on supports or supporting legs and locked, at sea
- movable inner ramp in sloped position, supported by hinges at one end and by a deck at the other, with possible intermediate supports, loaded, at harbour
- movable inner ramp in horizontal position, loaded and locked, at sea.

1.4.2 Loading cases

The scantlings of the structure are to be verified in both sea and harbour conditions for the following cases:

- loaded movable deck or inner ramp under loads according to the vehicle distribution indicated by the Designer
- loaded movable deck or inner ramp under uniformly distributed loads corresponding to a pressure, in kN/m², taken equal to:

$$p = \frac{n_V P_V + P_P}{A_P}$$

- empty movable deck under uniformly distributed masses corresponding to a pressure, in kN/m², taken equal to:

$$p = \frac{P_P}{A_P}$$

where:

n_V : Maximum number of vehicles loaded on the movable deck

P_V : Mass of a vehicle, in kN

P_P : Mass of the movable deck, in kN

A_P : Effective area of the movable deck, in m².

1.4.3 Still water and inertial pressures

The still water and inertial pressures transmitted to the movable deck or inner ramp structures are obtained, in kN/m², as specified in Tab 1.

Table 1 : Movable decks and inner ramps - Still water and inertial pressures

Ship condition	Load case	Still water pressure p_S and inertial pressure p_W, in kN/m²
Still water condition		$p_S = p$
Upright sea condition	"a"	No inertial pressure
	"b"	$p_{W,X} = p\dfrac{a_{X1}}{g}$ in x direction $p_{W,Z} = p\dfrac{a_{Z1}}{g}$ in z direction
Inclined sea condition (negative roll angle)	"c"	$p_{W,Y} = p\dfrac{C_{FA}a_{Y2}}{g}$ in y direction
	"d"	$p_{W,Z} = p\dfrac{C_{FA}a_{Z2}}{g}$ in z direction
Harbour condition (1)	during lifting	$p_{W,X} = 0{,}035\ p$ in x direction $p_{W,Y} = 0{,}087\ p$ in y direction $p_{W,Z} = 0{,}200\ p$ in z direction
	at rest	$p_{W,X} = 0{,}035\ p$ in x direction $p_{W,Y} = 0{,}087\ p$ in y direction $p_{W,Z} = 0{,}100\ p$ in z direction

(1) For harbour conditions, a heel angle of 5° and a trim angle of 2° are taken into account.

Note 1:

p : Pressure, in kN/m², to be calculated according to [1.4.2] for the condition considered

C_{FA} : Combination factor, to be taken equal to:
- $C_{FA} = 0{,}7$ for load case "c"
- $C_{FA} = 1{,}0$ for load case "d".

1.4.4 Checking criteria

It is to be checked that the combined stress σ_{VM} is in accordance with the criteria defined in Ch 7, Sec 3, [3.3.1].

1.4.5 Allowable deflection

The scantlings of main stiffeners and the distribution of supports are to be such that the deflection of the movable deck or inner ramp does not exceed 5 mm/m.

1.5 Supports, suspensions and locking devices

1.5.1 Scantlings of supports and wire suspensions are to be determined by direct calculation on the basis of the loads in [1.4.2] and [1.4.3], taking account of a safety factor at least equal to 5.

1.5.2 It is to be checked that the combined stress σ_{VM} in rigid supports and locking devices is in accordance with the criteria defined in Ch 7, Sec 3, [3.3.1].

2 External ramps

2.1 General

2.1.1 The external ramps are to be able to operate with a heel angle of 5° and a trim angle of 2°.

2.1.2 The external ramps are to be examined for their watertightness, if applicable, and as a support of vehicles at harbour.

2.1.3 The locking of external ramps in stowage position at sea is examined by the Society on a case-by-case basis.

2.1.4 The ship structure under the reactions due to the ramp is examined by the Society on a case-by-case basis.

Section 9 Arrangement of Hull and Superstructure Openings

1 General

1.1 Application

1.1.1 The requirements of this Section apply to the arrangement of hull and superstructure openings excluding hatchways, for which the requirements in Ch 8, Sec 7 apply.

1.2 Definitions

1.2.1 Standard height of superstructure

The standard height of superstructure is defined in Tab 1.

Table 1 : Standard height of superstructure h_S

Length L in m	h_S, in m	
	Raised quarter deck	All the other superstructures
L ≤ 30	0,90	1,80
30 < L ≤ 75	0,9 + 0,00667 (L – 30)	1,80
75 < L ≤ 125	1,2 + 0,012 (L – 75)	1,8 + 0,01 (L – 75)
L > 125	1,80	2,30

1.2.2 Standard sheer

The standard sheer is that defined according to regulation 38 of the International Load Line Convention 1966, as amended.

1.2.3 Exposed zones

Exposed zones are the boundaries of superstructures or deckhouses set in from the ship side at a distance less than or equal to 0,04 B.

1.2.4 Unexposed zones

Unexposed zones are the boundaries of deckhouses set in from the ship side at a distance greater than 0,04 B.

2 External openings

2.1 General

2.1.1 All external openings leading to compartments assumed intact in the damage analysis, which are below the final damage waterline, are required to be watertight.

2.1.2 External openings required to be watertight in accordance with [2.1.1] are to be of sufficient strength and, except for cargo hatch covers, are to be fitted with indicators on the bridge.

2.1.3 Openings in the shell plating below the deck limiting the vertical extent of damage are to be kept permanently closed while at sea. Should any of these openings be accessible during the voyage, they are to be fitted with a device which prevents unauthorized opening.

2.1.4 Notwithstanding the requirements of [2.1.3], the Society may authorize that particular doors may be opened at the discretion of the Master, if necessary for the operation of the ship and provided that the safety of the ship is not impaired.

2.1.5 Other closing appliances which are kept permanently closed at sea to ensure the watertight integrity of external openings are to be provided with a notice affixed to each appliance to the effect that it is to be kept closed. Manholes fitted with closely bolted covers need not be so marked.

For watertight doors, a plate called “Harlequin” may be fitted, in equivalence to this notice. This plate precise the opening condition for each tightness situation.

2.2 Closing devices subjected to weapon firing loads

2.2.1 In addition to the applicable requirements of this Section, the net scantlings of closing devices subjected to weapon firing loads are to be not less that those obtained from the applicable formulae in Part B, Chapter 7, where the pressures are to be calculated according to Ch 5, Sec 6, [9].

3 Sidescuttles, windows and skylights

3.1 General

3.1.1 Application

The requirements in [3.1] to [3.4] apply to sidescuttles and rectangular windows providing light and air, located in positions which are exposed to the action of sea and/or bad weather.

3.1.2 Sidescuttle definition

Sidescuttles are round or oval openings with an area not exceeding 0,16 m^2. Round or oval openings having areas exceeding 0,16 m^2 are to be treated as windows.

3.1.3 Window definition

Windows are rectangular openings generally, having a radius at each corner relative to the window size in accordance with recognized national or international standards, and round or oval openings with an area exceeding 0,16 m^2.

3.1.4 Number of openings in the shell plating

The number of openings in the shell plating are to be reduced to the minimum compatible with the design and proper working of the ship.

3.1.5 Material and scantlings

Sidescuttles and windows together with their glasses, deadlights and storm covers, if fitted, are to be of approved design and substantial construction in accordance with, or equivalent to, recognized national or international standards.

Non-metallic frames are not acceptable. The use of ordinary cast iron is prohibited for sidescuttles below the main watertight deck.

3.1.6 Means of closing and opening

The arrangement and efficiency of the means for closing any opening in the shell plating are to be consistent with its intended purpose and the position in which it is fitted is to be generally to the satisfaction of the Society.

3.1.7 Opening of sidescuttles

All sidescuttles, the sills of which are below the bulkhead deck, are to be of such construction as to prevent effectively any person opening them without the consent of the Master of the ship. Please also refer to Ch 2, Sec 1, Tab 2.

Sidescuttles and their deadlights which are not accessible during navigation are to be closed and secured before the ship leaves port.

The Society, at its discretion, may prescribe that the time of opening such sidescuttles in port and of closing and locking them before the ship leaves port is to be recorded in a log book.

3.2 Opening arrangement

3.2.1 General

Sidescuttles may not be fitted in such a position that their sills are below a line drawn parallel to the watertight deck at side and having its lowest point 0,025 B or 0,5 m, whichever is the greater distance, above the deepest subdivision load line.

3.2.2 Sidescuttles below (1,4 + 0,025 B) m above the water

Where in ‘tweendecks the sills of any of the sidescuttles are below a line drawn parallel to the bulkhead deck at side and having its lowest point (1,4 + 0,025 B) m above the water when the ship departs from any port, all the sidescuttles in that ‘tweendecks are to be closed watertight and locked before the ship leaves port, and they may not be opened before the ship arrives at the next port. In the application of this requirement, the appropriate allowance for fresh water may be made when applicable.

For any ship that has one or more sidescuttles so placed that the above requirements apply when it is floating at its deepest subdivision load line, the Society may indicate the limiting mean draught at which these sidescuttles are to have their sills above the line drawn parallel to the bulkhead deck at side, and having its lowest point (1,4 + 0,025 B) above the waterline corresponding to the limiting mean draught, and at which it is therefore permissible to depart from port without previously closing and locking them and to open them at sea under the responsibility of the Master during the voyage to the next port. In tropical zones as defined in the International Convention on Load Lines in force, this limiting draught may be increased by 0,3 m.

3.2.3 Cargo spaces

No sidescuttles may be fitted in any spaces which are appropriated exclusively for the carriage of cargo.

Sidescuttles may, however, be fitted in spaces appropriated alternatively for the carriage of cargo or passengers, but they are to be of such construction as to prevent effectively any person opening them or their deadlights without the consent of the Master.

If cargo is carried in such spaces, the sidescuttles and their deadlights are to be closed watertight and locked before the cargo is shipped. The Society, at its discretion, may prescribe that the time of closing and locking is to be recorded in a log book.

3.2.4 Non-opening type sidescuttles

Sidescuttles are to be of the non-opening type in the following cases:

- where they become immersed by any intermediate stage of flooding or the final equilibrium waterplane in any required damage case for ships subject to damage stability regulations
- where they are fitted outside the space considered flooded and are below the final waterline for those ships where the freeboard is reduced on account of subdivision characteristics when a freeboard calculation is undertaken.

3.2.5 Manholes and flush scuttles

Manholes and flush scuttles in positions 1 or 2, or within superstructures other than enclosed superstructures, are to be closed by substantial covers capable of being made watertight. Unless secured by closely spaced bolts, the covers are to be permanently attached.

3.2.6 Ships with several decks

In ships having several decks above the bulkhead deck, the arrangement of sidescuttles and rectangular windows is considered by the Society on a case-by-case basis.

Particular consideration is to be given to the ship side up to the upper deck and the front bulkhead of the superstructure.

3.2.7 Window arrangement

Windows may not be fitted below the watertight deck, in first tier end bulkheads or sides of enclosed superstructures and in first tier deckhouses considered as being buoyant in the stability calculations or protecting openings leading below.

In the front bulkhead of a superstructure situated on the upper deck, in the case of substantially increased watertight, rectangular windows with permanently fitted storm covers are acceptable.

3.2.8 Skylights

Fixed or opening skylights are to have glass thickness appropriate to their size and position as required for sidescuttles and windows. Skylight glasses in any position are to be protected from mechanical damage and, where fitted in positions 1 or 2, to be provided with permanently attached robust deadlights or storm covers.

3.2.9 Gangway and cargo ports

Gangway and cargo ports are to be of sufficient strength. They are to be effectively closed and secured watertight before the ship leaves port, and to be kept closed during navigation.

Such ports are in no case to be so fitted as to have their lowest point below the deepest subdivision load line.

3.3 Glasses

3.3.1 General

In general, toughened glasses with frames of special type are to be used in compliance with, or equivalent to, recognised national or international standards.

Direct metal to glass contact is to be avoided.

The use of clear plate glasses is considered by the Society on a case by case basis.

3.3.2 Design loads

The design load is to be determined in accordance with the applicable requirements of Ch 8, Sec 4, [2].

In damaged ship conditions, where windows or sidescuttles are located below the deepest equilibrium waterline, the design pressure p, in kN/m², is to be taken equal to:

$p = p_S + p_W$

where:

p_S : Still water pressure, taken equal to:

$p_S = \rho\, g\, d_F$

p_W : Wave pressure, taken equal to:

$$p_W = 0{,}6 \rho g h_1 e^{\frac{-2\pi(d_F)}{L}}$$

d_F : Distance, in m, from the calculation point to the deepest equilibrium waterline.

The deepest equilibrium waterlines are to be provided by the Designer under his own responsibility.

h_1 : Reference values of the ship relative motions in the upright ship condition, defined in Ch 5, Sec 3, [3.3].

3.3.3 Scantling

The windows and sidescuttles assessment methodology defined in this Article is equivalent to Standard ISO 11336-1:2012.

The scantling of windows and sidescuttle defined in this sub-article are provided for the following types of window or sidescuttle:

- monolithic window or sidescuttle (see [3.3.4])
- laminated window or sidescuttle (see [3.3.5])
- double windows unit with gap (see [3.3.9]).

All the window and sidescuttle edges are considered as simply supported.

3.3.4 Thickness of monolithic window

The thicknesses, in mm, of monolithic windows and sidescuttles are to be obtained from the following formula:

- rectangular window or sidescuttle:

$$t = 31,6s\sqrt{\frac{\beta p S_f}{R_m}}$$

- circular window or sidescuttle:

$$t = 17,4d\sqrt{\frac{p S_f}{R_m}}$$

where:

s : Shorter side, in m, of rectangular window or sidescuttle

Where the window is supported only on 2 edges, s is to be taken as the unsupported side

ℓ : Longer side, in m, of rectangular window or sidescuttle

d : Diameter, in m, of circular window or sidescuttle

R_m : Guaranteed minimum flexural strength, in N/mm², of material used. For guidance only, the guaranteed minimum flexural strength R_m for glass window is:

- for thermally or chemically toughened glass: R_m = 120 N/mm²
- for polymethylmethacrilate (PMMA) glass: R_m = 100 N/mm²
- for polycarbonate (PC) glass: R_m = 90 N/mm²

S_f : Safety factor taken equal to:

- 3,0 for thermally or chemically toughened glass:
- 3,5 for polymethylmethacrilate (PMMA) or polycarbonate (PC) glass:

β : Aspect ratio coefficient of the rectangular window or sidescuttle, obtained in Tab 1

Where the window is supported only by 2 edges, β is to be taken equal to 1,0.

The thickness of windows or sidescuttles having other shapes may be obtained by considering rectangles or circles of equivalent dimensions s_{eq}, ℓ_{eq} or d_{eq} as defined in Tab 3.

Table 2 : Coefficient β

ℓ/s	β
1,0	0,284
1,5	0,475
2,0	0,608
2,5	0,684
3,0	0,716
3,5	0,734
≥ 4,0	0,750

Table 3 : Equivalent dimensions for windows having other shapes

</tr>
</table>

3.3.5 Laminated window

Laminated windows are windows realized by placing an interlayer of resin (polyvinyl butyral as a general rule) between plies of same or different materials.

For laminated windows made with plies of the same material:

- When the mechanical properties of the interlayer material (the laminating adhesive material) are not known, the plies of the laminated window are considered as mechanically independent, and the equivalent thickness is to be calculated as defined in [3.3.6].
- When the mechanical properties of the interlayer material are known in terms of shear modulus, G, in N/mm^2, the plies of the laminated window are considered as mechanically collaborating, and the equivalent thickness is to be calculated as defined in [3.3.7].

When the laminated window is made with plies of different materials, they are considered as mechanically independent, and the equivalent thickness is to be calculated as defined in [3.3.8].

3.3.6 Thickness of laminated window with independent plies

The equivalent thickness t_{eq}, in mm, of laminates made of n independent plies of thicknesses $t_{p,1}$, $t_{p,2}$, …, $t_{p,n}$, is to comply with the following formula:

$$t_{eq} \geq t$$

where:

$$t_{eq} = \min[t_{eq,j}]$$

$$t_{eq,j} = \sqrt{\frac{\sum_{j=1}^{n} t_{p,j}^3}{t_{p,j}}}$$

j : Ply index, ranging from 1 to n

t : Thickness, in mm, of a monolithic window, calculated according to [3.3.4].

3.3.7 Thickness of laminated window with collaborating plies

The equivalent thickness t_{eq}, in mm, of laminates made of two collaborating plies of the same material, and of thicknesses t_1 and t_2 separated by an interlayer of thickness t_I is to comply with the following formula:

$$t_{eq} \geq t$$

where:

$t_{eq} = \min[t_{1eq,s}, t_{2eq,s}]$

$t_{1eq,s}$, $t_{2eq,s}$: Equivalent thickness for strength as obtained from the following formulae:

$$t_{1eq,s} = \sqrt{\frac{t_{eq,d}^3}{t_1 + 2\Gamma t_{s2}}}$$

$$t_{2eq,s} = \sqrt{\frac{t_{eq,d}^3}{t_2 + 2\Gamma t_{s1}}}$$

$t_{eq,d}$: Equivalent thickness for deflection as obtained from the following formula:

$$t_{1eq,d} = \sqrt[3]{t_1^3 + t_2^3 + 12\Gamma I_S}$$

Γ : Shear transfer coefficient as obtained from the following formula, without being taken less than 0 (independent plies behaviour) and more than 1,0 (monolithic behaviour):

$$\Gamma = \frac{1}{1 + 9{,}6\,\frac{E}{G} \cdot \frac{I_S}{hs^2} \cdot \frac{t_I}{s^2} \cdot \frac{1}{10^6}}$$

$$t_{s1} = \frac{hs \cdot t_1}{t_1 + t_2}$$

$$t_{s2} = \frac{hs \cdot t_2}{t_1 + t_2}$$

$$I_S = t_1 t_{s2}^2 + t_2 t_{s1}^2$$

$$hs = 0{,}5(t_1 + t_2) + t_I$$

G : Shear modulus of the interlayer at 25 °C, in N/mm², generally taken equal to 1,6 N/mm² for polyvinyl butyral (PVB).
For other interlayer materials the shear modulus value at 25 °C for short time duration load (60 s) shall be declared by the interlayer material manufacturer

E : Young's modulus of the plies, in N/mm²

s : Shorter side, in m, of rectangular window or sidescuttle.

In case of multiple (more than two plies) laminates the calculation is to be iterated. The iteration is to start from the outer ply (the one directly loaded by water pressure) and end with the inner ply.

3.3.8 Thickness of laminated window with plies of different materials

The equivalent thickness t_{eq}, in mm, of laminates made of n plies of different materials, of thicknesses $t_{p,1}$, $t_{p,2}$, …, $t_{p,n}$ and of Young's modulus $E_{p,1}$, $E_{p,2}$, ..., $E_{p,n}$ is to comply with the following formula:

$t_{eq} \geq t$

where:

$t_{eq} = \min[t_{eq,j}]$

$$t_{eq,j} = \sqrt{\frac{\sum_{j=1}^{n} E_{p,j} t_{p,j}^3}{E_{p,j} t_{p,j}}}$$

j : Ply index, ranging from 1 to n

t : Thickness, in mm, of a monolithic window, calculated according to [3.3.4] for the same material than the ply giving the minimum value of $t_{eq,j}$.

3.3.9 Thickness of double windows

Double windows are glass windows made of two plies of glass separated by an hermetically sealed spacebar.

The thickness of the ply exposed to the loads defined in [3.3.2] is to be calculated as per monolithic windows according to [3.3.4].

3.3.10 Thickness of glasses forming screen bulkheads or internal boundaries of deckhouses

The thickness of glasses forming screen bulkheads on the side of enclosed promenade spaces and that for rectangular windows in the internal boundaries of deckhouses which are protected by such screen bulkheads are considered by the Society on a case by case basis.

The Society may require both limitations on the size of rectangular windows and the use of glasses of increased thickness in way of front bulkheads which are particularly exposed to heavy sea.

3.3.11 Thickness of glasses subjected to weapon firing loads

The scantling of windows and side-scuttles exposed to weapon firing dynamic loads is to be as per [3.3.3], with pressure p, in kN/m², being taken equal to the relevant pressure calculated according to Ch 5, Sec 6, [9].

3.4 Deadlight arrangement

3.4.1 General

Sidescuttles to the following spaces are to be fitted with efficient, hinged inside deadlights:

- spaces within the first tier of enclosed superstructures
- first tier deckhouses on the watertight deck protecting openings leading below or considered buoyant in stability calculations.

3.4.2 Watertight deadlights

Efficient, hinged inside deadlights so arranged that they can be easily and effectively closed and secured watertight, are to be fitted to all sidescuttles except that abaft one eighth of the ship's length from the forward perpendicular and above a line drawn parallel to the bulkhead deck at side and having its lowest point at a height of (3,7 + 0,025 B) m above the deepest subdivision load line.

3.4.3 Openings at the side shell in the second tier

Sidescuttles and windows at the side shell in the second tier, protecting direct access below or considered buoyant in the stability calculations, are to be provided with efficient, hinged inside deadlights capable of being effectively closed and secured weathertight.

3.4.4 Openings set inboard in the second tier

Sidescuttles and windows set inboard from the side shell in the second tier, protecting direct access below to spaces listed in [3.4.1] are to be provided with either efficient, hinged inside deadlights or, where they are accessible, permanently attached external storm covers of approved design and substantial construction capable of being effectively closed and secured weathertight.

Cabin bulkheads and doors in the second tier separating sidescuttles and windows from a direct access leading below may be accepted in place of fitted deadlights or storm covers.

Note 1: Deadlights in accordance with recognized standards are fitted to the inside of windows and sidescuttles, while storm covers of comparable specifications to deadlights are fitted to the outside of windows, where accessible, and may be hinged or portable.

3.4.5 Deckhouses on superstructures of less than standard height

Deckhouses situated on a raised quarterdeck or on a superstructure of less than standard height may be treated as being on the second tier as far as the provision of deadlights is concerned, provided the height of the raised quarterdeck or superstructure is not less than the standard quarterdeck height.

3.4.6 Openings protected by a deckhouse

Where an opening in a superstructure deck or in the top of a deckhouse on the deck which gives access to a space below the waterteight deck or to a space within an enclosed superstructure is protected by a deckhouse, then it is considered that only those sidescuttles fitted in spaces which give direct access to an open stairway need to be fitted with deadlights.

4 Discharges

4.1 Arrangement of discharges

4.1.1 Inlets and discharges

All inlets and discharges in the shell plating are to be fitted with efficient and accessible arrangements for preventing the accidental admission of water into the ship.

4.1.2 Inboard opening of ash-chute, rubbish-chute, etc.

The inboard opening of each ash-shoot, rubbish-shoot, etc. is to be fitted with an efficient cover.

If the inboard opening is situated below the watertight deck, the cover is to be watertight, and in addition an automatic non-return valve is to be fitted in the chute in an easily accessible position above the deepest subdivision load line . When the chute is not in use, both the cover and the valve are to be kept closed and secured.

4.2 Arrangement of garbage chutes

4.2.1 Inboard end above the waterline

The inboard end is to be located above the waterline formed by an 8,5° heel, to port or starboard, at a draught corresponding deepest subdivision load line , but not less than 1000 mm above the deepest subdivision load line. Where the inboard end of the garbage chute exceeds 0,01 L above the deepest subdivision load line, valve control from the watertight deck is not required, provided the inboard gate valve is always accessible under service conditions.

4.2.2 Inboard end below the waterline

Where the inboard end of a garbage chute is below the margin line or the Vline then:

- the inboard end hinged cover/valve is to be watertight
- the valve is to be a screw-down non-return valve fitted in an easily accessible position above the deepest subdivision load line
- the screw-down non-return valve is to be controlled from a position above the watertight deck and provided with open/shut indicators. The valve control is to be clearly marked: “Keep closed when not in use”.

4.2.3 Gate valves

For garbage chutes, two gate valves controlled from the working deck of the chute may be accepted instead of a non-return valve with a positive means of closing it from a position above the watertight deck. In addition, the lower gate valve is to be controlled from a position above the watertight deck. An interlock system between the two valves is to be arranged.

The distance between the two gate valves is to be adequate to allow the smooth operation of the interlock system.

4.2.4 Hinged cover and discharge flap

The upper gate valve, as required in [4.2.3], may be replaced by a hinged weathertight cover at the inboard end of the chute together with a discharge flap which replaces the lower gate valve.

The cover and discharge flap are to be arranged with an interlock so that the flap cannot be operated until the hopper cover is closed.

4.2.5 Marking of valve and hinged cover

The gate valve controls and/or hinged cover are to be clearly marked: “Keep closed when not in use”.

4.3 Scantlings of garbage chutes

4.3.1 Material

The chute is to be constructed of steel. Other equivalent materials are considered by the Society on a case-by-case basis.

4.3.2 Wall thickness

The wall thickness of the chute up to, and including, the cover is to be not less than that obtained, in mm, from Tab 4.

Table 4 : Wall thickness of garbage chutes

External diameter d, in mm	Thickness, in mm
$d \leq 80$	7,0
$80 < d < 180$	7,0 + 0,03 (d – 80)
$180 \leq d \leq 220$	10,0 + 0,063 (d – 180)

5 Freeing ports

5.1 General provisions

5.1.1 General

Where bulwarks on the weather portions of watertight or superstructure decks form wells, ample provision is to be made for rapidly freeing the decks of water and for draining them.

A well is any area on the deck exposed to the weather, where water may be entrapped. Wells are considered to be deck areas bounded on four sides by deck structures; however, depending on their configuration, deck areas bounded on three or even two sides by deck structures may be deemed wells.

5.1.2 Freeing port areas

The minimum required freeing port areas in bulwarks on the watertight deck are specified in Tab 5.

5.1.3 Freeing port arrangement

Where a sheer is provided, two thirds of the freeing port area required is to be provided in the half of the well nearer the lowest point of the sheer curve.

Where the exposed watertight deck or an exposed superstructure deck has little or no sheer, the freeing port area is to be spread along the length of the well.

However, bulwarks may not have substantial openings or accesses near the breaks of superstructures, unless they are effectively detached from the superstructure sides.

5.1.4 Freeing port positioning

The lower edge of freeing ports is to be as near the deck as practicable, at not more than 100 mm above the deck.

All the openings in the bulwark are to be protected by rails or bars spaced approximately 230 mm apart.

Table 5 : Freeing port area in bulwark located on watertight deck

Ship types or ship particulars	Area A of freeing ports, in m^2	Applicable requirement
Ships fitted with a trunk having breadth ≥ 0,6 B	$0,33\ \ell_B\ h_B$	[5.3.1]
Ships fitted with continuous or substantially continuous trunk and/or hatch coamings	A_2	[5.3.1]
Ships fitted with non-continuous trunk and/ or hatch coamings	A_3	[5.3.2]
Ships fitted with open superstructure	A_S for superstructures A_W for wells	[5.4.2] [5.4.3]
Other ships	A_1	[5.2.1]

Note 1:
ℓ_B : Length, in m, of bulwark in a well at one side of the ship
h_B : Mean height, in m, of bulwark in a well of length ℓ_B .

5.1.5 Freeing port closures

If shutters or closures are fitted to freeing ports, ample clearance is to be provided to prevent jamming. Hinges are to have pins or bearings of non-corrodible material. If shutters are fitted with securing appliances, these appliances are to be of approved construction.

5.1.6 Gutter bars

Gutter bars greater than 300 mm in height fitted around the weather decks are to be treated as bulwarks. The freeing port area is to be calculated in accordance with the applicable requirements of this Section.

5.2 Freeing port area in a well not adjacent to a trunk or hatchways

5.2.1 Freeing port area A_1

Where the sheer in way of the well is standard or greater than the standard, the freeing port area on each side of the ship for each well is to be not less than that obtained, in m^2, in Tab 6.

In ships with no sheer, the above area is to be increased by 50%. Where the sheer is less than the standard, the percentage of increase is to be obtained by linear interpolation.

5.2.2 Minimum freeing port area for a deckhouse having a breadth not less than 0,8 B

Where a flush deck ship is fitted amidships with a deckhouse having a breadth not less than 0,8 B and the width of the passageways along the side of the ship less than 1,5 m, the freeing port area is to be calculated for two separate wells, before and abaft the deckhouse. For each of these wells, the freeing port area is to be obtained from Tab 5, where ℓ_B is to be taken equal to the actual length of the well considered (in this case the limitation $\ell_B \le 0,7$ L may not be applied).

5.2.3 Minimum freeing port area for screen bulkhead

Where a screen bulkhead is fitted across the full breadth of the ship at the fore end of a midship deckhouse, the weather deck is to be considered as divided into two wells, irrespective of the width of the deckhouse, and the freeing port area is to be obtained in accordance with [4.1.2].

Table 6 : Freeing port area A_1 in a well not adjacent to a trunk or hatchways

Location	Freeing port area A_1 , in m^2	
	$\ell_B \le 20$	$\ell_B > 20$
Watertight deck and raised quarterdecks	$0,7 + 0,035\ell_B + A_C$	$0,070\ell_B + A_C$
Superstructure decks	$0,35 + 0,0175\ell_B + 0,5A_C$	$0,035\ell_B + 0,5A_C$

Note 1:
ℓ_B : Length, in m, of bulwark in the well, to be taken not greater than 0,7 L
A_C : Area, in m^2, to be taken, with its sign, equal to:

$$A_C = \frac{\ell_W}{25}(h_B - 1,2) \quad \text{for } h_B > 1,2$$

$$A_C = 0 \quad \text{for } 0,9 \le h_B \le 1,2$$

$$A_C = \frac{\ell_W}{25}(h_B - 0,9) \quad \text{for } h_B < 0,9$$

h_B : Mean height, in m, of the bulwark in a well of length ℓ_B .

5.3 Freeing port area in a well contiguous to a trunk or hatchways

5.3.1 Freeing port area A2 for a continuous trunk or continuous hatchway coamings

Where the ship is fitted with a continuous trunk not included in the stability calculation or where continuous or substantially continuous hatchway side coamings are fitted between detached superstructures, the freeing port area is to be not less than that obtained, in m², from Tab 7.

Where the ship is fitted with a continuous trunk having breadth not less than 0,6 B, included in the stability calculation and where open rails on the weather parts of the watertight deck in way of the trunk for at least half the length of these exposed parts are not fitted, the freeing port area in the well contiguous to the trunk is to be not less than 33% of the total area of the bulwarks.

Table 7 : Freeing port area A_2 in a well contiguous to a continuous trunk or continuous hatchway coamings

Breadth B_H, in m	Freeing port area A_2, in m²
$B_H \le 0{,}4\ B$	$0{,}2\ \ell_B\ h_B$
$0{,}4\ B < B_H < 0{,}75\ B$	$\left[0{,}2 - 0{,}286\left(\frac{B_H}{B} - 0{,}4\right)\right]\ell_B h_B$
$B_H \ge 0{,}75\ B$	$0{,}1\ \ell_B\ h_B$

Note 1:

B_H : Breadth of the trunk or the hatchway, in m

ℓ_B : Length, in m, of bulwark in a well at one side of the ship

h_B : Mean height, in m, of bulwark in a well of length ℓ_B.

5.3.2 Freeing port area A_3 for a non-continuous trunk or non-continuous hatchway coamings

Where the free flow of water across the deck of the ship is impeded due to the presence of a non-continuous trunk, hatchway coaming or deckhouse in the whole length of the well considered, the freeing port area in the bulwark of this well is to be not less than that obtained, in m², from Tab 8.

Table 8 : Freeing port area A_3 in a well contiguous to a non-continuous trunk or non-continuous hatchway coamings

Free flow area f_P, in m²	Freeing port area A_3, in m²
$f_p \le A_1$	A_2
$A_1 < f_P < A_2$	$A_1 + A_2 - f_P$
$f_P \ge A_2$	A_1

Note 1:

f_P : Free flow area on deck, equal to the net area of gaps between hatchways, and between hatchways and superstructures and deckhouses up to the actual height of the bulwark

A_1, A_2 : Freeing port areas, in m², to be obtained from, respectively, Tab 6 and Tab 7.

5.4 Freeing port area in an open space within superstructures

5.4.1 General

In ships having superstructures on the watertight or superstructure decks, which are open at either or both ends to wells formed by bulwarks on the open decks, adequate provision for freeing the open spaces within the superstructures is to be provided.

5.4.2 Freeing port area A_S for open superstructures

The freeing port area on each side of the ship for the open superstructure is to be not less than that obtained, in m², from the following formula:

$$A_S = A_1 c_{SH}\left[1 - \left(\frac{\ell_W}{\ell_T}\right)^2\right]\left(\frac{b_0 h_S}{2\,\ell_T h_W}\right)$$

where:

ℓ_T : Total well length, in m, to be taken equal to: $\ell_T = \ell_W + \ell_S$

ℓ_W : Length, in m, of the open deck enclosed by bulwarks

ℓ_S : Length, in m, of the common space within the open superstructures

A_1 : Freeing port area, in m², required for an open well of length ℓ_T, in accordance with Tab 6, where A_C is to be taken equal to zero

c_{SH} : Coefficient which accounts for the absence of sheer, if applicable, to be taken equal to:
- c_{SH} = 1,0 in the case of standard sheer or sheer greater than standard sheer
- c_{SH} = 1,5 in the case of no sheer

b_0 : Breadth, in m, of the openings in the end bulkhead of enclosed superstructures
h_S : Standard superstructure height, in m, defined in [1.2.1]
h_W : Distance, in m, of the well deck above the watertight deck.

5.4.3 Freeing port area A_W for open well

The freeing port area on each side of the ship for the open well is to be not less than that obtained, in m², from the following formula:

$$A_W = A_1 c_{SH}\left(\frac{h_S}{2h_W}\right)$$

where:

A_1 : Freeing port area, in m², required for an open well of length ℓ_W, in accordance with Tab 6
c_{SH}, h_S, h_W, ℓ_W: Defined in [5.4.2].

5.4.4 The resulting freeing port areas for the open superstructure A_S and for the open well A_W are to be provided along each side of the open space covered by the open superstructure and each side of the open well, respectively.

6 Machinery space openings

6.1 Engine room skylights

6.1.1 Engine room skylights in position 1 or 2 are to be properly framed, securely attached to the deck and efficiently enclosed by steel casings of suitable strength. Where the casings are not protected by other structures, their strength will be considered by the Society on a case-by-case basis.

Skylights, where fitted with openings for light and air, are to have coamings of a height not less than:
- 900 mm, if in position 1
- 760 mm, if in position 2.

6.2 Closing devices

6.2.1 Machinery casings

Openings in machinery space casings in position 1 or 2 are to be fitted with doors of steel or other equivalent materials, permanently and strongly attached to the bulkhead, and framed, stiffened and fitted so that the whole structure is of equivalent strength to the unpierced bulkhead and weathertight when closed. The doors are to be capable of being operated from both sides and generally to open outwards to give additional protection against wave impact.

Other openings in such casings are to be fitted with equivalent covers, permanently attached in their proper position.

6.2.2 Height of the sill of the door

The height of the sill of the door is generally to be not less than:
- 600 mm above the deck if in position 1
- 380 mm above the deck if in position 2
- 230 mm in all the other cases.

However, height of coamings are to be compatible with use at sea and are not to be less than 300mm in position 1 and 150mm in position 2 in any case.

6.2.3 Double doors

Where casings are not protected by other structures, double doors (i.e. inner and outer doors) are required. An inner sill of 230 mm in conjunction with the outer sill of 600 mm is normally to be provided.

However, the height of this sill is to be compatible with use at sea and is not to be less than 300mm in position 1 and 150mm in position 2 in any case.

6.2.4 Fiddly openings

Fiddly openings are to be fitted with strong covers of steel or other equivalent material permanently attached in their proper positions and capable of being secured weathertight.

6.3 Coamings

6.3.1 Coamings of any fiddly, funnel or machinery space ventilator in an exposed position on the watertight deck or superstructure deck are to be as high above the deck as is reasonable and practicable.

In general, ventilators necessary to continuously supply the machinery space and, on demand, the emergency generator room are to have coamings whose height is in compliance with [8.1.3], but need not be fitted with weathertight closing appliances.

Where, due to the ship size and arrangement, this is not practicable, lesser heights for machinery space and emergency generator room ventilator coamings, fitted with weathertight closing appliances in accordance with [8.1.2], may be permitted by the Society in combination with other suitable arrangements to ensure an uninterrupted, adequate supply of ventilation to these spaces.

7 Companionway

7.1 General

7.1.1 Openings in watertight deck

Openings in watertight deck other than hatchways, machinery space openings, manholes and flush scuttles are to be protected by an enclosed superstructure or by a deckhouse or companionway of equivalent strength and weathertightness.

7.1.2 Openings in superstructures

Openings in an exposed superstructure deck or in the top of a deckhouse on the watertight deck which give access to a space below the watertight deck or a space within an enclosed superstructure are to be protected by an efficient deckhouse or companionway.

7.1.3 Openings in superstructures having a height less than standard height

Openings in the top of a deckhouse on a raised quarterdeck or superstructure of less than standard height, having a height equal to or greater than the standard quarterdeck height are to be provided with an acceptable means of closing but need not be protected by an efficient deckhouse or companionway provided the height of the deckhouse is at least the height of the superstructure.

7.2 Scantlings

7.2.1 Companionways on exposed decks protecting openings leading into enclosed spaces are to be of steel or equivalent material and strongly attached to the deck and are to have adequate scantlings.

7.3 Closing devices

7.3.1 Doors

Doorways in deckhouses or companionways leading to or giving access to spaces below the watertight deck or to enclosed superstructures are to be fitted with weathertight doors. The doors are to be made of steel or equivalent material, to be capable of being operated from both sides and generally to open outwards to give additional protection against wave impact.

Alternatively, if stairways within a deckhouse are enclosed within properly constructed companionways fitted with weathertight doors, the external door need not be watertight.

Where the closing appliances of access openings in superstructures and deckhouses are not weathertight, interior deck openings are to be considered exposed, i.e. situated in the open deck.

7.3.2 Height of sills

The height above the deck of sills to the doorways in companionways is to be not less than:

- 600 mm in position 1
- 380 mm in position 2.

Where access is not provided from above, the height of the sills to doorways in a poop bridge or deckhouse on the watertight deck is to be 600 mm.

Where access is provided to spaces inside a bridge or poop from the deck as an alternative to access from the watertight deck, the height of the sills into the bridge or poop is to be 380 mm. This also applies to deckhouses on the exposed deck.

However, height of sills are to be compatible with use at sea and are not to be less than 300mm in position 1 and 150 mm in position 2 in any case.

8 Ventilators

8.1 Closing appliances

8.1.1 General

Ventilator openings are to be provided with efficient weathertight closing appliances of steel or other equivalent material, designed to offer equivalent strength compared to the adjacent bulkhead or coaming in which they are fitted.

8.1.2 Closing appliance exemption

Ventilators need not be fitted with closing appliances, unless specifically required by the Society, if the coamings extend for more than:

- 4,5 m above the deck in position 1
- 2,3 m above the deck in position 2.

8.1.3 Closing appliances for ships not greater than 100 m in length

In ships not greater than 100 m in length, the closing appliances are to be permanently attached to the ventilator coamings.

8.1.4 Closing appliances for ships greater than 100 m in length

Where, in ships greater than 100 m in length, the closing appliances are not permanently attached, they are to be conveniently stowed near the ventilators to which they are to be fitted.

8.1.5 Ventilation of machinery spaces and emergency generator room

In order to satisfactorily ensure, in all weather conditions:

- the continuous ventilation of machinery spaces, and
- when necessary, the immediate ventilation of the emergency generator room,

the ventilators serving such spaces are to comply with [8.1.2], i.e. their openings are to be so located that they do not require closing appliances.

8.1.6 Reduced height of ventilator coamings for machinery spaces and emergency generator room

Where, due to the ship size and arrangement, the requirements in [8.1.5] are not practicable, lesser heights may be accepted for machinery space and emergency generator room ventilator coamings fitted with weathertight closing appliances in accordance with [8.1.1], [8.1.3] and [8.1.4] in combination with other suitable arrangements, such as separators fitted with drains, to ensure an uninterrupted, adequate supply of ventilation to these spaces.

8.1.7 Closing arrangements of ventilators led overboard or through enclosed superstructures

Closing arrangements of ventilators led overboard to the ship side or through enclosed superstructures are considered by the Society on a case-by-case basis. If such ventilators are led overboard more than 4,5 m above the watertight deck, closing appliances may be omitted provided that satisfactory baffles and drainage arrangements are fitted.

8.2 Coamings

8.2.1 General

Ventilators in position 1 or 2 to spaces below watertight decks or decks of enclosed superstructures are to have coamings of steel or other equivalent material, substantially constructed and efficiently connected to the deck.

Ventilators passing through superstructures other than enclosed superstructures are to have substantially constructed coamings of steel or other equivalent material at the watertight deck.

8.2.2 Scantlings

The scantlings of ventilator coamings exposed to the weather are to be not less than those obtained from Tab 9.

In exposed locations or for the purpose of compliance with buoyancy calculations, the height of coamings may be required to be increased to the satisfaction of the Society.

9 Tank cleaning openings

9.1 General

9.1.1 Ullage plugs, sighting ports and tank cleaning openings may not be arranged in enclosed spaces.

Table 9 : Scantlings of ventilator coamings

Feature	Scantlings
Height of the coaming above the deck	$h = 900$ mm in position 1 $h = 760$ mm in position 2
Thickness of the coaming, in mm **(1)**	$t = 5,5 + 0,01\ d_V$ with $7,5 \leq t \leq 10,0$
Support	If $h > 900$ mm, the coaming is to be suitably stiffened or supported by stays

(1) Where the height of the ventilator exceeds the height h, the thickness of the coaming may be gradually reduced, above that height, to a minimum of 6,5 mm.

Note 1:

d_V : Internal diameter of the ventilator, in mm.

Section 10 Helicopter Decks

Symbols

W_H : Maximum weight of the helicopter, in t

g : Gravity acceleration, in m/s²:

$g = 9,81$ m/s²

R_y : Minimum yield stress, in N/mm², of the material, to be taken equal to 235/k N/mm², unless otherwise specified

k : Material factor for steel, defined in Ch 4, Sec 1, [2.3].

1 Application

1.1 General

1.1.1 The requirements of this Section apply to areas equipped for the landing and take-off of helicopters with landing gears or landing skids, and located on a deck or on a platform permanently connected to the hull structure.

1.1.2 Helicopter deck or platform intended for the landing of helicopters having landing devices other than wheels or skids are to be examined by the Society on a case-by-case basis.

2 Definition

2.1 Landing gear

2.1.1 A landing gear may consist of a single wheel or a group of wheels.

3 General arrangement

3.1 Dimension of the landing area

3.1.1 The main dimensions of the landing area, its location on board, the approach sector for landing and take-off are to comply with the applicable requirements from the National or other Authorities, or contractual specifications.

3.2 Sheathing of the landing area

3.2.1 Within the landing area, a non-skid deck covering is recommended.

3.2.2 Where the deck or the platform is wood sheathed, special attention is to be paid to the fire protection.

3.3 Approach and landing area

3.3.1 The approach and the landing area are to be free of obstructions above the level of the deck or the platform.

Note 1: The following items may exceed the height of the landing area, but should not do so by more than 100 mm:

- the guttering or slightly raised kerb
- the lightning equipment
- the outboard edge of the safety net
- the foam monitors
- those handrails and other items associated with the landing area which are incapable of complete retraction or lowering for helicopter operations.

3.4 Safety net

3.4.1 It is recommended to provide a safety net at the sides of the deck or the platform.

3.5 Drainage system

3.5.1 Gutterways of adequate height and a drainage system are recommended on the periphery of the deck or the platform.

4 Design principles

4.1 General

4.1.1 Local deck strengthening is to be fitted at the connection of diagonals and pillars supporting platform.

4.2 Partial safety factors

4.2.1 The partial safety factors to be considered for checking helicopter deck and platform structures are specified in Tab 1.

Table 1 : Helicopter decks and platforms - Partial safety factors

Partial safety factors covering uncertainties regarding:	Partial safety factors			
	Symbol	Plating	Ordinary stiffeners	Primary supporting members
Still water pressure	γ_{S2}	1,00	1,00	1,00
Wave pressure	γ_{W2}	1,20	1,20	1,20
Note 1: Value of 1.1 may be considered instead of 1,2 when the deck is not located on the aft or the fore part of the ship				

5 Design loads

5.1 General

5.1.1 As a rule, the strength analysis for the situation of normal landing is not required as it is covered by the strength analysis in emergency landing, as defined in [5.2].

5.1.2 The following loads are to be considered for the scantling of the helicopter deck or landing platform:

- emergency landing load defined in [5.2]
- garage load, if any, defined in [5.3]
- loads due to ship accelerations and wind defined in [5.4]
- sea pressure obtained according to Ch 5, Sec 5, [3.2].

5.1.3 Helicopter having landing devices other than wheels

In case of a deck or a platform intended for the landing of helicopters having landing devices other than wheels (e.g. skates), the landing loads, the emergency loads and the garage loads, if any, are to be examined by the Society on a case-by-case basis.

5.2 Emergency landing load

5.2.1 The emergency landing force F_{EL} transmitted through one landing gear or one skid to the helicopter deck or platform is to be obtained, in kN, from the following formulae:

- helicopter with landing gears: $F_{EL} = 1,75\ g\ W_H$
- helicopter with landing skids: $F_{EL} = 2,50\ g\ W_H$

The point of application of the force F_{EL} is to be taken so as to produce the most severe stresses on the supporting structure.

5.3 Garage load

5.3.1 Where a garage zone is fitted in addition to the landing area, the still water and inertial forces transmitted trough each landing gear or each landing skid to the helicopter deck or platform, in kN, are to be obtained as specified in Ch 5, Sec 6, [4.1.1], where M is to be taken equal to:

- for helicopter with landing gears:

  M is the landing gear load, in t, to be specified by the Designer. If the landing gear load is not known, M is to be taken equal to:

  $$M = \frac{1,25}{n} W_H$$

  where n is the total number of landing gears

- for helicopter with landing skids:

  $M = 0,5\ W_H$

5.3.2 When helicopters are parked in an unprotected area, sea pressures on deck, as per Ch 5, Sec 5, [3], are to be considered simultaneously with the loads defined in [5.3.1].

5.4 Forces due to ship accelerations and wind

5.4.1 This Sub-Article applies to helicopter platforms which are not part of the ship hull structures.

5.4.2 The still water and inertial forces transmitted by the helicopter platform to the ship hull structures are to be determined, in kN, as specified in Tab 2.

Table 2 : Helicopter platforms - Still water and inertial forces

Ship condition	Load case	Still water force F_S and inertial force F_W, in kN
Still water condition		$F_S = (W_H + W_P)\,g$
Upright condition	"a"	No inertial force
	"b"	$F_{W,X} = (W_H + W_P)a_{X1} + 1{,}2A_{HX}$ in x direction $F_{W,Z} = (W_H + W_P)a_{Z1}$ in z direction
Inclined condition (negative roll angle) **(1)**	"c"	$F_{W,Y} = C_{FA}(W_H + W_P)a_{Y2} + 1{,}2A_{HY}$ in y direction
	"d"	$F_{W,Z} = C_{FA}(W_H + W_P)a_{Z2}$ in z direction

(1) Inclined condition is not applicable for ships less than 65 m in length.

Note 1:

- W_p : Structural weight of the helicopter platform, in t, to be evenly distributed, and to be taken not less than the value obtained from the following formula (W_p may be taken equal to zero when the structure of the landing area is part of the deck structure):
  $W_p = 0{,}2\ A_H$
- A_H : Area, in m², of the entire landing area
- a_{X1}, a_{Z1} : Accelerations, in m/s², determined at the helicopter center of gravity for the upright ship condition, and defined in Ch 5, Sec 3, [3.4]
- a_{Y2}, a_{Z2} : Accelerations, in m/s², determined at the helicopter center of gravity for the inclined ship condition, and defined in Ch 5, Sec 3, [3.4]
- A_{HX}, A_{HY} : Vertical areas, in m², of the helicopter platform in x and y directions respectively. Unless otherwise specified, A_{HX} and A_{HY} may be taken equal to $A_H/3$
- C_{FA} : Combination factor, to be taken equal to:
  - $C_{FA} = 0{,}7$ for load case "c"
  - $C_{FA} = 1{,}0$ for load case "d".

6 Scantlings

6.1 Net scantling

6.1.1 As specified in Ch 4, Sec 2, [1], all scantlings referred to in this Section are net, i.e. they do not include any margin for corrosion.

The net scantlings are obtained as specified in Ch 4, Sec 2, [1].

6.2 Plating

6.2.1 Load model

The following forces P_0 are to be considered independently:

- $P_0 = F_{EL}$

  where F_{EL} is the force corresponding to the emergency landing load, as defined in [5.2]
- $P_0 = \gamma_{s2}\ F_s + \gamma_{w2}\ F_{w,z}$

  where F_s and $F_{w,z}$ are the forces corresponding to the garage loads, as defined in [5.3], if applicable

6.2.2 Plating subjected to sea pressure

The net thickness of an helicopter deck or platform subject to forces defined in [6.2.1] is to be not less than the values obtained according to Ch 7, Sec 1, [4.3], considering λ equal to 1,0 in the particular case of a platform.

The value of P_0 when used in the formula of Ch 7, Sec 1, [4.3] is to be taken as specified in [5.2] for the emergency load and [5.3] for the garage load

6.3 Ordinary stiffeners

6.3.1 Load model

The following forces P_0 are to be considered independently:

- $P_0 = F_{EL}$
  where F_{EL} is the force corresponding to the emergency landing load, as defined in [5.2]
- $P_0 = \gamma_{s2}\ F_s + \gamma_{w2}\ F_{w,z}$
  where F_s and $F_{w,z}$ are the forces corresponding to the garage loads, as defined in [5.3], if applicable
- $P_0 = \gamma_{s2}\ F_s + \gamma_{w2}\ F_{w,z}$
  where F_s and $F_{w,z}$ are the forces corresponding to the loads due to ship accelerations and wind, as defined in [5.4]
- sea pressure loads as defined in [5.3.2].

6.3.2 Normal and shear stresses

Normal and shear stresses induced by loads and pressures in an ordinary stiffener are to be obtained according to:

- Ch 7, Sec 2, [3.4] for an ordinary stiffener subjected to sea pressure
- Ch 7, Sec 2, [3.5] for an ordinary stiffener subjected to loads transmitted by tyre prints.

6.3.3 Checking criteria

It is to be checked that the normal stress σ and the shear stress τ calculated according to [6.3.2] fulfill the following conditions:

$$\sigma \le \frac{R_y}{\gamma_R \gamma_m}$$

$$\tau \le 0{,}5\frac{R_y}{\gamma_R \gamma_m}$$

where:

γ_m : Partial safety factor covering uncertainties on the material, to be taken equal to 1,02

γ_R : Partial safety factor covering uncertainties on the resistance:

- γ_R = 1,02 for garage loads
- γ_R = 1,00 for emergency condition
- γ_R = 1,02 for loads dues to ship accelerations and wind.

6.4 Primary supporting members

6.4.1 Load model

The following forces P_0 are to be considered independently:

- $P_0 = F_{EL}$
  where F_{EL} is the force corresponding to the emergency landing load, as defined in [5.2]
- $P_0 = \gamma_{s2}\ F_s + \gamma_{w2}\ F_{w,z}$
  where F_s and $F_{w,z}$ are the forces corresponding to the garage loads, as defined in [5.3], if applicable
- $P_0 = \gamma_{s2}\ F_s + \gamma_{w2}\ F_{w,z}$
  where F_s and $F_{w,z}$ are the forces corresponding to the loads due to ship accelerations and wind, as defined in [5.4]
- sea pressure loads as defined in [5.3.2].

6.4.2 Load model for landing area located on a platform

The following loads are to be considered independently:

- sea pressure, as defined in Ch 5, Sec 5, [3.2]
- loads transmitted by tyre prints:
  - emergency landing load, as defined in [5.2]
  - garage load, if any, as defined in [5.3]
- loads due to ship accelerations and wind, as defined in [5.4].

6.4.3 Normal and shear stresses

Normal and shear stresses induced by loads and pressures in a primary supporting member are to be obtained according to Ch 7, App 1, [5], considering:

- for analyses based on finite element models:
  $\sigma = \text{Max}\ (\sigma_1\ ;\ \sigma_2)$ and $\tau = \tau_{12}$
- for analyses based on beam models:
  $\sigma = \sigma_1$ and $\tau = \tau_{12}$

6.4.4 Checking criteria

It is to be checked that the normal stress σ and the shear stress τ calculated according to [6.4.3] fulfill the following conditions:

$$\sigma \leq \frac{R_y}{\gamma_R \gamma_m}$$

$$\tau \leq 0{,}5\frac{R_y}{\gamma_R \gamma_m}$$

where:

γ_m : Partial safety factor covering uncertainties on the material to be taken equal to 1,02

γ_R : Partial safety factor covering uncertainties on the resistance:

- γ_R = 1,02 for garage loads
- γ_R = 1,00 for emergency condition
- γ_R = 1,02 for loads dues to ship accelerations and wind.

7 Lashing

7.1 General

7.1.1 Where lashing pots are fitted on helicopter deck, the strength of the structure in way of the lashing pots is to be assessed according to this Article.

7.1.2 As a rule, the fixed lashing devices are to be fitted in way of deck stiffening structural elements.

7.2 Documentation to be submitted

7.2.1 The following documentation is to be submitted to the Society for information:

- lashing arrangement showing clearly the lashing forces transmitted to the hull structures and pre-tensioning forces, if any
- Safe Working Load (SWL) and Breaking Load (BL) of the fixed and portable lashing devices
- details of welding between fixed lashing devices and deck structure

In the absence of information, the lashing force transmitted through one single lashing device may be taken equal to 50 kN acting at 45° with respect to the deck plan, in the most severe direction.

7.3 Design Load

7.3.1 The design load to be considered for the structural assessment of the deck structure in way of lashing devices is to be taken equal to 1,1 SWL.

7.4 Checking criteria

7.4.1 It is to be checked that the normal stress σ and the shear stress τ in way of all structure elements supporting lashing forces fulfill the following conditions:

$$\sigma \leq \frac{R_y}{\gamma_R \gamma_m}$$

$$\tau \leq 0{,}5\frac{R_y}{\gamma_R \gamma_m}$$

where:

γ_m : Partial safety factor covering uncertainties on the material, to be taken equal to 1,02

γ_r : Partial safety factor covering uncertainties on the resistance, to be taken as specified in Ch 7, Sec 3.

8 Recovery devices

8.1 Definition

8.1.1 A recovery device is a system used for free deck landing and to handle the helicopter to the hangar. It provides a means of securing the helicopter to the flight deck by aligning it with a deck-mounted track.

8.2 Documentation to be submitted

8.2.1 The following documentation is to be submitted to the Society for information:

- General arrangement showing the maximum reaction forces induced by the recovery device on the deck structure
- Drawing of the integration of the system within the ship structure, including scantling and welding details.

8.3 Checking criteria

8.3.1 It is to be checked that the normal stress σ and the shear stress τ in way of all structure elements supporting lashing forces fulfill the following conditions:

$$\sigma \leq \frac{R_y}{\gamma_R \gamma_m}$$

$$\tau \leq 0{,}5\frac{R_y}{\gamma_R \gamma_m}$$

where:

γ_m : Partial safety factor covering uncertainties on the material, to be taken equal to 1,02

γ_r : Partial safety factor covering uncertainties on the resistance, to be taken as specified in Ch 7, Sec 3.

CHAPTER 9
HULL OUTFITTING

Section 1	Rudders
Section 2	Bulwarks and Guard Rails
Section 3	Propeller Shaft Brackets
Section 4	Equipment
Section 5	Masts and Other Outfitting Components
Appendix 1	Criteria for Direct Calculation of Rudder Loads

Section 1 Rudders

Symbols

V_{AV} : Maximum ahead speed, in knots, with the ship on full load waterline; if V_{AV} is less than 10 knots, the maximum service speed is to be taken not less than the value obtained from the following formula:

$$V_{MIN} = \frac{V_{AV} + 20}{3}$$

V_{AD} : Maximum astern speed, in knots, to be taken not less than 0,5 V_{AV}. However, in case the maximum achievable astern speed indicated by the designer is less, the latest can be considered

A : Total area of the rudder blade, in m^2, bounded by the blade external contour, including the mainpiece and the part forward of the centreline of the rudder pintles, if any

k_1 : Material factor, defined in [1.4.1]

k : Material factor, defined in Ch 4, Sec 1, [2.3] (see also [1.4.5])

C_R : Rudder force, in N, acting on the rudder blade, defined in [2.1.1] and [2.2.1]

M_{TR} : Rudder torque, in N.m, acting on the rudder blade, defined in [2.1.2] and [2.2.2]

M_B : Bending moment, in N.m, in the rudder stock, defined in [4.1].

1 General

1.1 Application

1.1.1 Ordinary profile rudders

The requirements of this Section apply to ordinary profile rudders, without any special arrangement for increasing the rudder force, whose maximum orientation at maximum ship speed is limited to 35° on each side.

In general, an orientation greater than 35° is accepted for manoeuvres or navigation at very low speed.

When the maximum orientation at maximum speed is limited to angle smaller than 35° by physical or software devices, the Society may accept reductions, on a case-by-case basis.

1.1.2 High lift profiles

The requirements of this Section also apply to rudders fitted with flaps to increase rudder efficiency. For these rudder types, an orientation at maximum speed less than 35° may be accepted. In these cases, the rudder forces are to be calculated by the Designer for the most severe combinations between orientation angle and ship speed. These calculations are to be considered by the Society on a case-by-case basis.

The rudder scantlings are to be designed so as to be able to sustain possible failures of the orientation control system, or, alternatively, redundancy of the system itself may be required.

1.1.3 Steering nozzles

The requirements for steering nozzles are given in Article [10].

1.1.4 Special rudder types

Rudders others than those in [1.1.1], [1.1.2] and [1.1.3] will be considered by the Society on a case-by-case basis.

1.1.5 Materials

The requirements of the present section apply to rudders made of steel. Rudders made of other materials are to be considered on a case-by-case basis.

1.2 Gross scantlings

1.2.1 With reference to Ch 4, Sec 2, [1], all scantlings and dimensions referred to in this Section are gross, i.e. they include the margins for corrosion.

1.3 Arrangements

1.3.1 Effective means are to be provided for supporting the weight of the rudder without excessive bearing pressure, e.g. by means of a rudder carrier attached to the upper part of the rudder stock. The hull structure in way of the rudder carrier is to be suitably strengthened.

1.3.2 Suitable arrangements are to be provided to prevent the rudder from lifting.

In addition, structural rudder stops of suitable strength are to be provided, except where the steering gear is provided with its own rudder stopping devices, as detailed in Pt C, Ch 1, Sec 12.

1.3.3 In rudder trunks which are open to the sea, a seal or stuffing box is to be fitted above the deepest load waterline, to prevent water from entering the steering gear compartment and the lubricant from being washed away from the rudder carrier. If the top of the rudder trunk is below the deepest waterline two separate stuffing boxes are to be provided.

1.4 Materials

1.4.1 Rudder stocks, pintles, coupling bolts, keys and cast parts of rudders are to be made of rolled steel, steel forgings or steel castings according to the applicable requirements in NR216 Materials and Welding, Chapter 2.

1.4.2 The material used for rudder stocks, pintles, keys and bolts is to have a minimum yield stress not less than 200 N/mm².

1.4.3 The requirements relevant to the determination of scantlings contained in this Section apply to steels having a minimum yield stress equal to 235 N/mm².

Where the material used for rudder stocks, pintles, coupling bolts, keys and cast parts of rudders has a yield stress different from 235 N/mm², the scantlings calculated with the formulae contained in the requirements of this Section are to be modified, as indicated, depending on the material factor k_1, to be obtained from the following formula:

$$k_1 = \left(\frac{235}{R_{eH}}\right)^n$$

where:

R_{eH} : Yield stress, in N/mm², of the steel used, and not exceeding the lower of 0,7 R_m and 450 N/mm²

R_m : Minimum ultimate tensile strength, in N/mm² of the steel used,

n : Coefficient to be taken equal to:

- $n = 0{,}75$ for $R_{eH} > 235$ N/mm²
- $n = 1{,}00$ for $R_{eH} \leq 235$ N/mm².

1.4.4 Significant reductions in rudder stock diameter due to the application of steels with yield stresses greater than 235 N/mm² may be accepted by the Society subject to the results of a check calculation of the rudder stock deformations.

Large rudder stock deformations are to be avoided in order to avoid excessive edge pressures in way of bearings.

1.4.5 Welded parts of rudders are to be made of approved rolled hull materials. For these members, the material factor k defined in Ch 4, Sec 1, [2.3] is to be used.

2 Force and torque acting on the rudder

2.1 Rudder blade without cut-outs

2.1.1 Rudder blade description

A rudder blade without cut-outs may have trapezoidal or rectangular contour.

2.1.2 Rudder force

The rudder force C_R is to be obtained, in N, from the following formula:

$$C_R = 132\, n_R\, A\, V^2\, r_1\, r_2\, r_3$$

where:

n_R : Navigation coefficient, defined in Tab 1

V : V_{AV} or V_{AD}, depending on the condition under consideration (for high lift profiles, see [1.1.2])

r_1 : Shape factor, to be taken equal to:

$$r_1 = \frac{\lambda + 2}{3}$$

Table 1 : Navigation coefficient n_R

Navigation notation	Navigation coefficient n_R
Unrestricted navigation	1,00
Coastal area	0,85
Sheltered area	0,75

Table 2 : Values of coefficient r_2

Rudder profile type	r_2 for ahead condition	r_2 for astern condition
NACA 00 - Goettingen 	1,10	0,80
Hollow 	1,35	0,90
Flat side 	1,10	0,90
High lift 	1,70	1,30
Fish tail 	1,40	0,80
Single plate 	1,00	1,00

λ : Coefficient, to be taken equal to:

$$\lambda = \frac{h^2}{A_T}$$

and not greater than 2,0

h : Mean height, in m, of the rudder area to be taken equal to (see Fig 1):

$$h = \frac{z_3 + z_4 - z_2}{2}$$

A_T : Area, in m², to be calculated by adding the rudder blade area A to the area of the rudder post or rudder horn, if any, up to the height h

r_2 : Coefficient to be obtained from Tab 2. For other profiles than those defined in Tab 2, the value of r_2 is defined by the Society on a case-by-case basis

r_3 : Coefficient to be taken equal to:

- r_3 = 0,8 for rudders outside the propeller jet (centre rudders on twin screw ships, or similar cases)
- r_3 = 1,15 for rudders behind a fixed propeller nozzle
- r_3 = 1,0 in other cases.

2.1.3 Rudder torque

The rudder torque M_{TR}, for both ahead and astern conditions, is to be obtained, in N.m, from the following formula:

$M_{TR} = C_R\, r$

where:

r : Lever of force C_R, in m, equal to:

$$r = b\left(\alpha - \frac{A_F}{A}\right)$$

and to be taken not less than 0,1 b for the ahead condition b : Mean breadth, in m, of rudder area to be taken equal to (see Fig 1):

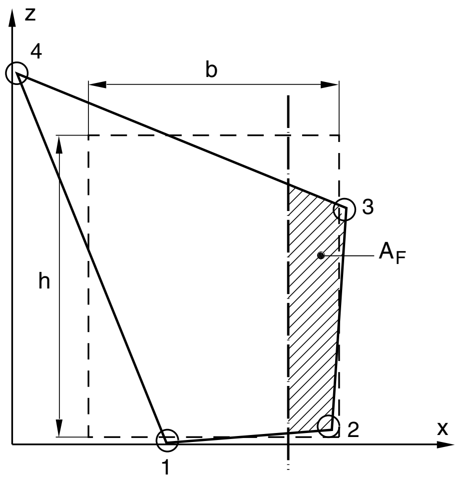
$$b = \frac{x_2 + x_3 - x_1}{2}$$

α : Coefficient to be taken equal to:

- α = 0,33 for ahead condition
- α = 0,66 for astern condition

A_F : Area, in m^2, of the rudder blade portion afore the centreline of rudder stock (see Fig 1).

Figure 1 : Geometry of rudder blade without cut-outs

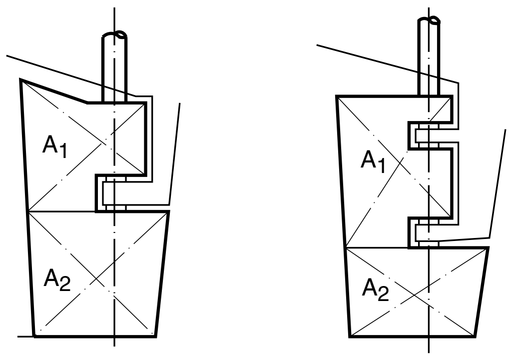


2.2 Rudder blade with cut-outs (semi-spade rudders)

2.2.1 Rudder blade description

A rudder blade with cut-outs may have trapezoidal or rectangular contour, as indicated in Fig 2.

Figure 2 : Rudder blades with cut-outs



2.2.2 Rudder force

The rudder force C_R, in N, acting on the blade is to be calculated in accordance with [2.1.2].

2.2.3 Rudder torque

The rudder torque M_{TR}, in N·m, is to be calculated in accordance with the following procedure.

The rudder blade area A is to be divided into two rectangular or trapezoidal parts having areas A_1 and A_2, defined in Fig 2, so that:

$A = A_1 + A_2$

The rudder forces C_{R1} and C_{R2}, acting on each part A_1 and A_2 of the rudder blade, respectively, are to be obtained, in N, from the following formulae:

$$C_{R1} = C_R \frac{A_1}{A}$$

$$C_{R2} = C_R \frac{A_2}{A}$$

The levers r_1 and r_2 of the forces C_{R1} and C_{R2}, respectively, are to be obtained, in m, from the following formulae:

$$r_1 = b_1\left(\alpha - \frac{A_{1F}}{A_1}\right)$$

$$r_2 = b_2\left(\alpha - \frac{A_{2F}}{A_2}\right)$$

where:

b_1, b_2 : Mean breadths of the rudder blade parts having areas A_1 and A_2, respectively, to be determined according to [2.1.3]

A_{1F}, A_{2F} : Areas, in m^2, of the rudder blade parts, defined in Fig 3

α : Coefficient to be taken equal to:

- $\alpha = 0,33$ for ahead condition
- $\alpha = 0,66$ for astern condition

For rudder parts located behind a fixed structure such as a rudder horn, α is to be taken equal to:

- $\alpha = 0,25$ for ahead condition
- $\alpha = 0,55$ for astern condition.

The torques M_{TR1} and M_{TR2}, relevant to the rudder blade parts A_1 and A_2 respectively, are to be obtained, in N.m, from the following formulae:

$M_{TR1} = C_{R1}\, r_1$

$M_{TR2} = C_{R2}\, r_2$

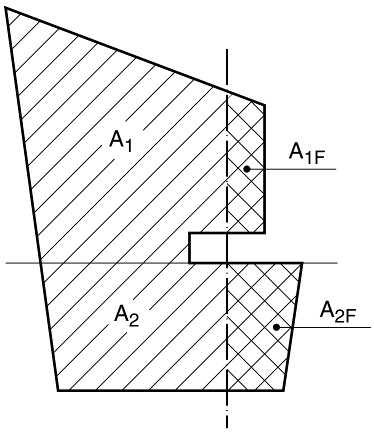
The total torque M_{TR} acting on the rudder stock, for both ahead and astern conditions, is to be obtained, in N.m, from the following formula:

$M_{TR} = M_{TR1} + M_{TR2}$

For the ahead condition only, M_{TR} is to be taken not less than the value obtained, in N.m, from the following formula:

$$M_{TR,MIN} = 0,1\, C_R \frac{A_1 b_1 + A_2 b_2}{A}$$

Figure 3 : Geometry of rudder blade with cut-outs



3 Loads acting on the rudder structure

3.1 General

3.1.1 Loads

The force and torque acting on the rudder, defined in Article [2], induce in the rudder structure the following loads:

- bending moment and torque in the rudder stock
- support forces
- bending moment, shear force and torque in the rudder body
- bending moment, shear force and torque in rudder horns and solepieces.

3.1.2 Direct load calculations

The bending moment in the rudder stock, the support forces, and the bending moment and shear force in the rudder body are to be determined through direct calculations to be performed in accordance to the static schemes and the load conditions specified in Ch 9, App 1.

For rudders with solepiece or rudder horns these structures are to be included in the calculation model in order to account for the elastic support of the rudder body.

The other loads (i.e. the torque in the rudder stock and in the rudder body and the loads in rudder horns and sole-pieces) are to be calculated as indicated in the relevant requirements of this Section.

3.1.3 Simplified methods for load calculation

For ordinary rudder types, the bending moment in the rudder stock, the support forces, and the bending moment and shear force in the rudder body may be determined through approximate methods specified in the relevant requirements of this Section.

The other loads (i.e. the torque in the rudder stock and in the rudder body and the loads in rudder horns and sole-pieces) are to be calculated as indicated in the relevant requirements of this Section.

4 Rudder stock scantlings

4.1 Bending moment

4.1.1 General

The bending moment M_B in the rudder stock is to be obtained as follows:

- for spade rudders, 2 bearing rudders with solepiece and 2 bearing semi-spade rudders with rudder horn:

  M_B is to be calculated according to:

  - [4.1.2] through a direct calculation, or
  - [4.1.3] through a simplified method

- for 3 bearing semi-spade rudders with rudder horn and for the rudder types shown in Fig 4:

  M_B may be taken equal to zero.

4.1.2 Bending moment calculated through a direct calculation

For spade rudders, 2 bearing rudders with solepiece and 2 bearing semi-spade rudders with rudder horn, where a direct calculation according to the static schemes and the load conditions specified in Ch 9, App 1 is carried out, the bending moment in the rudder stock is to be obtained as specified in Ch 9, App 1.

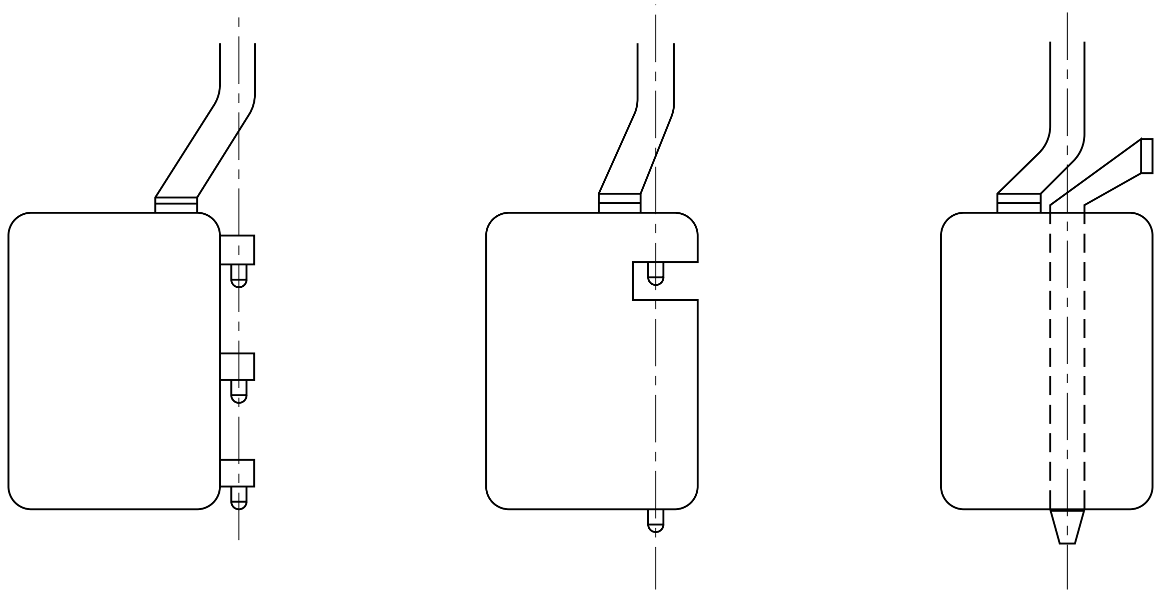
4.1.3 Bending moment calculated through a simplified method

For spade rudders, 2 bearing rudders with solepiece and 2 bearing semi-spade rudders with rudder horn, where a direct calculation according to the static schemes and the load conditions specified in Ch 9, App 1 is not carried out, the bending moment M_B in the rudder stock is to be obtained, in N.m, from the following formula:

$$M_B = 0{,}866\frac{HC_R}{A}$$

where H is defined, in m^3, in Tab 3.

Figure 4 : Rudder types



Hinged rudder with three bearings | Hinged rudder with three bearings | Simplex-type rudder

Table 3 : Factor H, in m^3

Spade rudders	2 bearing rudders with solepiece	2 bearing semi-spade rudders with rudder horn
		$H = A\left(H_C + \frac{H_2}{2}\right)$	$H = A\ a_1\ u\ H_1$	$H = 0{,}83\ B$ **(1)**

(1) B is the greater of the absolute values obtained from the following formulae:
- $B = A_1\ u\ H_1 + A_2\ (v\ H_1 + w\ H_2)$
- $B = A_1\ a_2\ H_1 - A_2\ (a_3\ H_1 + 0{,}5\ H_2)$

where a_1 , a_2 , a_3 , u, v and w are defined in Tab 4.

Table 4 : Coefficients for calculating the bending moment in the rudder stock

Coefficient	Value
a_1	$2{,}55 - 1{,}75\ c$
a_2	$1{,}75\ c^2 - 3{,}9\ c + 2{,}35$
a_3	$2{,}65\ c^2 - 5{,}9\ c + 3{,}25$
u	$1{,}10\ c^2 - 2{,}05\ c + 1{,}175$
v	$1{,}15\ c^2 - 1{,}85\ c + 1{,}025$
w	$-3{,}05\ c^4 + 8{,}14\ c^3 - 8{,}15\ c^2 + 3{,}81\ c - 0{,}735$

Note 1:

$$c = \frac{H_1}{H_1 + H_C}$$

H_1 , H_C : As defined in Tab 3, as applicable.

4.2 Scantlings

4.2.1 Rudder stock subjected to torque only

For rudder stocks subjected to torque only (3 bearing semi-spade rudders with rudder horn in Fig 2 and the rudder types shown in Fig 4), it is to be checked that the torsional shear stress τ, in N/mm^2, induced by the torque M_{TR} is in compliance with the following formula:

$\tau \leq \tau_{ALL}$

where:

τ_{ALL} : Allowable torsional shear stress, in N/mm^2: $\tau_{ALL} = 68 / k_1$

For this purpose, the rudder stock diameter is to be not less than the value obtained, in mm, from the following formula:

$d_T = 4{,}2\ (M_{TR}\ k_1)^{1/3}$

4.2.2 Rudder stock subjected to combined torque and bending

For rudder stocks subjected to combined torque and bending (spade rudders, 2 bearing rudders with solepiece and 2 bearing semi-spade rudders with rudder horn in Tab 3), it is to be checked that the equivalent stress σ_E induced by the bending moment M_B and the torque M_{TR} is in compliance with the following formula:

$\sigma_E \leq \sigma_{E,ALL}$

where:

σ_E : Equivalent stress to be obtained, in N/mm², from the following formula:

$$\sigma_E = \sqrt{\sigma_B^2 + 3\tau_T^2}$$

σ_B : Bending stress to be obtained, in N/mm², from the following formula:

$$\sigma_B = 10^3 \frac{10{,}2 M_B}{d_{TF}^3}$$

τ_T : Torsional stress to be obtained, in N/mm², from the following formula:

$$\tau_T = 10^3 \frac{5{,}1 M_{TR}}{d_{TF}^3}$$

$\sigma_{E,ALL}$: Allowable equivalent stress, in N/mm², equal to:

$\sigma_{E,ALL} = 118/k_1$ N/mm²

For this purpose, the rudder stock diameter is to be not less than the value obtained, in mm, from the following formula:

$$d_{TF} = 4{,}2(M_{TR}k_1)^{1/3}\left[1 + \frac{4}{3}\left(\frac{M_B}{M_{TR}}\right)^2\right]^{1/6}$$

In general, the diameter of a rudder stock subjected to torque and bending may be gradually tapered above the lower stock bearing so as to reach, from the diameter d_{TF}, the value of d_T in way of the quadrant or the tiller.

5 Rudder stock couplings

5.1 Horizontal flange couplings

5.1.1 General

In general, the coupling flange and the rudder stock are to be forged from a solid piece. A shoulder radius as large as practicable is to be provided for between the rudder stock and the coupling flange. This radius is to be not less than 0,13 d_1, where d_1 is the greater of the rudder stock diameters d_T and d_{TF}, in mm, to be calculated in compliance with the requirements in [4.2.1] and [4.2.2], respectively.

Where the rudder stock diameter does not exceed 350 mm, the coupling flange may be welded onto the stock provided that its thickness is increased by 10%, and that the weld extends through the full thickness of the coupling flange and that the assembly obtained is subjected to heat treatment. This heat treatment is not required if the diameter of the rudder stock is less than 75 mm.

Where the coupling flange is welded, the grade of the steel used is to be of weldable quality, particularly with a carbon content not greater than 0,25% and the welding conditions (preparation before welding, choice of electrodes, pre and post heating, inspection after welding) are to be defined to the satisfaction of the Society. The throat weld at the top of the flange is to be concave shaped to give a fillet shoulder radius as large as practicable. This radius is to be not less than 0,13 d_1, where d_1 is defined above.

5.1.2 Bolts

Horizontal flange couplings are to be connected by fitted bolts having a diameter not less than the value obtained, in mm, from the following formula:

$$d_B = 0{,}62\sqrt{\frac{d_1^3 k_{1B}}{n_B e_M k_{1S}}}$$

where:

d_1 : Rudder stock diameter, in mm, defined in [5.1.1]

k_{1S} : Material factor k_1 for the steel used for the rudder stock

k_{1B} : Material factor k_1 for the steel used for the bolts

e_M : Mean distance, in mm, from the bolt axes to the longitudinal axis through the coupling centre (i.e. the centre of the bolt system)

n_B : Total number of bolts, which is to be not less than 6.

Non-fitted bolts may be used provided that, in way of the mating plane of the coupling flanges, a key is fitted having a section of ($0{,}25d_T$ x $0{,}10d_T$) mm² and keyways in both the coupling flanges, and provided that at least two of the coupling bolts are fitted bolts.

The distance from the bolt axes to the external edge of the coupling flange is to be not less than 1,2 d_B.

5.1.3 Coupling flange

The thickness of the coupling flange is to be not less than the value obtained, in mm, from the following formula:

$$t_P = d_B\sqrt{\frac{k_{1F}}{k_{1B}}}$$

where:

d_B : Bolt diameter, in mm, calculated in accordance with [5.1.2], where the number of bolts n_B is to be taken not greater than 8

k_{1F} : Material factor k_1 for the steel used for the flange

k_{1B} : Material factor k_1 for the steel used for the bolts.

In any case, the thickness t_P is to be not less than 0,9 d_B.

5.1.4 Locking device

A suitable locking device is to be provided to prevent the accidental loosening of nuts.

5.2 Couplings between rudder stocks and tillers

5.2.1 Application

The requirements of this sub-Article apply in addition to those specified in Pt C, Ch 1, Sec 12.

The requirements specified in [5.2.3] and [5.2.4] apply to solid rudder stocks in steel and to tiller bosses, either in steel or in SG iron, with constant external diameter. Solid rudder stocks others than those above will be considered by the Society on a case-by-case basis, provided that the relevant calculations, to be based on the following criteria, are submitted to the Society:

- Young's modulus:
  - $E = 2{,}06.10^5$ N/mm^2 for steel
  - $E = 1{,}67.10^5$ N/mm^2 for SG iron
- Poisson's ratio:
  - $\nu = 0{,}30$ for steel
  - $\nu = 0{,}28$ for SG iron
- frictional coefficient:
  - $\mu = 0{,}15$ for contact steel/steel
  - $\mu = 0{,}13$ for contact steel/SG iron
- torque C_T transmissible through friction:

  $C_T \geq \eta\ M_{TR}$

  where η is defined in [5.2.3]
- combined stress in the boss:

  $$\sqrt{\sigma_R^2 + \sigma_T^2 - \sigma_R\sigma_T} \leq (0{,}5 + 0{,}2\ \eta)R_{eH}$$

  where σ_R and σ_T are, in N/mm^2, the radial compression stress and tangent tensile stress, respectively, induced by the grip pressure, considered as positive, and calculated at the bore surface ($\sigma_R = p_F$, where p_F is the grip pressure in the considered horizontal cross-section of the boss)
- where the rudder stock is hollow, the following strength criterion is to be complied with at any point of the rudder stock cross-section:

  $$\sqrt{\sigma_R^2 + \sigma_T^2 - \sigma_R\sigma_T + 3\tau^2} \leq 0{,}7\ R_{eH}$$

  where:

  σ_R, σ_T : Radial and tangent compressive stress, respectively, in N/mm^2, induced by the grip pressure, considered as positive

  τ : Shear stress, in N/mm^2, induced by the torque M_{TR}.

5.2.2 General

The entrance edge of the tiller bore and that of the rudder stock cone are to be rounded or bevelled.

The right fit of the tapered bearing is to be checked before final fit up, to ascertain that the actual bearing is evenly distributed and at least equal to 80% of the theoretical bearing area; push-up length is measured from the relative positioning of the two parts corresponding to this case.

The required push-up length is to be checked after releasing of hydraulic pressures applied in the hydraulic nut and in the assembly.

5.2.3 Push up length of cone couplings with hydraulic arrangements for assembling and disassembling the coupling

It is to be checked that the push up length Δ_E of the rudder stock tapered part into the tiller boss is in compliance with the following formula:

$\Delta_0 \leq \Delta_E \leq \Delta_1$

where:

$$\Delta_0 = 6,2\frac{M_{TR}\eta\gamma}{cd_M t_S \mu_A \beta}10^{-3}$$

$$\Delta_1 = \frac{2\eta + 5}{1,8}\cdot\frac{\gamma d_0 R_{eH}}{c}10^{-6}$$

η : Coefficient to be taken equal to:

- $\eta = 1$ for keyed connections
- $\eta = 2$ for keyless connections

c : Taper of conical coupling measured on diameter, to be obtained from the following formula:

$c = (d_U - d_0) / t_S$

t_S , d_U , d_0 : Geometrical parameters of the coupling, defined in Fig 5

β : Coefficient to be taken equal to:

$$\beta = 1 - \left(\frac{d_M}{d_E}\right)^2$$

d_M : Mean diameter, in mm, of the conical bore, to be obtained from the following formula:

$d_M = d_U - 0,5\ c\ t_S$

d_E : External boss diameter, in mm

μ_A : Coefficient to be taken equal to:

$$\mu_A = \sqrt{\mu^2 - 0,25c^2}$$

μ, γ : Coefficients to be taken equal to:

- for rudder stocks and bosses made of steel:

  $\mu = 0,15$

  $\gamma = 1,00$

- for rudder stocks made of steel and bosses made of SG iron:

  $\mu = 0,13$

  $\gamma = 1,24 - 0,1\ \beta$

R_{eH} : Defined in [1.4.3].

5.2.4 Boss of cone couplings with hydraulic arrangements for assembling and disassembling the coupling

The scantlings of the boss are to comply with the following formula:

$$\frac{1,8}{2\eta + 5}\frac{\Delta_E c}{\gamma d_0}10^6 \le R_{eH}$$

where:

Δ_E : Push-up length adopted, in mm

c, η, γ : Defined in [5.2.3]

d_0 : Defined in Fig 5

R_{eH} : Defined in [1.4.3].

5.2.5 Cylindrical couplings by shrink fit

It is to be checked that the diametral shrinkage allowance δ_E is in compliance with the following formula:

$\delta_0 \le \delta_E \le \delta_1$

where:

$$\delta_0 = 6,2\frac{M_{TR}\eta\gamma}{d_U t_S \mu \beta_1}$$

$$\delta_1 = \frac{2\eta + 5}{1,8}\gamma d_U R_{eH} 10^{-6}$$

η, μ, γ, c: Defined in [5.2.3]

d_U : Defined in Fig 5

β_1 : Coefficient to be taken equal to:

$$\beta_1 = 1 - \left(\frac{d_U}{d_E}\right)^2$$

R_{eH} : Defined in [1.4.3].

5.2.6 Keyless couplings through special devices

The use of special devices for frictional connections, such as expansible rings, may be accepted by the Society on a case-by-case basis provided that the following conditions are complied with:

- evidence that the device is efficient (theoretical calculations and results of experimental tests, references of behaviour during service, etc.) are to be submitted to the Society
- the torque transmissible by friction is to be not less than 2 M_{TR}
- design conditions [5.2.1]
- instructions provided by the manufacturer are to be complied with, notably concerning the pre-stressing of the tightening screws.

5.3 Cone couplings between rudder stocks and rudder blades

5.3.1 Taper on diameter

The taper on diameter of the cone couplings is to be in compliance with the following formulae:

- for cone couplings without hydraulic arrangements for assembling and disassembling the coupling:

$$\frac{1}{12} \le \frac{d_U - d_0}{t_S} \le \frac{1}{8}$$

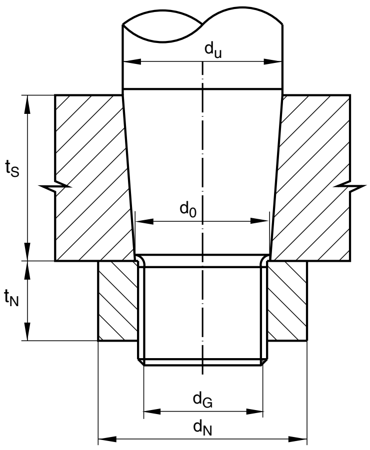
- for cone couplings with hydraulic arrangements for assembling and disassembling the coupling (assembling with oil injection and hydraulic nut):

$$\frac{1}{20} \le \frac{d_U - d_0}{t_S} \le \frac{1}{12}$$

where:

d_U , t_S , d_0 : Geometrical parameters of the coupling, defined in Fig 5.

Figure 5 : Geometry of cone coupling



5.3.2 Push up length of cone coupling with hydraulic arrangements for assembling and disassembling the coupling

It is to be checked that the push up length Δ_E of the rudder stock tapered part into the boss is in compliance with the following formula:

$\Delta_0 \le \Delta_E \le \Delta_1$

where Δ_0 and Δ_1 are to be obtained from the formulae in Tab 5.

5.3.3 Slogging nut

The coupling is to be secured by a slugging nut, whose dimensions are to be in accordance with the following formulae:

$t_S \ge 1{,}5\ d_1$

$d_G \ge 0{,}65\ d_1$

$t_N \ge 0{,}60\ d_G$

$d_N \ge 1{,}2\ d_0$ and, in any case, $d_N \ge 1{,}5\ d_G$

where:

t_S , d_G , t_N , d_N , d_1 , d_0 : Geometrical parameters of the coupling, defined in Fig 5.

The above minimum dimensions of the locking nut are only given for guidance, the determination of adequate scantlings being left to the Designer.

Table 5 : Push up length values

Rudder type	Δ_0	Δ_1
 Hinged rudder with three bearings  Hinged rudder with two bearings  Simplex - type  3 bearings semi-spade rudders with rudder horn	$6,2\dfrac{M_{TR}\eta\gamma}{c d_M t_S \mu_A \beta}$	$\dfrac{2\eta+5}{1,8}\dfrac{\gamma d_0 R_{eH}}{10^6 c}$
  Spade rudder  Simple pintle  Inserted pintle	the greater of: • $6,2\dfrac{M_{TR}\eta\gamma}{c d_M t_S \mu_A \beta}$ • $16\dfrac{M_{TR}\eta\gamma}{c t_S^2 \beta}\sqrt{\dfrac{d_{1L}^6 - d_{1S}^6}{d_{1S}^6}}$	$\dfrac{2\eta+5}{1,8}\dfrac{\gamma d_0 R_{eH}}{10^6 c(1+\rho_1)}$
High lift profile and special rudder types	the greater of: • $6,2\dfrac{M_{TR}\eta\gamma}{c d_M t_S \mu_A \beta}$ • $16\dfrac{M_{TR}\eta\gamma}{c t_S^2 \beta}\sqrt{\dfrac{d_{1L}^6 - d_{1S}^6}{d_{1S}^6}}$ • $6,2\dfrac{M_T\eta\gamma}{c d_M t_S \mu_A \beta}$ • $18,4\dfrac{M_F\eta\gamma}{c t_S^2 \beta}$	the greater of: • $\dfrac{2\eta+5}{1,8}\dfrac{\gamma d_0 R_{eH}}{10^6 c(1+\rho_1)}$ • $\dfrac{2\eta+5}{1,8}\dfrac{\gamma d_0 R_{eH}}{10^6 c(1+\rho_2)}$

Note 1:

$$\rho_1 = \frac{80\sqrt{d_{1L}^6 - d_{1S}^6}}{R_{eH} d_M t_S^2\left[1-\left(\frac{d_0}{d_E}\right)^2\right]}$$

$$\rho_2 = \frac{7,4 M_F \cdot 10^6}{R_{eH} d_M t_S^2\left[1-\left(\frac{d_0}{d_E}\right)^2\right]}$$

R_{eH} : Defined in [1.4.3]

M_F, M_T : Bending moment and torsional moment, respectively, in kN.m, provided by the manufacturer

d_{1L} : The greater of the rudder stock diameters d_T and d_{TF}, in mm, calculated in way of the lower part of the rudder stock (between the top of the rudder plate and the lower bearing of the rudder stock) in compliance with the requirements in [4.2.1] and [4.2.2], respectively, considering $k_1 = 1$

d_{1S} : The greater of the rudder stock diameters d_T and d_{TF}, in mm, calculated in way of the upper part of the rudder stock (at tiller level) in compliance with the requirements in [4.2.1] and [4.2.2], respectively, considering $k_1 = 1$

η, c, β, d_M, d_E, μ_A, μ, γ : Defined in [5.2.3]

t_S, d_U, d_0 : Defined in Fig 5.

5.3.4 Washer

For cone couplings with hydraulic arrangements for assembling and disassembling the coupling, a washer is to be fitted between the nut and the rudder gudgeon, having a thickness not less than 0,13 d_G and an outer diameter not less than 0,13 d_0 or 1,6 d_G, whichever is the greater.

5.3.5 Key

For cone couplings without hydraulic arrangements for assembling and disassembling the coupling, a key is to be fitted having a section of ($0,25\ d_T \times 0,10\ d_T$) mm^2 and keyways in both the tapered part and the rudder gudgeon.

The key is to be machined and located on the fore or aft part of the rudder. The key is to be inserted at half-thickness into stock and into the solid part of the rudder.

For cone couplings with hydraulic arrangements for assembling and disassembling the coupling, the key may be omitted. In this case the designer is to submit to the Society shrinkage calculations supplying all data necessary for the relevant check.

5.3.6 Instructions

All necessary instructions for hydraulic assembly and disassembly of the nut, including indication of the values of all relevant parameters, are to be available on board.

5.4 Vertical flange couplings

5.4.1 Vertical flange couplings are to be connected by fitted bolts having a diameter not less than the value obtained, in mm, from the following formula:

$$d_B = \frac{0,81\, d_1}{\sqrt{n_B}}\sqrt{\frac{k_{1B}}{k_{1S}}}$$

where:

d_1 : Rudder stock diameter, in mm, defined in [5.1.1]

k_{1S}, k_{1B} : Material factors, defined in [5.1.2]

n_B : Total number of bolts, which is to be not less than 8.

5.4.2 The first moment of area of the sectional area of bolts about the vertical axis through the centre of the coupling is to be not less than the value obtained, in cm^3, from the following formula:

$$M_S = 0,43\ d_1^3 \cdot 10^{-6}$$

where:

d_1 : Rudder stock diameter, in mm, defined in [5.1.1].

5.4.3 The thickness of the coupling flange, in mm, is to be not less than d_B , defined in [5.4.1].

5.4.4 The distance, in mm, from the bolt axes to the external edge of the coupling flange is to be not less than $1,2\ d_B$, where d_B is defined in [5.4.1].

5.4.5 A suitable locking device is to be provided to prevent the accidental loosening of nuts.

5.5 Couplings by continuous rudder stock welded to the rudder blade

5.5.1 When the rudder stock extends through the upper plate of the rudder blade and is welded to it, the thickness of this plate in the vicinity of the rudder stock is to be not less than $0,20\ d_1$, where d_1 is defined in [5.1.1].

5.5.2 The welding of the upper plate of the rudder blade with the rudder stock is to be made with a full penetration weld and is to be subjected to non-destructive inspection through dye penetrant or magnetic particle test and ultrasonic testing.

The throat weld at the top of the rudder upper plate is to be concave shaped to give a fillet shoulder radius as large as practicable. This radius is to be not less than $0,20\ d_1$, where d_1 is defined in [5.1.1].

5.6 Skeg connected with rudder trunk

5.6.1 In case of a rudder trunk connected with the bottom of a skeg, the throat weld is to be concave shaped to give a fillet shoulder radius as large as practicable. This radius is considered by the Society on a case-by-case basis.

6 Rudder stock and pintle bearings

6.1 Forces on rudder stock and pintle bearings

6.1.1 Where a direct calculation according to the static schemes and the load conditions specified in Ch 9, App 1 is carried out, the support forces are to be obtained as specified in Ch 9, App 1.

Where such a direct calculation is not carried out, the support forces F_{A1} and F_{A2} acting on the rudder stock bearing and on the pintle bearing, respectively, are to be obtained, in N, from the following formulae:

$$F_{A1} = \left(\frac{A_{G1}}{A} + 0,87\frac{h_0}{H_0}\right)C_R$$

$$F_{A2} = \frac{A_{G2}}{A}C_R$$

where:

A_{G1} , A_{G2} : Portions of the rudder blade area A, in m², supported by the rudder stock bearing and by the pintle bearing respectively, to be not less than the value obtained from Tab 6

h_0 : Coefficient defined in Tab 6

H_0 : Distance, in m, between the points at mid-height of the upper and lower rudder stock bearings.

6.2 Rudder stock bearing

6.2.1 The mean bearing pressure acting on the rudder stock bearing is to be in compliance with the following formula:

$p_F \leq p_{F,ALL}$

where:

p_F : Mean bearing pressure acting on the rudder stock bearings, in N/mm², equal to:

$$p_F = \frac{F_{A1}}{d_m h_m}$$

F_{A1} : Force acting on the rudder stock bearing, in N, calculated as specified in [6.1.1]

d_m : Actual inner diameter, in mm, of the rudder stock bearings

h_m : Bearing length, in mm. For the purpose of this calculation, h_m is to be taken not greater than:

- 1,2 d_m for spade rudders
- d_m for rudder of other types

$p_{F,ALL}$: Allowable bearing pressure, in N/mm², defined in Tab 7.

Values greater than those given in Tab 7 may be accepted by the Society on the basis of specific tests.

6.2.2 An adequate lubrication of the bearing surface is to be ensured.

6.3 Pintle bearings

6.3.1 The mean bearing pressure acting on the gudgeons is to be in compliance with the following formula:

$p_F \leq p_{F,ALL}$

where:

p_F : Mean bearing pressure acting on the gudgeons, in N/mm², equal to:

$$p_F = \frac{F_{A2}}{d_A h_L}$$

F_{A2} : Force acting on the pintle, in N, calculated as specified in [6.1.1]

d_A : Actual diameter, in mm, of the rudder pintles

h_L : Bearing length, in mm (see [6.3.3])

$p_{F,ALL}$: Allowable bearing pressure, in N/mm², defined in Tab 7.

Values greater than those given in Tab 7 may be accepted by the Society on the basis of specific tests.

6.3.2 An adequate lubrication of the bearing surface is to be ensured.

6.3.3 The bearing length h_L , in mm, is to be not less than d_A, where d_A is defined in [6.4.1]. For the purpose of the calculation in [6.3.1], the bearing length is to be taken not greater than 1,2 d_A.

6.3.4 The manufacturing tolerance t_0 on the diameter of metallic supports is to be not less than the value obtained, in mm, from the following formula:

$$t_0 = \frac{d_A}{1000} + 1$$

In the case of non-metallic supports, the tolerances are to be carefully evaluated on the basis of the thermal and distortion properties of the materials employed.

In any case, the tolerance on support diameter is to be not less than 1,5 mm.

6.4 Pintles

6.4.1 Rudder pintles are to have a diameter not less than the value obtained, in mm, from the following formula:

$$d_A = \frac{0,38V_{AV}}{V_{AV}+3}\sqrt{F_{A2}k_1}+f_C$$

where:

F_{A2} : Force, in N, acting on the pintle, calculated as specified in [6.1.1]

f_C : Coefficient depending on corrosion, whose value may generally be obtained from the following formula:

$$f_C = 30\sqrt{k_1}$$

The Society may accept lower values of f_C , considering the ship dimensions and satisfactory service experience of corrosion control systems adopted.

6.4.2 Provision is to be made for a suitable locking device to prevent the accidental loosening of pintles.

6.4.3 The pintles are to have a conical coupling with a taper on diameter in accordance with [5.3.1].

The conical coupling is to be secured by a nut, whose dimensions are to be in accordance with [5.3.3].

6.4.4 The length of the pintle housing in the gudgeon is to be not less than the value obtained, in mm, from the following formula:

$$h_L = 0,35\sqrt{F_{A2}k_1}$$

where:

F_{A2} : Force, in N, acting on the pintle, calculated as specified in [6.1.1].

The thickness of pintle housing in the gudgeon, in mm, is to be not less than 0,25 d_A, where d_A is defined in [6.4.1].

7 Rudder blade scantlings

7.1 General

7.1.1 Application

The requirements in [7.1] to [7.6] apply to streamlined rudders and, when applicable, to rudder blades of single plate rudders.

7.1.2 Rudder blade structure

The structure of the rudder blade is to be such that stresses are correctly transmitted to the rudder stock and pintles. To this end, horizontal and vertical web plates are to be provided.

Horizontal and vertical webs acting as main bending girders of the rudder blade are to be suitably reinforced.

7.1.3 Access openings

Streamlined rudders, including those filled with pitch, cork or foam, are to be fitted with plug-holes and the necessary devices to allow their mounting and dismounting.

Access openings to the pintles are to be provided. If necessary, the rudder blade plating is to be strengthened in way of these openings.

The corners of openings intended for the passage of the rudder horn heel and for the dismantling of pintle or stock nuts are to be rounded off with a radius as large as practicable.

Where the access to the rudder stock nut is closed with a welded plate, a full penetration weld is to be provided.

7.1.4 Connection of the rudder blade to the trailing edge for rudder blade area greater than 6 m²

Where the rudder blade area is greater than 6 m², the connection of the rudder blade plating to the trailing edge is, in general, to be made by means of a forged or cast steel fashion piece, a flat or a round bar.

Other arrangements proposed by the shipyard may be accepted by the Society, on a case-by-case basis.

7.2 Strength checks

7.2.1 Bending stresses

For the generic horizontal section of the rudder blade, it is to be checked that the bending stress σ, in N/mm², induced by the loads defined in [3.1], is in compliance with the following formula:

$\sigma \leq \sigma_{ALL}$

where:

σ_{ALL} : Allowable bending stress, in N/mm², specified in Tab 8.

Table 8 : Allowable stresses for rudder blade scantlings

Type of rudder blade	Allowable bending stress σ_{ALL} in N/mm²	Allowable shear stress τ_{ALL} in N/mm²	Allowable equivalent stress $\sigma_{E,ALL}$ in N/mm²
Without cut-outs	110/k	50/k	120/k
With cut-outs (see Fig 2)	75/k	50/k	100/k

7.2.2 Shear stresses

For the generic horizontal section of the rudder blade it is to be checked that the shear stress τ, in N/mm², induced by the loads defined in [3.1], is in compliance with the following formula:

$\tau \leq \tau_{ALL}$

where:

τ_{ALL} : Allowable shear stress, in N/mm², specified in Tab 8.

7.2.3 Combined bending and shear stresses

For the generic horizontal section of the rudder blade, it is to be checked that the equivalent stress σ_E is in compliance with the following formula:

$\sigma_E \leq \sigma_{E,ALL}$

where:

σ_E : Equivalent stress induced by the loads defined in [3.1], to be obtained, in N/mm², from the following formula:

$$\sigma_E = \sqrt{\sigma^2 + 3\tau^2}$$

Where unusual rudder blade geometries make it practically impossible to adopt ample corner radiuses or generous tapering between the various structural elements, the equivalent stress σ_E is to be obtained by means of direct calculations aiming at assessing the rudder blade areas where the maximum stresses, induced by the loads defined in [3.1], occur

σ : Bending stress, in N/mm²

τ : Shear stress, in N/mm²

$\sigma_{E,ALL}$: Allowable equivalent stress, in N/mm², specified in Tab 8.

7.3 Rudder blade plating

7.3.1 Plate thickness

The thickness of each rudder blade plate panel is to be not less than the value obtained, in mm, from the following formula:

$$t_F = \left(5{,}5 s\beta\sqrt{T + \frac{C_R 10^{-4}}{A}} + 2{,}5\right)\sqrt{k}$$

where:

β : Coefficient equal to:

$$\beta = \sqrt{1{,}1 - 0{,}5\left(\frac{s}{b_L}\right)^2}$$

to be taken not greater than 1,0 if $b_L/s > 2{,}5$

s : Length, in m, of the shorter side of the plate panel

b_L : Length, in m, of the longer side of the plate panel.

7.3.2 Thickness of the top and bottom plates of the rudder blade

The thickness of the top and bottom plates of the rudder blade is to be not less than the thickness t_F defined in [7.3.1] for the attached side plating.

Where the rudder is connected to the rudder stock with a coupling flange, the thickness of the top plate which is welded in extension of the rudder flange is to be not less than 1,1 times the thickness calculated above.

7.3.3 Web spacing

The spacing between horizontal web plates is to be not greater than 1,20 m.

Vertical webs are to have spacing not greater than twice that of horizontal webs.

7.3.4 Web thickness

Web thickness is to be at least 70% of that required for rudder plating and in no case is it to be less than 8 mm, except for the upper and lower horizontal webs, for which the requirements in [7.3.2] apply.

When the design of the rudder does not incorporate a mainpiece, this is to be replaced by two vertical webs closely spaced, having thickness not less than that obtained from Tab 9. In rudders having area less than 6 m^2, one vertical web only may be accepted provided its thickness is at least twice that of normal webs.

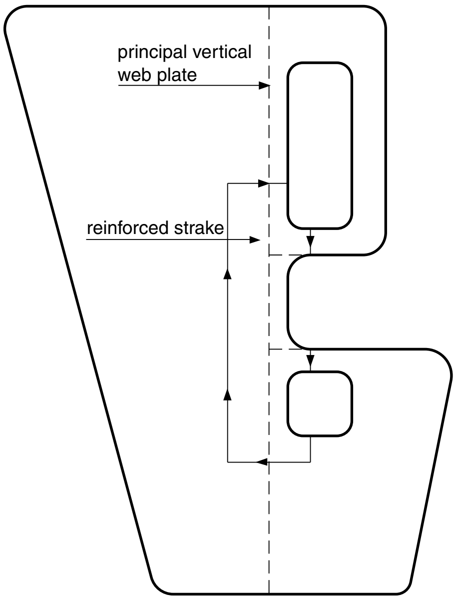
7.3.5 Thickness of side plating and vertical web plates welded to solid part or to rudder flange

The thickness, in mm, of the vertical web plates welded to the solid part where the rudder stock is housed, or welded to the rudder flange, as well as the thickness of the rudder side plating under this solid part, or under the rudder coupling flange, is to be not less than the value obtained, in mm, from Tab 9.

7.3.6 Reinforced strake of semi-spade rudders

A reinforced strake is to be provided in the lower pintle zone of semi-spade rudders. Its thickness is to be not less than 1,6 t_F , where t_F is defined in [7.3.1]. This strake is to be extended forward of the main vertical web plate (see Fig 6).

Figure 6 : Reinforced strake extension for semi-spade rudders



7.3.7 Main vertical webs of semi-spade rudders

The thickness of the main vertical web plate in the area between the rudder blade upper part and the pintle housing of semi-spade rudders is to be not less than 2,6 t_F , where t_F is defined in [7.3.1].

Under the pintle housing, the thickness of this web is to be not less than the value obtained from Tab 9.

Where two main vertical webs are fitted, the thicknesses of these webs are to be not less than the values obtained from Tab 9 depending on whether the web is fitted in a rudder blade area without opening or if the web is along the recess cut in the rudder for the passage of the rudder horn heel.

7.3.8 Welding

The welded connections of blade plating to vertical and horizontal webs are to be in compliance with the applicable requirements of NR216 Materials and Welding.

Where the welds of the rudder blade are accessible only from outside of the rudder, slots on a flat bar welded to the webs are to be provided to support the weld root, to be cut on one side of the rudder only.

7.3.9 Rudder nose plate thickness

Rudder nose plates are to have a thickness not less than 1,25 t_F , where t_F is defined in [7.3.1].

In general this thickness need not exceed 22 mm, unless otherwise required in special cases to be considered individually by the Society.

Table 9 : Thickness of the vertical webs and rudder side plating welded to solid part or to rudder flange

Type of rudder	Thickness of vertical web plates, in mm		Thickness of rudder plating, in mm	
	Rudder blade without opening	At opening boundary	Rudder blade without opening	Area with opening
Hinged rudders, Simplex type rudders and semi-spade with three bearings rudders  	t_F	1,3 t_F	t_F	1,2 t_F
Rudder without intermediate pintles 	1,2 t_F	1,6 t_F	1,2 t_F	1,4 t_F
Spade and one bearing rudders  	1,4 t_F	2,0 t_F	1,3 t_F	1,6 t_F
Note 1: t_F : Defined in [7.3.1].				

7.4 Connections of rudder blade structure with solid parts in forged or cast steel

7.4.1 General

Solid parts in forged or cast steel which ensure the housing of the rudder stock or of the pintle are in general to be connected to the rudder structure by means of two horizontal web plates and two vertical web plates.

7.4.2 Minimum section modulus of the connection with the rudder stock housing

The section modulus of the cross-section of the structure of the rudder blade which is connected with the solid part where the rudder stock is housed, which is made by vertical web plates and rudder plating, is to be not less than that obtained, in cm³, from the following formula:

$$w_S = c_S d_1^3 \left(\frac{H_E - H_X}{H_E}\right)^2 \frac{k}{k_1} 10^{-4}$$

where:

c_S : Coefficient, to be taken equal to:
- c_S = 1,0 if there is no opening in the rudder plating
- c_S = 1,5 if there is an opening in the considered cross-section of the rudder

d_1 : Rudder stock diameter, in mm, defined in [5.1.1]

H_E : Vertical distance, in m, between the lower edge of the rudder blade and the upper edge of the solid part

H_X : Vertical distance, in m, between the considered cross-section and the upper edge of the solid part

k, k_1 : Material factors, defined in [1.4], for the rudder blade plating and the rudder stock, respectively.

7.4.3 Calculation of the actual section modulus of the connection with the rudder stock housing

The actual section modulus of the cross-section of the structure of the rudder blade which is connected with the solid part where the rudder stock is housed is to be calculated with respect to the symmetrical axis of the rudder.

The breadth of the rudder plating to be considered for the calculation of this actual section modulus is to be not greater than that obtained, in m, from the following formula:

$$b = s_V + 2\frac{H_X}{m}$$

where:

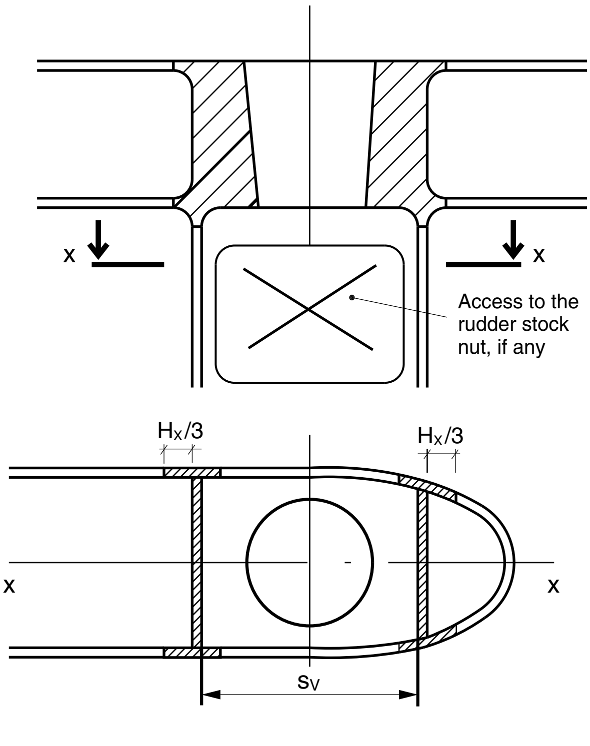
s_V : Spacing, in m, between the two vertical webs (see Fig 7)

H_X : Distance defined in [7.4.2]

m : Coefficient to be taken, in general, equal to 3.

Where openings for access to the rudder stock nut are not closed by a full penetration welded plate according to [7.1.3], they are to be deducted (see Fig 7).

Figure 7 : Cross-section of the connection between rudder blade structure and rudder stock housing



7.4.4 Thickness of horizontal web plates

In the vicinity of the solid parts, the thickness of the horizontal web plates, as well as that of the rudder blade plating between these webs, is to be not less than the greater of the values obtained, in mm, from the following formulae:

$$t_H = 1{,}2\ t_F$$

$$t_H = 0{,}045\frac{d_S^2}{s_H}$$

where:

t_F : Defined in [7.3.1]

d_S : Diameter, in mm, to be taken equal to:

- d_1 for the solid part connected to the rudder stock
- d_A for the solid part connected to the pintle

d_1 : Rudder stock diameter, in mm, defined in [5.1.1]

d_A : Pintle diameter, in mm, defined in [6.4.1]

s_H : Spacing, in mm, between the two horizontal web plates.

Different thickness may be accepted when justified on the basis of direct calculations submitted to the Society for approval.

7.4.5 Thickness of side plating and vertical web plates welded to the solid part

The thickness of the vertical web plates welded to the solid part where the rudder stock is housed as well as the thickness of the rudder side plating under this solid part is to be not less than the values obtained, in mm, from Tab 9.

7.4.6 Solid part protrusions

The solid parts are to be provided with protrusions. Vertical and horizontal web plates of the rudder are to be butt welded to these protrusions.

These protrusions are not required when the web plate thickness is less than:

- 10 mm for web plates welded to the solid part on which the lower pintle of a semi-spade rudder is housed and for vertical web plates welded to the solid part of the rudder stock coupling of spade rudders
- 20 mm for the other web plates.

If no protrusions are provided, vertical and horizontal webs are to be welded by full penetration welds. Particular precautions are to be taken for these welds. The Society may request full Non Destructive Testing to be carried out on the concerned welds, and machining of welds if necessary.

7.5 Connection of the rudder blade with the rudder stock by means of horizontal flanges

7.5.1 Minimum section modulus of the connection

The section modulus of the cross-section of the structure of the rudder blade which is directly connected with the flange, which is made by vertical web plates and rudder blade plating, is to be not less than the value obtained, in cm^3, from the following formula:

$w_S = 1,3\ d_1^3\ 10^{-4}$

where d_1 is the greater of the rudder stock diameters d_T and d_{TF}, in mm, to be calculated in compliance with the requirements in [4.2.1] and [4.2.2], respectively, taken k_1 equal to 1.

7.5.2 Actual section modulus of the connection

The section modulus of the cross-section of the structure of the rudder blade which is directly connected with the flange is to be calculated with respect to the symmetrical axis of the rudder.

For the calculation of this actual section modulus, the length of the rudder cross-section equal to the length of the rudder flange is to be considered.

Where the rudder plating is provided with an opening under the rudder flange, the actual section modulus of the rudder blade is to be calculated in compliance with [7.4.3].

7.5.3 Welding of the rudder blade structure to the rudder blade flange

The welds between the rudder blade structure and the rudder blade flange are to be full penetrated (or of equivalent strength) and are to be 100% inspected by means of non-destructive tests.

Where the full penetration welds of the rudder blade are accessible only from outside of the rudder, a backing flat bar is to be provided to support the weld root.

The external fillet welds between the rudder blade plating and the rudder flange are to be of concave shape and their throat thickness is to be at least equal to 0,5 times the rudder blade thickness.

Moreover, the rudder flange is to be checked before welding by non-destructive inspection for lamination and inclusion detection in order to reduce the risk of lamellar tearing.

7.5.4 Thickness of side plating and vertical web plates welded to the rudder flange

The thickness of the vertical web plates directly welded to the rudder flange as well as the plating thickness of the rudder blade upper strake in the area of the connection with the rudder flange is to be not less than the values obtained, in mm, from Tab 9.

7.6 Single plate rudders

7.6.1 Mainpiece diameter

The mainpiece diameter is to be obtained from the formulae in [4.2].

In any case, the mainpiece diameter is to be not less than the stock diameter.

For spade rudders the lower third may taper down to 0,75 times the stock diameter.

7.6.2 Blade thickness

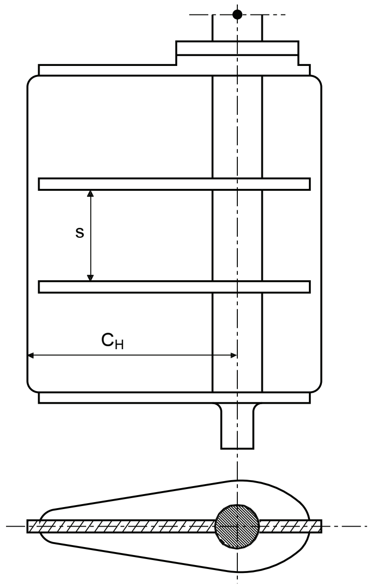
The blade thickness is to be not less than the value obtained, in mm, from the following formula:

$$t_B = (1{,}5sV_{AV} + 2{,}5)\sqrt{k}$$

where:

s : Spacing of stiffening arms, in m, to be taken not greater than 1 m (see Fig 8).

Figure 8 : Single plate rudder



7.6.3 Arms

The thickness of the arms is to be not less than the blade thickness.

The section modulus of the generic section is to be not less than the value obtained, in cm^3, from the following formula:

$$Z_A = 0{,}5\ s\ C_H^2\ V_{AV}^2\ k$$

where (see Fig 8):

C_H : Horizontal distance, in m, from the aft edge of the rudder to the centreline of the rudder stock

s : Defined in [7.6.2].

8 Rudder horn and solepiece scantlings

8.1 General

8.1.1 The weight of the rudder is normally supported by a carrier bearing inside the rudder trunk.

In the case of unbalanced rudders having more than one pintle, the weight of the rudder may be supported by a suitable disc fitted in the solepiece gudgeon.

Robust and effective structural rudder stops are to be fitted, except where adequate positive stopping arrangements are provided in the steering gear, in compliance with the applicable requirements of Pt C, Ch 1, Sec 12.

8.2 Rudder horn

8.2.1 General

When the connection between the rudder horn and the hull structure is designed as a curved transition into the hull plating, special consideration is to be paid to the effectiveness of the rudder horn plate in bending and to the stresses in the transverse web plates.

8.2.2 Loads

The following loads acting on the generic section of the rudder horn are to be considered:

- bending moment
- shear force
- torque.

The requirements in [8.2.3], [8.2.4] and [8.2.5] apply for calculating the above loads in the case of 2 bearing semi-spade rudders.

In the case of 3 bearing semi-spade rudders, these loads are to be calculated on the basis of the support forces at the lower and upper pintles, obtained according to [6.1].

8.2.3 Bending moment

For 2 bearing semi-spade rudders, the bending moment acting on the generic section of the rudder horn is to be obtained, in N·m, from the following formula:

$M_H = F_{A1}\ z$

where:

F_{A1} : Support force, in N, to be determined through a direct calculation to be performed in accordance with the static schemes and the load conditions specified in Ch 9, App 1. As an alternative, it may to be obtained from the following formula:

$$F_{A1} = C_R \frac{b}{\ell_{20} + \ell_{30}}$$

b, ℓ_{20}, ℓ_{30} : Distances, in m, defined in Fig 9

z : Distance, in m, defined in Fig 10, in any case to be taken less than the distance d, in m, defined in the same figure.

Figure 9 : Geometrical parameters for the calculation of the bending moment in rudder horn

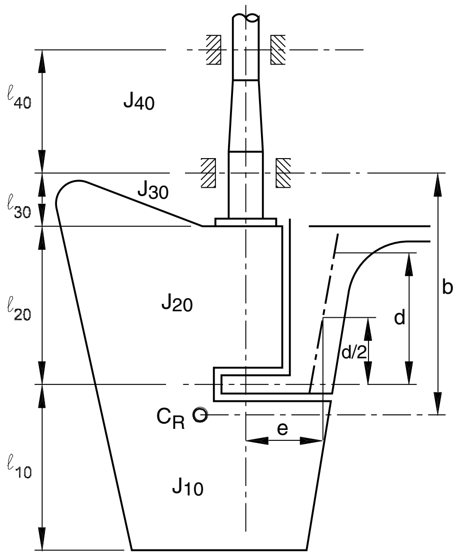


Figure 10 : Rudder horn geometry

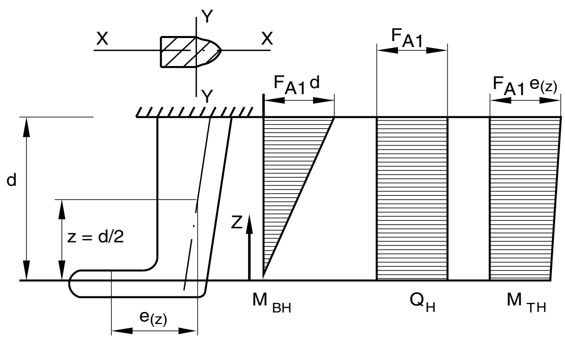


8.2.4 Shear force

The shear force Q_H acting on the generic section of the rudder horn is to be obtained, in N, from the following formula:

$Q_H = F_{A1}$

where:

F_{A1} : Force, in N, defined in [8.2.3].

8.2.5 Torque

The torque acting on the generic section of the rudder horn is to be obtained, in N.m, from the following formula:

$M_T = F_{A1}\ e$

where:

F_{A1} : Force, in N, defined in [8.2.3]

e : Distance, in m, defined in Fig 10.

8.2.6 Shear stress check

For the generic section of the rudder horn it is to be checked that:

$\tau_S + \tau_T \leq \tau_{ALL}$

where:

τ_S : Shear stress to be obtained, in N/mm², from the following formula:

$$\tau_S = \frac{F_{A1}}{A_H}$$

F_{A1} : Force, in N, defined in [8.2.3]

A_H : Shear sectional area of the rudder horn in Y direction, in mm²

τ_T : Torsional stress to be obtained for hollow rudder horn, in N/mm², from the following formula:

$$\tau_T = \frac{M_T 10^3}{2 A_T t_H}$$

For solid rudder horn, τ_T is to be considered by the Society on a case-by-case basis

M_T : Torque, in N·m, defined in [8.2.5]

A_T : Area of the horizontal section enclosed by the rudder horn, in mm²

t_H : Plate thickness of rudder horn, in mm

τ_{ALL} : Allowable torsional shear stress, in N/mm²:

$\tau_{ALL} = 48 / k_1$

8.2.7 Combined stress strength check

For the generic section of the rudder horn within the length d, defined in Fig 10, it is to be checked that:

$\sigma_E \leq \sigma_{E,ALL}$

$\sigma_B \leq \sigma_{B,ALL}$

where:

σ_E : Equivalent stress to be obtained, in N/mm², from the following formula:

$$\sigma_E = \sqrt{\sigma_B^2 + 3(\tau_S^2 + \tau_T^2)}$$

Where unusual rudder horn geometries make it practically impossible to adopt ample corner radiuses or generous tapering between the various structural elements, the equivalent stress s_E is to be obtained by means of direct calculations aiming at assessing the rudder horn areas where the maximum stresses, induced by the loads defined in [3.1], occur

σ_B : Bending stress to be obtained, in N/mm², from the following formula:

$$\sigma_B = \frac{M_H}{W_X}$$

M_H : Bending moment at the section considered, in N·m, defined in [8.2.3]

W_X : Section modulus, in cm³, around the horizontal axis X (see Fig 10)

τ_S , τ_T : Shear and torsional stresses, in N/mm², defined in [8.2.6]

$\sigma_{E,ALL}$: Allowable equivalent stress, in N/mm², equal to: $\sigma_{E,ALL} = 120/k_1$ N/mm²

$\sigma_{B,ALL}$: Allowable bending stress, in N/mm², equal to: $\sigma_{B,ALL} = 67/k_1$ N/mm².

8.3 Solepieces

8.3.1 Bending moment

The bending moment acting on the generic section of the solepiece is to be obtained, in N·m, from the following formula:

$M_S = F_{A1}\, x$

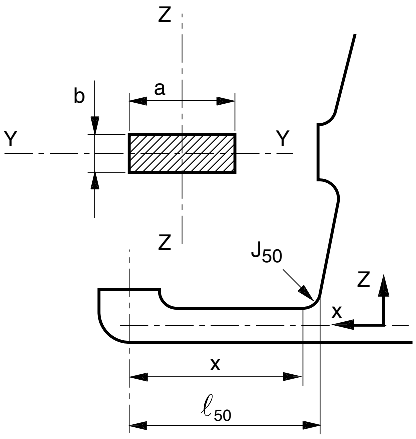
where:

F_{A1} : Supporting force, in N, in the pintle bearing, to be determined through a direct calculation to be performed in accordance with the static schemes and the load conditions specified in Ch 9, App 1; where such a direct calculation is not carried out, this force may be taken equal to:

$$F_{A1} = \frac{C_R}{2}$$

x : Distance, in m, defined in Fig 11.

Figure 11 : Solepiece geometry



8.3.2 Strength checks

For the generic section of the solepiece within the length ℓ_{50}, defined in Fig 11, it is to be checked that

$\sigma_E \leq \sigma_{E,ALL}$

$\sigma_B \leq \sigma_{B,ALL}$

$\tau \leq \tau_{ALL}$

where:

σ_E : Equivalent stress to be obtained, in N/mm², from the following formula:

$$\sigma_E = \sqrt{\sigma_B^2 + 3\tau^2}$$

σ_B : Bending stress to be obtained, in N/mm², from the following formula:

$$\sigma_B = \frac{M_S}{W_Z}$$

τ : Shear stress to be obtained, in N/mm², from the following formula:

$$\tau = \frac{F_{A1}}{A_S}$$

M_S : Bending moment at the section considered, in N·m, defined in [8.3.1]

F_{A1} : Force, in N, defined in [8.3.1]

W_Z : Section modulus, in cm³, around the vertical axis Z (see Fig 11)

A_S : Shear sectional area in Y direction, in mm²

$\sigma_{E,ALL}$: Allowable equivalent stress, in N/mm², equal to: $\sigma_{E,ALL} = 115/k_1$ N/mm²

$\sigma_{B,ALL}$: Allowable bending stress, in N/mm², equal to: $\sigma_{B,ALL} = 80/k_1$ N/mm²

τ_{ALL} : Allowable shear stress, in N/mm², equal to: $\tau_{ALL} = 48/k_1$ N/mm².

8.3.3 Minimum section modulus around the horizontal axis

The section modulus around the horizontal axis Y (see Fig 11) is to be not less than the value obtained, in cm³, from the following formula:

$W_Y = 0,5\ W_Z$

where:

W_Z : Section modulus, in cm³, around the vertical axis Z (see Fig 11).

9 Simplex rudder shaft

9.1 Scantlings

9.1.1 Diameter of the rudder shaft

The rudder shaft diameter is to be not less than the value obtained, in mm, from the following formula:

$$d = 17{,}9\left(\frac{\alpha A(V_{AV} + 2)^2}{\ell}\right)^{1/3}$$

where:

α : Coefficient equal to:

- $\alpha = b\,(\ell - b + a)$ if $a \le b$
- $\alpha = a\,(\ell - a + b)$ if $a > b$

a, b, ℓ : Geometrical parameters, in m, defined in Fig 12.

9.1.2 Sectional area of rudder shaft

The overall sectional area of the rudder shaft is to be not less than the greater of the following values:

- 70% of the sectional area for the propeller post defined in Ch 8, Sec 2, [6.3]
- value of the sectional area of the pintle supporting half the rudder blade, whose diameter is to be calculated from the formula in [6.4.1].

If the latter value is the greater, it is to be applied only where the rudder bears on the rudder shaft; in such case, it is recommended that an overthickness or a bush is provided in way of the bearing areas.

9.1.3 Bearings

The bearing length of the rudder shaft is to be not less than 1,2 d, where d is the shaft diameter defined in [9.1.1].

The mean pressure acting on the bearings is not to exceed the relevant allowable values, defined in Tab 7.

9.2 Connections

9.2.1 Connection with the hull

The shaft is to be connected with the hull by means of a vertical coupling flange having thickness at least equal to d/4, where d is the shaft diameter, obtained from the formula in [9.1.1] (see Fig 12).

The coupling flange is to be secured by means of six fitted bolts. The shank diameter of the bolts is to be not less than the coupling flange thickness defined above.

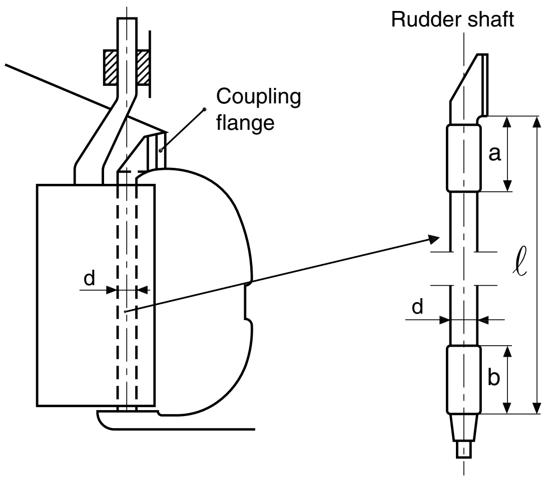
The distance from the bolt centre lines to the coupling flange edge is to be not less than 1,17 times the bolt diameter defined above.

9.2.2 Connection with the solepiece

The rudder shaft is to be connected with the solepiece by means of a cone coupling, having a taper on the radius equal to about 1/10 and housing length not less than 1,1 d, where d is obtained from the formula in [9.1.1] (See Fig 12).

The mean pressure exerted by the rudder shaft on the bearing is to be not greater than the relevant allowable bearing pressure, defined in Tab 6 assuming a rudder with two pintles.

Figure 12 : Simplex rudder shaft geometry



10 Steering nozzles

10.1 General

10.1.1 The requirements of this Article apply to scantling steering nozzles for which the power transmitted to the propeller is less than the value obtained, in kW, from the following formula:

$$P = \frac{16900}{d_M}$$

where:

d_M : Inner diameter of the nozzle, in m.

Nozzles for which the power transmitted is greater than the value obtained from the above formula are considered on a case-by-case basis.

The following requirements may apply also to fixed nozzle scantlings.

10.1.2 Nozzles normally consist of a double skin cylindrical structure stiffened by ring webs and other longitudinal webs placed perpendicular to the nozzle.

At least two ring webs are to be fitted, one of which, of greater thickness, is to be placed in way of the axis of rotation of the nozzle.

For nozzles with an inner diameter d_M exceeding 3 m, the number of ring webs is to be suitably increased.

10.1.3 Care is to be taken in the manufacture of the nozzle to ensure the welded connection between plating and webs.

10.1.4 The internal part of the nozzle is to be adequately protected against corrosion.

10.2 Nozzle plating and internal diaphragms

10.2.1 The thickness of the inner plating of the nozzle is to be not less than the value obtained, in mm, from the following formulae:

$$t_F = (0{,}085\sqrt{Pd_M} + 9{,}65)\sqrt{k} \qquad \text{for} \quad P \le \frac{6100}{d_M}$$

$$t_F = (0{,}085\sqrt{Pd_M} + 11{,}65)\sqrt{k} \qquad \text{for} \quad P > \frac{6100}{d_M}$$

where:

P, d_M : Defined in [10.1.1].

The thickness t_F is to be extended to a length, across the transverse section containing the propeller blade tips, equal to one third of the total nozzle length.

Outside this length, the thickness of the inner plating is to be not less than (t_F – 7) mm and, in any case, not less than 7 mm.

10.2.2 The thickness of the outer plating of the nozzle is to be not less than (t_F – 9) mm, where t_F is defined in [10.2.1] and, in any case, not less than 7 mm.

10.2.3 The thicknesses of ring webs and longitudinal webs are to be not less than (t_F – 7) mm, where t_F is defined in [10.2.1], and, in any case, not less than 7 mm.

However, the thickness of the ring web, in way of the headbox and pintle support structure, is to be not less than t_F.

The Society may consider reduced thicknesses where an approved stainless steel is used, in relation to its type.

10.3 Nozzle stock

10.3.1 The diameter of the nozzle stock is to be not less than the value obtained, in mm, from the following formula:

$d_{NTF} = 64{,}2\ (M_T\ k_1)^{1/3}$

where:

M_T : Torque, to be taken as the greater of those obtained, in N·m, from the following formulae:

- $M_{TAV} = 0{,}3\ S_{AV}\ a$
- $M_{TAD} = S_{AD}\ b$

S_{AV} : Force, in N, equal to: $S_{AV} = 150\ V^2_{AV}\ A_N$

S_{AD} : Force, in N, equal to: $S_{AD} = 200\ V^2_{AD}\ A_N$

A_N : Area, in m², equal to: $A_N = 1{,}35\ A_{1N} + A_{2N}$

A_{1N} : Area, in m², equal to: $A_{1N} = L_M\ d_M$

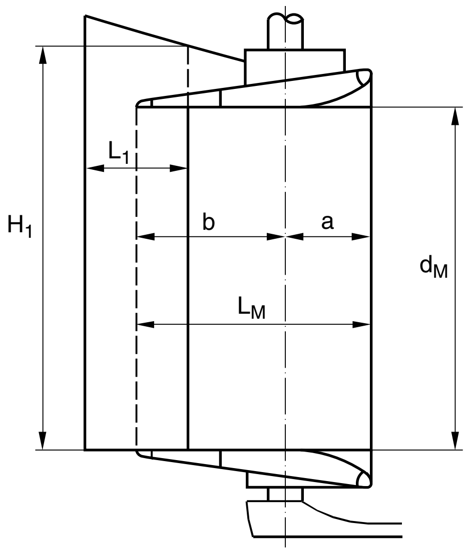
A_{2N} : Area, in m², equal to: $A_{2N} = L_1\ H_1$

a, b, L_M, d_M, L_1, H_1 : Geometrical parameters of the nozzle, in m, defined in Fig 13.

The diameter of the nozzle stock may be gradually tapered above the upper stock bearing so as to reach, in way of the tiller or quadrant, the value obtained, in mm, from the following formula:

$d_{NT} = 0{,}75\ d_{NTF}$

Figure 13 : Geometrical parameters of the nozzle



10.4 Pintles

10.4.1 The diameter of the pintles is to be not less than the value obtained, in mm, from the following formula:

$$d_A = \left(\frac{11 V_{AV}}{V_{AV}+3}\sqrt{S_{AV}} + 30\right)\sqrt{k_1}$$

where:

S_{AV} : Defined in [10.3.1].

10.4.2 The net pintle length h_A, in mm, is to be not less than 1,2 d_A , where d_A is defined in [10.4.1].

Smaller values of h_A may be accepted provided that the pressure on the gudgeon bearing p_F is in compliance with the following formula:

$p_F \leq p_{F,ALL}$

where:

p_F : Mean bearing pressure acting on the gudgeon, to be obtained in N/mm², from the following formula:

$$p_F = 10^3 \frac{0,6S'}{d'_A h'_A}$$

S' : The greater of the values S_{AV} and S_{AD} , in kN, defined in [10.3.1]

d'_A : Actual pintle diameter, in mm

h'_A : Actual bearing length of pintle, in mm

$p_{F,ALL}$: Allowable bearing pressure, in N/mm², defined in Tab 7.

In any case, h_A is to be not less than d_A .

10.5 Nozzle coupling

10.5.1 Diameter of coupling bolts

The diameter of the coupling bolts is to be not less than the value obtained, in mm, from the following formula:

$$d_B = 0,23 d_{NTF}\sqrt{\frac{k_{1B}}{k_{1A}}}$$

where:

d_{NTF} : Diameter of the nozzle stock, in mm, defined in [10.3.1]

k_{1A} : Material factor k_1 for the steel used for the stock

k_{1B} : Material factor k_1 for the steel used for the bolts.

Non-fitted bolts may be used provided that, in way of the mating plane of the coupling flanges, a key is fitted having a section of (0,25 d_{NT} x 0,10 d_{NT}) mm², where d_{NT} is defined in [10.3.1], and keyways in both the coupling flanges, and provided that at least two of the coupling bolts are fitted bolts.

The distance from the bolt axes to the external edge of the coupling flange is to be not less than 1,2 d_B .

10.5.2 Thickness of coupling flange

The thickness of the coupling flange is to be not less than the value obtained, in mm, from the following formula:

$$t_P = d_{NTF}\sqrt{\frac{k_{1F}}{k_{1B}}}$$

where:

d_{NTF} : Diameter of the nozzle stock, in mm, defined in [10.3.1]

k_{1B}, : Material factor k_1 for the steel used for the bolts

k_{1F} : Material factor k_1 for the steel used for the coupling flange.

10.5.3 Push up length of cone couplings with hydraulic arrangements for assembling and disassembling the coupling

It is to be checked that the push up length Δ_E of the nozzle stock tapered part into the boss is in compliance with the following formula:

$\Delta_0 \le \Delta_E \le \Delta_1$

where:

Δ_0 : The greater of:

- $6,2\dfrac{M_{TR}\eta\gamma}{c d_M t_S \mu_A \beta}$
- $16\dfrac{M_{TR}\eta\gamma}{c t_S^2 \beta}\sqrt{\dfrac{d_{NTF}^6 - d_{NT}^6}{d_{NT}^6}}$

$$\Delta_1 = \frac{2\eta + 5}{1,8}\,\frac{\gamma d_0 R_{eH}}{10^6 c(1+\rho_1)}$$

$$\rho_1 = \frac{80\sqrt{d_{NTF}^6 - d_{NT}^6}}{R_{eH} d_M t_S^2\left[1 - \left(\dfrac{d_0}{d_{NTF}}\right)^2\right]}$$

d_{NTF} : Nozzle stock diameter, in mm, to be obtained from the formula in [10.3.1], considering $k_1 = 1$

d_{NT} : Nozzle stock diameter, in mm, to be obtained from the formula in [10.3.1], considering $k_1 = 1$

η, c, β, d_M, d_E, μ_A, μ, γ : Defined in [5.2.3]

t_S, d_U, d_0 : Defined in Fig 5

R_{eH} : Defined in [1.4.3].

10.5.4 Locking device

A suitable locking device is to be provided to prevent the accidental loosening of nuts.

11 Azimuth propulsion system

11.1 General

11.1.1 Arrangement

The azimuth propulsion system is constituted by the following sub-systems (see Fig 14):

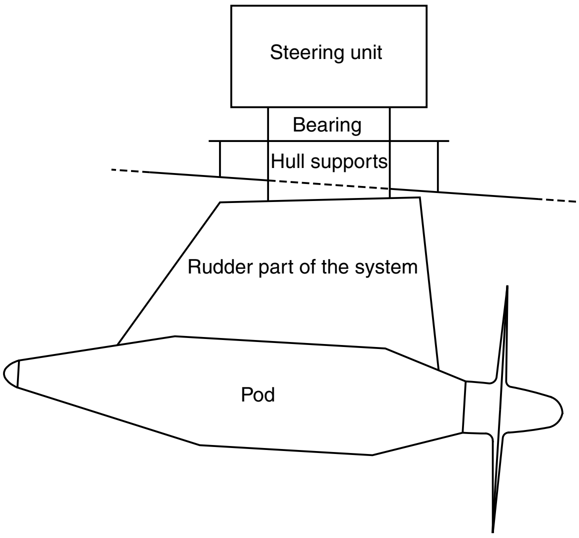
- the steering unit
- the bearing
- the hull supports
- the rudder part of the system
- the pod, which contains the electric motor in the case of a podded propulsion system.

11.1.2 Application

The requirements of this Article apply to the scantlings of the hull supports, the rudder part and the pod.

The steering unit and the bearing are to comply with the requirements in Pt C, Ch 1, Sec 12 and Pt C, Ch 1, Sec 13, respectively.

Figure 14 : Azimuth propulsion system



11.1.3 Operating conditions

The maximum angle at which the azimuth propulsion system can be oriented on each side when the ship navigates at its maximum speed is to be specified by the Designer. Such maximum angle is generally to be less than 35° on each side.

In general, orientations greater than this maximum angle may be considered by the Society for azimuth propulsion systems during manoeuvres, provided that the orientation values together with the relevant speed values are submitted to the Society for approval.

11.2 Arrangement

11.2.1 Plans to be submitted

In addition to the plans showing the structural arrangement of the pod and the rudder part of the system, the plans showing the arrangement of the azimuth propulsion system supports are to be submitted to the Society for approval. The scantlings of the supports and the maximum loads which acts on the supports are to be specified in these drawings.

11.2.2 Locking device

The azimuth propulsion system is to be mechanically lockable in a fixed position, in order to avoid rotations of the system and propulsion in undesirable directions in the event of damage.

11.3 Design loads

11.3.1 The lateral pressure to be considered for scantling of plating and ordinary stiffeners of the azimuth propulsion system is to be determined for an orientation of the system equal to the maximum angle at which the azimuth propulsion system can be oriented on each side when the ship navigates at its maximum speed.

The total force which acts on the azimuth propulsion system is to be obtained by integrating the lateral pressure on the external surface of the system.

The calculations of lateral pressure and total force are to be submitted to the Society for information.

11.4 Plating

11.4.1 Plating of the rudder part of the azimuth propulsion system

The thickness of plating of the rudder part of the azimuth propulsion system is to be not less than that obtained, in mm, from the formulae in [7.3.1], in which the term C_R/A is to be replaced by the lateral pressure calculated according to [11.3].

11.4.2 Plating of the pod

The thickness of plating of the pod is to be not less than that obtained, in mm, from the formulae in Ch 7, Sec 1, where the lateral pressure is to be calculated according to [11.3].

11.4.3 Webs

The thickness of webs of the rudder part of the azimuth propulsion system is to be determined according to [7.3.4], where the lateral pressure is to be calculated according to [11.3].

11.5 Ordinary stiffeners

11.5.1 Ordinary stiffeners of the pod

The scantlings of ordinary stiffeners of the pod are to be not less than those obtained from the formulae in Ch 7, Sec 2, where the lateral pressure is to be calculated according to [11.3].

11.6 Primary supporting members

11.6.1 Analysis criteria

The scantlings of primary supporting members of the azimuth propulsion system are to be obtained through direct calculations, to be carried out according to the following requirements:

- the structural model is to include the pod, the rudder part of the azimuth propulsion system, the bearing and the hull supports
- the boundary conditions are to represent the connections of the azimuth propulsion system to the hull structures
- the loads to be applied are those defined in [11.6.2].

The direct calculation analyses (structural model, load and stress calculation, strength checks) carried out by the Designer are to be submitted to the Society for information.

11.6.2 Loads

The following loads are to be considered in the direct calculation of the primary supporting members of the azimuth propulsion system:

- gravity loads
- buoyancy
- maximum loads calculated for an orientation of the system equal to the maximum angle at which the azimuth propulsion system can be oriented on each side when the ship navigates at its maximum speed
- maximum loads calculated for the possible orientations of the system greater than the maximum angle at the relevant speed (see [11.1.3])
- maximum loads calculated for the crash stop of the ship obtained through inversion of the propeller rotation
- maximum loads calculated for the crash stop of the ship obtained through a 180° rotation of the pod.

11.6.3 Strength check

It is to be checked that the Von Mises equivalent stress σ_E in primary supporting members, calculated, in N/mm², for the load cases defined in [11.6.2], is in compliance with the following formula:

$\sigma_E \leq \sigma_{ALL}$

where:

σ_{ALL} : Allowable stress, in N/mm², to be taken equal to the lesser of the following values:
- $0,275\ R_m$
- $0,55\ R_{eH}$

R_m : Tensile strength, in N/mm², of the material, defined in Ch 4, Sec 1, [2]

R_{eH} : Minimum yield stress, in N/mm², of the material, defined in Ch 4, Sec 1, [2].

11.7 Hull supports of the azimuth propulsion system

11.7.1 Analysis criteria

The scantlings of hull supports of the azimuth propulsion system are to be obtained through direct calculations, to be carried out in accordance with the requirements in [11.6.1].

11.7.2 Loads

The loads to be considered in the direct calculation of the hull supports of the azimuth propulsion system are those specified in [11.6.2].

11.7.3 Strength check

It is to be checked that the Von Mises equivalent stress σ_E in hull supports, in N/mm², calculated for the load cases defined in [11.6.2], is in compliance with the following formula:

$\sigma_E \leq \sigma_{ALL}$

where:

σ_{ALL} : Allowable stress, in N/mm², equal to:

$\sigma_{ALL} = 65/k$ N/mm²

k : Material factor, defined in Ch 4, Sec 1, [2.3].

Values of σ_E greater than σ_{ALL} may be accepted by the Society on a case-by-case basis, depending on the localization of σ_E and on the type of direct calculation analysis.

Section 2 Bulwarks and Guard Rails

1 General

1.1 Introduction

1.1.1 The requirements of this Section apply to the arrangement of bulwarks and guard rails provided at boundaries of the main watertight deck, superstructure decks and tops of the first tier of deckhouses located on the main watertight deck.

1.2 General

1.2.1 Efficient bulwarks or guard rails are to be fitted at the boundaries of all exposed parts of the main watertight deck and superstructure decks directly attached to the main watertight deck, as well as the first tier of deckhouses fitted on the main watertight deck and the superstructure ends.

1.2.2 The height of the bulwarks or guard rails is to be at least 1 m from the deck. However, where their height would interfere with the normal operation of the ship, a lesser height may be accepted, if adequate protection is provided.

1.2.3 Where superstructures are connected by trunks, open rails are to be fitted for the whole length of the exposed parts of the main watertight deck.

1.2.4 In case a freeboard calculation is undertaken, in type A and B-100 ships, open rails on the weather parts of the main watertight deck for at least half the length of the exposed parts are to be fitted.

Alternatively, freeing ports complying with Ch 8, Sec 9, [5] are to be fitted.

1.2.5 In ships with bulwarks and trunks of breadth not less than 0,6 B, which are included in the stability calculation, open rails on the weather parts of the main watertight deck in way of the trunk for at least half the length of the exposed parts are to be fitted.

Alternatively, freeing ports complying with Ch 8, Sec 9, [4.3.1] are to be fitted.

1.2.6 In ships having superstructures which are open at either or both ends, adequate provision for freeing the space within such superstructures is to be provided.

1.2.7 The freeing port area in the lower part of the bulwarks is to be in compliance with the applicable requirements of Ch 8, Sec 9, [5].

2 Bulwarks

2.1 General

2.1.1 The requirement of this Article apply to bulwarks made of steel. Bulwarks made of other material are to be examined on a case-by-case basis.

2.1.2 As a rule, plate bulwarks are to be stiffened at the upper edge by a suitable bar and supported either by stays or plate brackets spaced not more than 2,0 m apart.

Bulwarks are to be aligned with the beams located below or are to be connected to them by means of local transverse stiffeners.

As an alternative, the lower end of the stay may be supported by a longitudinal stiffener.

2.1.3 In type A, B-60 and B-100 ships, the spacing forward of 0,07 L from the fore end of brackets and stays is to be not greater than 1,2 m.

2.1.4 Where bulwarks are cut completely, the scantlings of stays or brackets are to be increased with respect to those given in [2.2].

2.1.5 As a rule, bulwarks are not to be connected either to the upper edge of the sheerstrake plate or to the stringer plate.

Failing this, the detail of the connection will be examined by the Society on a case-by-case basis.

2.2 Scantlings

2.2.1 The thickness of bulwarks on the main watertight deck not exceeding 1100 mm in height is to be not less than:

- 5,5 mm for $L \leq 30$ m
- 6,0 mm for $30 < L \leq 120$ m
- 6,5 mm for $120 < L \leq 150$ m
- 7,0 mm for $L > 150$ m.

Where the height of the bulwark is equal to or greater than 1800 mm, its thickness is to be equal to that calculated for the side of a superstructure situated in the same location as the bulwark.

For bulwarks between 1100 mm and 1800 mm in height, their thickness is to be calculated by linear interpolation.

The thickness of bulwarks not located on the main watertight deck is to be determined as for the side of a superstructure considered in the same location as the bulwark.

2.2.2 Bulwark plating and stays are to be adequately strengthened in way of eyeplates used for shrouds or other tackles in use for cargo gear operation, as well as in way of hawserholes or fairleads provided for mooring or towing.

2.2.3 At the ends of partial superstructures and for the distance over which their side plating is tapered into the bulwark, the latter is to have the same thickness as the side plating; where openings are cut in the bulwark at these positions, adequate compensation is to be provided either by increasing the thickness of the plating or by other suitable means.

2.2.4 The section modulus of stays in way of the lower part of the bulwark is to be not less than the value obtained, in cm^3, from the following formula:

$$Z = 40\, s\, (1 + 0{,}01\, L)\, h_B^2$$

where:

L : Length of ship, in m, to be assumed not greater than 100 m

s : Spacing of stays, in m

h_B : Height of bulwark, in m, measured between its upper edge and the deck.

The actual section of the connection between stays and deck structures is to be taken into account when calculating the above section modulus.

To this end, the bulb or face plate of the stay may be taken into account only where welded to the deck; in this case the beam located below is to be connected by double continuous welding.

For stays with strengthening members not connected to the deck, the calculation of the required minimum section modulus is considered by the Society on a case-by-case basis.

At the ends of the ship, where the bulwark is connected to the sheerstrake, an attached plating having width not exceeding 600 mm may also be included in the calculation of the actual section modulus of stays.

2.2.5 Openings in bulwarks are to be arranged so that the protection of the crew is to be at least equivalent to that provided by the horizontal courses in [3.1.2].

For this purpose, vertical rails or bars spaced approximately 230 mm apart may be accepted in lieu of rails or bars arranged horizontally.

2.2.6 In the case of ships intended for the carriage of timber deck cargoes, the specific provisions of the main watertight regulations are to be complied with.

2.2.7 Bulwarks located in the bow flare area as defined in Ch 8, Sec 1, [4.1.2] are to be reinforced according to Ch 8, Sec 1, [4], considering the stays as cantilever primary supporting members.

3 Guard rails

3.1

3.1.1 Where guard rails are provided, the upper edge of sheerstrake is to be kept as low as possible.

3.1.2 The opening below the lowest course is to be not more than 230 mm. The other courses are to be not more than 380 mm apart.

3.1.3 In the case of ships with rounded gunwales or sheerstrake, the stanchions are to be placed on the flat part of the deck.

3.1.4 Fixed, removable or hinged stanchions are to be fitted about 1,5 m apart. At least every third stanchion is to be supported by a bracket or stay. However, other arrangement may be considered on a case-by-case basis (e.g. stanchions directly screwed in exposed decks), when strength is deemed equivalent.

Removable or hinged stanchions are to be capable of being locked in the upright position.

3.1.5 Wire ropes may only be accepted in lieu of guard rails in special circumstances and then only in limited lengths. Wires are to be made taut by means of turnbuckles.

3.1.6 Chains may only be accepted in short lengths in lieu of guard rails if they are fitted between two fixed stanchions and/or bulwarks.

Section 3 Propeller Shaft Brackets

Symbols

θ : Angle defined in Fig 1 and Fig 2

D_e : Propeller diameter, in m

L : Bracket length, in m (see Fig 1 and Fig 2)

A : Bracket cross-sectional area, in m²

$$K_6 = \frac{2 - \frac{\ell}{L_1} - \frac{\ell}{L_1^2}}{4\left(1 + \frac{\ell}{L_1} + \frac{\ell}{L_1^2}\right)}$$

L_1 : Length, in m, of the bracket between the hull and the intersection point with the propeller bossing, obtained as follows:

$L_1 = L - \ell$

ℓ : Distance, in m, from the above intersection point to the intersection between the barycentre axes of the brackets (see Fig 1 and Fig 2).

1 General

1.1 Bracket configuration

1.1.1 Propeller shafting is generally supported by two brackets, a main one connected to the propeller bossing and an intermediate one between the main one and the ship hull.

The main bracket is to be of double arm type, while the intermediate one may be of single arm type.

2 Double arm brackets of propeller shaft

2.1 General

2.1.1 Double arm brackets of propeller shaft are generally to be radial or tangential, as schematically shown in, respectively, Fig 1 and Fig 2. Other arrangements proposed by the shipyard may be accepted by the Society, on a case-by-case basis.

Usually, the vertical plane passing through the base chord of the bracket is parallel to the ship symmetry plane. When this is not the case, the brackets are said to be twisted and the twist angle is to be identified.

The brackets should be in a lateral plane. However, when more space is needed between the brackets and the propeller, or when brackets normal to the hull are considered, the bracket inclination angle is to be toward the aft.

Figure 1 : Radial type double arm bracket

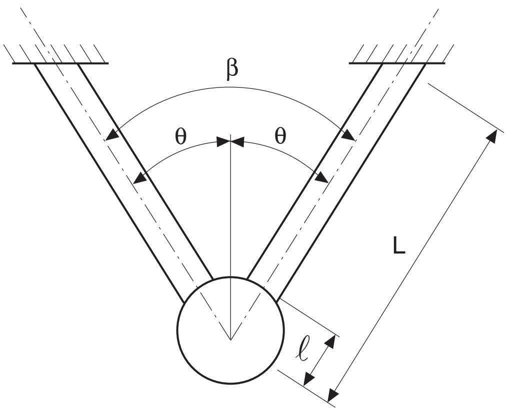


Figure 2 : Tangential type double arm bracket

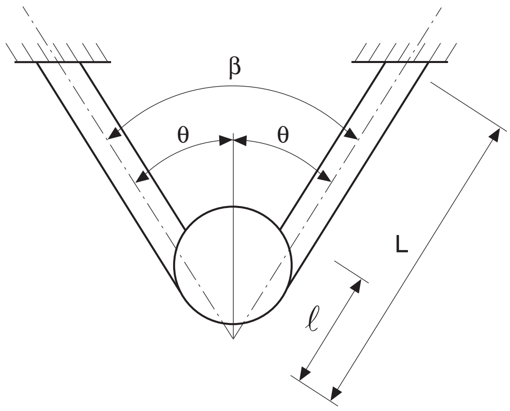


2.1.2 The hull structure in the zone where the propeller brackets are attached to the hull is to be capable of completely absorbing the forces induced by the brackets; in particular, the connection with the primary longitudinal structural members is important. The connections brackets-hull and brackets-propeller bossing are to be rounded. Alternative designs of connections between internal hull structure and propeller bossing avoiding excessive stress concentration may be accepted, subject to special examination.

2.1.3 The lowest natural frequency of the brackets should exceed the blade frequency with not less than 20%.

In cases where this is not possible, the above requirement should be fulfilled for the second resonance frequency and, furthermore, the blade frequency should be at least twice the lowest natural frequency.

2.2 Limit state verification - Loss of blade

2.2.1 General

In the case of loss of a propeller blade, it is to be verified that the maximum global stress σ_{TOT} induced in the propeller brackets do not exceed the permissible stress σ_P :

$\sigma_{TOT} \le \sigma_P$

where:

$\sigma_P = 0{,}48\ \sigma_y$

with:

σ_y : Yield stress of the material.

2.2.2 Maximum global stress

The maximum global stress acting on the propeller shaft bracket is to be determined as the sum of the maximum bending induced stress and the compressive stress at that instant:

$\sigma_{TOT} = \sigma_x + \sigma_c$

where:

$\sigma_x = \text{Max}\ (\sigma_A\ ;\ \sigma_B)$, with σ_A and σ_B defined in [2.2.3]

σ_c : Compressive stress when the bending stress is maximized, defined in [2.2.4].

2.2.3 Acting bending stresses

As the brackets are subjected to combined bending (longitudinal and transverse) the stress can achieve its greatest values at two locations, A and B (see Fig 3).

The stress is therefore to be determined at both locations and the acting stress σ_x is then taken equal to the greater value.

The stress in point A is determined as follows:

$$\sigma_A = \frac{M_{L,\,max}}{W_{zz}}$$

where:

$M_{L,\,max}$: Maximum longitudinal bending moment in the bracket, defined in [2.2.5]

W_{zz} : Section modulus around z axis.

The stress in point B is determined as follows:

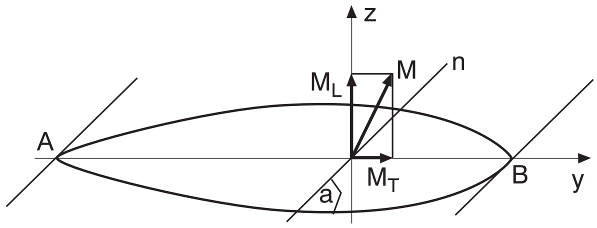
$$\sigma_B = \frac{M_{T\varphi}}{I_{yy}} Z_B + \frac{M_{L,\,max}}{I_{zz}} Y_B$$

where:

$M_{T\varphi}$: Transverse moment in the bracket when the longitudinal moment is maximum, as defined in [2.2.6]

I_{yy} : Sectional moment of inertia around y axis
I_{zz} : Sectional moment of inertia around z axis
Z_B : Distance from point B to the neutral axis for transverse bending
Y_B : Distance from point B to the neutral axis for longitudinal bending.

Figure 3 : Locations of maximum stress under combined bending



2.2.4 Compressive stress

The compressive stress, acting in the brackets when the longitudinal bending moment is maximized, is to be determined as follows:

$$\sigma_c = \frac{P}{2A}\left(\frac{\sin\varphi}{\sin\theta} + \frac{\cos\varphi}{\cos\theta}\right)$$

where:

P : Centrifugal force of the lost blade, in N, to be taken equal to (see Fig 4):
$P = m\,\omega^2\,\rho$
with:
m : Weight of the blade, in kg
ω : Angular velocity, in rad/s, equal to: $\omega = 2\,\pi\,RPM / 60$, with:
RPM : Maximum number of revolutions per minute of the propeller
ρ : Distance from the centre of gravity of the blade to the propeller axis

φ : Phase angle for which the bending stress in the bracket is maximized.
The phase angle maximizing the bending induced stress is to be determined from:

$$\tan\varphi = \frac{2K_6}{\tan\theta}$$

2.2.5 Maximum longitudinal moment in bracket

The maximum longitudinal bending moment, in N·m, acting in the brackets is defined as follows:

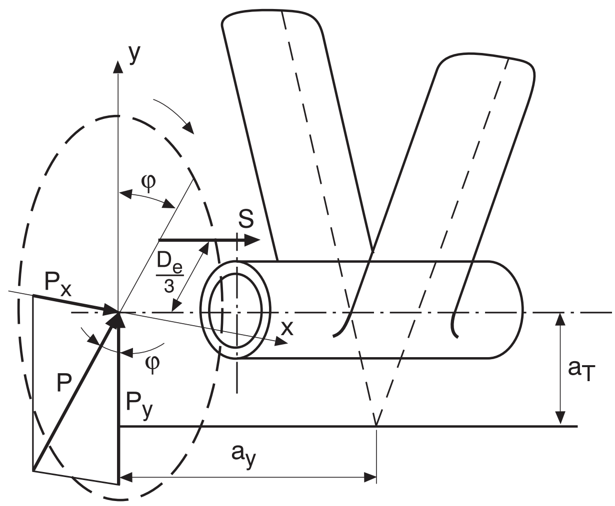
$$M_{L,\,max} = \frac{4K_6^2\cos\theta + \sin\theta\tan\theta}{2\sin\theta\cos\theta\sqrt{4K_6^2 + \tan^2\theta}}\left(Pa_y + \frac{SD_e}{3}\right)$$

where:

S : Thrust of the lost blade (see Fig 4), in N, to be obtained as the total thrust of the propeller divided by the number of propeller blades

a_y : Distance from the propeller to the brackets, in m (see Fig 4).

Figure 4 : Definition of forces, directions and distances



2.2.6 Maximum transverse moment in bracket

The maximum transverse bending moment, in N·m, acting in the brackets is defined as follows:

$$M_{T\varphi} = K_6 P a_T \frac{2K_6}{\sqrt{4K_6^2 + \tan^2\theta}}$$

where:

P : Defined in [2.2.4]

a_T : Defined in Fig 4, in m.

2.2.7 Resonance

In case of loss of a propeller blade, it is to be verified that the bracket lowest natural frequency f_1 is at least 20% larger than the exciting frequency of the damaged propeller f_{dam}:

$f_1 \geq 1,2\ f_{dam}$

where:

f_1 : Determined as described in [2.3.2]

f_{dam} = RPM / 60, in Hz, with:

RPM : Maximum number of revolutions per minute of the propeller.

2.3 Other verifications

2.3.1 Stability under compression

The maximum compressive stress σ_{max} acting on the brackets is defined as follows:

$$\sigma_{max} = \frac{P}{2A}\left(\frac{1}{\sin\theta\sqrt{1+\tan^2\theta}} + \frac{\tan\theta}{\cos\theta\sqrt{1+\tan^2\theta}}\right)$$

It is to be verified that σ_{max} does not exceed the critical instability stress σ_{cr}, in N/m², defined as follows:

$$\sigma_{cr} = \pi^2 \frac{EI_{min}}{0,64AL^2}$$

where:

E : Young's modulus, equal to $2,06\cdot10^{11}$ N/m² for steel

I_{min} : Minimum moment of inertia of the bracket cross-section, in m⁴.

2.3.2 Resonance

In general, it is to be verified that either:

a) the bracket lowest natural frequency f_1 exceeds with at least 20% the blade frequency f_{bl}, or

b) the blade frequency f_{bl} is at least twice as large as the bracket lowest natural frequency f_1 and 20% smaller than the second natural frequency f_2,

which can be expressed by:

- $f_1 > 1,20\ f_{bl}$
- $0,8\ f_2 > f_{bl} > 2\ f_1$

where:

f_{bl} : Blade frequency, in Hz, equal to:

$f_{bl} = n \cdot$ RPM / 60, with:

n : Number of blades

RPM : Maximum number of revolutions per minute of the propeller

$$f_i = \frac{\lambda_i^2}{2\pi L^2}\sqrt{\frac{EI_{min}}{w + w_e}}$$

with:

λ_1 : Factor equal to:

- 1,875 in case of a single arm bracket
- 3,927 in case of double arm brackets

λ_2 : Factor equal to:

- 4,694 in case of a single arm bracket
- 7,069 in case of double arm brackets

E, I_{min} : Defined in [2.3.1]

w : Mass of the bracket per unit length, in kg/m

w_e : Added mass of water per unit length, in kg/m.

The added mass of water is to be determined as, unless otherwise agreed with the Society:

$w_e = \rho\ (A_{cir} - A)$

where:

ρ : Density of sea water, equal to 1025 kg/m^3

A_{cir} : Area of the circle circumscribing the bracket profile, in m^2.

Section 4 Equipment

Symbols

EN : Equipment Number defined in [2.1]

σ_{ALL} : Allowable stress, in N/mm², used for the yielding check, to be taken as follows:

σ_{ALL} = Min (0,67 R_{eH} ; 0,40 R_m)

R_{eH} : Minimum yield stress, in N/mm², of the material, defined in Ch 4, Sec 1, [2]

R_m : Tensile strength, in N/mm², of the material, defined in Ch 4, Sec 1, [2].

1 General

1.1 General

1.1.1 The minimum requirements in Articles [2] to [4] apply to temporary mooring of a ship within or near harbour, or in a sheltered area, when the ship is awaiting a berth, the tide, etc.

Therefore, the equipment complying with the requirements in Articles [2] to [4] is not intended for holding a ship off fully exposed coasts in rough weather or for stopping a ship which is moving or drifting.

The requirements in Articles [2] and [4] are based on a wind speed of 25 m/s, a current speed of 2,5 m/s and a water depth of 50 m.

For a water depth greater than 50 m, a length of chain cable greater than the one obtained from Tab 1 may be accepted by the Society, on the basis of justificative calculation submitted by the shipyard.

1.1.2 The equipment complying with the requirements in Articles [2] to [4] is intended for holding a ship in good holding ground, where the conditions are such as to avoid dragging of the anchor. In poor holding ground the holding power of the anchors is to be significantly reduced.

1.1.3 It is assumed that under normal circumstances a ship will use one anchor only.

2 Equipment number

2.1 Equipment number

2.1.1 General

All ships are to be provided with equipment in anchors and chain cables (or ropes according to [3.2.5]), to be obtained from Tab 1, based on their Equipment Number EN.

In general, stockless anchors are to be adopted.

For ships with EN greater than 16000, the determination of the equipment will be considered by the Society on a case-by-case basis.

For ships of special design or ships engaged in special services or on special voyages, the Society may consider equipment other than that given in Tab 1.

Table 1 : Equipment

Equipment number EN A < EN ≤ B		Stockless anchors		Stud link chain cables for anchors			
		N **(1)**	Mass per anchor, in kg	Total length, in m	Diameter, in mm		
A	B				Q1	Q2	Q3
50	70	2	240	220,0	16,0	14,0	
70	90	2	300	247,5	17,5	16,0	
90	110	2	360	247,5	19,0	17,5

2.1.2 Equipment number for ships with perpendicular superstructure front bulkhead

The equipment number EN is to be obtained from the following formula:

$EN = \Delta^{2/3} + 2\ h\ B + 0{,}1\ A$

where:

Δ : Moulded displacement of the ship, in t, to the full load waterline "end of life"

h : Effective height, in m, from the full load waterline to the top of the uppermost house, to be obtained in accordance with the following formula:

$h = a + \Sigma h_n$

when calculating h, sheer and trim are to be disregarded

a : Distance amidships between the full load waterline and the exposed deck, in m

h_n : Height, in m, at the centreline of tier "n" of superstructures or deckhouses having a breadth greater than B/4. Where a house having a breadth greater than B/4 is above a house with a breadth of B/4 or less, the upper house is to be included and the lower ignored

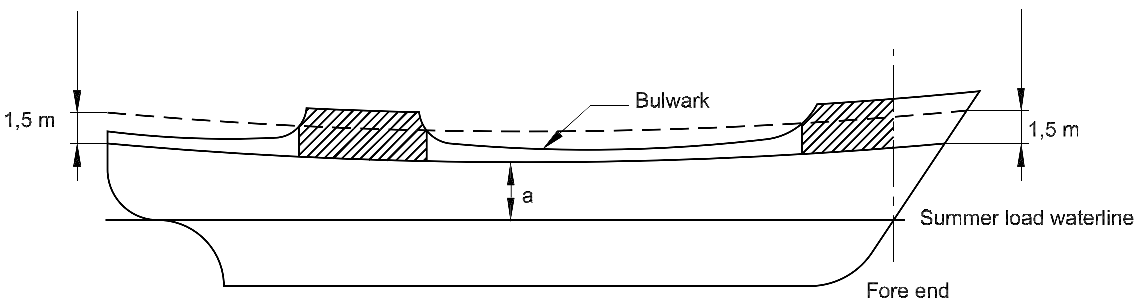
A : Area, in m², in profile view, of the parts of the hull, superstructures and houses above the full load waterline which are within the length L_E and also have a breadth greater than B/4

L_E : Equipment length, in m, equal to L without being taken neither less than 96% nor greater than 97% of the total length of the full load waterline.

Fixed screens or bulwarks 1,5 m or more in height are to be regarded as parts of houses when determining h and A. In particular, the hatched area shown in Fig 1 is to be included.

The height of hatch coamings and that of any deck cargo, such as containers, may be disregarded when determining h and A.

Figure 1 : Ships with perpendicular front bulkhead
Effective area of bulwarks or fixed screen to be included in the equipment number



2.1.3 Equipment number for ships with inclined superstructure front bulkhead

For ships having superstructures with the front bulkhead with an angle of inclination aft, the equipment number EN is to be obtained from the following formula:

$EN = \Delta^{2/3} + 2\ (a\ B + \Sigma\ b_N\ h_N \sin\theta_N) + 0{,}1\ A$

where:

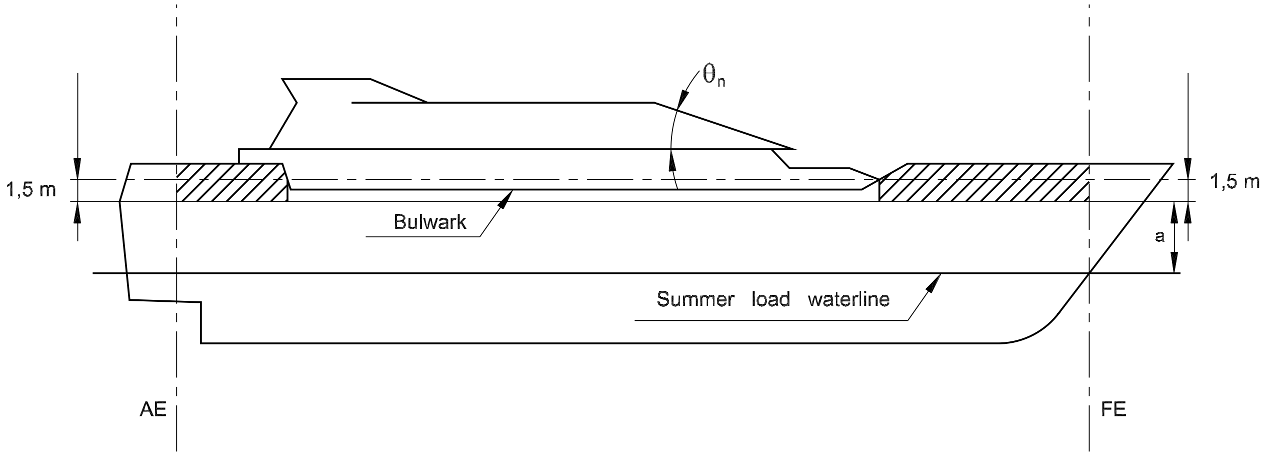
Δ, a, h_N , A: Defined in [2.1.2]

θ_N : Angle of inclination aft of each front bulkhead, shown in Fig 2

b_N : Greatest breadth, in m, of each tier n of superstructures or deckhouses having a breadth greater than B/4.

Fixed screens or bulwarks 1,5 m or more in height are to be regarded as parts of houses when determining h and A. In particular, the hatched area shown in Fig 2 is to be included.

Figure 2 : Ships with inclined front bulkhead
Effective area of bulwarks or fixed screen to be included in the equipment number



3 Equipment

3.1 Anchors

3.1.1 General

The scantlings of anchors are to be in compliance with the following requirements.

Anchors are to be constructed and tested in compliance with approved plans.

3.1.2 Ordinary anchors

The required mass for each anchor is to be obtained from Tab 1.

The individual mass of a main anchor may differ by ± 7% from the mass required for each anchor, provided that the total mass of anchors is not less than the total mass required in Tab 1.

The mass of the head of an ordinary stockless anchor, including pins and accessories, is to be not less than 60% of the total mass of the anchor.

Where a stock anchor is provided, the mass of the anchor, excluding the stock, is to be not less than 80% of the mass required in Tab 1 for a stockless anchor. The mass of the stock is to be not less than 25% of the mass of the anchor without the stock but including the connecting shackle.

3.1.3 High and very high holding power anchors

High holding power (HHP) and very high holding power (VHHP) anchors, i.e. anchors for which a holding power higher than that of ordinary anchors has been proved according to NR216 Materials and Welding, Ch 4, Sec 1, [1], do not require prior adjustment or special placement on the sea bottom.

Where HHP or VHHP anchors are used as bower anchors, the mass of each anchor is to be not less than 75% or 50%, respectively, of that required for ordinary stockless anchors in Tab 1.

The mass of VHHP anchors is to be, in general, less than or equal to 1500 kg.

3.1.4 Third anchor

Where three anchors are provided, two are to be connected to their own chain cables and positioned on board always ready for anchoring.

The third anchor is intended as a spare and is not required for the purpose of classification.

3.1.5 Test for high holding power anchors approval

For approval and/or acceptance as a HHP anchor, comparative tests are to be performed on various types of sea bottom. Such tests are to show that the holding power of the HHP anchor is at least twice the holding power of an ordinary stockless anchor of the same mass.

For approval and/or acceptance as a HHP anchor of a whole range of mass, such tests are to be carried out on anchors whose sizes are, as far as possible, representative of the full range of masses proposed. In this case, at least two anchors of different sizes are to be tested. The mass of the maximum size to be approved is to be not greater than 10 times the maximum size tested. The mass of the smallest is to be not less than 0,1 times the minimum size tested.

3.1.6 Test for very high holding power anchors approval

For approval and/or acceptance as a VHHP anchor, comparative tests are to be performed at least on three types of sea bottom: soft mud or silt, sand or gravel and hard clay or similar compounded material. Such tests are to show that the holding power of the VHHP anchor is to be at least four times the holding power of an ordinary stockless anchor of the same mass or at least twice the holding power of a previously approved HHP anchor of the same mass.

The holding power test load is to be less than or equal to the proof load of the anchor, specified in NR216 Materials and Welding, Ch 4, Sec 1, [1.6].

For approval and/or acceptance as a VHHP anchor of a whole range of mass, such tests are to be carried out on anchors whose sizes are, as far as possible, representative of the full range of masses proposed. In this case, at least three anchors of different sizes are to be tested. relevant to the bottom, middle and top of the mass range.

3.1.7 Specification for test on high holding power and very high holding power anchors

Tests are generally to be carried out from a tug. Shore based tests may be accepted by the Society on a case-by-case basis.

Alternatively, sea trials by comparison with a previous approved anchor of the same type (HHP or VHHP) of the one to be tested may be accepted by the Society on a case-by-case basis.

For each series of sizes, the two anchors selected for testing (ordinary stockless and HHP anchors for testing HHP anchors, ordinary stockless and VHHP anchors or, when ordinary stockless anchors are not available, HHP and VHHP anchors for testing VHHP anchors) are to have the same mass.

The length of chain cable connected to each anchor, having a diameter appropriate to its mass, is to be such that the pull on the shank remains practically horizontal. For this purpose a value of the ratio between the length of the chain cable paid out and the water depth equal to 10 is considered normal. A lower value of this ratio may be accepted by the Society on a case-by-case basis.

Three tests are to be carried out for each anchor and type of sea bottom.

The pull is to be measured by dynamometer; measurements based on the RPM/bollard pull curve of tug may, however, be accepted instead of dynamometer readings.

Note is to be taken where possible of the stability of the anchor and its ease of breaking out.

3.2 Chain cables for anchors

3.2.1 Material

The chain cables are classified as grade Q1, Q2 or Q3 depending on the type of steel used and its manufacture.

The characteristics of the steel used and the method of manufacture of chain cables are to be approved by the Society for each manufacturer. The material from which chain cables are manufactured and the completed chain cables themselves are to be tested in accordance with the applicable requirements of NR216 Materials and Welding, Ch 4, Sec 1.

Chain cables made of grade Q1 may not be used with high holding power and very high holding power anchors.

3.2.2 Stud link chain cables

The mass and geometry of stud link chain cables, including the links, are to be in compliance with the requirements in NR216 Materials and Welding, Ch 4, Sec 1.

The diameter of stud link chain cables is to be not less than the values given in Tab 1.

3.2.3 Studless link chain cables

For ships with EN less than 90, studless short link chain cables may be accepted by the Society as an alternative to stud link chain cables, provided that the equivalence in strength is based on proof load, defined in NR216 Materials and Welding, Ch 4, Sec 1, [3], and that the steel grade of the studless chain is equivalent to the steel grade of the stud chains it replaces, as defined in [3.2.1].

3.2.4 Chain cable arrangement

Chain cables are to be made by lengths of 27,5 m each, joined together by Dee or lugless shackles.

The total length of chain cable, required in Tab 1, is to be divided in approximately equal parts between the two anchors ready for use.

Where different arrangements are provided, they are considered by the Society on a case-by-case basis. In particular, different lengths of chain cable for each anchor may be accepted, provided each mooring line is appropriate for 50m water depth.

Where the ship may anchor in areas with current speed greater than 2,5 m/s, the Society may require a length of heavier chain cable to be fitted between the anchor and the rest of the chain in order to enhance anchor bedding.

3.2.5 Wire ropes

As an alternative to the stud link or short link chain cables mentioned, wire ropes may be used in the following cases:

- wire ropes for both the anchors, for ship length less than 30 m
- wire rope for one of the two anchors, for ship length between 30 m and 40 m.

The wire ropes above are to have a total length equal to 1,5 times the corresponding required length of stud link chain cables, obtained from Tab 1, and a minimum breaking load equal to that given for the corresponding stud link chain cable (see [3.2.2]).

A short length of chain cable is to be fitted between the wire rope and the anchor, having a length equal to 12,5 m or the distance from the anchor in the stowed position to the winch, whichever is the lesser.

3.3 Attachment pieces

3.3.1 General

Where the lengths of chain cable are joined to each other by means of shackles of the ordinary Dee type, the anchor may be attached directly to the end link of the first length of chain cable by a Dee type end shackle.

A detachable open link in two parts riveted together may be used in lieu of the ordinary Dee type end shackle; in such case the open end link with increased diameter, defined in [3.3.2], is to be omitted.

Where the various lengths of chain cable are joined by means of lugless shackles and therefore no special end and increased diameter links are provided, the anchor may be attached to the first length of chain cable by a special pear-shaped lugless end shackle or by fitting an attachment piece.

3.3.2 Scantlings

The diameters of the attachment pieces, in mm, are to be not less than the values indicated in Tab 2.

Attachment pieces may incorporate the following items between the increased diameter stud link and the open end link:

- swivel, having diameter equal to 1,2 d
- increased stud link, having diameter equal to 1,1 d.

Where different compositions are provided, they will be considered by the Society on a case-by-case basis.

Table 2 : Diameters of attachment pieces

Attachment piece	Diameter, in mm
End shackle	1,4 d
Open end link	1,2 d
Increased stud link	1,1 d
Common stud link	d
Lugless shackle	d
Note 1: d : Diameter, in mm, of the common link	

3.3.3 Material

Attachment pieces, joining shackles and end shackles are to be of such material and design as to provide strength equivalent to that of the attached chain cable, and are to be tested in accordance with the applicable requirements of NR216 Materials and Welding, Ch 4, Sec 1.

3.4 Towlines

3.4.1 General

The towlines are given as a guidance, but are not required as a condition of classification.

The towlines having the characteristics defined in Tab 3 are intended as those belonging to the ship to be towed by a tug or another ship.

3.4.2 Materials

Towlines may be of wire, natural or synthetic fibre or a mixture of wire and fibre.

The breaking loads defined in Tab 3 refer to steel wires or natural fibre ropes.

Steel wires and fibre ropes are to be tested in accordance with the applicable requirements in NR216 Materials and Welding, Ch 4, Sec 1.

3.4.3 Steel wires

Steel wires are to be made of flexible galvanized steel and are to be of types defined in Tab 4.

3.4.4 Synthetic fibre ropes

Where synthetic fibre ropes are adopted, their size is to be determined taking into account the type of material used and the manufacturing characteristics of the rope, as well as the different properties of such ropes in comparison with natural fibre ropes.

The breaking load of synthetic fibre ropes B_{LS} is to be not less than that obtained, in kN, from the following formula:

$B_{LS} = K\, B_{L0}$

where:

B_{L0} : Breaking load, in kN, for the towline, defined in Tab 3,

K : Coefficient to be taken equal to:

K = 1,3 for polypropylene towlines

K = 1,2 for towlines made in other synthetic material.

Fibre rope diameters are to be not less than 20 mm.

3.4.5 Equivalence between the breaking loads of synthetic and natural fibre ropes

Generally, fibre ropes are to be made of polyamide or other equivalent synthetic fibres.

The equivalence between the breaking loads of synthetic fibre ropes B_{LS} and of natural fibre ropes B_{LN} is to be obtained, in kN, from the following formula:

$B_{LS} = 7{,}4\ \delta\ B_{LN}^{8/9}$

where:

δ : Elongation to breaking of the synthetic fibre rope, to be assumed not less than 30%.

Table 3 : Towlines and mooring lines

Equipment number EN A< EN ≤ B		Towlines		Equipment number EN A< EN ≤ B		Towlines

Table 4 : Steel wire composition

Breaking load B_L ,in kN	Steel wire components		
	Number of threads	Ultimate tensile strength of threads, in N/mm²	Composition of wire
$B_L < 216$	72	1420 ÷ 1570	6 strands with 7-fibre core
$216 < B_L < 490$	144	1570 ÷ 1770	6 strands with 7-fibre core
$B_L > 490$	216 or 222	1770 ÷ 1960	6 strands with 1-fibre core

3.5 Hawse pipes

3.5.1 Hawse pipes are to be built according to sound marine practice.

Their position and slope are to be so arranged as to create an easy lead for the chain cables and efficient housing for the anchors, where the latter are of the retractable type, avoiding damage to the hull during these operations.

For this purpose chafing lips of suitable form with ample lay-up and radius adequate to the size of the chain cable are to be provided at the shell and deck. The shell plating in way of the hawse pipes is to be reinforced as necessary.

3.5.2 All mooring units and accessories, such as timbler, riding and trip stoppers are to be securely fastened, to the Surveyor's satisfaction.

3.6 Windlass

3.6.1 General

The Rule Note NR626 "Anchor Windlass and Chain Stoppers" is to be applied, considering the windlass brake capacity defined in [3.6.2].

The deck in way of the windlass is to be suitably reinforced. The windlass, its frame and the stoppers are to be efficiently bedded to the deck.

3.6.2 Brake capacity

Based on mooring line arrangements with brakes engaged and cable lifter disengaged, the capacity HL (Holding Load), in kN, of the windlass brake is to be sufficient to withstand the following design loads without any permanent deformation of the stressed parts and without brake slip:

- 0,8 times the breaking load BL of the chain, if not combined with a chain stopper
- 0,45 times the breaking load BL of the chain, if combined with a chain stopper.

3.7 Chain stoppers

3.7.1 A chain stopper is generally to be fitted between the windlass and the hawse pipe in order to relieve the windlass of the pull of the chain cable when the ship is at anchor. The chain stopper is to comply with applicable requirements given in the Rule Note NR626 "Anchor Windlass and Chain Stoppers".

For the same purpose, a piece of chain cable may be used with a rigging screw capable of supporting the weight of the anchor when housed in the hawse pipe or a chain tensioner. Such arrangements are not to be considered as chain stoppers.

3.7.2 Where the windlass is at a distance from the hawse pipes and no chain stoppers are fitted, suitable arrangements are to be provided to lead the chain cables to the windlass.

3.8 Chain locker

3.8.1 The capacity of the chain locker is to be adequate to stow all chain cable equipment and provide an easy direct lead to the windlass.

3.8.2 Where two chains are used, the chain lockers are to be divided into two compartments, each capable of housing the full length of one line.

3.8.3 The inboard ends of chain cables are to be secured to suitably reinforced attachments in the structure by means of end shackles, whether or not associated with attachment pieces.

Generally, such attachments are to be able to withstand a force not less than 15% of the breaking load of the chain cable.

In an emergency, the attachments are to be easily released from outside the chain locker.

3.8.4 Where the chain locker is arranged aft of the collision bulkhead, its boundary bulkheads are to be watertight and a drainage system is to be provided.

4 Mooring arrangement

4.1 General

4.1.1 The mooring lines and the hawser for mooring to a buoy are to be in accordance with the following sub-articles. The other mooring equipment are outside the scope of classification.

4.2 Mooring lines

4.2.1 Minimum breaking load

The minimum breaking load BL, in KN, of the mooring lines is given by:

BL = FS / N

with:

FS : Static force, in kN, induced by wind on the ship in the transverse direction given by the following formula:
$FS = 2,382\ A\ (h + 18) / (h + 60)$

h : Mean height, in m, above waterline to be taken as:
$h = 2\ A / 3\ L_E$

A : Area, in m^2, as given in [2.1.2]

L_E : Length, in m, as given in [2.1.2]

N : Number of breast lines.

4.2.2 Number

As a rule, two breast lines are to be fitted on board. However, for large ships, the number of breast lines may be increased in order to ensure that the diameter of the lines will be less than 72 mm, which is considered to be the maximum permissible diameter for handiness.

All the mooring lines are to be made of the same material and have the same diameter. However, when this diameter is greater than 63 mm, the head and stern lines will be replaced by four ones with lower diameter.

As a minimum, eight mooring lines are to be fitted on board:

- one head line and one stern line
- one forward spring and one after spring
- one forward breast line and one after breast line
- two spare lines (one breast line and one spring).

4.2.3 Length

As a rule, the length of the breast lines and the springs is to be between 0,7 L_E and L_E.

The length of head and stern lines is to be equal to 1,5 times the length of the other mooring lines.

4.2.4 Material

Mooring lines may be of natural or synthetic fibre or a mixture of wire and fibre.

4.3 Hawser for mooring to a buoy

4.3.1 Material

Each ship is to have a special hawser for mooring to a buoy. As a rule, this hawser is to be made of steel wire made of six strands with 7-fibre core.

4.3.2 Minimum breaking load

The minimum breaking load R, in daN, of the hawser is given by the relation:

$$(R \cdot 10^{-3})^{0,5} > 0,17\ \Delta^{1/3} + 2$$

where Delta

Δ : Displacement, in t, as given in [2.1.2].

Section 5 Masts and Other Outfitting Components

1 Masts

1.1 Application

1.1.1 The requirements of this Article apply to the arrangement of masts fitted on weather deck or on superstructure decks for supporting lights or other important fittings having significant mass with respect to the one of the mast structure.

The requirements in [1.2] apply for static analysis of masts subjected to still water, inertial and wind loads.

The requirements in [1.3] apply for the dynamic analysis of masts.

1.2 Static analysis of masts

1.2.1 General

In general, the inertial loads acting on the mast structures are to be obtained from a complete analysis of the ship motion and accelerations in irregular waves, whose results are to be submitted to the Society for approval. These loads are to be obtained as those that can be reached with a probability of 10^{-5} per cycle.

Extreme wind values are to be considered in association with these inertial loads.

However, when deemed acceptable by the Society, the design loads in [1.2.2] may be used for the structural analysis of masts.

1.2.2 Design loads

The design loads are constituted by still water, inertial and wind loads. The structural weight of the mast and the weight of the mast fittings and devices are to be taken into account when calculating the still water force F_S and the inertial force F_W, as indicated in Tab 1.

The wind force F_{Wind}, to be considered as being perpendicular to the surface of the mast exposed to the wind, is to be obtained, in N, from the following formula:

$F_{Wind} = 0,613\ C_S\ V^2\ A$

where:

C_S : Shape coefficient, to be taken equal to:
- C_S = 1,6 for lattice and flat-sided masts
- C_S = 0,9 for masts with circular cross-sections
- C_S = 1,2 for mast fittings

V : Wind speed, in m/s, to be taken, in general, not less than 63 m/s

A : Projected area, in m², of all the mast surfaces exposed to wind.

1.2.3 Structural analysis

In general, the structural analysis of masts is to be based on direct calculations performed through three-dimensional models. Direct calculations are to be carried out according to the following requirements:

- the structural modelling is to comply with the requirements from Ch 7, App 1, [2] to Ch 7, App 1, [4]
- the loads to be applied on the model are to comply with [1.2.1]
- the stress calculation is to comply with the requirements in Ch 7, App 1, [5].

However, structural analysis of masts based on isolate beam models, performed according to the requirements in Ch 7, Sec 3, [2], may be carried out when deemed acceptable by the Society depending on the structural typology and arrangement adopted for the mast.

When three-dimensional direct calculations are carried out, the structural model of the mast is to include a suitable portion of the hull structure supporting the mast, in order to avoid that the unavoidable inaccuracy in the modelling of the boundary conditions affect the results in the area to be analysed.

1.2.4 Strength check criteria of mast structures

The following strength checks of mast structures are to be carried out:

- yielding check, to be carried out according to Ch 7, Sec 3
- local buckling check of plate panels, to be carried out according to Ch 7, Sec 1, [5]
- column buckling check, to be carried out according to Ch 7, Sec 3, [5.2] and Ch 7, Sec 3, [5.3].

1.3 Dynamic analysis of masts

1.3.1 General

The dynamic analysis of masts is to be based on direct calculations performed through three-dimensional models.

The criteria adopted for structural modelling are to comply with the requirements specified in Ch 7, App 1.

In any case, the mesh accuracy is to be such that the stiffness and the mass distribution of the model elements of the mast, of the mast foundation and of the surrounding hull structure properly represent those of the actual structure.

1.3.2 Normal mode analysis

It is to be checked that each normal mode frequency f_{Ni} , in Hz, of the mast is in compliance with one of the following formulae:

$f_{Ni} < 0,8\ f_{E,MIN}$

$f_{Ni} > 1,2\ f_{E,MAX}$

where:

$f_{E,MIN}$, $f_{E,MAX}$: The lesser and the greater values, in Hz, respectively, among the possible excitations frequencies due to the ship motions or the propulsion system, to be calculated for the ship at the following speeds:

- cruise speed
- maximum continuous rate speed
- patrol speed.

The normal mode calculation method and the number of normal modes to be taken into account are considered by the Society on a case-by-case basis.

When at least one of the mast normal mode frequencies does not comply with the above formulae, a dynamic analysis is to be carried out according to the requirements in [1.3.2].

1.3.3 Dynamic analysis

It is to be checked that the dynamic effects induced in the mast by the ship's motions or propulsion system excitations are within the allowable limits, when this is required according to [1.3.2].

The dynamic effects are to be calculated by means of a dynamic analysis aiming at evaluating the response of the mast in the frequency domain.

When the dynamic analysis is based on normal models, their number is, in general, to be such that the modal effective mass is not less than 95% of the mass of the system constituted by the mast and its supporting structure.

The modal effective mass is defined as:

$$\sum_{i=1}^{N} \gamma_i^2$$

where γ_i is the i^{th} modal participation factor and N is the number of the considered normal modes.

The dynamic analysis criteria and the relevant allowable limits are considered by the Society on a case-by-case basis.

Where requested by the interested parties, the allowable limits may also take into account the serviceability limits of the mast fittings, i.e. the limits at which the efficiency of the mast fitting is impaired (e.g. because of excessive vibration level).

2 Outfitting components subjected to weapon firing loads

2.1 General

2.1.1 These requirements apply to the outfitting components that, because of their relative location with respect to a weapon, could be subjected to the weapon firing loads, but have not been designed to sustain them. Such components are to be completely enclosed within a protecting structure whose strength with respect to the weapon firing loads is to be checked by means of the applicable formulae in Part B, Chapter 7, where the loads are to be calculated according to Ch 5, Sec 6, [9].

If necessary, the protecting structure is to be provided with openings and closing devices. The strength of the closing devices is to be checked against the weapon firing loads as the protecting structure.

Table 1 : Still water force F_S and inertial force F_W

Ship condition	Load case	Forces F_S and F_W, in kN	
Still water condition		$F_{S,X} = 0,035\ g\ \Sigma_i\ W_i$ $F_{S,Y} = 0,087\ g\ \Sigma_i\ W_i$ $F_{S,Z} = g\ \Sigma_i\ W_i$	in x direction **(1)** in y direction **(2)** in z direction
Upright condition	"a"	No inertial force	
	"b"	$F_{W,X} = \Sigma_i\ a_{X1,i}\ W_i$ $F_{W,Z} = \Sigma_i\ a_{Z1,i}\ W_i$	in x direction in z direction
Inclined condition	"c"	$F_{W,Y} = C_{FA}\ \Sigma_i\ a_{Y2,i}\ W_i$	in y direction
	"d"	$F_{W,Z} = C_{FA}\ \Sigma_i\ a_{Z2,i}\ W_i$	in z direction

(1) Still water force corresponding to a ship trim angle equal to 2°. Other trim angle values may be accepted if adequate documentation is provided to the Society

(2) Still water force corresponding to a ship heel angle equal to 5°. Other heel angle values may be accepted if adequate documentation is provided to the Society.

Note 1:

W_i : Mass, in t, of each one of the N mast components considered (i = 1 to N). It includes also the mass of mast structure and the mass of mast fittings and devices

$a_{X1,i}$, $a_{Z1,i}$: Reference values of the accelerations a_{X1}, a_{Z1} in the upright ship condition, defined in Ch 5, Sec 3, 3.4, calculated in way of the centre of gravity of each one of the N mast components considered (i = 1 to N)

$a_{Y2,i}$, $a_{Z2,i}$: Reference values of the accelerations a_{Y2}, a_{Z2} in the inclined ship condition, defined in Ch 5, Sec 3, 3.4, calculated in way of the centre of gravity of each one of the N mast components considered (i = 1 to N)

C_{FA} : Combination factor, to be taken equal to:

- C_{FA} = 0,7 for load case "c"
- C_{FA} = 1,0 for load case "d".

Appendix 1 Criteria for Direct Calculation of Rudder Loads

Symbols

ℓ_{10} , ℓ_{20} , ℓ_{30} , ℓ_{40} : Lengths, in m, of the individual girders of the rudder system (see Fig 1, Fig 2 and Fig 3)

ℓ_{50} : Length, in m, of the solepiece (see Fig 2 and Fig 4)

J_{10} , J_{20} , J_{30} , J_{40} : Moments of inertia about the x axis, in cm^4, of the individual girders of the rudder system having lengths ℓ_{10}, ℓ_{20}, ℓ_{30}, ℓ_{40} (see Fig 1, Fig 2 and Fig 3). For rudders supported by a solepiece only, J_{20} indicates the moment of inertia of the pintle in the sole piece

J_{50} : Moment of inertia about the z axis, in cm^4, of the solepiece (see Fig 2 and Fig 4)

C_R : Rudder force, in N, acting on the rudder blade, defined in Ch 9, Sec 1, [2.1.1]

C_{R1} , C_{R2} : Rudder forces, in N, defined in Ch 9, Sec 1, [2.2.3].

1 Criteria for direct calculation of the loads acting on the rudder structure

1.1 General

1.1.1 Application

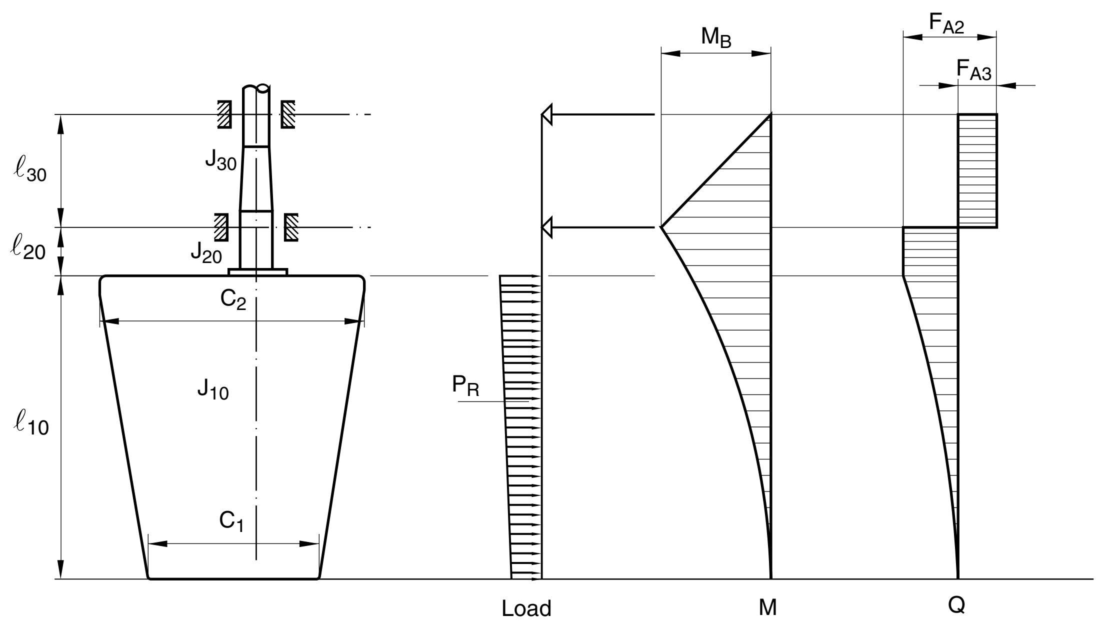
The requirements of this Appendix apply to the following types of rudders:

- spade rudders (see Fig 1)
- 2 bearing rudders with solepiece (see Fig 2)
- 2 bearing semi-spade rudders with rudder horn (see Fig 3).

The requirements of this Appendix provide the criteria for calculating the following loads:

- bending moment M_B in the rudder stock
- support forces F_A
- bending moment M_R and shear force Q_R in the rudder body.

Figure 1 : Spade rudders



1.1.2 Load calculation

The loads in [1.1.1] are to be calculated through direct calculations based on the model specified in Fig 1, Fig 2 and Fig 3, depending on the type of rudder.

They are to be used for the stress analysis required in:

- Ch 9, Sec 1, [4], for the rudder stock
- Ch 9, Sec 1, [6], for the rudder pintles and the pintle bearings
- Ch 9, Sec 1, [7] for the rudder blade
- Ch 9, Sec 1, [8] for the rudder horn and the solepiece.

Figure 2 : 2 bearing rudders with solepiece

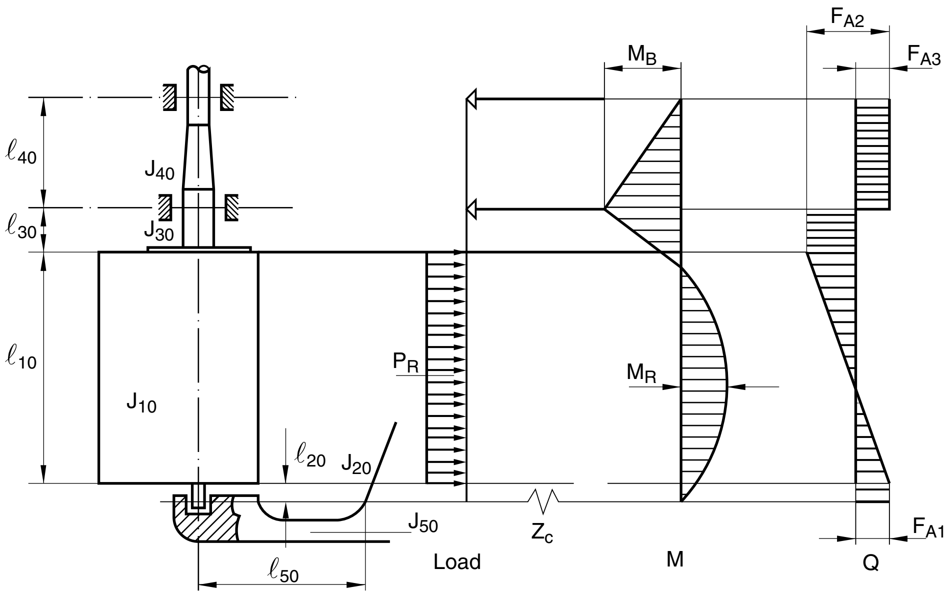


Figure 3 : 2 bearing semi-spade rudders with rudder horn

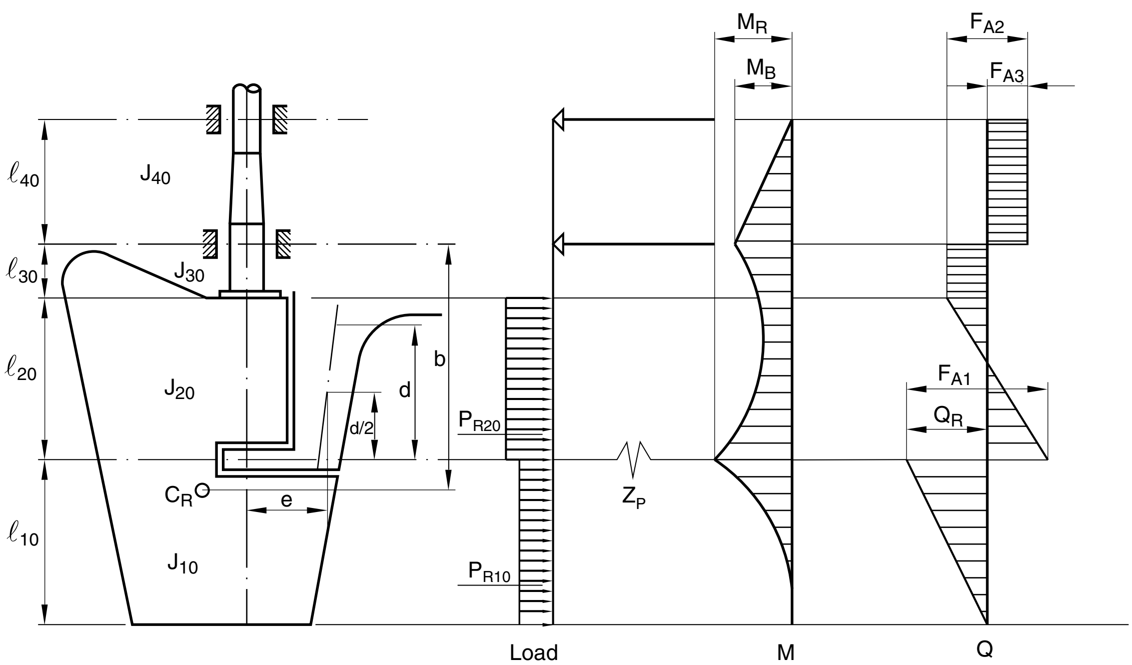

Figure 4 : Solepiece geometry

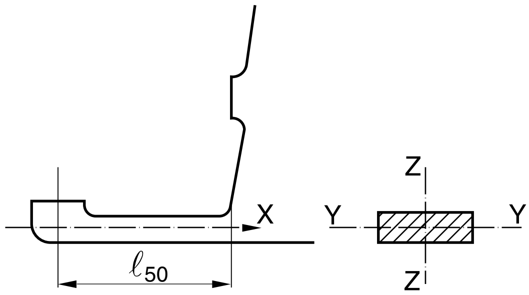


1.1.3 Specific case of spade rudders

For spade rudders, the results of direct calculations carried out in accordance with [1.1.2] may be expressed in an analytical form. The loads in [1.1.1] may therefore be obtained from the following formulae:

- maximum bending moment in the rudder stock, in N·m:

$$M_B = C_R\left(\ell_{20} + \frac{\ell_{10}(2C_1 + C_2)}{3(C_1 + C_2)}\right)$$

  where C_1 and C_2 are the lengths, in m, defined in Fig 1

- support forces, in N:

$$F_{A3} = \frac{M_B}{\ell_{30}}$$

  $F_{A2} = C_R + F_{A3}$

- maximum shear force in the rudder body, in N:

  $Q_R = C_R$

1.2 Data for the direct calculation

1.2.1 Forces per unit length

The following forces per unit length are to be calculated, in N/m, according to [1.3]:

- p_R for spade rudders and rudders with solepiece (see Fig 1 and Fig 2, respectively)
- p_{R10} and p_{R20} for semi-spade rudders with rudder horn (see Fig 3).

1.2.2 Spring constant

The following support spring constants are to be calculated, in N/m, according to [1.4]:

- Z_C for rudders with solepiece (see Fig 2)
- Z_P for semi-spade rudders with rudder horn (see Fig 3).

1.3 Force per unit length on the rudder body

1.3.1 Spade rudders and 2 bearing rudders with solepiece

The force per unit length p_R (see Fig 1 and Fig 2) acting on the rudder body is to be obtained, in N/m, from the following formula:

$$p_R = \frac{C_R}{\ell_{10}}$$

1.3.2 2 bearing semi-spade rudders with rudder horn

The forces per unit length p_{R10} and p_{R20} (see Fig 1) acting on the rudder body are to be obtained, in N/m, from the following formulae:

$$p_{R10} = \frac{C_{R2}}{\ell_{10}}$$

$$p_{R20} = \frac{C_{R1}}{\ell_{20}}$$

1.4 Support spring constant

1.4.1 Sole piece

The spring constant Z_C for the support in the solepiece (see Fig 2) is to be obtained, in N/m, from the following formula:

$$Z_C = \frac{6180 J_{50}}{\ell_{50}^3}$$

1.4.2 Rudder horn

The spring constant Z_P for the support in the rudder horn (see Fig 3) is to be obtained, in N/m, from the following formula:

$$Z_P = \frac{1}{f_B + f_T}$$

where:

f_B : Unit displacement of rudder horn due to a unit force of 1 N acting in the centroid of the rudder horn, to be obtained, in m/N, from the following formula:

$$f_B = 1{,}3\frac{d^3}{6180 J_N}$$

d : Height, in m, of the rudder horn, defined in Fig 3

J_N : Moment of inertia of rudder horn about the x axis, in cm^4 (see Fig 5)

f_T : Unit displacement due to torsion to be obtained, in m/N, from the following formula:

$$f_T = 10^{-8}\frac{de^2}{3140 F_T^2}\sum_i \frac{u_i}{t_i}$$

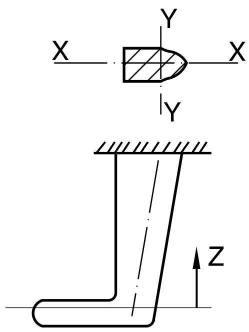
d, e : Lengths, in m, defined in Fig 3

F_T : Mean sectional area of rudder horn, in m^2

u_i : Length, in mm, of the individual plates forming the mean horn sectional area

t_i : Thickness of the individual plates mentioned above, in mm.

Figure 5 : Rudder horn geometry



CHAPTER 10
CORROSION PROTECTION AND LOADING INFORMATION

Section 1 Protection of Hull Metallic Structures
Section 2 Loading Manual and Loading Instruments

Section 1 Protection of Hull Metallic Structures

1 Protection by coating

1.1 General

1.1.1 It is the responsibility of the Shipbuilder and the Owner to choose the coating and have it applied in accordance with the manufacturer's requirements.

1.2 Structures to be protected

1.2.1 All salt water ballast spaces with boundaries formed by the hull envelope are to have a corrosion protective coating, epoxy or equivalent, applied in accordance with the manufacturer's requirements.

1.2.2 Corrosion protection of spaces other than ballast spaces is not a Class requirement.

1.2.3 Narrow spaces are generally to be filled by an efficient protective product, particularly at the ends of the ship where inspections and maintenance are not easily practicable due to their inaccessibility. Other equivalent dispositions may be accepted, such as demonstrated air watertightness without painting.

2 Cathodic protection

2.1 General

2.1.1 Internal structures in spaces intended to carry liquids may be provided with cathodic protection.

Cathodic protection may be fitted in addition to the required corrosion protective coating, if any.

2.1.2 Details concerning the type of anodes used and their location and attachment to the structure are to be submitted to the Society for approval.

2.2 Anodes

2.2.1 Magnesium or magnesium alloy anodes are not permitted in oil cargo tanks.

2.2.2 Aluminium anodes are only permitted in cargo tanks of tankers in locations where the potential energy does not exceed 28 kg·m. The height of the anode is to be measured from the bottom of the tank to the centre of the anode, and its weight is to be taken as the weight of the anode as fitted, including the fitting devices and inserts.

However, where aluminium anodes are located on horizontal surfaces such as bulkhead girders and stringers not less than 1 m wide and fitted with an upstanding flange or face flat projecting not less than 75 mm above the horizontal surface, the height of the anode may be measured from this surface.

Aluminium anodes are not to be located under tank hatches or Butterworth openings, unless protected by the adjacent structure.

2.2.3 There is no restriction on the positioning of zinc anodes.

2.2.4 Anodes are to have steel cores and are to be declared by the Manufacturer as being sufficiently rigid to avoid resonance in the anode support and designed so that they retain the anode even when it is wasted.

2.2.5 The steel inserts are to be attached to the structure by means of a continuous weld. Alternatively, they may be attached to separate supports by bolting, provided a minimum of two bolts with lock nuts are used. However, other mechanical means of clamping may be accepted.

2.2.6 The supports at each end of an anode may not be attached to separate items which are likely to move independently.

2.2.7 Where anode inserts or supports are welded to the structure, they are to be arranged by the Shipyard so that the welds are clear of stress peaks.

2.3 Impressed current systems

2.3.1 Impressed current systems are not permitted in oil cargo tanks.

3 Protection against galvanic corrosion

3.1 General

3.1.1 Non-stainless steel is to be electrically insulated from stainless steel or from aluminium alloys.

3.1.2 Where stainless steel or aluminium alloys are fitted in the same tank as non-stainless steel, a protective coating is to cover both materials.

4 Protection of bottom by ceiling

4.1 General

4.1.1 In double bottom ships, ceiling is to be laid over the inner bottom and lateral bilges, if any.

Ceiling on the inner bottom is not required where the thickness of the inner bottom is increased in accordance with Ch 7, Sec 1, [2.3.1].

4.2 Arrangement

4.2.1 Planks forming ceiling over the bilges and on the inner bottom are to be easily removable to permit access for maintenance.

4.2.2 Where the double bottom is intended to carry fuel oil, ceiling on the inner bottom is to be separated from the plating by means of battens 30 mm high, in order to facilitate the drainage of oil leakages to the bilges.

4.2.3 Where the double bottom is intended to carry water, ceiling on the inner bottom may lie next to the plating, provided a suitable protective composition is applied beforehand.

4.2.4 The Shipyard is to take care that the attachment of ceiling does not affect the tightness of the inner bottom.

4.2.5 In single bottom ships, ceiling is to be fastened to the reversed frames by galvanized steel bolts or any other equivalent detachable connection.

A similar connection is to be adopted for ceiling over the lateral bilges in double bottom ships.

4.3 Scantlings

4.3.1 The thickness of ceiling boards, when made of pine, is to be not less than 60 mm. Under cargo hatchways, the thickness of ceiling is to be increased by 15 mm.

Where the floor spacing is large, the thicknesses may be considered by the Society on a case-by-case basis.

5 Protection of decks by wood sheathing

5.1 General

5.1.1 Where decks are intended to carry specific loads, such as caterpillar trucks and unusual vehicles, the Society may require such decks wood sheathed.

5.2 Arrangement

5.2.1 Wood sheathing is to be fixed to the plating by welded studs or bolts of at least 12 mm in diameter, every second frame.

5.2.2 Before fitting the wood sheathing, deck plates are to be provided with protective coating declared to be suitable by the Shipyard.

Caulking is the Shipyard's responsibility.

5.3 Scantlings

5.3.1 The thickness of wood sheathing of decks is to be not less than:

- 65 mm for wood sheathing made of pine
- 50 mm for wood sheathing made of hardwood, such as teak.

The width of planks is not to exceed twice their thickness.

Section 2 Loading Manual and Loading Instruments

1 Definitions

1.1 Perpendiculars

1.1.1 Forward perpendicular

The forward perpendicular is the perpendicular to the waterline at the forward side of the stem on the full load waterline.

1.1.2 After perpendicular

The after perpendicular is the perpendicular to the waterline at the after side of the rudder post on the full load waterline. For ships without rudder post, the after perpendicular is the perpendicular to the waterline at the centre of the rudder stock on the full load waterline.

1.1.3 Midship perpendicular

The midship perpendicular is the perpendicular to the waterline at half the distance between forward and after perpendiculars.

2 Loading manual and loading instrument requirement criteria

2.1 General

2.1.1 The loading instrument is ship specific onboard equipment and the results of the calculations are only applicable to the ship for which it has been approved.

An approved loading instrument may not replace an approved loading manual.

3 Loading manual

3.1 Definitions

3.1.1 A loading manual is a document which describes:

- the loading conditions on which the design of the ship has been based, including permissible limits of still water bending moment and shear force
- the results of the calculations of still water bending moments, shear forces and, where applicable, limitations due to torsional and lateral loads
- the allowable local loading for the structure (hatch covers, decks, double bottom, etc.).

3.2 Conditions of approval

3.2.1 The approved loading manual is to be based on the final data of the ship. The manual is to include the design (full load and operational) loading conditions, subdivided into departure and arrival conditions as appropriate, upon which the approval of the hull scantlings is based, defined in Ch 5, Sec 2, [2.1.2].

In the case of modifications resulting in changes to the main data of the ship, a new approved loading manual is to be issued.

3.2.2 Language

The loading manual is to be prepared in a language understood by the users. If this is not English, a translation into English is to be included.

4 Loading instrument

4.1 Definitions

4.1.1 A loading instrument is an instrument which is either analog or digital and by means of which it can be easily and quickly ascertained that, at specified read-out points, the still water bending moments, shear forces and still water torsional moments and lateral loads, where applicable, in any load or ballast condition, do not exceed the specified permissible values.

An operational manual is always to be provided for the loading instrument.

Single point loading instruments are not acceptable.

4.2 Conditions of approval

4.2.1 The loading instrument is subject to approval, which is to include:

- verification of type approval, if any
- verification that the final data of the ship have been used
- acceptance of number and position of all read-out points
- acceptance of relevant limits for read-out points
- checking of proper installation and operation of the instrument on board, under agreed test conditions, and that a copy of the operation manual is available.

4.2.2 In the case of modifications implying changes in the main data of the ship, the loading instrument is to be modified accordingly and approved.

4.2.3 The operation manual and the instrument output are to be prepared in a language understood by the users. If this is not English, a translation into English is to be included.

4.2.4 The operation of the loading instrument is to be verified upon installation under the agreed test conditions. It is to be checked that the agreed test conditions and the operation manual for the instrument are available on board.

4.2.5 When the loading instrument also performs stability calculations, it is to be approved for stability purposes in accordance with the procedures indicated in [4.5] and [4.6], as applicable.

4.3 Approval procedure

4.3.1 General

The loading instrument approval process includes the following procedures for each ship:

- data verification which results in endorsed test conditions
- approval of computer hardware, where necessary, as specified in Pt C, Ch 3, Sec 6, [2.4]
- installation testing which results in an Installation Test Report.

4.3.2 Data verification approval - Endorsed test conditions

The Society is to verify the results and actual ship data used by the calculation program for the particular ship on which the program will be installed.

Upon application for data verification, the Society is to advise the applicant of a minimum of four loading conditions, taken from the ship approved loading manual, which are to be used as the test conditions. Within the range of these test conditions, each compartment is to be loaded at least once. The test conditions normally cover the range of load draughts from the deepest envisaged loaded condition to the light ballast condition. In addition, the lightship test condition is to be submitted.

When the loading instrument also performs stability calculations, the test conditions are to be taken from the ship approved trim and stability booklet.

The data indicated in [4.3.3] and contained in the loading program are to be consistent with the data specified in the approved loading manual. Particular attention is drawn to the final lightship weight and centres of gravity derived from the inclining experiment or lightweight check.

The approval of the computer application software is based on the acceptance of the results of the test conditions according to [4.4], [4.5] and [4.6] as applicable.

When the requested information has been submitted and the results of the test conditions are considered satisfactory, the Society endorses the test conditions, a copy of which is to be available on board.

4.3.3 Data to be submitted

The following data, submitted by the applicant, are to be consistent with the as-built ship:

- identification of the calculation program including the version number
- main dimensions, hydrostatic particulars and, if applicable, ship profile
- position of the forward and after perpendiculars and, if appropriate, the calculation method to derive the forward and after draughts at the actual position of the ship draught marks
- ship lightweight and lightweight distribution along the ship length
- lines plans and/or offset tables
- compartment definitions, including frame spacing and centre of volumes, together with capacity tables (sounding/ullage tables), if appropriate
- deadweight definitions for each loading condition.

4.3.4 Installation testing

During the installation test, one of the ship senior officers is to operate the loading instrument and calculate the test conditions. This operation is to be witnessed by a Surveyor of the Society. The results obtained from the loading instrument are to be identical to those stated in the endorsed test conditions. If the numerical output from the loading instrument is different from the endorsed test conditions, no approval will be confirmed.

An installation test is also to be carried out on the second nominated computer, when applicable as indicated in Pt C, Ch 3, Sec 6, [2.4], which would be used in the event of failure of the first computer. Where the installation test is carried out on a type approved computer, a second nominated computer and test are not required.

Subject to the satisfactory completion of installation tests, the Society's Surveyor endorses the test conditions, adding details of the place and the date of the installation test survey, as well as the Society stamp and the Surveyor's signature.

4.3.5 Operational manual

A uniquely identified ship specific operational manual is to be submitted to the Society for documentation.

The operational manual is to be written in a concise and unambiguous manner. The use of illustrations and flowcharts is recommended.

The operational manual is to contain:

- a general description of the program denoting identification of the program and its stated version number
- details of the hardware specification needed to run the loading program
- a description of error messages and warnings likely to be encountered, and unambiguous instructions for subsequent actions to be taken by the user in each case
- where applicable, the shear force correction factors
- where applicable, the local permissible limits for single and two adjacent hold loadings as a function of the appropriate draught and the maximum weight for each hold
- where applicable, the Society's restrictions (maximum allowable load on double bottom, maximum specific gravity allowed in liquid cargo tanks, maximum filling level or percentage in liquid cargo tanks)
- example of a calculation procedure supported by illustrations and sample computer output
- example computer output of each screen display, complete with explanatory text.

4.3.6 Calculation program specifications

The software is to be written so as to ensure that the user cannot alter the critical ship data files containing the following information:

- lightship weight and lightship weight distribution and associated centres of gravity
- the Society's structural limitations or restrictions
- geometric hull form data
- hydrostatic data and cross curves, where applicable
- compartment definitions, including frame spacing and centre of volumes, together with capacity tables (sounding/ullage tables), if appropriate.

Any changes in the software are to be made by the manufacturer or his appointed representative and the Society is to be informed immediately of such changes. Failure to advise of any modifications to the calculation program may invalidate the approval issued. In cases where the approval is considered invalid by the Society, the modified calculation program is to be re-assessed in accordance with the approval procedure.

4.3.7 Functional specification

The calculation program is to be user-friendly and designed such that it limits possible input errors by the user.

The forward, midship and after draughts, at the respective perpendiculars, are to be calculated and presented to the user on screen and hardcopy output in a clear and unambiguous manner.

It is recommended that the forward, midship and after draughts, at the actual position of the ship draught marks are calculated and presented to the user on screen and hard copy output in a clear and unambiguous manner.

The displacement is to be calculated for the specified loading condition and corresponding draught readings and presented to the user on screen and hardcopy output.

The loading instrument is to be capable of producing print-outs of the results in both numerical and graphical forms. The numerical values are to be given in both forms, as absolute values and as the percentage of the permissible values. This print-out is to include a description of the corresponding loading condition.

All screen and hardcopy output data is to be presented in a clear and unambiguous manner with an identification of the calculation program (the version number is to be stated).

4.4 Hull girder forces and moments

4.4.1 General

The loading program is to be capable of calculating the following hull girder forces and moments in accordance with Ch 5, Sec 2, [2]:

- still water shear force (SWSF) including the shear force correction, where applicable
- still water bending moment (SWBM).

Table 1 : Data to be provided to (or accepted by) the Society

Calculation	Data
Still water shear force (SWSF)	• The read-out points (frame locations) for the SWSF calculations. These points are normally selected at the position of the transverse bulkhead or other obvious boundaries. Additional read-out points may be specified between the bulkheads of long holds or tanks or between container stacks • Shear force correction factors and method of application • The permissible seagoing and harbour SWSF limits at the read-out points. Where appropriate, additional sets of permissible SWSF values may be specified
Still water bending moment (SWBM)	• The read-out points (frame locations) for the SWBM calculations. These points are normally selected at the position of the transverse bulkhead, mid-hold or other obvious boundaries • The permissible seagoing and harbour SWBM limits at the read-out points. Where appropriate, additional sets of permissible SWBM values may be specified

The data which are to be provided to, or accepted by, the Society are specified in Tab 1.

Read-out points are usually to be selected at the position of the transverse bulkheads or other obvious boundaries.

The calculated forces and moments are to be displayed in both graphical and tabular formats, including the percentage of permissible values. The screen and hardcopy output is to display the calculated forces or moments, and the corresponding permissible limits, at each specified read-out point. Alternative limits may be considered by the Society on a case-by-case basis.

4.4.2 Acceptable tolerances

The accuracy of the calculation program is to be within the acceptable tolerance band, specified in Tab 2, of the results at each read-out point obtained by the Society, using an independent program or the approved loading manual with identical input.

Table 2 : Tolerance band for the comparison of computational accuracy

Computation	Tolerance (percentage of the permissible values)
Still water shear force	± 5%
Still water bending moment	± 5%

4.4.3 Permissible limits and restrictions

The user is to be able to view the following Society structural limitations in a clear and unambiguous manner:

- all permissible still water shear forces and still water bending moments
- cargo hold weight
- ballast tank/hold capacities
- filling restrictions.

It is to be readily apparent to the user when any of the structural limits has been exceeded.

4.5 Intact stability

4.5.1 Application

The loading instrument approval for stability purposes is required when a loading instrument to be installed on board a ship performs stability calculations, as stated in [4.2.5].

4.5.2 Data verification approval - Endorsed test conditions

The requirements in [4.3.2] apply. In addition, at least one of the four loading conditions required is to show the compartments, intended for liquid loads in which the free surface effect is considerable, filled in order to have the maximum free surface moment.

The additional data necessary for the approval of the loading instrument for stability purposes are specified in [4.5.3].

In order to obtain the approval of the loading instrument, all the intact stability requirements (and relevant criteria) applicable to the ship, reported in Ch 3, Sec 2 as well as in [4.5.2], are to be available in the computer output; the lack of any one of them is sufficient to prevent the endorsement of the test conditions.

4.5.3 Additional data to be submitted

In addition to the data required in [4.3.3], the following are to be submitted:

- cross curves of stability calculated on a free trimming basis, for the ranges of displacement and trim anticipated in normal operating conditions, with indication of the volumes which have been considered in the computation of these curves
- capacity tables indicating, for each compartment or space, the values of the co-ordinates X_G, Y_G and Z_G of the centre of gravity, as well as the inertia, corresponding to an adequate number of filling percentages
- list of all the openings (location, tightness, means of closure), pipes or other sources which may lead to progressive flooding
- deadweight definitions for each loading condition in which, for any load taken into account, the following information is to be specified:
  - weight and centre of gravity co-ordinates
  - percentage of filling (if liquid load)
  - free surface moment (if liquid load)
- information on loading restrictions (maximum filling level or percentage in liquid cargo tanks, maximum KG or minimum GM curve or table which can be used to determine compliance with the applicable intact and damage stability criteria), when applicable
- all the intact stability criteria applicable to the ship concerned.

4.6 Damage stability

4.6.1 Application

The loading instrument approval for stability purposes is required when a loading instrument to be installed on board a ship performs damage stability calculations, as stated in [4.2.5].

In such case, the loading instrument is also to perform intact stability calculations, and therefore the approval is to be based on the requirements specified in [4.5].

Additional requirements relevant to damage stability are given in [4.6.2] and [4.6.3].

4.6.2 Data verification approval - Endorsed test conditions

The requirements specified in [4.5.2] apply.

The additional data necessary for the approval of the loading instrument for stability purposes are specified in [4.6.3].

The approval of damage stability calculations performed by a loading instrument is limited to those relevant to deterministic damage stability rules specified in Part D. In order to obtain the approval of the loading instrument, all the damage stability requirements (and relevant criteria) applicable to the ship are to be available in the computer output. The lack of any one of them is sufficient to prevent the endorsement of the test conditions.

4.6.3 Additional data to be submitted

In addition to the data required in [4.5.3], the following are to be submitted:

- list of all the damage cases which are to be considered in accordance with the relevant deterministic damage stability rules

  Each damage case is to clearly indicate all the compartments or spaces taken into account, as well as the permeability associated with each compartment or space.

  This information is to be taken from the approved damage stability documentation, and the source details are to be clearly indicated; in the case of unavailability of such documentation, the above-mentioned information may be requested from the Society.
- all the damage stability criteria applicable to the ship concerned.

Part B
Hull and Stability

CHAPTER 11
CONSTRUCTION AND TESTING

Section 1	Welding and Weld Connections
Section 2	Special Structural Details
Section 3	Testing
Appendix 1	Welding Details
Appendix 2	Reference Sheets for Special Structural Details

Section 1 Welding and Weld Connections

1 General

1.1 Application

1.1.1 The requirements of this Section apply for the preparation, execution and inspection of welded connections in hull structures.

They are to be complemented by the criteria given in Ch 11, App 1, to which reference is made. These criteria being given as recommendations, minor departures may be accepted by the Society, on a case-by-case basis.

The general requirements relevant to fabrication by welding and qualification of welding procedures are given in NR216 Materials and Welding, Chapter 5.

1.1.2 Weld connections are to be executed according to the approved plans. Any detail not specifically represented in the plans is, if any, to comply with the applicable requirements.

1.1.3 It is understood that welding of the various types of steel is to be carried out by means of welding procedures approved for the purpose, even though an explicit indication to this effect may not appear on the approved plans.

1.1.4 The quality standard adopted by the shipyard is to be submitted to the Society and applies to all constructions unless otherwise specified on a case-by-case basis.

1.2 Base material

1.2.1 The requirements of this Section apply for the welding of hull structural steels or aluminium alloys of the types considered in NR216 Materials and Welding, or other types accepted as equivalent by the Society.

1.2.2 The service temperature is intended to be the ambient temperature, unless otherwise stated.

1.3 Welding consumables and procedures

1.3.1 Approval of welding consumables and procedures

Welding consumables and welding procedures adopted are to be approved by the Society.

The requirements for the approval of welding consumables are given in NR216 Materials and Welding, Chapter 11.

The requirements for the approval of welding procedures are given in NR216 Materials and Welding, Chapter 12.

1.3.2 Consumables

For welding of hull structural steels, the minimum consumable grades to be adopted are specified in Tab 1 depending on the steel grade.

Consumables used for manual or semi-automatic welding (covered electrodes, flux-cored and flux-coated wires) of higher strength hull structural steels are to be at least of hydrogen-controlled grade H15 (H). Where the carbon equivalent C_{eq} is not more than 0,41% and the thickness is below 30 mm, any type of approved higher strength consumables may be used at the discretion of the Society.

Especially, welding consumables with hydrogen-controlled grade H15 (H) and H10 (HH) shall be used for welding hull steel forgings and castings of respectively ordinary strength level and higher strength level.

1.4 Personnel and equipment

1.4.1 Welders

Manual and semi-automatic welding is to be performed by welders certified by the Society as specified in the Rule Note NR476 Approval Testing of Welders. The welders are to be employed within the limits of their respective approval.

1.4.2 Automatic welding operators

Personnel manning automatic welding machines and equipment are to be competent and sufficiently trained.

1.4.3 Organisation

The internal organization of the shipyard is to be such as to ensure compliance in full with the requirements in [1.4.1] and [1.4.2] and to provide for assistance and inspection of welding personnel, as necessary, by means of a suitable number of competent supervisors.

Table 1 : Consumable grades

Steel grade	Consumable minimum grade	
	Butt welding, partial and full T penetration welding	Fillet welding
A	1	1
B - D	2	
E	3	
AH32 - AH36 DH32 - DH36	2Y	2Y
EH32 - EH36	3Y	
FH32 - FH36	4Y	
AH40	2Y40	2Y40
DH40 - EH40	3Y40	
FH40	4Y40	
Note 1: Welding consumables approved for welding higher strength steels (Y) may be used in lieu of those approved for welding normal strength steels having the same or a lower grade; welding consumables approved in grade Y40 may be used in lieu of those approved in grade Y having the same or a lower grade. **Note 2:** In the case of welded connections between two hull structural steels of different grades, as regards strength or notch toughness, welding consumables appropriate to one or the other steel are to be adopted.		

1.4.4 NDE operators

Non-destructive tests are to be carried out by qualified personnel, certified by the Society, or by recognized bodies in compliance with appropriate standards.

The qualifications are to be appropriate to the specific applications.

1.4.5 Technical equipment and facilities

The welding equipment is to be appropriate to the adopted welding procedures, of adequate output power and such as to provide for stability of the arc in the different welding positions.

In particular, the welding equipment for special welding procedures is to be provided with adequate and duly calibrated measuring instruments, enabling easy and accurate reading, and adequate devices for easy regulation and regular feed.

Manual electrodes, wires and fluxes are to be stored in suitable locations so as to ensuring their preservation in proper condition. Especially, where consumables with hydrogen-controlled grade are to be used, proper precautions are to be taken to ensure that manufacturer's instructions are followed to obtain (drying) and maintain (storage, maximum time exposed, re-backing, ...) hydrogen-controlled grade.

1.5 Documentation to be submitted

1.5.1 The structural plans to be submitted for approval, according to Ch 1, Sec 3, are to contain the necessary data relevant to the fabrication by welding of the structures and items represented as far as class is concerned.

For important structures, the main sequences of prefabrication, assembly and welding and non-destructive examination planned are also to be represented in the plans.

1.5.2 A plan showing the location of the various steel types is to be submitted at least for outer shell, deck and bulkhead structures.

1.6 Design

1.6.1 General

For the various structural details typical of welded construction in shipbuilding and not dealt with in this Section, the rules of good practice, recognized standards and past experience are to apply as agreed by the Society.

1.6.2 Plate orientation

The plates of the shell and strength deck are generally to be arranged with their length in the fore-aft direction. Possible exceptions to the above will be considered by the Society on a case-by-case basis; tests as deemed necessary (for example, transverse impact tests) may be required by the Society.

1.6.3 Overall arrangement

Particular consideration is to be given to the overall arrangement and structural details of highly stressed parts of the hull.

Drawings relevant to the special details specified in Ch 11, Sec 2 are to be submitted.

1.6.4 Prefabrication sequences

Prefabrication sequences are to be arranged so as to facilitate positioning and assembling as far as possible.

The amount of welding to be performed on board is to be limited to a minimum and restricted to easily accessible connections.

1.6.5 Distance between welds

Welds located too close to one another are to be avoided. The minimum distance between two adjacent welds is considered on a case-by-case basis, taking into account the level of stresses acting on the connected elements.

In general, the distance between two adjacent butts in the same strake of shell or deck plating is to be greater than two frame spaces.

2 Type of connections and preparation

2.1 General

2.1.1 The type of connection and the edge preparation are to be appropriate to the welding procedure adopted, the structural elements to be connected and the stresses to which they are subjected.

2.2 Butt welding

2.2.1 General

In general, butt connections of plating are to be full penetration, welded on both sides except where special procedures or specific techniques, considered equivalent by the Society, are adopted.

Connections different from the above may be accepted by the Society on a case-by-case basis; in such cases, the relevant detail and workmanship specifications are to be approved.

2.2.2 Welding of plates with different thicknesses

In the case of welding of plates with a difference in gross thickness equal to, or greater than:

- 3 mm, if the thinner plate has a gross thickness equal to, or less than, 10 mm
- 4 mm, if the thinner plate has a gross thickness greater than 10 mm,

a taper having a length of not less than 4 times the difference in gross thickness is to be adopted for connections of plating perpendicular to the direction of main stresses. For connections of plating parallel to the direction of main stresses, the taper length may be reduced to 3 times the difference in gross thickness.

When the difference in thickness is less than the above values, it may be accommodated in the weld transition between plates.

For large thicknesses (e.g. 25mm), other criteria may be considered on a case-by-case basis, when deemed equivalent.

2.2.3 Edge preparation, root gap

Typical edge preparations and gaps are indicated in Ch 11, App 1.

The acceptable root gap is to be in accordance with the adopted welding procedure and relevant bevel preparation.

2.2.4 Butt welding on permanent backing

Butt welding on permanent backing, i.e. butt welding assembly of two plates backed by the flange or the face plate of a stiffener, may be accepted where back welding is not feasible or in specific cases deemed acceptable by the Society.

The type of bevel and the gap between the members to be assembled are to be such as to ensure a proper penetration of the weld on its backing and an adequate connection to the stiffener as required.

2.2.5 Section, bulbs and flat bars

When lengths of longitudinals of the shell plating and strength deck within 0,6 L amidships, or elements in general subject to high stresses, are to be connected together by butt joints, these are to be full penetration. Other solutions may be adopted if deemed acceptable by the Society on a case-by-case basis.

The work is to be done in accordance with an approved procedure; in particular, this requirement applies to work done on board or in conditions of difficult access to the welded connection. Special measures may be required by the Society.

2.3 Fillet welding

2.3.1 General

In general, ordinary fillet welding (without bevel) may be adopted for T connections of the various simple and composite structural elements.

Where stress level is high or where there is a possibility of local laminations, partial or full T penetration welding according to [2.4] may be requested by the Society.

2.3.2 Fillet welding types

Fillet welding may be of the following types:

- continuous fillet welding, where the weld is constituted by a continuous fillet on each side of the abutting plate (see [2.3.3])
- intermittent fillet welding, which may be subdivided (see [2.3.4]) into:
  - chain welding
  - scallop welding
  - staggered welding.

2.3.3 Continuous fillet welding

Continuous fillet welding is to be adopted:

- for watertight connections
- for connections of brackets, lugs and scallops
- at the ends of connections for a length of at least 75 mm
- where intermittent welding is not allowed, according to [2.3.4].

Continuous fillet welding may also be adopted in lieu of intermittent welding wherever deemed suitable, and it is recommended where the spacing p, calculated according to [2.3.4], is low.

2.3.4 Intermittent welding

The spacing p and the length d, in mm, of an intermittent weld, shown in:

- Fig 1 for chain welding
- Fig 2 for scallop welding
- Fig 3 for staggered welding,

are to be such that:

$$\frac{p}{d} \leq \varphi$$

where the coefficient φ is defined in Tab 1 and Tab 2 for the different types of intermittent welding, depending on the type and location of the connection.

In general, staggered welding is not allowed for connections subjected to high alternate stresses.

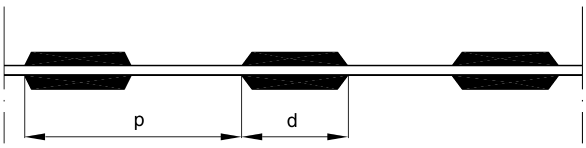
In addition, the following limitations are to be complied with:

- chain welding (see Fig 1):

  $d \geq 75$ mm

  $p - d \leq 200$ mm

Figure 1 : Intermittent chain welding



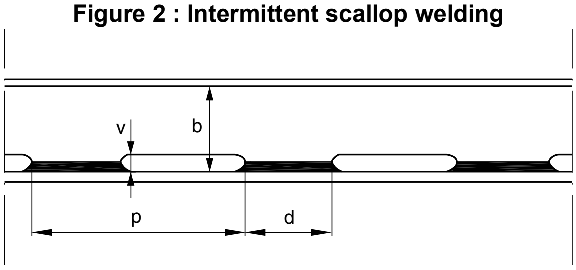
- scallop welding (see Fig 2):

  $d \geq 75$ mm

  $p - d \leq 150$ mm

  $v \leq 0,25\ b$, without being greater than 75 mm

Figure 2 : Intermittent scallop welding



- staggered welding (see Fig 3):

  $d \geq 75$ mm

  $p - 2d \leq 300$ mm

  $p \leq 2d$ for connections subjected to high alternate stresses.

Figure 3 : Intermittent staggered welding

			top and bottom plates of rudder plating	0,35				
		solid parts or rudder stock		according to Ch 9, Sec 1, [7.4] or Ch 9, Sec 1, [7.5]				

(1) In connections for which $w_F \geq 0,35$, continuous fillet welding is to be adopted.
(2) For coefficient φ, see [2.3.4]. In connections for which no φ value is specified for a certain type of intermittent welding, such type is not permitted and continuous welding is to be adopted.
(3) CH = chain welding, SC = scallop welding, ST = staggered welding.
(4) Ends of ordinary stiffeners means the area extended 75 mm from the span ends. Where end brackets are fitted, ends means the area extended in way of brackets and at least 50 mm beyond the bracket toes.
(5) In tanks intended for the carriage of ballast or fresh water, continuous welding with $w_F = 0,35$ is to be adopted.
(6) For connections not mentioned, the requirements for the central part apply.
(7) A is the face plate sectional area of the side girders, in cm².

2.3.5 Throat thickness of fillet weld T connections

The throat thickness of fillet weld T connections is to be obtained, in mm, from the following formula:

$$t_T = w_F t \frac{p}{d}$$

where:

w_F : Welding factor, defined in Tab 2 for the various hull structural connections; for connections of primary supporting members belonging to single skin structures and not mentioned in Tab 2, w_F is defined in Tab 3

t : Actual gross thickness, in mm, of the structural element which constitutes the web of the T connection

p, d : Spacing and length, in mm, of an intermittent weld, defined in [2.3.4].

For continuous fillet welds, p/d is to be taken equal to 1.

In no case may the throat thickness be less than:

- 3,0 mm, where the gross thickness of the thinner plate is less than 6 mm
- 3,5 mm, otherwise.

The throat thickness may be required by the Society to be increased, depending on the results of structural analyses.

The leg length of fillet weld T connections is to be not less than 1,4 times the required throat thickness.

2.3.6 Weld dimensions in a specific case

Where intermittent fillet welding is adopted with:

- length d = 75 mm
- throat thickness t_T specified in Tab 4 depending on the thickness t defined in [2.3.5],

the weld spacing may be taken equal to the value p_1 defined in Tab 1. The values of p_1 in Tab 2 may be used when 8 mm ≤ t ≤ 16 mm.

For thicknesses t less than 8 mm, the values of p_1 may be increased, with respect to those in Tab 2, by:

- 10 mm, for chain or scallop welding
- 20 mm, for staggered welding,

without exceeding the limits given in [2.3.4].

For thicknesses t greater than 16 mm, the values of p_1 are to be reduced, with respect to those in Tab 2, by:

- 10 mm, for chain or scallop welding
- 20 mm, for staggered welding.

Table 3 : Welding factor w_F and coefficient φ for connections of primary supporting members

Primary supporting member	Connection of	Connection to		w_F **(1)**	φ **(2) (3)** CH	SC	ST	p_1, in mm (see [2.3.6])**(3)**
General**(4)**	web, where A < 65 cm²	plating and face plate	at ends	0,20				
			elsewhere	0,15	3,0	3,0		CH/SC 210
	web, where A ≥ 65 cm²	plating		0,35				
		face plate	at ends	0,35				
			elsewhere	0,25	1,8	1,8		CH/SC 130
	end brackets	face plate		0,35				
In tanks, where A < 65 cm² **(5)**	web	plating	at ends	0,25				
			elsewhere	0,20	2,2	2,2		CH/SC 160
		face plate	at ends	0,20				
			elsewhere	0,15	3,0	3,0		CH/SC 210
	end brackets	face plate		0,35				
In tanks, where A ≥ 65 cm²	web	plating	at ends	0,45				
			elsewhere	0,35				
		face plate		0,35				
	end brackets	face plate		0,45				

(1) In connections for which $w_F \geq 0,35$, continuous fillet welding is to be adopted.
(2) For coefficient φ, see [2.3.4]. In connections for which no φ value is specified for a certain type of intermittent welding, such type is not permitted.
(3) CH = chain welding, SC = scallop welding, ST = staggered welding.
(4) For cantilever deck beams, continuous welding is to be adopted.
(5) For primary supporting members in tanks intended for the carriage of ballast or fresh water, continuous welding is to be adopted.
Note 1: A is the face plate sectional area of the primary supporting member, in cm².
Note 2: Ends of primary supporting members means the area extended 20% of the span from the span ends. Where end brackets are fitted, ends means the area extended in way of brackets and at least 100 mm beyond the bracket toes.

Table 4 : Required throat thickness t_T

t, in mm	t_T, in mm	t, in mm	t_T, in mm
6	3,0	17	7,0
8	3,5	18	7,0
9	4,0	19	7,5
10	4,5	20	7,5
11	5,0	21	8,5
12	5,5	22	8,5
13	6,0	23	9,0
14	6,0	24	9,0
15	6,5	25	10,0
16	6,5	26	10,0

2.3.7 Throat thickness of welds between cut-outs

The throat thickness of the welds between the cut-outs in primary supporting member webs for the passage of ordinary stiffeners is to be not less than the value obtained, in mm, from the following formula:

$$t_{TC} = t_T \frac{\varepsilon}{\lambda}$$

where:

t_T : Throat thickness defined in [2.3.5]

ε, λ : Dimensions, in mm, to be taken as shown in:

- Fig 4, for continuous welding
- Fig 5, for intermittent scallop welding.

Figure 4 : Continuous fillet welding between cut-outs

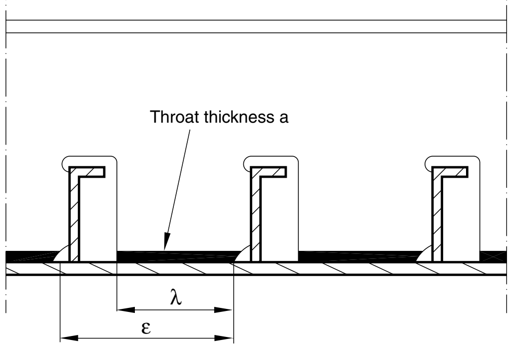

Figure 5 : Intermittent scallop fillet welding between cut-outs

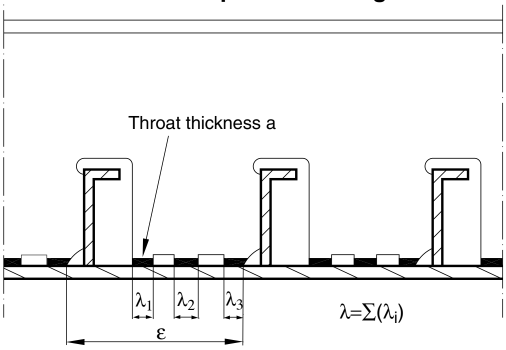


2.3.8 Throat thickness of welds connecting ordinary stiffeners with primary supporting members

The throat thickness of fillet welds connecting ordinary stiffeners and collar plates, if any, to the web of primary supporting members is to be not less than $0,35t_W$, where t_W is the web gross thickness, in mm. Further requirements are specified in Ch 11, Sec 2.

Where primary supporting member web stiffeners are welded to ordinary stiffener face plates, in certain cases the Society may require the above throat thickness to be obtained, in mm, from the following formula:

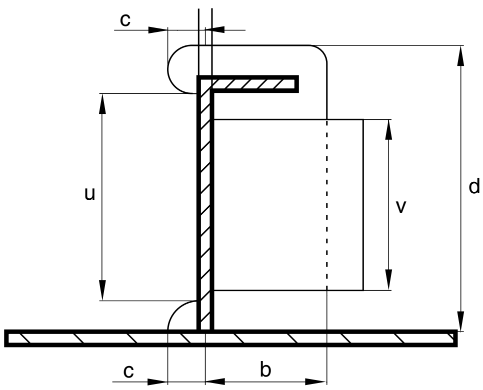
$$t_T = \frac{4(p_S + p_W)s\ell\left(1 - \frac{s}{2\ell}\right)}{u + v\left(\frac{c + 0,2d}{b + 0,2d}\right)}$$

where:

p_S, p_W : Still water and wave pressure, respectively, in kN/m², acting on the ordinary stiffener, defined in Ch 7, Sec 2, [3.3.2]

b,c,d,u,v: Main dimensions, in mm, of the cut-out shown in Fig 6.

Figure 6 : End connection of ordinary stiffener - Dimensions of the cut-out



2.3.9 Throat thickness of deep penetration fillet welding

When fillet welding is carried out with automatic welding procedures, the throat thickness required in [2.3.5] may be reduced up to 15%, depending on the properties of the electrodes and consumables. However, this reduction may not be greater than 1,5 mm.

The same reduction applies also for semi-automatic procedures where the welding is carried out in the downhand position.

2.4 Partial and full T penetration welding

2.4.1 General

Partial or full T penetration welding is to be adopted for connections subjected to high stresses for which fillet welding is considered unacceptable by the Society.

Partial or full T penetration welding is required, depending on the ship type. Further requirements are specified in Ch 11, Sec 2.

Typical edge preparations are indicated in:

- for partial penetration welds: Fig 7 and Fig 8, in which f, in mm, is to be taken between 3 mm and t/3, and α between 45° and 60°
- for full penetration welds: Fig 9 and Fig 10, in which f, in mm, is to be taken between 0 and 3 mm, and α between 45° and 60°.

  Back gouging is generally required for full penetration welds.

2.4.2 Lamellar tearing

Precautions are to be taken in order to avoid lamellar tears, which may be associated with:

- cold cracking when performing T connections between plates of considerable thickness or high restraint
- large fillet welding and full penetration welding on higher strength steels.

Figure 7 : Partial penetration weld

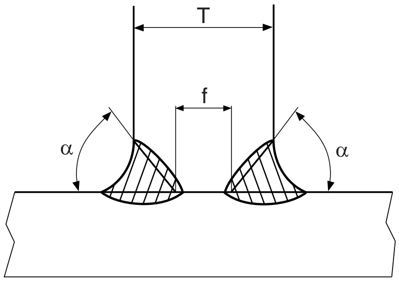


Figure 8 : Partial penetration weld

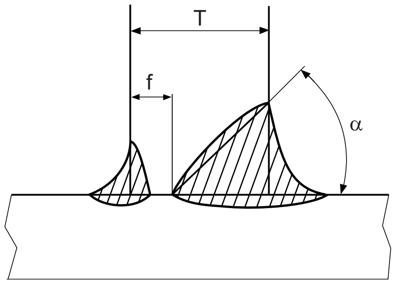

Figure 9 : Full penetration weld

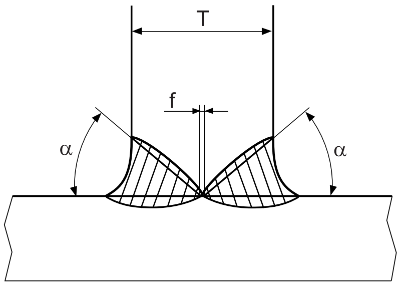

Figure 10 : Full penetration weld

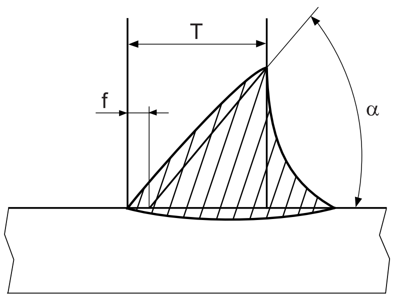


2.5 Lap-joint welding

2.5.1 General

Lap-joint welding may be adopted for:

- peripheral connection of doublers
- internal structural elements subjected to very low stresses.

Elsewhere, lap-joint welding may be allowed by the Society on a case-by-case basis, if deemed necessary under specific conditions.

Continuous welding is generally to be adopted.

2.5.2 Gap

The surfaces of lap-joints are to be in sufficiently close contact.

2.5.3 Dimensions

The dimensions of the lap-joint are to be specified and are considered on a case-by-case basis. Typical details are given in Ch 11, App 1, [1.3].

2.6 Slot welding

2.6.1 General

Slot welding may be adopted in very specific cases subject to the special agreement of the Society, e.g. for doublers according to Ch 4, Sec 3, [2.1].

In general, slot welding of doublers on the outer shell and strength deck is not permitted within 0,6 L amidships. Beyond this zone, slot welding may be accepted by the Society on a case-by-case basis.

Slot welding is, in general, permitted only where stresses act in a predominant direction. Slot welds are, as far as possible, to be aligned in this direction.

2.6.2 Dimensions

Slot welds are to be of appropriate shape (in general oval) and dimensions, depending on the plate thickness, and may not be completely filled by the weld.

Typical dimensions of the slot weld and the throat thickness of the fillet weld are given in Ch 11, App 1.

The distance between two consecutive slot welds is to be not greater than a value which is defined on a case-by-case basis taking into account the:

- transverse spacing between adjacent slot weld lines
- stresses acting in the connected plates
- structural arrangement below the connected plates.

2.7 Plug welding

2.7.1 Plug welding may be adopted only when accepted by the Society on a case-by-case basis, according to specifically defined criteria. Typical details are given in Ch 11, App 1.

3 Specific weld connections

3.1 Corner joint welding

3.1.1 Corner joint welding, as adopted in some cases at the corners of tanks, performed with ordinary fillet welds, is permitted provided the welds are continuous and of the required size for the whole length on both sides of the joint.

3.1.2 Alternative solutions to corner joint welding may be considered by the Society on a case-by-case basis.

3.2 Bilge keel connection

3.2.1 Except where indicated, the following requirements apply to single web bilge keels. Additional requirements for other types of design will be considered on a case-by-case basis.

3.2.2 The ground bar is to be connected to the shell with a continuous fillet weld, and the bilge keel to the ground bar with a continuous fillet weld in accordance with Tab 5. Throat thicknesses differing from these values will be specially considered by the Society, if designed so that joints between the bilge keel and ground bar will fail before the joints between the ground bar and shell.

3.2.3 In the case of box type bilge keels, direct connection of members to the shell (i.e. without doublers) is to be by continuous full tee penetration welding. The type of bevel and the gap between the members to be assembled are to be such as to ensure a proper penetration of the welds.

3.2.4 Butt welds, in the bilge keel and ground bar, are to be well clear of each other and of butts in the shell plating as shown in Fig 11. In general, shell butts are to be flush in way of the ground bar and ground bar butts are to be flush in way of the bilge keel. Direct connection between ground bar butt welds and shell plating is not permitted. This may be obtained by use of removable backing.

In the case of box type bilge keels, the butt welds in longitudinal members of the bilge keel are to be shifted from the shell butts.

3.2.5 At the ends of the ground bar, the throat thickness is to be increased as given in Tab 5, without exceeding 0,707 times the as-built thickness of the ground bar as shown in Fig 11. The welded transition at the ends of the ground bar to the plating connection should be formed with the weld flank angle of 45° or less.

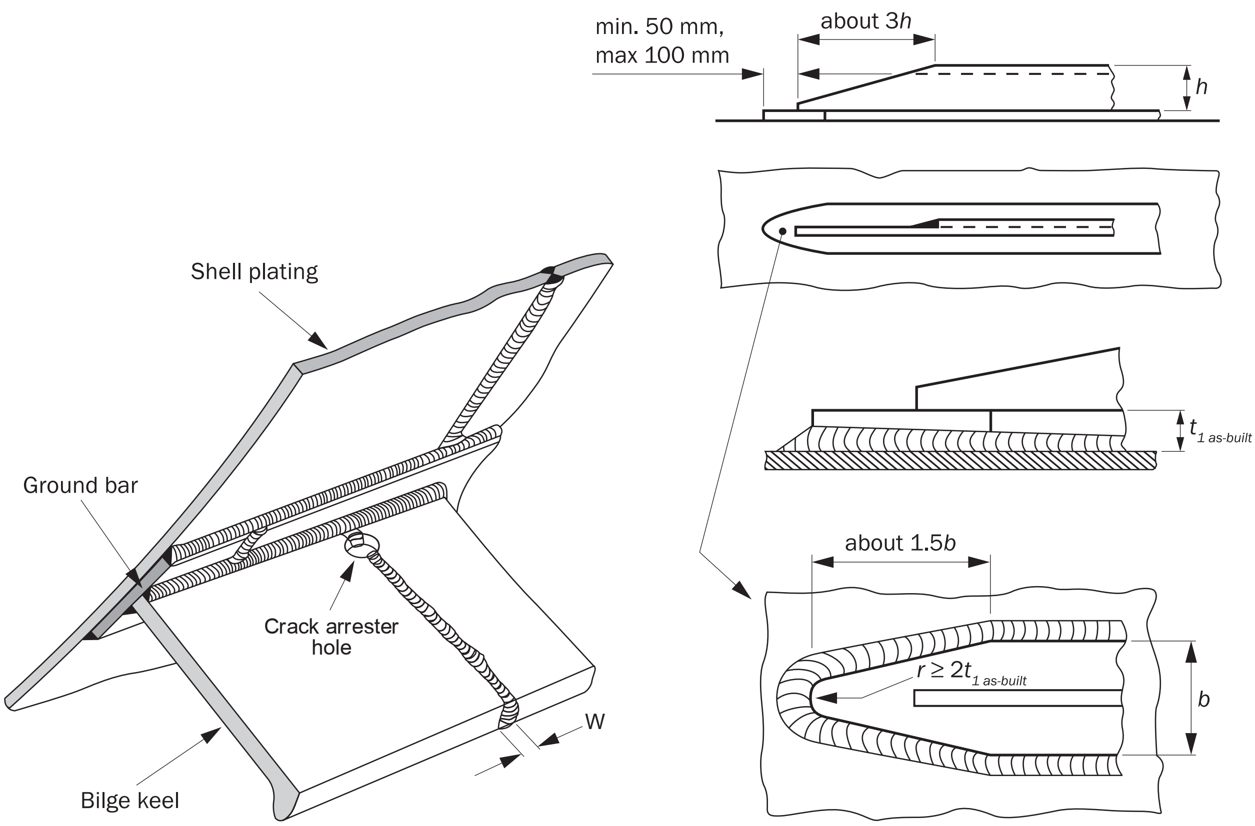
3.2.6 In general, scallops and cut-outs are not to be used in single web bilge keels. Crack arresting holes are to be drilled in the bilge keel butt welds as close as practicable to the ground bar. The diameter of the hole is to be greater than the width W of the butt weld and is to be a minimum of 25 mm. Where the butt weld has been subject to non-destructive examination, the crack arresting hole may be omitted.

Table 5 : Connections of single web bilge keels

Structural items being joined	Throat thickness of weld, in mm	
	At ends **(1)**	Elsewhere
Ground bar to the shell	0,44 $t_{1as\text{-}built}$	0,34 $t_{1as\text{-}built}$
Bilge keel web to ground bar	0,34 $t_{2as\text{-}built}$	0,21 $t_{2as\text{-}built}$

$t_{1as\text{-}built}$: As-built thickness of ground bar, in mm
$t_{2as\text{-}built}$: As-built thickness of web of bilge keel, in mm.
(1) Zone “b” in Ch 4, Sec 4, Fig 3 and Ch 4, Sec 4, Fig 4 for definition of “ends”

Figure 11 : Connections of single web bilge keels



3.3 Connection between propeller post and propeller shaft bossing

3.3.1 Fabricated propeller posts are to be welded with full penetration welding to the propeller shaft bossing.

3.4 Bar stem connection

3.4.1 The bar stem is to be welded to the bar keel generally with butt welding.

The shell plating is also to be welded directly to the bar stem with butt welding.

4 Workmanship

4.1 Welding procedures and consumables

4.1.1 The various welding procedures and consumables are to be used within the limits of their approval and in accordance with the conditions of use specified in the respective approval documents.

4.2 Welding operations

4.2.1 Weather protection

Adequate protection from the weather is to be provided to parts being welded; in any event, such parts are to be dry.

In welding procedures using bare, cored or coated wires with gas shielding, the welding is to be carried out in weather protected conditions, so as to ensure that the gas outflow from the nozzle is not disturbed by winds and draughts.

4.2.2 Butt connection edge preparation

The edge preparation is to be of the required geometry and correctly performed. In particular, if edge preparation is carried out by flame, it is to be free from cracks or other detrimental notches.

Recommendations for edge preparation are given in the "Guide for welding".

4.2.3 Surface condition

The surfaces to be welded are to be free from rust, moisture and other substances, such as mill scale, slag caused by oxygen cutting, grease or paint, which may produce defects in the welds.

Effective means of cleaning are to be adopted particularly in connections with special welding procedures; flame or mechanical cleaning may be required.

The presence of a shop primer may be accepted, provided it has been approved by the Society.

Shop primers are to be approved by the Society for a specific type and thickness according to NR216 Materials and Welding, Ch 5, Sec 3.

4.2.4 Assembling and gap

The setting appliances and system to be used for positioning are to ensure adequate tightening adjustment and an appropriate gap of the parts to be welded, while allowing maximum freedom for shrinkage to prevent cracks or other defects due to excessive restraint.

The gap between the edges is to comply with the required tolerances or, when not specified, it is to be in accordance with normal good practice.

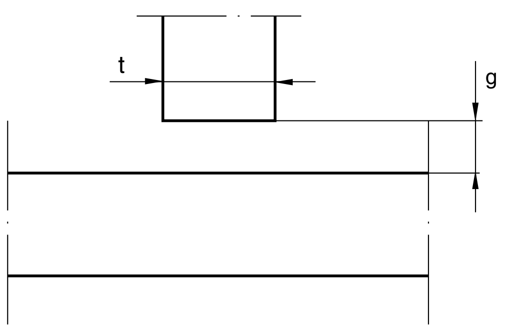
4.2.5 Gap in fillet weld T connections

In fillet weld T connections, a gap g, as shown in Fig 12, not greater than 2 mm may be accepted without increasing the throat thickness calculated according to [2.3.5] to [2.3.9], as applicable.

In the case of a gap greater than 2 mm, the above throat thickness is to be increased accordingly as specified in Ch 11, Sec 2 for some special connections of various ship types.

In any event, the gap g may not exceed 4 mm.

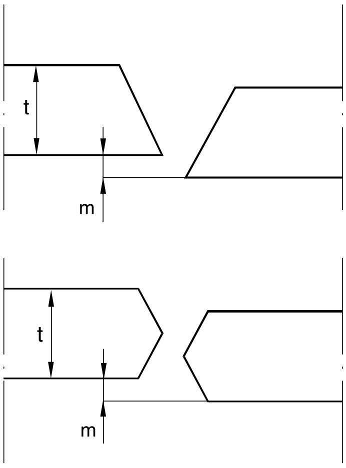
Figure 12 : Gap in fillet weld T connections



4.2.6 Plate misalignment in butt connections

The misalignment m, measured as shown in Fig 13, between plates with the same gross thickness t is to be less than 0,15 t, without being greater than 3 mm.

Figure 13 : Plate misalignment in butt connections



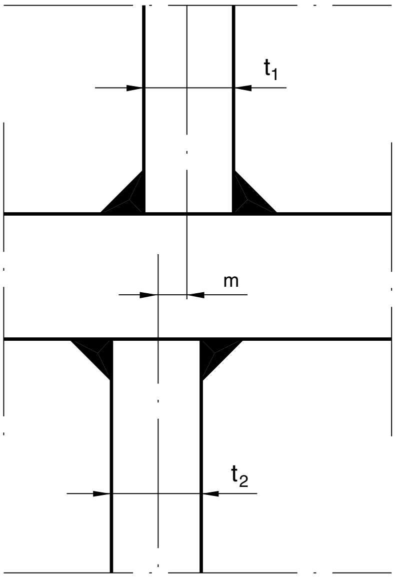
4.2.7 Misalignment in cruciform connections

The misalignment m in cruciform connections, measured on the median lines as shown in Fig 14, is to be less than:

- t/2, in general, where t is the gross thickness of the thinner abutting plate
- the values specified in Ch 11, Sec 2 for some special connections of various ship types.

The Society may require lower misalignment to be adopted for cruciform connections subjected to high stresses.

Figure 14 : Misalignment in cruciform connections



4.2.8 Assembling of aluminium alloy parts

When welding aluminium alloy parts, particular care is to be taken so as to:

- reduce as far as possible restraint from welding shrinkage, by adopting assembling and tack welding procedures suitable for this purpose
- keep possible deformations within the allowable limits.

4.2.9 Preheating and interpass temperatures

Suitable preheating, to be maintained during welding, and slow cooling may be required by the Society on a case-by-case basis.

4.2.10 Welding sequences

Welding sequences and direction of welding are to be determined so as to minimize deformations and prevent defects in the welded connection.

All main connections are generally to be completed before the ship is afloat.

Departures from the above provision may be accepted by the Society on a case-by-case basis, taking into account any detailed information on the size and position of welds and the stresses of the zones concerned, both during ship launching and with the ship afloat.

4.2.11 Interpass cleaning

After each run, the slag is to be removed by means of a chipping hammer and a metal brush; the same precaution is to be taken when an interrupted weld is resumed or two welds are to be connected.

4.2.12 Stress relieving

It is recommended and in some cases it may be required that special structures subject to high stresses, having complex shapes and involving welding of elements of considerable thickness (such as rudder spades and stern frames), are prefabricated in parts of adequate size and stress-relieved in the furnace, before final assembly, at a temperature within the range 550°C ÷ 620°C, as appropriate for the type of steel. Concerned structures are agreed on case-by-case basis.

4.3 Crossing of structural elements

4.3.1 In the case of T crossing of structural elements (one element continuous, the other physically interrupted at the crossing) when it is essential to achieve structural continuity through the continuous element (continuity obtained by means of the welded connections at the crossing), particular care is to be devoted to obtaining the correspondence of the interrupted elements on both sides of the continuous element. Suitable systems for checking such correspondence are to be adopted.

5 Modifications and repairs during construction

5.1 General

5.1.1 Deviations in the joint preparation and other specified requirements, in excess of the permitted tolerances and found during construction, are to be repaired as agreed with the Society on a case-by-case basis.

5.2 Gap and weld deformations

5.2.1 Welding by building up of gaps exceeding the required values and repairs of weld deformations may be accepted by the Society upon special examination.

5.3 Defects

5.3.1 Defects and imperfections on the materials and welded connections found during construction are to be evaluated for possible acceptance on the basis of the applicable requirements of the Society.

Where the limits of acceptance are exceeded, the defective material and welds are to be discarded or repaired, as deemed appropriate by the Surveyor on a case-by-case basis.

When any serious or systematic defect is detected either in the welded connections or in the base material, the manufacturer is required to promptly inform the Surveyor and submit the repair proposal.

The Surveyor may require destructive or non-destructive examinations to be carried out for initial identification of the defects found and, in the event that repairs are undertaken, for verification of their satisfactory completion.

5.4 Repairs on structures already welded

5.4.1 In the case of repairs involving the replacement of material already welded on the hull, the procedures to be adopted are to be agreed with the Society on a case-by-case basis.

6 Inspections and checks

6.1 General

6.1.1 Materials, workmanship, structures and welded connections are to be subjected, at the beginning of the work, during construction and after completion, to inspections by the Shipbuilder suitable to check compliance with the applicable requirements, approved plans and standards.

6.1.2 The Shipbuilder is to make available to the Surveyor a list of the manual welders and welding operators and their respective qualifications.

The Shipbuilder's internal organisation is responsible for ensuring that welders and operators are not employed under improper conditions or beyond the limits of their respective valid qualifications and that welding procedures are adopted within the approved limits and under the appropriate operating conditions.

6.1.3 The Shipbuilder is responsible for ensuring that the operating conditions, welding procedures and work schedule are in accordance with the applicable requirements, approved plans and recognised good welding practice.

6.1.4 The Shipbuilder is responsible for ensuring that non-destructive examination (NDE) procedures and plans are adhered to during the construction and that NDE reports are made available to the Society.

6.2 Non-destructive examination (NDE)

6.2.1 Non-destructive examination techniques refer to the testing methods applicable to the detection of surface imperfections (Visual Testing, Magnetic particle Testing, Liquid penetrant Testing) or sub-surface imperfections (Ultrasonic Testing, Radiographic Testing).

6.2.2 NDE of hull welds are to be performed in accordance with written procedures accepted by the Society. Such procedures are to contain appropriate details about the applied codes or standards, testing method, equipment, calibration, testing conditions and personnel qualification. For each NDE technique, appropriate details means typically the details described in IACS Recommendation 20.

6.2.3 The NDE acceptance criteria defined by the Shipbuilder are to be submitted to the Society and should comply with the IACS Recommendation 20 or with a recognized standard which has been accepted by the Society.

Where applicable, specific criteria defined in Ch 11, Sec 2, for special structural details are to be referred to.

6.2.4 All finished welds are to be subjected to visual testing by the Shipbuilder's qualified personnel.

6.2.5 After completion of the welding operation and workshop inspection, the structure is to be presented to the Surveyor for general visual examination at a suitable stage of fabrication.

As far as possible, the results on non-destructive examinations are to be submitted.

6.2.6 Radiographic testing is to be carried out on the welded connections of the hull in accordance with [6.3]. The results are to be made available to the Society. The Surveyor may require to witness some testing preparations.

6.2.7 The Society may accept radiographic testing to be replaced by ultrasonic testing.

6.2.8 The Shipbuilder's NDE plan describing the extent, type and location of NDE is to be submitted to the Society for acceptance.

6.2.9 When the non-destructive examinations reveal the presence of unacceptable indications, the relevant connection is to be repaired to an extent and according to a procedure agreed with the Surveyor.

The repaired zone is then to be submitted to non-destructive examination, using a method deemed suitable by the Surveyor to verify that the repair is satisfactory.

Additional examinations may be required by the Surveyor on a case-by-case basis.

6.2.10 Ultrasonic and magnetic particle testing may also be required by the Surveyor in specific cases to check the base material.

6.3 Radiographic testing

6.3.1 Radiographic testing is to be carried out on the welded butts of shell plating, strength deck plating as well as of members contributing to the longitudinal strength.

Radiographic Testing may also be required for the joints of members subject to heavy stresses.

The requirements [6.3.2] to [6.3.5] constitute general rules: the number of radiographs may be increased where requested by the Surveyor, mainly where visual inspection or radiographic soundings have revealed major defects, specially for butts of sheerstrake, stringer plate, bilge strake or keel plate.

Provisions alteration to these rules may be accepted by the Society when justified by the organisation of the Shipbuilder or of the inspection department. The inspection is then to be equivalent to that deduced from [6.3.2] to [6.3.5].

6.3.2 As far as automatic welding of the panels butt welds during the premanufacturing stage is concerned, the Shipbuilder is to carry out random non-destructive testing of the welds (radiographic or ultrasonic testing) in order to ascertain the regularity and the constancy of the welding inspection.

6.3.3 In the midship area, radiographies are to be taken at the joinings of panels.

Each radiography is situated in a butt joint at a cross-shaped welding.

In a given ship cross-section bounded by the panels, a radiography is to be made of each butt of sheerstrake, stringer, bilge and keel plate; in addition, the following radiographies are to be taken:

- bottom plating: two
- deck plating: two
- side shell plating: two on each side.

For ships where $B + D \leq 15$ m, only one radiography for each of the above items is required.

This requirement remains applicable where panel butts are shifted or where some strakes are built independently from the panels. It is recommended to take most of these radiographies at the intersections of butt and panel seams.

Still in the midship area, radiographic testing is to be carried out, at random, of the following main members of the structure:

- butts of continuous longitudinal bulkheads
- butts of longitudinal stiffeners, deck and bottom girders contributing to the overall strength
- assembly joints of insert plates at the corners of the openings.

Moreover, radiographic testing is to be carried out, at random, of the weldings of the bilge keel and of intermediate flat.

6.3.4 Outwards the midship area, a programme of radiographic testing at random is to be set up by the Shipbuilder in agreement with the Surveyor for the major points. It is further recommended to take:

- a number of radiographies of the very thick parts and those comprising restrained joint, such as sternframes, shaft brackets, stabiliser recesses, masts
- a complete set of radiographies or to increase the number of radiographies for the first joint of a series of identical joints. This recommendation is applicable not only to the assembly joints of prefabricated members completed on the slip, but also to joints completed in the workshop to prepare such prefabricated members.

6.3.5 Where a radiography is rejected and where it is decided to carry out a repair, the Shipbuilder is to determine the length of the defective part, then a set of radiographies of the repaired joint and of adjacent parts is to be taken. Where the repair has been decided by the inspection office of the Shipbuilder, the film showing the initial defect is to be submitted to the Surveyor together with the film taken after repair of the joint.

Section 2 Special Structural Details

Symbols

T_B : Ship draught in light ballast condition, see Ch 5, Sec 1, [2.4.3].

1 General

1.1 Application

1.1.1 Special structural details are those characterized by complex geometry, possibly associated with high or alternate stresses.

1.1.2 For special structural details, specific requirements are to be fulfilled during:

- design
- construction
- selection of materials
- welding
- survey.

The purpose of these requirements is specified in [1.2] to [1.6].

1.1.3 Special structural details are those listed in Article [2] together with the specific requirements which are to be fulfilled.

Other structural details may be considered by the Society as special details, when deemed necessary on the basis of the criteria in [1.1.1]. The criteria to be fulfilled in such cases are defined by the Society on a case-by-case basis.

1.1.4 As regards matters not explicitly specified in Article [2], the rule requirements are to be complied with in any event, in particular:

- Part B, Chapter 4 for design principles and structural arrangements
- Part B, Chapter 7 for structural scantling
- Part B, Chapter 11 for construction and welding requirements
- the applicable requirements in Part D and Part E.

1.2 Design requirements

1.2.1 General requirements

Design requirements specify:

- the local geometry, dimensions and scantlings of the structural elements which constitute the detail
- any local strengthening
- the cases where a fatigue check is to be carried out according to Ch 7, Sec 4.

1.2.2 Fatigue check requirements

Where a fatigue check is to be carried out, the design requirements specify (see Ch 7, Sec 4, [1.1]):

- the locations (hot spots) where the stresses are to be calculated and the fatigue check performed
- the direction in which the normal stresses are to be calculated
- the stress concentration factors K_h and $K\ell$ to be used for calculating the hot spot stress range.

1.3 Constructional requirements

1.3.1 Constructional requirements specify the allowable misalignment and tolerances, depending on the detail arrangement and any local strengthening.

1.4 Material requirements

1.4.1 Material requirements specify the material quality to be used for specific elements which constitute the detail, depending on their manufacturing procedure, the type of stresses they are subjected to, and the importance of the detail with respect to the ship operation and overall safety.

In addition, these requirements specify where material inspections are to be carried out.

1.5 Welding requirements

1.5.1 Welding requirements specify where partial or full T penetration welding (see Ch 11, Sec 1, [2.4]) or any particular welding type or sequence is to be adopted. In addition, these requirements specify when welding procedures are to be approved.

Since weld shape and undercuts are influencing factors on fatigue behaviour, fillet welds are to be elongated in the direction of the highest stresses and care is to be taken to avoid undercuts, in particular at the hot spots.

1.6 Survey requirements

1.6.1 Survey requirements specify where non-destructive examinations of welds are to be carried out and, where this is the case, which type is to be adopted.

2 List and characteristics of special structural details

2.1 General

2.1.1 This Article lists and describes, depending on the ship type, the special structural details and specifies the specific requirements which are to be fulfilled according to [1.2] to [1.6]. This is obtained through:

- a description of the hull areas where the details are located
- the detail description
- the requirements for the fatigue check
- a reference to a sheet in the Appendixes where a picture of the detail is shown together with the specific requirements which are to be fulfilled.

2.1.2 The special structural details relevant to all types of longitudinally framed ships are listed and described in Tab 1.

Table 1 : Special structural details

Area reference number	Area description	Detail description	Fatigue check	Reference tables in Ch 11, App 2
1	Part of side extended: • longitudinally, between the after peak bulkhead and the collision bulkhead • vertically, between 0,7 T_B and 1,15 T from the baseline	Connection of side longitudinal ordinary stiffeners with transverse primary supporting members	No	Ch 11, App 2, Tab 1 to Ch 11, App 2, Tab 6
		Connection of side longitudinal ordinary stiffeners with stiffeners of transverse primary supporting members, or transverse bulkheads	for $L \geq 90$ m	Ch 11, App 2, Tab 7 to Ch 11, App 2, Tab 13
2	Double bottom in way of transverse bulkheads	Connection of bottom and inner bottom longitudinal ordinary stiffeners with floors	for $L \geq 90$ m	Ch 11, App 2, Tab 14 to Ch 11, App 2, Tab 17
3	Hatch corners	Deck plating in way of hatch corners	No	Ch 11, App 2, Tab 18
		Ends of longitudinal hatch coamings	No	Ch 11, App 2, Tab 19 and Ch 11, App 2, Tab 20

Section 3 Testing

1 Pressure tests

1.1 Application

1.1.1 The following requirements determine the testing conditions for:

- gravity tanks, excluding independent tanks of less than 5m^3 in capacity
- watertight or weathertight structures.

The purpose of these tests is to check the tightness and/or the strength of structural elements.

1.1.2 Tests are to be carried out in the presence of the Surveyor at a stage sufficiently close to completion so that any subsequent work would not impair the strength and tightness of the structure.

In particular, tests are to be carried out after air vents and sounding pipes are fitted.

When tests are performed before final air vents and sounding pipes are fitted, temporary air vents and sounding pipes may be accepted, provided they are deemed equivalent by the Surveyor.

1.1.3 The Society may accept that structural testing of a sister ship is limited to a single tank for each type of structural arrangement.

However, if the Surveyor detects anomalies, he may require the number of tests is increased or that the same number of tests is provided as for the first ship in a series.

1.2 Definitions

1.2.1 Shop primer

Shop primer is a thin coating applied after surface preparation and prior to fabrication as a protection against corrosion during fabrication.

1.2.2 Protective coating

Protective coating is a final coating protecting the structure from corrosion.

1.2.3 Structural testing

Structural testing is a hydrostatic test carried out to demonstrate the tightness of the tanks and the structural adequacy of the design. Where practical limitations prevail and hydrostatic testing is not feasible (for example when it is difficult, in practice, to apply the required head at the top of the tank), hydropneumatic testing may be carried out instead.

Structural testing is to be carried out according to [2.2].

1.2.4 Hydropneumatic testing

Hydropneumatic testing is a combination of hydrostatic and air testing, consisting in filling the tank to the top with water and applying an additional air pressure.

Hydropneumatic testing is to be carried out according to [2.3].

1.2.5 Leak testing

Leak testing is an air or other medium test carried out to demonstrate the tightness of the structure.

Leak testing is to be carried out according to [2.4].

1.2.6 Hose testing

Hose testing is carried out to demonstrate the tightness of structural items not subjected to hydrostatic or leak testing and of other components which contribute to the watertight or weathertight integrity of the hull.

Hose testing is to be carried out according to [2.5].

1.2.7 Sister ship

A sister ship is a ship having the same main dimensions, general arrangement, capacity plan and structural design as those of the first ship in a series.

2 Watertight compartments

2.1 General

2.1.1 The requirements in [2.1] to [2.6] intend generally to verify the adequacy of the structural design of the tanks, based on the loading conditions which prevailed when determining the tank structure scantlings.

2.1.2 General requirements for testing of watertight compartments are given in Tab 1, in which the types of testing referred to are defined in [1.2].

2.2 Structural testing

2.2.1 Structural testing may be carried out before or after launching.

2.2.2 Structural testing may be carried out after application of the shop primer.

2.2.3 Structural testing may be carried out after the protective coating has been applied, provided that one of the following two conditions is satisfied:

- all the welds are completed and carefully inspected visually to the satisfaction of the Surveyor prior to the application of the protective coating
- leak testing is carried out prior to the application of the protective coating.

In the absence of leak testing, protective coating is to be applied after the structural testing of:

- all erection welds, both manual and automatic
- all manual fillet weld connections on tank boundaries and manual penetration welds.

2.3 Hydropneumatic testing

2.3.1 When a hydropneumatic testing is performed, the conditions are to simulate, as far as practicable, the actual loading of the tank.

The value of the additional air pressure is at the discretion of the Society, but is to be at least as defined in [2.4.2] for leak testing.

The same safety precautions as for leak testing (see [2.4.2]) are to be adopted.

2.4 Leak testing

2.4.1 An efficient indicating liquid, such as a soapy water solution, is to be applied to the welds.

2.4.2 Where leak testing is carried out, in accordance with Tab 1, an air pressure of $0,15 \cdot 10^5$ Pa is to be applied during the test.

Prior to inspection, it is recommended that the air pressure in the tank should be raised to $0,2 \cdot 10^5$ Pa and kept at this level for approximately 1 hour to reach a stabilized state, with a minimum number of personnel in the vicinity of the tank, and then lowered to the test pressure.

The test may be conducted after the pressure has reached a stabilized state at $0,2 \cdot 10^5$ Pa, without lowering the pressure, provided the Society is satisfied of the safety of the personnel involved in the test.

2.4.3 A U-tube filled with water up to a height corresponding to the test pressure is to be fitted to avoid overpressure of the compartment tested and verify the test pressure.

The U-tube is to have a cross-section larger than that of the pipe supplying air.

In addition, the test pressure is also to be verified by means of one master pressure gauge.

Alternative means which are considered to be equivalently reliable may be accepted at the discretion of the Surveyor.

2.4.4 Leak testing is to be carried out, prior to the application of a protective coating, on all fillet weld connections on tank boundaries, and penetration and erection welds on tank boundaries excepting welds made by automatic processes.

Selected locations of automatic erection welds and pre-erection manual or automatic welds may be required to be similarly tested to the satisfaction of the Surveyor, taking account of the quality control procedures operating in the shipyard.

For other welds, leak testing may be carried out after the protective coating has been applied, provided that such welds have been carefully inspected visually to the satisfaction of the Surveyor.

2.4.5 Any other recognized method may be accepted to the satisfaction of the Surveyor.

2.5 Hose testing

2.5.1 When hose testing is required to verify the tightness of the structures, as defined in Tab 1, the minimum pressure in the hose, at least equal to $2,0 \cdot 10^5$ Pa, is to be applied at a maximum distance of 1,5 m.

The nozzle diameter is to be not less than 12 mm.

Table 1 : Watertight compartments - General testing requirements

<table>
<tr><th>Compartment or structure to be tested</th><th>Type of testing</th><th>Structural test pressure</th><th>Remarks</th></tr>
<tr><td>Double bottom tanks</td><td>Structural (1)</td><td>The greater of the following:
• head of water up to the top of overflow
• head of water up to the margin line</td><td>Tank boundaries tested from at least one side</td></tr>

</table>

(1) Hydropneumatic or leak testing may be accepted under the conditions specified in [2.3] and [2.4], respectively, provided that at least one tank of each type is structurally tested, to be selected in connection with the approval of the design. In general, structural testing need not be repeated for subsequent ships of a series of identical new buildings. If the structural test reveals weakness or severe faults not detected by the leak test, all tanks are to be structurally tested.
(2) Where applicable, the highest point of the tank is to be measured to deck and excluding hatches.
(3) Hydropneumatic or leak testing may be accepted under the conditions specified in [2.3] and [2.4], respectively, when, at the Society’s discretion, it is considered significant also in relation to the construction techniques and the welding procedures adopted.
(4) When a hose test cannot be performed without damaging possible outfitting (machinery, cables, switchboards, insulation, etc.) already installed, it may be replaced, at the Society’s discretion, by a careful visual inspection of all the crossings and welded joints. Where necessary, a dye penetrant test or ultrasonic leak test may be required.
(5) The means of closure are to be subjected to a hose test after fitting on board.
(6) A prototype pressure test of each type and size of hatch may be carried out instead of individual hatch tests.

2.6 Other testing methods

2.6.1 Other testing methods may be accepted, at the discretion of the Society, based upon equivalency considerations.

3 Miscellaneous

3.1 Watertight decks, trunks, etc.

3.1.1 *After completion, a hose or flooding test is to be applied to watertight decks and a hose test to watertight trunks, tunnels and ventilators.*

3.2 Doors in bulkheads above the bulkhead deck

3.2.1 Doors are to be designed and constructed as weathertight doors and, after installation, subjected to a hose test from each side for weathertightness.

3.3 Semi-watertight doors

3.3.1 These means of closure are to be subjected to a structural test at the manufacturer's works. The head of water is to be up to the highest waterline after damage at the equilibrium of the intermediate stages of flooding. The duration of the test is to be at least 30 min.

A leakage quantity of approximately 100 l/hour is considered as being acceptable for a 1,35 m^2 opening.

The means of closure are to be subjected to a hose test after fitting on board.

3.4 Steering nozzles

3.4.1 Upon completion of manufacture, the nozzle is to be subjected to a leak test.

3.5 Working test of windlass

3.5.1 The working test of the windlass is to be carried out on board in the presence of a Surveyor.

3.5.2 The test is to demonstrate that the windlass complies with the requirements of Ch 9, Sec 4, [3.6] and, in particular, that it works adequately and has sufficient power to successively weigh the two bower anchors (excluding the housing of the anchors in the hawse pipe) when both are suspended to 82,5 m of chain cable, at a speed not less than 9 m/min.

3.5.3 Where two windlasses operating separately on each chain cable are adopted, the weighing test is to be carried out for both, weighing an anchor suspended to 82,5m of chain cable and verifying that speed for the weighing (excluding the housing in the hawse pipe) is not less than 9m/min.

Appendix 1 Welding Details

1 Contents

1.1 General

1.1.1 Types and edge plate preparation of the manual welds carried out on the various parts of the hull are dealt with in this Appendix.
Other types and tolerances may be used after special examination of the Society.

1.1.2 The method used to prepare the parts to be welded is left to the discretion of each shipyard, according to its own technology and experience. It is approved at the same time as the approval of the welding procedures referred to in Ch 11, Sec 1, [1.3.1].

1.2 Butt welding edge preparation

1.2.1 Typical butt weld plate edge preparation for manual welding is specified in Tab 1 and Tab 2.

1.3 Lap-joint, slot and plug welding

1.3.1 Welding details of lap-joint, slot and plug welds are specified in Tab 3.

Table 1 : Typical butt weld plate edge preparation (manual welding) - See Note 1

Detail	Standard
Single vee butt, one side welding with backing strip (temporary or permanent) 	$3 \leq G \leq 9$ mm $30° \leq \theta \leq 45°$
Single vee butt 	$G \leq 3$ mm $50° \leq \theta \leq 70°$ $R \leq 3$ mm
Note 1: Different plate edge preparation may be accepted or approved by the Society on the basis of an appropriate welding procedure specification.	

Table 2 : Typical butt weld plate edge preparation (manual welding) - See Note 1

Detail	Standard
Square butt 	t ≤ 5 mm G = 3 mm
Single bevel butt 	t > 5 mm G ≤ 3 mm R ≤ 3 mm 50° ≤ θ ≤ 70°
Double bevel butt 	t > 19 mm G ≤ 3 mm R ≤ 3 mm 50° ≤ θ ≤ 70°
Double vee butt, uniform bevels 	G ≤ 3 mm R ≤ 3 mm 50° ≤ θ ≤ 70°
Double vee butt, non-uniform bevels 	G ≤ 3 mm R ≤ 3 mm 6 ≤ h ≤ t/3 mm θ = 50° α = 90°
Note 1: Different plate edge preparation may be accepted or approved by the Society on the basis of an appropriate welding procedure specification.	

Table 3 : Typical lap joint, plug and slot welding (manual welding)

Detail	Standard	Remark
Fillet weld in lap joint 	$b = 2\ t_2 + 25$ mm	location of lap joint to be approved by the Society
Fillet weld in joggled lap joint 	$b \geq 2\ t_2 + 25$ mm	
Plug welding 	• $t \leq 12$ mm $\ell = 60$ mm $R = 6$ mm $40° \leq \theta \leq 50°$ $G = 12$ mm $L > 2\ \ell$ • $12 \text{ mm} < t \leq 25$ mm $\ell = 80$ mm $R = 0,5\ t$ mm $\theta = 30°$ $G = t$ mm $L > 2\ \ell$	
Slot welding 	• $t \leq 12$ mm $G = 20$ mm $\ell = 80$ mm $2\ \ell \leq L \leq 3\ \ell$, max 250 mm • $t > 12$ mm $G = 2\ t$ $\ell = 100$ mm $2\ \ell \leq L \leq 3\ \ell$, max 250 mm	

Appendix 2 Reference Sheets for Special Structural Details

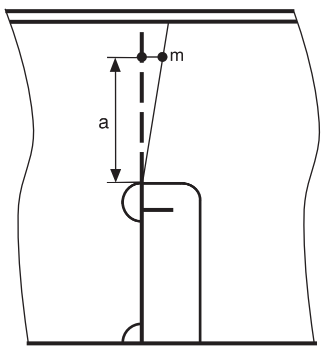
1 Contents

1.1 General

1.1.1 This Appendix includes the reference sheets for special structural details, as referred to in Ch 11, Sec 2.

Table 1 :

AREA 1: Side between $0,7T_B$ and $1,15T$ from the baseline	Connection of side longitudinal ordinary stiffeners with transverse primary supporting members - No collar plate	Sheet 1.1



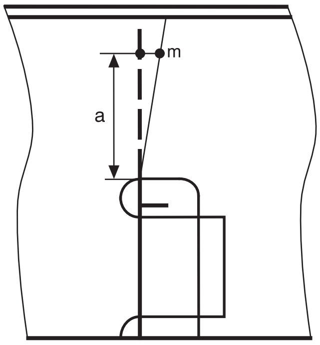
t_W = web thickness of transverse primary supporting member

SCANTLINGS:	FATIGUE:
Net sectional area of the web stiffener according to Ch 4, Sec 3, [4.7].	Fatigue check not required.
CONSTRUCTION:	**NDE:**
• Web stiffener not compulsory. When fitted, its misalignment m with the web of the side longitudinal ≤ a / 50. • Cut-outs in the web free of sharp notches. • Gap between web and side longitudinal to be not greater than 4 mm.	Visual examination 100%.
WELDING AND MATERIALS:	

Welding requirements:
- continuous fillet welding along the connection of web with side longitudinal,
- throat thickness according to Ch 11, Sec 1, [2.3.7]; in case of gap g greater than 2 mm, increase the throat thickness by 0,7 (g – 2) mm,
- weld around the cuts in the web at the connection with the longitudinal and the side shell,
- avoid burned notches on web.

Table 2 :

AREA 1: Side between $0,7T_B$ and 1,15T from the baseline	Connection of side longitudinal ordinary stiffeners with transverse primary supporting members - One collar plate	Sheet 1.2



t_W = web thickness of transverse primary supporting member
t_{CP} = collar plate thickness

SCANTLINGS:	FATIGUE:
Net sectional area of the web stiffener according to Ch 4, Sec 3, [4.7].	Fatigue check not required.
CONSTRUCTION:	**NDE:**
• Web stiffener not compulsory. When fitted, its misalignment m with the web of the side longitudinal ≤ a / 50. • Misalignment between web and collar plate ≤ t_{CP}. • Cut-outs in the web free of sharp notches. • Gap between web and side longitudinal and between collar plate and side longitudinal to be not greater than 4 mm.	Visual examination 100%.

WELDING AND MATERIALS:

- Welding requirements:
  - continuous fillet welding along the connection of web and collar plate with side longitudinal and at the lap joint between web and collar plate,
  - throat thickness according to Ch 11, Sec 1, [2.3.7]; in case of gap g greater than 2 mm, increase the throat thickness by 0,7 (g – 2) mm,
  - weld around the cuts in the web at the connection with the longitudinal and the side shell,
  - avoid burned notches on web.
- Fillet welding of overlapped joint to be done all around.

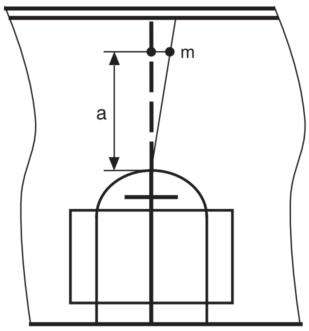
Table 4 :

AREA 1: Side between 0,7T_B and 1,15T from the baseline	Connection of side longitudinal ordinary stiffeners with transverse primary supporting members - Two collar plates	Sheet 1.4



t_W = web thickness of transverse primary supporting member
t_{CP} = collar plate thickness

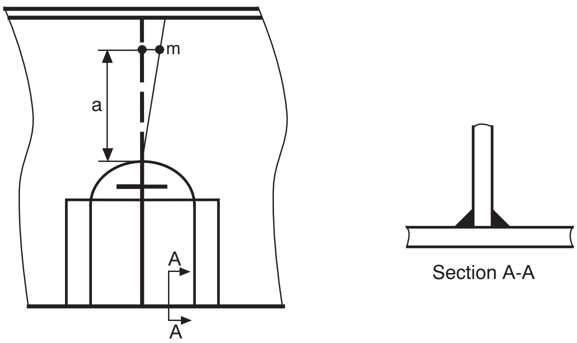
SCANTLINGS:	FATIGUE:
Net sectional area of the web stiffener according to Ch 4, Sec 3, [4.7].	Fatigue check not required.
CONSTRUCTION:	**NDE:**
• Web stiffener not compulsory. When fitted, its misalignment m with the web of the side longitudinal ≤ a / 50. • Misalignment between collar plates across the side longitudinal ≤ t_{CP} / 2. • Cut-outs in the web free of sharp notches. • Gap between collar plates and side longitudinal to be not greater than 4 mm.	Visual examination 100%.

WELDING AND MATERIALS:

- Welding requirements:
  - continuous fillet welding along the connection of collar plates with side longitudinal and at the lap joint between web and collar plates,
  - throat thickness according to Ch 11, Sec 1, [2.3.7]; in case of gap g greater than 2 mm, increase the throat thickness by 0,7 (g – 2) mm,
  - avoid burned notches on web.
- Fillet welding of overlapped joint to be done all around.

Table 5 :

AREA 1: Side between 0,7T_B and 1,15T from the baseline	Connection of side longitudinal ordinary stiffeners with transverse primary supporting members - Two large collar plates	Sheet 1.5



t_W = web thickness of transverse primary supporting member
t_{CP} = collar plate thickness

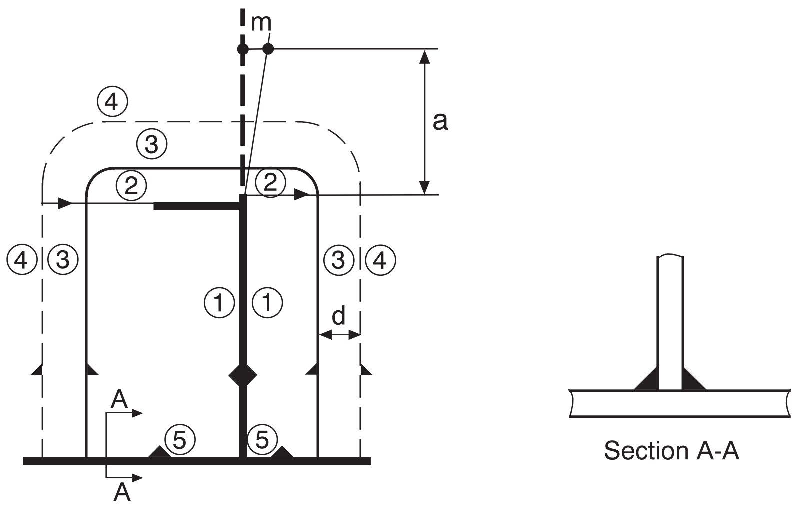
SCANTLINGS:	FATIGUE:
Net sectional area of the web stiffener according to Ch 4, Sec 3, [4.7].	Fatigue check not required.
CONSTRUCTION:	**NDE:**
• Web stiffener not compulsory. When fitted, its misalignment m with the web of the side longitudinal ≤ a / 50. • Misalignment between collar plates across the side longitudinal ≤ t_{CP} / 2. • Cut-outs in the web free of sharp notches. • Gap between collar plates and side longitudinal to be not greater than 4 mm.	Visual examination 100%.

WELDING AND MATERIALS:

- Welding requirements:
  - continuous fillet welding along the connection of collar plates with side longitudinal and at the lap joint between web and collar plates,
  - throat thickness according to Ch 11, Sec 1, [2.3.7]; in case of gap g greater than 2 mm, increase the throat thickness by 0,7 (g – 2) mm,
  - T joint connection of collar plates with side shell: see section A-A,
  - avoid burned notches on web.
- Fillet welding of overlapped joint to be done all around.

Table 6 :

AREA 1: Side between 0,7T_B and 1,15T from the baseline	**Watertight connection of side longitudinal ordinary stiffeners with watertight side diaphragms or transverse bulkheads – Example of connection with lugs**	**Sheet 1.6**



t_W = transverse bulkhead web thickness
t_L = lug thickness

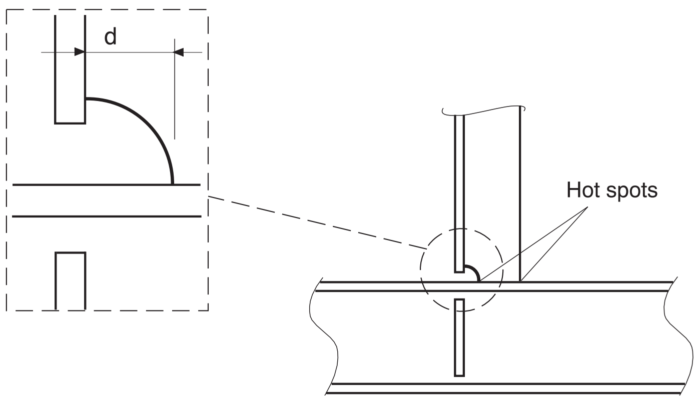
SCANTLINGS:	**FATIGUE:**
• d = 30 ÷ 60 mm. • $t_L \geq t_W$.	Fatigue check not required.
CONSTRUCTION:	**NDE:**
• Web stiffener not compulsory. When fitted, its misalignment m with the web of the side longitudinal ≤ a / 50. • Misalignment between lugs across the side longitudinal ≤ t_L / 2. • Misalignment at the butts within lug parts ≤ t_L / 5. • Gap between bulkhead plating and lugs to be not greater than 4 mm.	• Visual examination 100%. • Magnetic particle or dye penetrant examination: when deemed necessary depending on the quality of the lap joint weld.

WELDING AND MATERIALS:

Welding requirements:
- continuous fillet welding along the connection of lugs with the side longitudinal and at the lap joints between web and lugs,
- throat thickness according to Ch 11, Sec 1, [2.3.7]; in case of gap g greater than 2 mm, increase the throat thickness by 0,7 (g – 2) mm,
- T joint connection of collar plates with side shell: see section A-A,
- welding sequence: 1 to 5 (see sketch).

Table 7 :

AREA 1: Side between 0,7T_B and 1,15T from the baseline	Connection of side longitudinal ordinary stiffeners with stiffeners of transverse primary supporting members - No bracket	Sheet 1.7



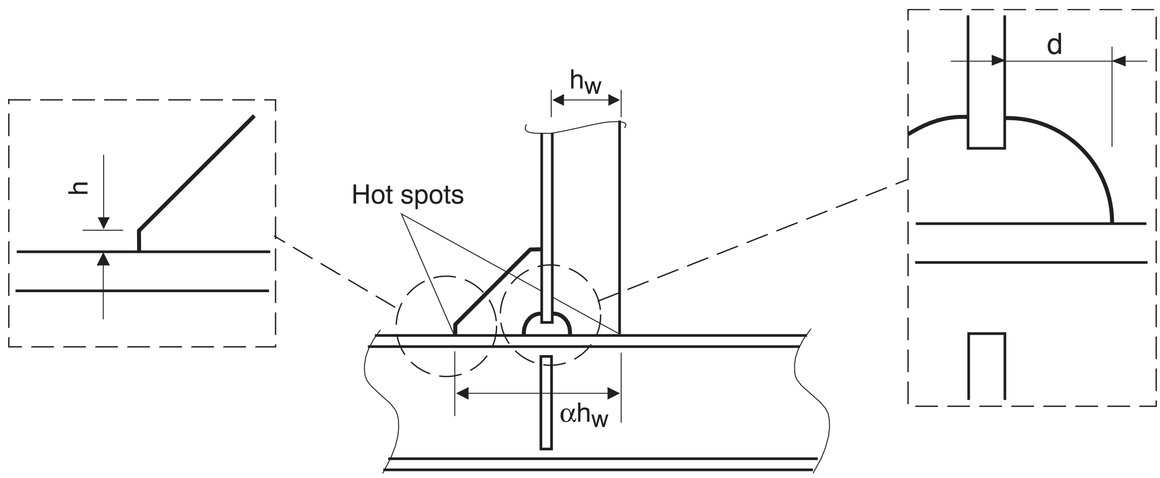
t = minimum thickness between those of:
- web of side longitudinal,
- stiffener of transverse primary supporting member.

SCANTLINGS:	FATIGUE:
d to be as small as possible, maximum 35 mm recommended.	Fatigue check to be carried out for L ≥ 90 m: • with non-watertight collar plate: K_h = 1,30 $K\ell$ = 1,65 • with full collar plate (watertight): K_h = 1,25 $K\ell$ = 1,50
CONSTRUCTION:	**NDE:**
• Misalignment between side longitudinal and web stiffener ≤ t / 3. • In case of fillet welding, misalignment may be as necessary to allow the required fillet throat size, but ≤ t / 2. For bulbs, a misalignment of 6 mm may be accepted.	Visual examination 100%.

WELDING AND MATERIALS:
Welding requirements: - continuous fillet welding, - weld around the stiffener's toes, - fair shape of fillet at toes in longitudinal direction.

Table 8 :

AREA 1: Side between 0,7T_B and 1,15T from the baseline	**Connection of side longitudinal ordinary stiffeners with stiffeners of transverse primary supporting members - One bracket**	**Sheet 1.8**

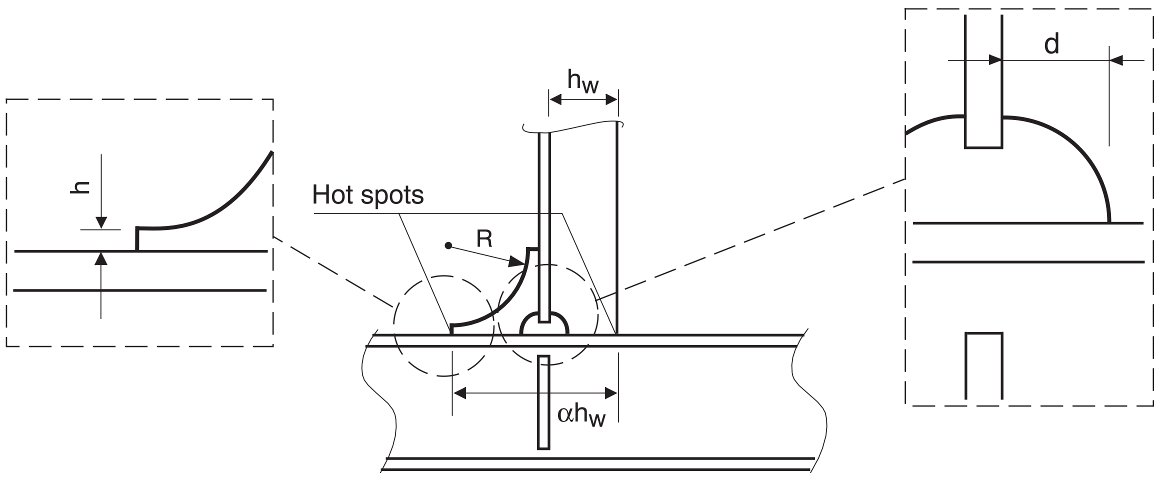


t = minimum thickness among those of the connected elements

SCANTLINGS:	**FATIGUE:**
• $\alpha \geq 2$. • Bracket to be symmetric. • h as necessary to allow the required fillet throat size, but ≤ 15 mm. • d to be as small as possible, maximum 35 mm recommended. • Thickness of the bracket to be not less than that of web stiffener.	Fatigue check to be carried out for L ≥ 90 m: • with non-watertight collar plate: - for $2 \leq \alpha < 2{,}5$ $K_h = 1{,}20$ $K\ell = 1{,}40$ - for $\alpha \geq 2{,}5$ $K_h = 1{,}15$ $K\ell = 1{,}40$ • with full collar plate (watertight): - for $2 \leq \alpha < 2{,}5$ $K_h = 1{,}15$ $K\ell = 1{,}32$ - for $\alpha \geq 2{,}5$ $K_h = 1{,}10$ $K\ell = 1{,}32$
CONSTRUCTION:	**NDE:**
• Misalignment between side longitudinal, web stiffener and bracket ≤ t / 3. • In case of fillet welding, misalignment may be as necessary to allow the required fillet throat size, but ≤ t / 2. For bulbs, a misalignment of 6 mm may be accepted.	Visual examination 100%.
WELDING AND MATERIALS:	
Welding requirements: - continuous fillet welding, - weld around the stiffener's toes, - fair shape of fillet at toes in longitudinal direction.	

Table 9 :

AREA 1: Side between 0,7T_B and 1,15T from the baseline	Connection of side longitudinal ordinary stiffeners with stiffeners of transverse primary supporting members - One radiused bracket	Sheet 1.9



t = minimum thickness among those of the connected elements

SCANTLINGS:	FATIGUE:
• $\alpha \geq 2$. • Bracket to be symmetric. • $R \geq 1,5\ (\alpha - 1)\ h_W$ • h as necessary to allow the required fillet throat size, but ≤ 15 mm. • d to be as small as possible, maximum 35 mm recommended. • Thickness of the bracket to be not less than that of web stiffener.	Fatigue check to be carried out for L ≥ 90 m: • with non-watertight collar plate: - for $2 \leq \alpha < 2,5$ $K_h = 1,15$ $K\ell = 1,35$ - for $\alpha \geq 2,5$ $K_h = 1,10$ $K\ell = 1,35$ • with full collar plate (watertight): - for $2 \leq \alpha < 2,5$ $K_h = 1,13$ $K\ell = 1,30$ - for $\alpha \geq 2,5$ $K_h = 1,08$ $K\ell = 1,30$
CONSTRUCTION:	**NDE:**
• Misalignment between side longitudinal, web stiffener and bracket ≤ t / 3. • In case of fillet welding, misalignment may be as necessary to allow the required fillet throat size, but ≤ t / 2. For bulbs, a misalignment of 6 mm may be accepted.	Visual examination 100%.

WELDING AND MATERIALS:
Welding requirements: - continuous fillet welding, - weld around the stiffener's toes, - fair shape of fillet at toes in longitudinal direction.

Table 10 :

WELDING AND MATERIALS:		
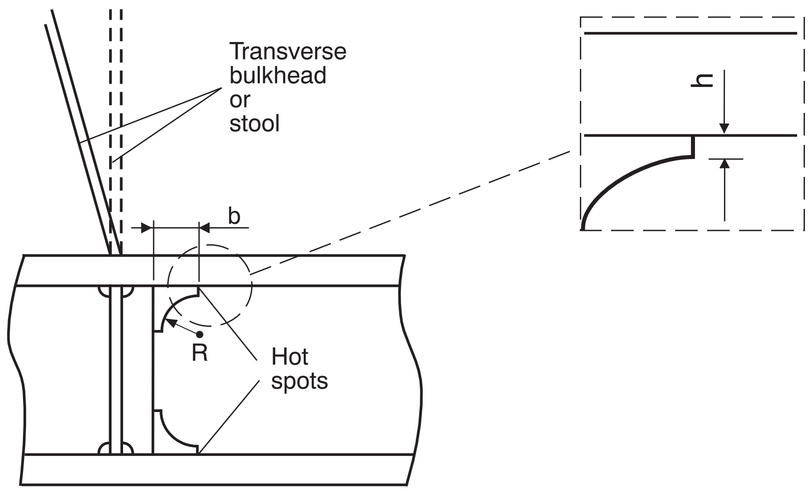
Welding requirements: - floor stiffeners and brackets to be connected with continuous fillet welding to bottom and inner bottom longitudinals, - partial penetration welding between stiffeners and brackets, - weld all around the stiffeners and brackets, - fair shape of fillet at toes in longitudinal direction.		

Table 16 :

AREA 2: Double bottom in way of transverse bulkheads	Connection of bottom and inner bottom longitudinal ordinary stiffeners with floors - Radiused brackets	Sheet 2.3



t = minimum thickness among those of the connected elements

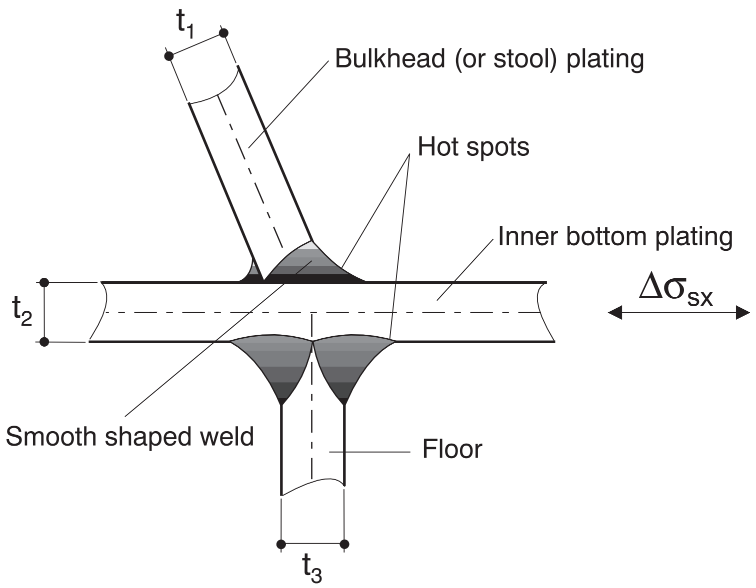
SCANTLINGS:	FATIGUE:
• Brackets to be symmetric. • R ≥ 1,5 b • h as necessary to allow the required fillet throat size, but ≤ 15 mm.	Fatigue check to be carried out for L ≥ 90 m: K_h = 1,25 $K\ell$ = 1,50
CONSTRUCTION:	**NDE:**
• Misalignment between webs of bottom and inner bottom longitudinal with floor stiffener ≤ t / 3. • In case of fillet weld, misalignment may be as necessary to allow the required fillet leg size, but ≤ t / 2. For bulbs, a misalignment of 6 mm may be accepted.	Visual examination 100%.

WELDING AND MATERIALS:

Welding requirements:
- floor stiffeners and brackets to be connected with continuous fillet welding to bottom and inner bottom longitudinals,
- partial penetration welding between stiffeners and brackets,
- weld all around the stiffeners and brackets,
- fair shape of fillet at toes in longitudinal direction.

Table 17 :

AREA 2: Double bottom in way of transverse bulkheads	Connection of inner bottom with transverse bulkheads or lower stools	Sheet 2.4



Hot spot stresses:
$\Delta\sigma_{SX} = K_{SX} \cdot \Delta\sigma_{sX}$

$t = \min(t_1, t_2, t_3)$

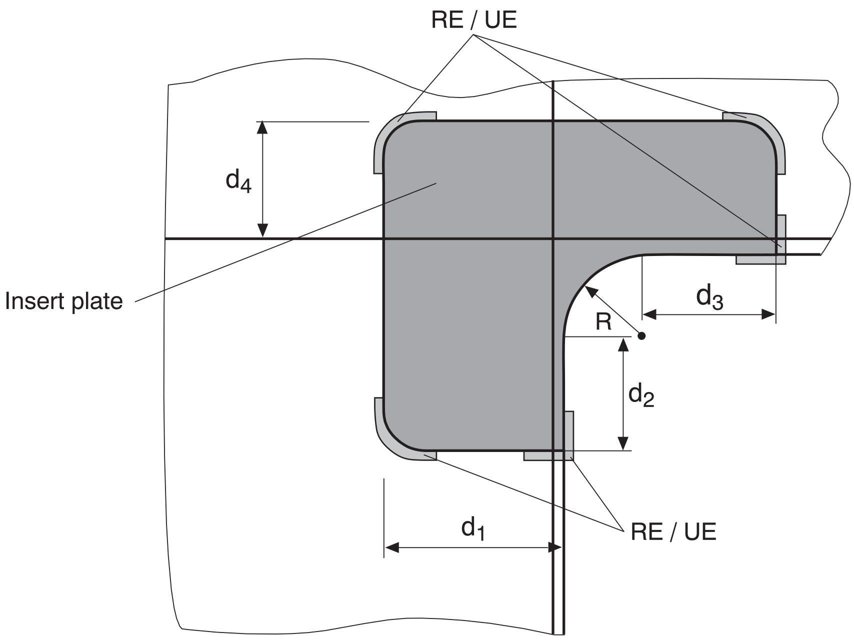
SCANTLINGS:	FATIGUE:
	Fatigue check to be carried out for $L \geq 90$ m: $K_{SX} = 3,85$
CONSTRUCTION:	**NDE:**
• Misalignment (median lines) between floor and bulkhead (or stool) plating $\leq t / 3$. • Cut-outs for connections of the inner bottom longitudinals to double bottom floors to be closed by collar plates welded to the inner bottom.	The following NDE are required: • VE 100%, • UE 35% of full penetration weld for absence of cracks, lack of penetration and lamellar tears.

WELDING AND MATERIALS:

- Welding requirements:
  - bulkhead (or stool) plating and supporting floors generally to be connected with full penetration welding to inner bottom plating (if not full penetration welding, the weld preparation is to be indicated on the approved drawings),
  - special approval of the procedure on a sample representative of the actual conditions foreseen in production,
  - welding sequence against the risk of lamellar tearing,
  - weld finishing well faired to the inner bottom plating.
- Material requirements:
  - the strake of inner bottom plating in way of the connection is recommended to be of Z25/ZH25 quality. If a steel of such a quality is not adopted, 100% UE of the plate in way of the weld is required prior to and after welding.
- Partial fillet welding may also be accepted in place of full penetration welding between floor and inner bottom plating. In such a case, the preparation is to be specified on drawing.

Table 18 :

AREA 3: Hatch corners	Deck plating in way of hatch corners	Sheet 3.1



SCANTLINGS:	FATIGUE:
• Insert plates with circular profiles in general to be fitted in way of corners of hatchways located within the cargo area. The radius of circular corners to be in accordance with Ch 4, Sec 6, [6.2.1]. • Insert plates not required in way of corners of hatchways located in the above positions, where corners have an elliptical or parabolic profile according to Ch 4, Sec 6, [6.2.2]. • Where insert plates are required, their thickness to be defined according to Ch 4, Sec 6, [6.2.3] and their extension to be such that d_1 , d_2 , d_3 and $d_4 \geq s$, s being the ordinary frame spacing.	Fatigue check not required.
CONSTRUCTION:	**NDE:**
• Corners of insert plates to be rounded, unless corresponding to joints of deck strakes. • Insert cut edges to be carefully executed.	The following NDE are required: • VE 100%, • RE / UE in areas indicated in the sketch.

WELDING AND MATERIALS:

- Welding requirements:
  - welds recommended to be continued on auxiliary pieces temporarily fitted at the free end of each joint, to be cut away; the joint ends are to be carefully ground.
- Materials requirements:
  - insert plate material of same or higher quality than the adjacent deck plating, depending on the insert thickness according to Ch 4, Sec 1, [2].

Table 19 :

<table>
<tr><td>AREA 3: Hatch corners</td><td>Ends of longitudinal hatch coamings - Bracket welded to deck plating</td><td>Sheet 3.2</td></tr>
<tr><td colspan="2"></td><td>t_A = minimum among:
- thickness of bracket flange at lower end,
- deck plating thickness,
- under deck transverse stiffener web thickness,

t_B = minimum among:
- bracket web thickness,
- deck plating thickness,
- thickness of the under deck longitudinal member.</td></tr>
<tr><td>SCANTLINGS:</td><td colspan="2">FATIGUE:</td></tr>
<tr><td>An additional under deck transverse stiffener is to be fitted in way of termination bracket toe, where the toe is clear of normal stiffener.</td><td colspan="2">Fatigue check not required.</td></tr>
<tr><td>CONSTRUCTION:</td><td colspan="2">NDE:</td></tr>
<tr><td>• Misalignment between bracket flange and under deck transverse stiffener ≤ t_A / 3.
• Misalignment between bracket and under deck longitudinal ≤ t_B / 3.</td><td colspan="2">The following NDE are required:
• VE 100%, with particular care for the weld shape and undercuts on deck plating at the bracket flange connection,
• UE 100% of full penetration welds for absence of cracks, lack of penetration and lamellar tears.</td></tr>
<tr><td colspan="3">WELDING AND MATERIALS:</td></tr>
<tr><td colspan="3">Welding requirements:
- bracket flange to be connected with full penetration welding to deck plating, with half V bevel and weld shape elongated on deck plating (see sketch),
- ends of bracket webs to be connected with full penetration welding to deck plating for the extension shown in the sketch, with half X bevel,
- under deck transverse stiffener to be connected with full penetration welding to deck plating in way of the bracket flange,
- care is to be taken to ensure soundness of the crossing welds at the bracket toe, if the case, adopting small scallop to be closed by welding.</td></tr>
</table>

Machinery, Systems and Fire Protection

Chapter 1	Machinery
Chapter 2	Electrical Installations
Chapter 3	Automation
Chapter 4	Fire Protection, Detection and Extinction

January 2024

Table of Content

Chapter 1 Machinery

Section 1 General Requirements

1 General 31
- 1.1 Application
- 1.2 Additional requirements
- 1.3 Documentation to be submitted
- 1.4 Definitions

2 Design and construction 31
- 2.1 General
- 2.2 Materials, welding and testing
- 2.3 Vibrations
- 2.4 Operation in inclined position
- 2.5 Ambient conditions
- 2.6 Power of machinery
- 2.7 Astern power
- 2.8 Safety devices
- 2.9 Fuels

3 Arrangement and installation on board 33
- 3.1 General
- 3.2 Floors
- 3.3 Bolting down
- 3.4 Safety devices on moving parts
- 3.5 Gauges
- 3.6 Ventilation in machinery spaces
- 3.7 Hot surfaces and fire protection
- 3.8 Communications
- 3.9 Machinery remote control, alarms and safety systems

4 Tests and trials 35
- 4.1 Works tests
- 4.2 Trials on board

Section 2 Diesel Engines

1 General 36
- 1.1 Application
- 1.2 Documentation to be submitted
- 1.3 Definitions

2 Design and construction 38
- 2.1 General
- 2.2 Materials and welding
- 2.3 Crankshaft
- 2.4 Crankcase
- 2.5 Cylinder overpressure gauge
- 2.6 Scavenge manifolds
- 2.7 Systems
- 2.8 Starting air system
- 2.9 Cooling system
- 2.10 Control and monitoring

3 Arrangement and installation 45
- 3.1 Starting arrangements
- 3.2 Turning gear
- 3.3 Trays
- 3.4 Exhaust gas system

Table of Content

4 Type tests, material tests, workshop inspection and testing, certification 46

4.1 Type tests - General
4.2 Type tests of engines not admitted to an alternative inspection scheme
4.3 Type tests of engines admitted to an alternative inspection scheme
4.4 Material and non-destructive tests
4.5 Workshop inspections and testing
4.6 Certification

Section 3 Pressure Equipment

1 General 54

1.1 Principles
1.2 Application
1.3 Definitions
1.4 Classes
1.5 Applicable Rules
1.6 Documentation to be submitted

2 Design and construction - Scantlings of pressure parts 59

2.1 General
2.2 Materials
2.3 Permissible stresses
2.4 Cylindrical, spherical and conical shells with circular cross-sections subject to internal pressure
2.5 Dished heads subject to pressure on the concave (internal) side
2.6 Dished heads subject to pressure on the convex (external) side
2.7 Flat heads
2.8 Openings and branches (nozzles)
2.9 Regular pattern openings - Tube holes
2.10 Water tubes, superheaters and economiser tubes of boilers
2.11 Additional requirements for fired pressure vessels
2.12 Additional requirements for vertical boilers and fire tube boilers
2.13 Bottles containing pressurised gases
2.14 Heat exchangers

3 Design and construction - Equipment 87

3.1 All pressure vessels
3.2 Boilers and steam generators
3.3 Thermal oil heaters and thermal oil installation
3.4 Special types of pressure vessels
3.5 Other pressure vessels

4 Design and construction - Fabrication and welding 92

4.1 General
4.2 Welding design
4.3 Miscellaneous requirements for fabrication and welding
4.4 Preparation of parts to be welded
4.5 Tolerances after construction
4.6 Preheating
4.7 Post-weld heat treatment
4.8 Welding samples
4.9 Specific requirements for class 1 vessels
4.10 Specific requirements for class 2 vessels
4.11 Specific requirements for class 3 vessels

5 Design and construction - Control and monitoring 104

5.1 Boiler control and monitoring system
5.2 Pressure vessel instrumentation
5.3 Thermal oil heater control and monitoring
5.4 Control and monitoring requirements

Table of Content

6 Arrangement and installation 108

6.1 Foundations
6.2 Boilers
6.3 Pressure vessels
6.4 Thermal oil heaters

7 Material test, workshop inspection and testing, certification 109

7.1 Material testing
7.2 Workshop inspections
7.3 Hydrostatic tests
7.4 Certification

Section 4 Steam Turbines

1 General 112

1.1 Application
1.2 Documentation to be submitted

2 Design and construction 112

2.1 Materials
2.2 Design and constructional details
2.3 Welded fabrication
2.4 Control, monitoring and shut-off devices

3 Arrangement and installation 116

3.1 Foundations
3.2 Jointing of mating surfaces
3.3 Piping installation
3.4 Hot surfaces
3.5 Alignment
3.6 Circulating water system
3.7 Gratings
3.8 Drains
3.9 Instruments

4 Material tests, workshop inspection and testing, certification 116

4.1 Material tests
4.2 Inspections and testing during construction
4.3 Certification

Section 5 Gas Turbines

1 General 119

1.1 Application
1.2 Definition of rated power
1.3 Documentation to be submitted

2 Design and construction 120

2.1 General
2.2 Materials
2.3 Stress analyses
2.4 Design and constructional details
2.5 Welded fabrication
2.6 Control, monitoring and shut-off devices

3 Arrangement and installation 123

3.1 Foundations
3.2 Joints of mating surfaces
3.3 Piping installation
3.4 Hot surfaces
3.5 Alignment
3.6 Gratings
3.7 Drains
3.8 Instruments

4 Material tests, workshop inspection and testing, certification 124

4.1 Type tests - General
4.2 Material tests
4.3 Inspections and testing during construction
4.4 Certification

Section 6 Gearing

1 General 126

1.1 Application
1.2 Documentation to be submitted

2 Design of gears - Determination of the load capacity of cylindrical gears 130

2.1 Symbols, units, definitions
2.2 Principle
2.3 General influence factors
2.4 Calculation of surface durability
2.5 Calculation of tooth bending strength
2.6 Calculation of scuffing resistance

3 Design of gears - Determination of the load capacity of bevel gears 155

3.1 Symbols, units, definitions
3.2 Principle
3.3 General influence factors
3.4 Calculation of surface durability
3.5 Calculation of tooth bending strength
3.6 Calculation of scuffing resistance

4 Design and construction - except tooth load capacity 168

4.1 Materials
4.2 Teeth
4.3 Wheels and pinions
4.4 Shafts and bearings
4.5 Casings
4.6 Lubrication
4.7 Control and monitoring

5 Installation 171

5.1 General
5.2 Fitting of gears

6 Certification, inspection and testing 171

6.1 General
6.2 Workshop inspection and testing

Section 7 Main Propulsion Shafting

1 General 173

1.1 Application
1.2 Documentation to be submitted

2 Design and construction 174

2.1 Materials
2.2 Shafts - Scantling
2.3 Liners
2.4 Aft bearings
2.5 Couplings
2.6 Design of oil control systems for clutches
2.7 Monitoring

3 Arrangement and installation 180

3.1 General
3.2 Protection of propeller shaft against corrosion
3.3 Shaft alignment

4 Material tests, workshop inspection and testing, certification 182

4.1 Material and non-destructive tests, workshop inspections and testing
4.2 Certification

Section 8 Propellers

1 General 183

1.1 Application
1.2 Definitions
1.3 Documentation to be submitted

2 Design and construction 185

2.1 Materials
2.2 Solid propellers - Blade thickness
2.3 Built-up propellers and controllable pitch propellers
2.4 Skewed propellers
2.5 Ducted propellers
2.6 Features

3 Arrangement and installation 189

3.1 Fitting of propeller on the propeller shaft

4 Testing and certification 192

4.1 Material tests
4.2 Testing and inspection
4.3 Certification

Section 9 Shaft Vibrations

1 General 193

1.1 Application

2 Design of systems in respect of vibrations 193

2.1 Principle
2.2 Modifications of existing plants

3 Torsional vibrations 193

3.1 Documentation to be submitted
3.2 Definitions, symbols and units
3.3 Calculation principles
3.4 Permissible limits for torsional vibration stresses in crankshaft, propulsion shafting and other transmission shafting
3.5 Permissible vibration levels in components other than shafts
3.6 Torsional vibration measurements

4 Bending vibrations 198

4.1 General
4.2 Documentation to be submitted
4.3 Calculation principles
4.4 Bending vibration measurements

5 Axial vibrations 199

5.1 General
5.2 Documentation to be submitted
5.3 Calculation principles
5.4 Axial vibration measurements

Section 10 Piping Systems

1 General 201

1.1 Application
1.2 Documentation to be submitted
1.3 Definitions
1.4 Symbols and units
1.5 Class of piping systems

2 General requirements for design and construction 203

2.1 Materials
2.2 Thickness of pressure piping
2.3 Calculation of high temperature pipes
2.4 Junction of pipes
2.5 Protection against overpressure
2.6 Flexible hoses and expansion joints
2.7 Valves and accessories
2.8 Sea inlets and overboard discharges
2.9 Control and monitoring

3 Welding of steel piping 219

3.1 Application
3.2 General
3.3 Design of welded joints
3.4 Preparation of elements to be welded and execution of welding
3.5 Post-weld heat treatment
3.6 Inspection of welded joints

4 Bending of pipes 222

4.1 Application
4.2 Bending process
4.3 Heat treatment after bending

5 Arrangement and installation of piping systems 223

5.1 General
5.2 Location of tanks and piping system components
5.3 Passage through watertight bulkheads or decks
5.4 Independence of lines
5.5 Prevention of progressive flooding
5.6 Provision for expansion
5.7 Supporting of the pipes
5.8 Protection of pipes
5.9 Valves, accessories and fittings
5.10 Additional arrangements for flammable fluids

6 Bilge systems 227

6.1 Principle
6.2 Design of bilge systems
6.3 Drainage arrangements of vehicle and ro-ro spaces and ammunition storages fitted with a fixed pressure water-spraying fire-extinguishing system
6.4 Draining of machinery spaces
6.5 Draining of dry cofferdams, dry fore and after peaks and dry spaces above fore and after peaks, tunnels and refrigerated spaces
6.6 Bilge pumps
6.7 Size of bilge pipes
6.8 Bilge accessories
6.9 Bilge piping arrangement

7 Ballast systems 230

7.1 Design of ballast systems
7.2 Ballast pumping arrangement

Table of Content

8 Scuppers and sanitary discharges 231

8.1 Application
8.2 Principle
8.3 Drainage from spaces below the bulkhead deck or within enclosed superstructures and deckhouses on or above the bulkhead deck
8.4 Drainage of enclosed vehicle and ro-ro spaces situated on the bulkhead deck
8.5 Drainage arrangement of vehicle and ro-ro spaces or ammunition spaces fitted with a fixed pressure water-spraying fire-extinguishing system
8.6 Arrangement of discharges from spaces below the margin line
8.7 Arrangement of discharges from spaces above the margin line
8.8 Summary table of overboard discharge arrangements
8.9 Valves and pipes
8.10 Arrangement of scuppers

9 Air, sounding and overflow pipes 235

9.1 Air pipes
9.2 Sounding pipes
9.3 Overflow pipes
9.4 Constructional requirements applying to sounding, air and overflow pipes

10 Cooling systems 239

10.1 Application
10.2 Principle
10.3 Design of sea water cooling systems
10.4 Design of fresh water cooling systems
10.5 Design of oil cooling systems
10.6 Control and monitoring
10.7 Arrangement of cooling systems

11 Fuel oil and JP5-NATO (F44) systems 242

11.1 Application
11.2 Principle
11.3 General
11.4 Design of fuel oil and JP5-NATO (F44) filling and transfer systems
11.5 Arrangement of fuel oil, bunkers and JP5-NATO (F44) tanks
11.6 Design of fuel oil tanks and bunkers and JP5-NATO (F44) tanks
11.7 Design of fuel oil heating systems
11.8 Design of fuel oil and JP5-NATO (F44) treatment systems
11.9 Design of fuel supply systems
11.10 Control and monitoring
11.11 Construction of fuel oil and JP5-NATO (F44) piping systems
11.12 Arrangement of fuel oil and JP5-NATO (F44) piping systems

12 Lubricating oil systems 246

12.1 Application
12.2 Principle
12.3 General
12.4 Design of lubricating oil tanks
12.5 Control and monitoring
12.6 Construction of lubricating oil piping systems

13 Hydraulic systems 248

13.1 Application
13.2 Principle
13.3 General
13.4 Design of hydraulic systems
13.5 Design of hydraulic tanks and other components
13.6 Control and monitoring
13.7 Construction of hydraulic oil piping systems

14 Steam systems 250

14.1 Application
14.2 Principle
14.3 Design of steam lines

Table of Content

15	Boiler feed water and condensate systems	252

15.1 Application
15.2 Principle
15.3 Design of boiler feed water systems
15.4 Design of condensate systems
15.5 Control and monitoring
15.6 Arrangement of feed water and condensate piping

16	Compressed air systems	254

16.1 Application
16.2 Principle
16.3 Design of starting air systems
16.4 Design of control and monitoring air systems
16.5 Design of air compressors
16.6 Control and monitoring of compressed air systems
16.7 Materials
16.8 Arrangement of compressed air piping systems
16.9 Compressed breathable air systems

17	Combustion air and exhaust gas systems	257

17.1 General
17.2 Design of combustion air and exhaust systems
17.3 Materials
17.4 Arrangement of combustion air and exhaust piping systems

18	Oxyacetylene welding systems	258

18.1 Application
18.2 Definitions
18.3 Design of oxyacetylene welding systems
18.4 Arrangement of oxyacetylene welding systems

19	Certification, inspection and testing of piping systems	260

19.1 Application
19.2 Type tests of flexible hoses and expansion joints
19.3 Type tests of air pipe closing devices
19.4 Type tests of mechanical pipe joints
19.5 Testing of materials
19.6 Hydrostatic testing of piping systems and their components
19.7 Testing of piping system components during manufacturing
19.8 Inspection and testing of piping systems

Section 11 Exhaust Gas Pollution Prevention System

1	General	267

1.1 Application
1.2 Definitions
1.3 Documents to be submitted

2	Installation requirements	267

2.1 General
2.2 Design
2.3 Availability
2.4 Arrangement

3	Storage and use of SCR reductant	269

3.1 Application
3.2 Storage tank
3.3 Ventilation
3.4 Piping
3.5 Materials
3.6 Protection of crew members

4 Storage and use of other substances mentioned in IMDG Code 270

4.1 Application
4.2 Risk analysis
4.3 Containment of leakage
4.4 Storage tank
4.5 Ventilation
4.6 Piping

Section 12 Steering Gear

1 General 271

1.1 Application
1.2 Documentation to be submitted
1.3 Definitions
1.4 Symbols

2 Design and construction 273

2.1 General
2.2 Strength, performance and power operation of the steering gear
2.3 Control of the steering gear
2.4 Availability
2.5 Mechanical components
2.6 Hydraulic system
2.7 Electrical systems
2.8 Alarms and indications

3 Design and construction - Requirements for ships equipped with several rudders 284

3.1 Principle
3.2 Synchronisation

4 Design and construction - Requirements for ships equipped with thrusters as steering means 284

4.1 Principle
4.2 Steering arrangements
4.3 Use of water-jets

5 Arrangement and installation 286

5.1 Steering gear room arrangement
5.2 Rudder actuator installation
5.3 Overload protections
5.4 Means of communication
5.5 Operating instructions

6 Certification, inspection and testing 287

6.1 Type tests of hydraulic pumps
6.2 Testing of materials
6.3 Inspection and tests during manufacturing
6.4 Inspection and tests after completion

Section 13 Thrusters

1 General 289

1.1 Application
1.2 Definitions
1.3 Thrusters intended for propulsion
1.4 Documentation to be submitted

2 Design and construction 291

2.1 Materials
2.2 Transverse thrusters and azimuth thrusters
2.3 Water-jets
2.4 Alarm, monitoring and control systems

Table of Content

3 Testing and certification 293

3.1 Material tests
3.2 Testing and inspection
3.3 Certification

Section 14 Refrigerating Installations

1 General 294

1.1 Application

2 Minimum design requirements 294

2.1 Refrigerating installation components
2.2 Refrigerants

3 Instrumentation 295

3.1 Thermometers in refrigerated spaces

4 Installations related to preservation of ships' victuals 296

4.1 Victuals chamber
4.2 Instrumentation

Section 15 Turbochargers

1 General 297

1.1 Application
1.2 Documentation to be submitted

2 Design and construction 297

2.1 Materials
2.2 Design
2.3 Monitoring

3 Arrangement and installation 298

3.1 General

4 Type tests, material tests, workshop inspection and testing, certification 298

4.1 Type tests
4.2 Material tests
4.3 Workshop inspections and testing
4.4 Certification

Section 16 Tests on Board

1 General 300

1.1 Application
1.2 Purpose of shipboard tests
1.3 Documentation to be submitted

2 General requirements for shipboard tests 300

2.1 Trials at the moorings
2.2 Sea trials

3 Shipboard tests for machinery 301

3.1 Conditions of sea trials
3.2 Navigation and manoeuvring tests
3.3 Tests of diesel engines
3.4 Tests of gas turbines
3.5 Tests of electric propulsion system
3.6 Tests of gears
3.7 Tests of main propulsion shafting and propellers
3.8 Tests of piping systems
3.9 Tests of steering gear

4 Inspection of machinery after sea trials 304

4.1 General
4.2 Diesel engines

Appendix 1 Check of the Scantlings of Crankshafts for Diesel Engines

1 General 306

1.1 Application
1.2 Documentation to be submitted
1.3 Principles of calculation
1.4 Symbols

2 Calculation of alternating stresses 308

2.1 Calculation of alternating stresses due to bending moments and shearing forces
2.2 Calculation of alternating torsional stresses

3 Calculation of stress concentration factors 311

3.1 General

4 Additional bending stresses 313

4.1

5 Calculation of the equivalent alternating stress 314

5.1 General
5.2 Equivalent alternating stress

6 Calculation of the fatigue strength 314

6.1

7 Calculation of shrink-fit of semi-built crankshafts 315

7.1 General
7.2 Minimum required oversize of shrink-fit
7.3 Maximum permissible oversize of shrink-fit

8 Acceptability criteria 315

8.1

Appendix 2 Plastic Pipes

1 General 316

1.1 Application
1.2 Use of plastic pipes
1.3 Specifications
1.4 Terms and conditions

2 General requirements 317

2.1 Strength
2.2 Axial strength
2.3 Impact resistance
2.4 Temperature
2.5 Requirements depending on service and/or location

3 Material approval and quality control during manufacture 321

3.1 General

4 Arrangement and installation of plastic pipes 321

4.1 Supports
4.2 Expansion
4.3 External loads
4.4 Strength of connections
4.5 Installation of conductive pipes
4.6 Application of fire protection coatings
4.7 Penetration of fire divisions and watertight bulkheads or decks
4.8 Control during installation
4.9 Testing after installation on board

5 Test specification for plastic pipes 323

5.1 Scope
5.2 Documentation
5.3 Testing

Appendix 3 Independent Fuel Oil Tanks

1 General 326

1.1 Application
1.2 Documents to be submitted
1.3 Symbols and units

2 Design and installation of tanks 326

2.1 Materials
2.2 Scantling of steel tanks
2.3 Installation

Appendix 4 Special Approval of Alloy Steel used for Intermediate Shaft Material

1 General 330

1.1 Application
1.2 Torsional fatigue test
1.3 Cleanliness requirements
1.4 Inspection

Chapter 2 Electrical Installations

Section 1 General

1 Application 333

1.1 General
1.2 References to other regulations and standards

2 Documentation to be submitted 333

2.1

3 Definitions 334

3.1 General
3.2 Essential services
3.3 Primary essential services
3.4 Secondary essential services
3.5 Services for habitability
3.6 Safety voltage
3.7 Low-voltage systems
3.8 High-voltage systems
3.9 Basic insulation
3.10 Supplementary insulation
3.11 Double insulation
3.12 Reinforced insulation
3.13 Earthing
3.14 Normal operational and habitable condition
3.15 Emergency condition
3.16 Main source of electrical power
3.17 Dead ship condition
3.18 Main generating station
3.19 Main switchboard
3.20 Emergency switchboard
3.21 Emergency source of electrical power
3.22 Section boards
3.23 Distribution board
3.24 Final sub-circuit

3.25 Hazardous areas
3.26 High fire risk areas
3.27 Certified safe-type equipment
3.28 Environmental categories

Section 2 General Design Requirements

1 Environmental conditions 339

1.1 General
1.2 Ambient air temperatures
1.3 Humidity
1.4 Cooling water temperatures
1.5 Salt mist
1.6 Inclinations
1.7 Vibrations
1.8 Shock

2 Quality of power supply 341

2.1 General
2.2 A.c. distribution systems
2.3 D.c. distribution systems
2.4 Harmonic distortions

3 Electromagnetic susceptibility 342

3.1

4 Materials 342

4.1 General
4.2 Insulating materials for windings
4.3 Insulating materials for cables

5 Construction 342

5.1 General
5.2 Degree of protection of enclosures

6 Protection against explosion hazard 343

6.1 Protection against explosive gas or vapour atmosphere hazard
6.2 Protection against combustible dust hazard

Section 3 System Design

1 Supply systems and characteristics of the supply 344

1.1 Supply systems
1.2 Maximum voltages

2 Sources of electrical power 345

2.1 General
2.2 Main source of electrical power
2.3 Emergency source of electrical power
2.4 Use of emergency generator in port

3 Distribution 348

3.1 Earthed distribution systems
3.2 Insulated distribution systems
3.3 General requirements for distribution systems
3.4 Main distribution of electrical power
3.5 Emergency distribution of electrical power
3.6 Shore/Ship supply
3.7 Supply of motors
3.8 Specific requirements for special power services
3.9 Power supply to heaters
3.10 Power supply to lighting installations
3.11 Special lighting services
3.12 Navigation and signalling lights
3.13 General emergency alarm system
3.14 Public address system
3.15 Combined general emergency alarm - public address system
3.16 Control and indication circuits
3.17 Power supply to the speed control systems of main propulsion engines
3.18 Power supply to the speed control systems of generator sets
3.19 Harmonic distortion for ship electrical distribution system including harmonics filters

4 Degrees of protection of the enclosures 354

4.1 General
4.2 Installation of electrical and electronic equipment in engine rooms protected by fixed water-based local application fire-fighting systems (FWBLAFFS)

5 Diversity (demand) factors 356

5.1 General

6 Environmental categories of the equipment 357

6.1 Environmental categories

7 Electrical protection 357

7.1 General requirements for overcurrent protection
7.2 Short-circuit currents
7.3 Selection of equipment
7.4 Protection against short-circuit
7.5 Continuity of supply and continuity of service
7.6 Protection against overload
7.7 Localization of over-current protection
7.8 Protection of generators
7.9 Protection of circuits
7.10 Protection of motors
7.11 Protection of storage batteries
7.12 Protection of shore power connection
7.13 Protection of measuring instruments, pilot lamps and control circuits
7.14 Protection of transformers

8 System components 362

8.1 General

9 Electrical cables 362

9.1 General
9.2 Choice of insulation
9.3 Choice of protective covering
9.4 Cables in refrigerated spaces
9.5 Cables in areas with a risk of explosion
9.6 Cables in circuits required to be operable under fire condition
9.7 Cables for submerged bilge pumps
9.8 Internal wiring of switchboards and other enclosures for equipment
9.9 Current carrying capacity of cables
9.10 Minimum nominal cross-sectional area of conductors
9.11 Choice of cables

10	Electrical installations in hazardous areas	369

10.1 Electrical equipment
10.2 Electrical cables
10.3 Electrical installations in battery rooms
10.4 Electrical installations in paint stores
10.5 Electrical installations in stores for welding gas (acetylene) bottles
10.6 Ammunition spaces

Section 4 Rotating Machines

1	Constructional requirements for generators and motors	373

1.1 Mechanical construction
1.2 Sliprings, commutators and brushes
1.3 Terminal connectors
1.4 Electrical insulation

2	Special requirements for generators	373

2.1 Prime movers, speed governors and overspeed protection
2.2 A.c. generators
2.3 Approval of generating gensets

3	Testing of rotating machines	374

3.1 General
3.2 Shaft material
3.3 Tests

4	Description of the test	375

4.1 Examination of the technical documentation, as appropriate, and visual inspection
4.2 Insulation resistance measurement
4.3 Winding resistance measurement
4.4 Verification of the voltage regulation system
4.5 Rated load test and temperature rise measurements
4.6 Overload/overcurrent tests
4.7 Verification of steady short-circuit conditions
4.8 Overspeed test
4.9 Dielectric strength test
4.10 No load test
4.11 Verification of degree of protection
4.12 Verification of bearings

Section 5 Transformers

1	Constructional requirements	378

1.1 Construction
1.2 Terminals
1.3 Voltage variation, short-circuit conditions and parallel operation
1.4 Electrical insulation and temperature rise

2	Testing	379

2.1 General
2.2 Tests on transformers
2.3 Insulation tests

Section 6 Semiconductor Converters

1	Constructional and operational requirements	381

1.1 Construction
1.2 Protection
1.3 Parallel operation with other power sources
1.4 Temperature rise
1.5 Creepage and clearance distances

2 Requirements for uninterruptible power system (UPS) units as alternative and/or transitional power 382

2.1 Definitions
2.2 Design and construction
2.3 Location
2.4 Performance

3 Testing 383

3.1 General
3.2 Tests on convertors
3.3 Additional testing and survey for uninterruptible power system (UPS) units as alternative and/ or transitional power
3.4 Insulation test

Section 7 Storage Batteries and Chargers

1 Constructional requirements for batteries 385

1.1 General
1.2 Vented batteries
1.3 Valve-regulated sealed batteries
1.4 Tests on batteries

2 Constructional requirements for chargers 385

2.1 Characteristics
2.2 Tests on chargers

Section 8 Switchgear and Controlgear Assemblies

1 Constructional requirements for main and emergency switchboards 387

1.1 Construction
1.2 Busbars and bare conductors
1.3 Internal wiring
1.4 Switchgear and controlgear
1.5 Auxiliary circuits
1.6 Instruments

2 Constructional requirements for section boards and distribution boards 390

2.1 Construction

3 Testing 390

3.1 General
3.2 Inspection of equipment, check of wiring and electrical operation test
3.3 High voltage test
3.4 Measurement of insulation resistance

Section 9 Cables

1 Constructional requirements 392

1.1 Construction
1.2 Conductors
1.3 Insulating materials
1.4 Inner covering, fillers and binders
1.5 Protective coverings (armour and sheath)
1.6 Identification

2 Testing 393

2.1 Type tests
2.2 Routine tests

Section 10 Miscellaneous Equipment

1 Switchgear and controlgear, protective devices 394

1.1 General
1.2 Circuit-breakers
1.3 Protection devices

2 Lighting fittings 394

2.1 Applicable requirements
2.2 Construction

3 Accessories 395

3.1 Applicable requirements
3.2 Construction

4 Plug-and-socket connections 395

4.1 Applicable requirements

5 Heating and cooking appliances 395

5.1 Applicable requirements
5.2 General
5.3 Space heaters
5.4 Cooking appliances
5.5 Fuel oil and lube oil heaters
5.6 Water heaters

Section 11 Location

1 General 397

1.1 Location
1.2 Areas with a risk of explosion

2 Main electrical system 397

2.1 Location in relation to the emergency system
2.2 Main switchboard

3 Emergency electrical system 397

3.1 Spaces for the emergency source
3.2 Location in relation to the main electrical system
3.3 Emergency switchboard
3.4 Emergency battery

4 Distribution boards 398

4.1 Distribution boards for cargo spaces and similar spaces
4.2 Distribution board for navigation lights

5 Cable runs 398

5.1 General
5.2 Location of cables in relation to the risk of fire and overheating
5.3 Location of cables in relation to electromagnetic interference
5.4 Services with a duplicate feeder
5.5 Emergency circuits

6 Storage batteries 399

6.1 General
6.2 Large vented batteries
6.3 Moderate vented batteries
6.4 Small vented batteries
6.5 Ventilation

Section 12 Installation

1 General 401

1.1 Protection against injury or damage caused by electrical equipment
1.2 Protection against damage to electrical equipment
1.3 Accessibility
1.4 Environmentally controlled spaces

2 Earthing of non-current carrying parts 401

2.1 Parts which are to be earthed
2.2 Methods of earthing
2.3 Earthing connections
2.4 Connection to the ship's structure
2.5 Earthed distribution systems
2.6 Aluminium superstructures

3 Rotating machines 403

3.1 General

4 Semiconductor convertors 403

4.1 Semiconductor power convertors

5 Vented type storage batteries 403

5.1 General
5.2 Protection against corrosion

6 Switchgear and controlgear assemblies 404

6.1 Main switchboard
6.2 Emergency switchboard
6.3 Section boards and distribution boards

7 Cables 404

7.1 General
7.2 Radius of bend
7.3 Fixing of cables
7.4 Mechanical protection
7.5 Penetrations of bulkheads and decks
7.6 Expansion joints
7.7 Cables in closed pipes or conduits
7.8 Cables in casings or trunking and conduits with removable covers
7.9 Cable ends
7.10 Joints and tappings (branch circuit)
7.11 Earthing and continuity of metal coverings of cables
7.12 Earthing and continuity of metal pipes, conduits and trunking or casings
7.13 Precautions for single-core cables for a.c.
7.14 Cables in refrigerated spaces
7.15 Cables in areas with a risk of explosion
7.16 Cables in the vicinity of radio equipment
7.17 Cables for submerged bilge pumps

8 Various appliances 411

8.1 Lighting fittings
8.2 Heating appliances
8.3 Heating cables and tapes or other heating elements

Section 13 High Voltage Installations

1 General 413

1.1 Field of application
1.2 Nominal system voltage
1.3 High-voltage, low-voltage segregation

2 System design 413

2.1 Distribution
2.2 Degrees of protection
2.3 Insulation
2.4 Protection

3 Rotating machinery 415

3.1 Stator windings of generators
3.2 Temperature detectors
3.3 Tests

4 Power transformers 415

4.1 General

5 Cables 415

5.1 General

6 Switchgear and controlgear assemblies 415

6.1 General
6.2 Construction
6.3 Auxiliary systems
6.4 High voltage test

7 Installation 416

7.1 Electrical equipment
7.2 Cables

Section 14 Electric Propulsion Plant

1 General 418

1.1 Applicable requirements
1.2 Operating conditions

2 Design of the propulsion plant 418

2.1 General
2.2 Power supply
2.3 Auxiliary machinery
2.4 Electrical Protection
2.5 Excitation of electric propulsion motor

3 Construction of rotating machines and semiconductor convertors 419

3.1 Ventilation
3.2 Protection against moisture and condensate
3.3 Rotating machines
3.4 Semiconductor convertors

4 Control and monitoring 420

4.1 General
4.2 Power plant control systems
4.3 Indicating instruments
4.4 Alarm system
4.5 Reduction of power

5 Installation 422

5.1 Ventilation of spaces
5.2 Cable runs

6 Tests 422

6.1 Test of rotating machines

7 Specific requirements for PODs 422

7.1 General
7.2 Rotating commutators
7.3 Electric motors
7.4 Instrumentation and associated devices
7.5 Additional tests

Section 15 Testing

1 General 424

1.1 Rule application
1.2 Insulation-testing instruments

2 Type approved components 424

2.1

3 Insulation resistance 424
3.1 Lighting and power circuits
3.2 Internal communication circuits
3.3 Switchboards
3.4 Generators and motors
4 Earth 425
4.1 Electrical constructions
4.2 Metal-sheathed cables, metal pipes or conduits
5 Operational tests 425
5.1 Generating sets and their protective devices
5.2 Switchgear
5.3 Consuming devices
5.4 Communication systems
5.5 Installations in areas with a risk of explosion
5.6 Voltage drop

Chapter 3 Automation

Section 1 General Requirements

1 General 428
1.1 Field of application
1.2 Regulations and standards
1.3 Definitions
1.4 General
2 Documentation 429
2.1 General
2.2 Documents to be submitted
2.3 Documents for type approval of equipment
3 Environmental and supply conditions 430
3.1 General
3.2 Power supply conditions
4 Materials and construction 430
4.1 General
4.2 Type approved components

Section 2 Design Requirements

1 General 431
1.1
2 Power supply of automation systems 431
2.1 General
2.2 Electrical power supply
3 Control systems 431
3.1 General
3.2 Local control
3.3 Remote control systems
3.4 Automatic control systems

4 Control of propulsion machinery 432

4.1 Remote control
4.2 Remote control from navigating bridge
4.3 Automatic control
4.4 Automatic control of propulsion and manoeuvring units
4.5 Clutches
4.6 Brakes

5 Communications 434

5.1 Communications between navigating bridge and machinery space
5.2 Engineers' alarm

6 Remote control of valves 434

6.1

7 Alarm system 434

7.1 General requirements
7.2 Alarm functions

8 Safety system 435

8.1 Design
8.2 Function
8.3 Shutdown
8.4 Standby systems
8.5 Testing

Section 3 Computer Based Systems

1 General requirements 437

1.1 Application
1.2 Requirement for ship
1.3 Requirements for computerized systems
1.4 References

2 Definitions 437

2.1 Stakeholders
2.2 Objects
2.3 System categories
2.4 Other terminology

3 Documentation and test attendance 439

3.1

4 Requirements for software and supporting hardware 440

4.1 Life cycle approach
4.2 Limited approval
4.3 Modifications during operation
4.4 System security

5 Requirements for hardware 443

5.1 Requirements for hardware regarding environment
5.2 Requirements for hardware regarding construction

6 Requirements for data communication links for Category II and III systems 443

6.1 General requirements
6.2 Specific requirements for wireless data links

Section 1 General Requirements

1 General

1.1 Application

1.1.1 Part C, Chapter 1 applies to the design, construction, installation, tests and trials of main propulsion and essential auxiliary machinery systems and associated equipment, boilers and pressure vessels, piping systems, and steering and manoeuvring systems installed on board classed ships, as indicated in each Section of this Chapter.

For computerized Machinery systems, requirements contained in Part C, Chapter 3 shall be refered to.

1.2 Additional requirements

1.2.1 Additional requirements for machinery are given in:

- Part D, for the assignment of the service notations
- Part E, for the assignment of additional class notations.

1.3 Documentation to be submitted

1.3.1 Before the actual construction is commenced, the Manufacturer, Designer or Shipbuilder is to submit to the Society the documents (plans, diagrams, specifications and calculations) requested in the relevant Sections of this Chapter.

1.4 Definitions

1.4.1 Dead ship condition

Dead ship condition is the condition under which the main propulsion plant, boilers and auxiliaries are not in operations due to absence of power.

Note 1: Dead ship condition is the condition in which the entire machinery installation, including the power supply, is out of operation and the auxiliary services such as compressed air, starting current from batteries etc. for bringing the main propulsion into operation and for the restoring of the main power supply are not available.

2 Design and construction

2.1 General

2.1.1 The machinery, boilers and other pressure vessels, associated piping systems and fittings are to be of a design and construction adequate for the service for which they are intended and shall be so installed and protected as to reduce to a minimum any danger to persons on board, due regard being paid to moving parts, hot surfaces and other hazards.

The design is to have regard to materials used in construction, the purpose for which the equipment is intended, the working conditions to which it will be subjected and the environmental conditions on board.

2.1.2 Propulsion machinery and related auxiliaries are to be so designed and installed as to comply with the availability requirements stated in Part D for the service notation of the ship and with the requirements of Part E, Chapter 3 when the ship is to be assigned an **AVM** additional class notation.

2.2 Materials, welding and testing

2.2.1 General

Materials, welding and testing procedures are to be in accordance with the requirements of NR216 Materials and Welding, and those given in the other Sections of this Chapter. In addition, for machinery components fabricated by welding the requirements given in [2.2.2] apply.

2.2.2 Welded machinery components

Welding processes and welders are to be approved by the Society in accordance with NR216 Materials and Welding, Chapter 12 and NR476 Approval testing of welders.

References to welding procedures adopted are to be clearly indicated on the plans submitted for approval.

Joints transmitting loads are to be either:

- full penetration butt-joints welded on both sides, except when an equivalent procedure is approved
- full penetration T- or cruciform joints.

2.3 Vibrations

2.3.1 Special consideration is to be given to the design, construction and installation of propulsion machinery systems and auxiliary machinery so that any mode of their vibrations shall not cause undue stresses in this machinery in the normal operating ranges.

2.4 Operation in inclined position

2.4.1 Main propulsion machinery and all auxiliary machinery essential to the propulsion and the safety of the ship are, as fitted in the ship, be designed to operate when the ship is upright and when inclined at any angle of list either way and trim by bow or stern as stated in Tab 1.

The Society may permit deviations from angles given in Tab 1, taking into consideration the type, size and service conditions of the ship.

Machinery with a horizontal rotation axis is generally to be fitted on board with such axis arranged alongships. If this is not possible, the Manufacturer is to be informed at the time the machinery is ordered.

2.5 Ambient conditions

2.5.1 Machinery and systems covered by the Rules are to be designed to operate properly under the ambient conditions specified in Tab 2, unless otherwise specified in each Section of this Chapter.

Table 1 : Inclination of ship

Installations, components	Angle of inclination (degrees) **(1)**			
	Athwartship		Fore and aft	
	static	dynamic	static	dynamic
Main and auxiliary machinery	15	22,5	5	7,5
Safety equipment, e.g. emergency power installations, emergency fire pumps and their devices Switch gear, electrical and electronic appliances **(3)** and remote control systems	22,5 **(2)**	22,5 **(2)**	10	10

(1) Athwartship and fore-and-aft inclinations may occur simultaneously.
(2) In ships for the carriage of liquefied gases and of chemicals the emergency power supply must also remain operable with the ship flooded to a final athwartship inclination up to a maximum of 30°.
(3) Up to an angle of inclination of 45° no undesired switching operations or operational changes may occur.

Table 2 : Ambient conditions

AIR TEMPERATURE	
Location, arrangement	Temperature range, in °C
In enclosed spaces	between 0 and +45**(2)**
On machinery components, boilers In spaces subject to higher or lower temperatures	according to specific local conditions
On exposed decks	between –25 and +45**(1)**

WATER TEMPERATURE	
Coolant	Temperature, in °C
Sea water or, if applicable, sea water at charge air coolant inlet	up to +32

(1) Electronic appliances are to be designed for an air temperature up to 55°C (for electronic appliances see also Part C, Chapter 2).
(2) Different temperatures may be accepted by the Society in the case of ships intended for restricted service.

2.5.2 The full propulsion capability of the ship is to remain available under the following temperature conditions unless other specification:

- air: from –15 to +35°C
- water: from –2 to +30°C.

2.6 Power of machinery

2.6.1 Unless otherwise stated in each Section of this Chapter, where scantlings of components are based on power, the values to be used are determined as follows:

- for main propulsion machinery, the power/rotational speed for which classification is requested. This power/rotational speed should take in account the most stress-inducing propulsion system configuration mode.
- for auxiliary machinery, the power/rotational speed which is available in service.

2.7 Astern power

2.7.1 Sufficient power for going astern is to be provided to secure proper control of the ship in all normal circumstances.

Note 1: Attention is to be paid to maximum stopping distance and to minimum astern thrust, which may be imposed by the ship specification.

For main propulsion systems with reversing gears, controllable pitch propellers or electrical propeller drive, running astern is not to lead to an overload of propulsion machinery.

During the sea trials, the ability of the main propulsion machinery to reverse the direction of thrust of the propeller is to be demonstrated and recorded (see also Ch 1, Sec 16).

2.8 Safety devices

2.8.1 Where risk from overspeeding of machinery exists, means are to be provided to ensure that the safe speed is not exceeded.

2.8.2 Where main or auxiliary machinery including pressure vessels or any parts of such machinery are subject to internal pressure and may be subject to dangerous overpressure, means shall be provided, where practicable, to protect against such excessive pressure.

2.8.3 Main turbine propulsion machinery and, where applicable, main internal combustion propulsion machinery and auxiliary machinery shall be provided with automatic shut-off arrangements in the case of failures, such as lubricating oil supply failure, which could lead rapidly to complete breakdown, serious damage or explosion.

The Society may permit provisions for overriding automatic shut-off devices.

See also the specific requirements given in the other Sections of this Chapter.

2.9 Fuels

2.9.1 Fuel oils employed for engines and boilers are, in general, to have a flash point (determined using the closed cup test) of not less than 60°C.

For ships assigned with a restricted navigation notation, or whenever special precautions are taken to the Society’s satisfaction, fuel oils having a flash point of less than 60°C but not less than 43°C may be used for engines, provided that, from previously effected checks, it is evident that the temperature of spaces where fuel oil is stored or employed will be at least 10°C below the fuel oil flash point at all times.

Fuel oil having flash points of less than 43°C may be employed on board provided that it is stored on an open deck.

3 Arrangement and installation on board

3.1 General

3.1.1 Provision shall be made to facilitate cleaning, inspection and maintenance of main propulsion and auxiliary machinery, including boilers and pressure vessels.

Suitable demountable openings are to be foreseen in decks and bulkheads for the purpose of disembarking main machinery whose maintenance is intended to be carried out ashore.

Easy access to the various parts of the propulsion machinery is to be provided by means of metallic ladders and gratings fitted with strong and safe handrails.

Spaces containing main and auxiliary machinery are to be provided with adequate lighting and ventilation.

3.1.2 In machinery spaces of Category A, electric switchboard, cabinet or junction box and electric equipment of essential services are to be located above the level corresponding to the lowest generating line of the propeller shaft.

In machinery spaces without propeller shaft this level is corresponding to the lowest generating line of the output shaft of main or auxiliary prime mover installed.

3.2 Floors

3.2.1 Floors in engine rooms are to be made of steel, divided into easily removable panels.

3.3 Bolting down

3.3.1 Bedplates of machinery are to be securely fixed to the supporting structures by means of foundation bolts which are to be distributed as evenly as practicable and of a sufficient number and size so as to ensure a perfect fit.

Where the bedplates bear directly on the inner bottom plating, the bolts are to be fitted with suitable gaskets so as to ensure a tight fit and are to be arranged with their heads within the double bottom.

Continuous contact between bedplates and foundations along the bolting line is to be achieved by means of chocks of suitable thickness, carefully arranged to ensure a complete contact.

The same requirements apply to thrust block and shaft line bearing foundations.

Particular care is to be taken to obtain a perfect levelling and general alignment between the propulsion engines and their shafting (see Ch 1, Sec 7).

3.3.2 Chocking resins are to be type approved.

3.4 Safety devices on moving parts

3.4.1 Suitable protective devices are to be provided in way of moving parts (flywheels, couplings, etc.) in order to avoid injuries to personnel.

3.5 Gauges

3.5.1 All gauges are to be grouped, as far as possible, near each manoeuvring position; in any event, they are to be clearly visible.

3.6 Ventilation in machinery spaces

3.6.1 Machinery spaces are to be sufficiently ventilated so as to ensure that when machinery or boilers therein are operating at full power in all weather condition, including heavy weather, a sufficient supply of air is maintained to the spaces for the safety of personnel and the operation of the machinery, without exceeding the temperature values under Tab 2.

Special attention is to be paid both to air delivery and extraction and to air distribution in the various spaces.

The ventilation is to be so arranged as to prevent any accumulation of flammable gases or vapours.

Machinery air intake is to be ducted from an open space; the size and fittings of ducts are to be such as to satisfy the machinery flow, pressure and quality requirements for developing maximum continuous power.

3.7 Hot surfaces and fire protection

3.7.1 Surfaces, having temperature exceeding 60°C, with which the crew are likely to come into contact during operation are to be suitably protected or insulated.

Surfaces of machinery with temperatures above 220°C, e.g. steam, thermal oil and exhaust gas lines, silencers, exhaust gas boilers and turbochargers, are to be effectively insulated with non-combustible material or equivalently protected to prevent the ignition of combustible materials coming into contact with them. Where the insulation used for this purpose is oil absorbent or may permit the penetration of oil, the insulation is to be encased in steel sheathing or equivalent material.

Fire protection, detection and extinction is to comply with the requirements of Part C, Chapter 4.

3.8 Communications

3.8.1 At least two independent means are to be provided for communicating orders from the navigating bridge to the position in the machinery space or in the control room from which the speed and the direction of the thrust of the propellers are normally controlled; one of these is to be an engine room telegraph, which provides visual indication of the orders and responses both in the machinery space and on the navigating bridge, with audible alarm mismatch between order and response.

Appropriate means of communication shall be provided from the navigating bridge and the engine room to any other position from which the speed and direction of thrust of the propellers may be controlled.

The second means for communicating orders is to be fed by an independent power supply and is to be independent of other means of communication.

Where the main propulsion system of the ship is controlled from the navigating bridge by a remote control system, the second means of communication may be the same bridge control system.

The engine room telegraph is required in any case, even if the remote control of the engine is foreseen, irrespective of whether the engine room is attended.

For ships assigned with a restricted navigation notation these requirements may be relaxed at the Society's discretion.

3.9 Machinery remote control, alarms and safety systems

3.9.1 For remote control systems of main propulsion machinery and essential auxiliary machinery and relevant alarms and safety systems, the requirements of Part C, Chapter 3 apply.

4 Tests and trials

4.1 Works tests

4.1.1 Equipment and its components are subjected to works tests which are detailed in the relevant Sections of this Chapter and are to be witnessed by the Surveyor.

In particular cases, where such tests cannot be performed in the workshop, the Society may allow them to be carried out on board, provided this is not judged to be in contrast either with the general characteristics of the machinery being tested or with particular features of the shipboard installation. In such cases, the Surveyor entrusted with the acceptance of machinery on board and the purchaser are to be informed in advance and the tests are to be carried out in accordance with the provisions of NR216 Materials and Welding relative to incomplete tests.

All boilers, all parts of machinery, all steam, hydraulic, pneumatic and other systems and their associated fittings which are under internal pressure shall be subjected to appropriate tests including a pressure test before being put into service for the first time as detailed in the other Sections of this Chapter.

4.2 Trials on board

4.2.1 Trials on board of machinery are detailed in Ch 1, Sec 16.

Section 2 Diesel Engines

1 General

1.1 Application

1.1.1 Diesel engines listed below are to be designed, constructed, installed, tested and certified in accordance with the requirements of this Section, under the supervision and to the satisfaction of a Surveyor of the Society:

a) main propulsion engines

b) engines driving electric generators, including emergency generators

c) engines driving other auxiliaries essential for safety and navigation when they develop a power of 110 kW and over.

All other engines are to be designed and constructed according to sound marine practice, with the equipment required in [2.4.4], and delivered with the relevant works' certificate (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.3]).

Engines intended for propulsion of lifeboats and compression ignition engines intended for propulsion of rescue boats are to comply with the relevant Rules requirements.

Other procedures proposed or accepted by the ship Owner will be also considered on a case by case basis.

In addition to the requirements of this Section, those given in Ch 1, Sec 1 apply.

1.2 Documentation to be submitted

1.2.1 The Manufacturer is to submit to the Society the documents listed in Tab 1 for engine type approval.

Plans listed under items 2 and 3 in Tab 1 are also to contain details of the lubricating oil sump in order to demonstrate compliance with Ch 1, Sec 1, [2.4].

Where changes are made to an engine type for which the documents listed in Tab 1 have already been examined or approved, the engine Manufacturer is to resubmit to the Society for consideration and approval only those documents concerning the engine parts which have undergone substantial changes.

If the engines are manufactured by a licensee, the licensee is to submit, for each engine type, a list of all the drawings specified in Tab 1, indicating for each drawing the relevant number and revision status from both licensor and licensee.

Where the licensee proposes design modifications to components, the associated documents are to be submitted by the licensee to the Society for approval or for information purposes. In the case of significant modifications, the licensee is to provide the Society with a statement confirming the licensor's acceptance of the changes. In all cases, the licensee is to provide the Surveyor entrusted to carry out the testing, with a complete set of the documents specified in Tab 1.

Table 1 : Documentation to be submitted

No.	I/A**(1)**	Document	Document details
1	I	Engine particulars as per the Society form "Particulars of diesel engines" or equivalent form	–
2	I	Engine transverse cross-section	Max inclination angles, oil surface lines, oil suction strum position
3	I	Engine longitudinal section	Max inclination angles, oil surface lines, oil suction strum position
4	I / A	Bedplate or crankcase, cast or welded For welded bedplates or cranks, welding details and instructions	Design of welded joints, electrodes used, welding sequence, heat treatment, non-destructive examinations
5	A	Thrust bearing assembly **(2)**	–
6	I / A	Thrust bearing bedplate, cast or welded. For welded bedplates or cranks, welding details and instructions **(2)**	Design of welded joints, electrodes used, welding sequence, heat treatment, non-destructive examinations
7	I / A	Frame/column, cast or welded with welding details and instructions **(3)**	Design of welded joints, electrodes used, welding sequence, heat treatment, non-destructive examinations
8	I	Tie rod	–
9	I	Cylinder cover, assembly	–

No.	I/A**(1)**	Document	Document details
10	I	Cylinder jacket or engine block **(3)** **(4)**	–
11	I	Cylinder liner **(4)**	–
12	A	Crankshaft, details, for each cylinder number	–
13	A	Crankshaft, assembly, for each cylinder number	–
14	A	Thrust shaft or intermediate shaft (if integral with engine)	–
15	A	Coupling bolts	–
16	A	Counterweights (if not integral with crankshaft), with associated fastening bolts	Bolt fastening instructions
17	I	Connecting rod	–
18	I	Connecting rod, assembly **(4)**	Bolt fastening instructions
19	I	Crosshead, assembly **(4)**	–
20	I	Piston rod, assembly **(4)**	–
21	I	Piston, assembly	–
22	I	Camshaft drive, assembly	–
23	A	Material specifications of main parts of engine, with detailed information on: - non-destructive tests, and - pressure tests	Required for items 4, 7, 8, 9, 10, 11, 12, 15, 18, 21, including acceptable defects and repair procedures Required for items 4, 7, 9, 10, 11, 21 and for injection pumps and exhaust manifold
24	A	Arrangement of foundation bolts (for main engines only)	–
25	A	Schematic layout or other equivalent documents for starting air system on the engine **(5)**	–
26	A	Schematic layout or other equivalent documents for fuel oil system on the engine **(5)**	–
27	A	Schematic layout or other equivalent documents for lubricating oil system on the engine **(5)**	–
28	A	Schematic layout or other equivalent documents for cooling water system on the engine **(5)**	–
29	A	Schematic diagram of engine control and safety system on the engine **(5)** (see also [2.10])	List, specification and layout of sensors, automatic controls and other control and safety devices
30	I	Shielding and insulation of exhaust pipes, assembly	–
31	A	Shielding of high pressure fuel pipes, assembly (see also [2.7.2])	Recovery and leak detection devices
32	A	Crankcase explosion relief valves **(6)** (see also [2.4.4])	Volume of crankcase and other spaces (camshaft drive, scavenge, etc.)
33	I	Operation and service manuals	–
34	I	Data sheet for torsional vibration calculations	Inertia and stiffness
35	I	Bearing load calculation or oil film thickness calculation	–

(1) A = to be submitted for approval ; I = to be submitted for information.
Where two indications I / A are given, the first refers to cast design and the second to welded design.
(2) To be submitted only if the thrust bearing is not integral with the engine and not integrated in the engine bedplate.
(3) Only for one cylinder.
(4) To be submitted only if sufficient details are not shown on the engine transverse and longitudinal cross-sections.
(5) Dimensions and materials of pipes, capacity and head of pumps and compressors and any additional functional information are to be included. The layout of the entire system is also required, if this is part of the goods to be supplied by the engine Manufacturer.
(6) Required only for engines with cylinder bore of 200 mm and above or crankcase gross volume of 0,6 m^3 and above.

1.3 Definitions

1.3.1 Engine type

In general, the type of an engine is defined by the following characteristics:

- the cylinder diameter
- the piston stroke
- the method of injection (direct or indirect injection)
- the kind of fuel (liquid, gaseous or dual-fuel)
- the working cycle (4-stroke, 2-stroke)
- the gas exchange (naturally aspirated or supercharged)
- the maximum continuous power per cylinder at the corresponding speed and/or brake mean effective pressure corresponding to the above-mentioned maximum continuous power
- the method of pressure charging
- the charging air cooling system (with or without intercooler, number of stages, etc.)
- cylinder arrangement (in-line or V-type).

1.3.2 Engine power

The maximum continuous power is the maximum power at ambient reference conditions [1.3.3] which the engine is capable of delivering continuously, at nominal maximum speed, in the period of time between two consecutive overhauls.

Power, speed and the period of time between two consecutive overhauls are to be stated by the Manufacturer and agreed by the Society.

Note 1: Power corrections are to be made in accordance with ISO 3046 standard.

The rated power is the maximum power at ambient reference conditions [1.3.3] which the engine is capable of delivering as set after works trials (fuel stop power) at the maximum speed allowed by the governor.

The rated power for engines driving electric generators is the nominal power, taken at the net of overload, at ambient reference conditions [1.3.3], which the engine is capable of delivering as set after the works trials [4.5].

1.3.3 Ambient reference conditions

The power of engines as per [1.1.1], items a), b) and c) is to be referred to the following conditions:

- barometric pressure = 0,1 MPa
- relative humidity = 60%
- ambient air temperature = 45°C
- sea water temperature (and temperature at inlet of sea water cooled charge air cooler) = 32°C.

In the case of ships assigned with a navigation notation other than unrestricted navigation, different temperatures may be accepted by the Society.

The engine Manufacturer is not expected to provide the above ambient conditions at a test bed. The rating is to be adjusted according to a recognised standard accepted by the Society.

1.3.4 Same type of engines

Two diesel engines are considered to be of the same type when they do not substantially differ in design and construction characteristics, such as those listed in the engine type definition as per [1.3.4], it being taken for granted that the documentation concerning the essential engine components listed in [1.2] and associated materials employed has been submitted, examined and, where necessary, approved by the Society.

2 Design and construction

2.1 General

2.1.1 Operating conditions

Attention is to be paid to the specific operating conditions of the engine (e.g. continuous operation at low load) which may be imposed by the ship specification.

2.2 Materials and welding

2.2.1 Crankshaft materials

In general, crankshafts are to be of forged steel having a tensile strength not less than 400 N/mm^2 and not greater than 1000 N/mm^2.

The use of forged steels of higher tensile strength is subject to special consideration by the Society in each case.

The Society, at its discretion and subject to special conditions (such as restrictions in ship navigation), may accept crankshafts made of cast carbon steel or cast alloyed steel of appropriate quality and manufactured by a suitable procedure having a tensile strength as follows:

- between 400 N/mm² and 560 /mm² for cast carbon steel
- between 400 N/mm² and 700 N/mm² for cast alloyed steel.

2.2.2 Welded frames and foundations

Steels used in the fabrication of welded frames and bedplates are to comply with the requirements of NR216 Materials and Welding is to be in accordance with the requirements of Ch 1, Sec 1, [2.2].

2.3 Crankshaft

2.3.1 Check of the scantling

The check of crankshaft strength is to be carried out in accordance with Ch 1, App 1.

Other methods accepted by the ship Owner will be considered on a case by case basis.

2.4 Crankcase

2.4.1 Strength

The scantling of crankcases and crankcase doors is to be designed to be of sufficient strength, and the doors are to be securely fastened so that they will not be readily displaced by an explosion.

2.4.2 Ventilation and drainage

Ventilation of crankcase, and any arrangement which could produce a flow of external air within the crankcase, is in principle not permitted.

Vent pipes, where provided, are to be as small as practicable. If provision is made for the forced extraction of gases from the crankcase (e.g. for detection of explosive mixtures), the vacuum in the crankcase is not to exceed $2{,}5.10^{-4}$ MPa.

Where two or more engines are installed, their vent pipes and lubricating oil drain pipes are to be independent to avoid intercommunication between crankcases.

Lubricating oil drain pipes from the engine sump to the drain tank are to be submerged in the latter at their outlet ends.

2.4.3 Warning notice

A warning notice is to be fitted, preferably on a crankcase door on each side of the engine, or alternatively on the control stand.

This warning notice is to specify that whenever overheating is suspected in the crankcase, the crankcase doors or sight holes are not to be opened until a reasonable time has elapsed after stopping the engine, sufficient to permit adequate cooling of the crankcase.

2.4.4 Crankcase explosion relief valves

a) Diesel engines of a cylinder diameter of 200 mm and above or a crankcase gross volume of 0,6 m³ and above are to be provided with crankcase explosion relief valves in accordance with the following requirements.

b) Engines having a cylinder bore not exceeding 250 mm, are to have at least one valve near each end, but over eight crankthrows, an additional valve is to be fitted near the middle of the engine. Engines having a cylinder bore exceeding 250 mm, but not exceeding 300 mm, are to have at least one valve in way of each alternate crankthrow, with a minimum of two valves. Engines having a cylinder bore exceeding 300 mm are to have at least one valve in way of each main crankthrow.

c) Additional relief valves are to be fitted on separate spaces of the crankcase, such as gear or chain cases for camshaft or similar drives, when the gross volume of such spaces is 0,6 m³ or above. Scavenge spaces in open connection to the cylinders are to be fitted with explosion relief valves.

d) The free area of each relief valve is not to be less than 45 cm².

e) The combined free area of the valves fitted on an engine is not to be less than 115 cm² per cubic metre of the crankcase gross volume. (See Note 1).

f) Crankcase explosion relief valves are to be provided with lightweight spring-loaded valve discs or other quick-acting and self closing devices to relieve a crankcase of pressure in the event of an internal explosion and to prevent any inrush of air thereafter.

g) The valve discs in crankcase explosion relief valves are to be made of ductile material capable of withstanding the shock of contact with stoppers at the full open position.

h) Crankcase explosion relief valves are to be designed and constructed to open quickly and to be fully open at a pressure not greater than 0,02 MPa.

i) Crankcase explosion relief valves are to be provided with a flame arrester that permits flow for crankcase pressure relief and prevents passage of flame following a crankcase explosion.

j) Crankcase explosion relief valves are to be type tested in a configuration that represents the installation arrangements that will be used on an engine.

The purpose of type testing crankcase explosion valves is:

- to verify the effectiveness of the flame arrester
- to verify that the valve closes after an explosion
- to verify that the valve is gas/air tight after an explosion
- to establish the level of overpressure protection provided by the valve.

Where crankcase relief valves are provided with arrangements for shielding emissions from the valve following an explosion, the valve is to be type tested to demonstrate that the shielding does not adversely affect the operational effectiveness of the valve.

k) Crankcase explosion relief valves are to be provided with a copy of the manufacturer's installation and maintenance manual that is pertinent to the size and type of valve being supplied for installation on a particular engine.

The manual is to contain the following information:

- description of valve with details of function and design limits
- copy of type test certification
- installation instructions
- maintenance in service instructions to include testing and renewal of any sealing arrangements
- actions required after a crankcase explosion.

l) A copy of the installation and maintenance manual required in i) above is to be provided on board the unit.

m) Valves are to be provided with suitable markings that include the following information:

- name and address of manufacturer
- designation and size
- month/year of manufacture
- approved installation orientation.

Note 1: The total volume of the stationary parts within the crankcase may be discounted in estimating the crankcase gross volume (rotating and reciprocating components are to be included in the gross volume).

2.5 Cylinder overpressure gauge

2.5.1 Means are to be provided to indicate a predetermined overpressure in the cylinders of engines having a bore exceeding 230 mm.

2.6 Scavenge manifolds

2.6.1 Fire-extinguishing

For two-stroke crosshead type engines, scavenge spaces in open connection (without valves) to the cylinders are to be connected to a fixed fire-extinguishing system, which is to be entirely independent of the fire-extinguishing system of the machinery space.

2.6.2 Blowers

Where a single two-stroke propulsion engine is equipped with an independently driven blower, alternative means to drive the blower or an auxiliary blower are to be provided ready for use.

2.6.3 Relief valves

Scavenge spaces in open connection to the cylinders are to be fitted with explosion relief valves in accordance with [2.4.4].

2.7 Systems

2.7.1 General

In addition to the requirements of the present sub-article, those given in Ch 1, Sec 10 are to be satisfied.

Flexible hoses in the fuel and lubricating oil system are to be limited to the minimum and are to be type approved.

2.7.2 Fuel oil system

Relief valves discharging back to the suction of the pumps or other equivalent means are to be fitted on the delivery side of the pumps.

In fuel oil systems for propulsion machinery, filters are to be fitted and arranged so that an uninterrupted supply of filtered fuel oil is ensured during cleaning operations of the filter equipment, except when otherwise stated in Ch 1, Sec 10.

a) All external high pressure fuel delivery lines between the high pressure fuel pumps and fuel injectors are to be protected with a shielded piping system capable of containing fuel from a high pressure line failure.

A shielded pipe incorporates an outer pipe into which the high pressure fuel pipe is placed forming a permanent assembly.

The shielded piping system is to include a means for collection of leakages and arrangements are to be provided for an alarm to be given in the event of a fuel line failure.

If flexible hoses are used for shielding purposes, these are to be approved by the Society.

When in fuel oil return piping the pulsation of pressure with peak to peak values exceeds 2 MPa, shielding of this piping is also required as above.

b) For ships classed for restricted navigation, the requirements under a) may be relaxed at the Society’s discretion.

2.7.3 Lubricating oil system

Efficient filters are to be fitted in the lubricating oil system when the oil is circulated under pressure.

In such lubricating oil systems for propulsion machinery, filters are to be arranged so that an uninterrupted supply of filtered lubricating oil is ensured during cleaning operations of the filter equipment, except when otherwise stated in Ch 1, Sec 10.

Relief valves discharging back to the suction of the pumps or other equivalent means are to be fitted on the delivery side of the pumps.

The relief valves may be omitted provided that the filters can withstand the maximum pressure that the pump may develop.

Where necessary, the lubricating oil is to be cooled by means of suitable coolers.

2.7.4 Charge air system

a) Requirements relevant to design, construction, arrangement, installation, tests and certification of exhaust gas turbochargers are given in Ch 1, Sec 15.

b) When two-stroke propulsion engines are supercharged by exhaust gas turbochargers which operate on the impulse system, provision is to be made to prevent broken piston rings entering turbocharger casings and causing damage to blades and nozzle rings.

2.8 Starting air system

2.8.1 The requirements given in [3.1] apply.

2.9 Cooling system

2.9.1 The requirements given in Ch 1, Sec 10, [10] apply.

2.10 Control and monitoring

2.10.1 General

In addition to those of this item, the general requirements given in Part C, Chapter 3 apply.

2.10.2 Governors of main and auxiliary engines

Each engine, except the auxiliary engines for driving electric generators for which [2.10.5] applies, is to be fitted with a speed governor so adjusted that the engine does not exceed the rated speed by more than 15%.

2.10.3 Overspeed protective devices of main and auxiliary engines

In addition to the speed governor, each

- main propulsion engine having a rated power of 220kW and above, which can be declutched or which drives a controllable pitch propeller, and
- auxiliary engine having a rated power of 220kW and above, except those for driving electric generators, for which [2.10.6] applies,

is to be fitted with a separate overspeed protective device so adjusted that the engine cannot exceed the rated speed n by more than:

- 12% in case of mechanical device
- 15% in case of electrical device.

Equivalent arrangements may be accepted subject to special consideration by the Society in each case.

The overspeed protective device, including its driving mechanism or speed sensor, is to be independent of the governor.

2.10.4 Governors for auxiliary engines driving electric generators

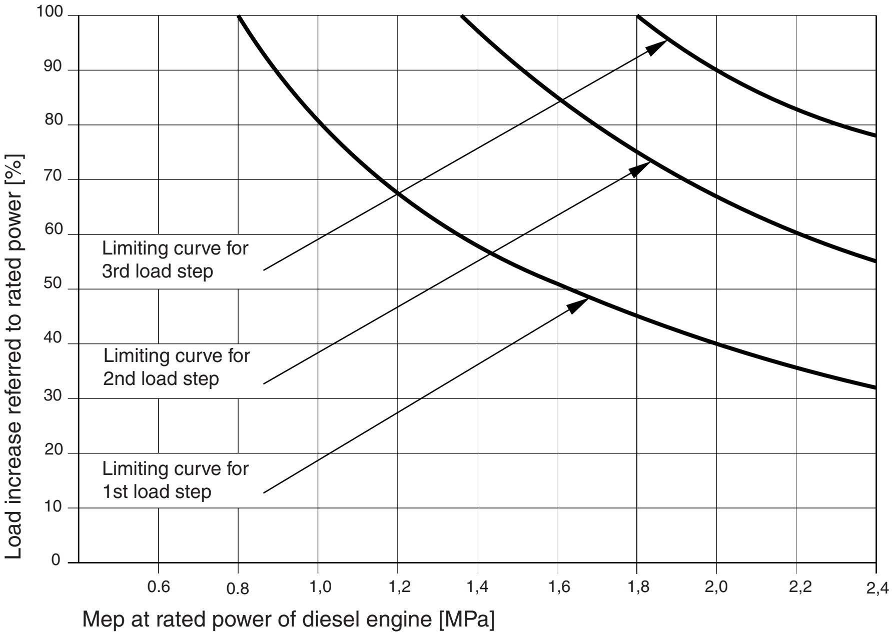
a) Auxiliary engines intended for driving electric generators are to be fitted with a speed governor which prevents any transient speed variations in excess of 10% of the rated speed when the rated power is suddenly thrown off or specific loads are suddenly thrown on.

b) At all loads between no load and rated power, the permanent speed variation is not to be more than 5% of the rated speed.

c) Prime movers are to be selected in such a way that they meet the load demand within the ship’s mains and, when running at no load, can satisfy the requirement in item a) above if suddenly loaded to 50% of the rated power of the generator, followed by the remaining 50% after an interval sufficient to restore speed to steady state. Steady state conditions (see Note 1) are to be achieved in not more than 5 s.

Note 1: Steady state conditions are those at which the envelope of speed variation does not exceed ±1% of the declared speed at the new power.

Figure 1 : Limiting curves for loading 4-stroke diesel engines step by step from no load to rated power as a function of the brake mean effective pressure



d) Application of the electrical load in more than 2 load steps can only be allowed if the conditions within the ship's mains permit the use of those auxiliary engines which can only be loaded in more than 2 load steps (see Fig 1 for guidance) and provided that this is already allowed for in the designing stage.

This is to be verified in the form of system specifications to be approved and to be demonstrated at ship's trials. In this case, due consideration is to be given to the power required for the electrical equipment to be automatically switched on after blackout and to the sequence in which it is connected

This also applies to generators to be operated in parallel and where the power is to be transferred from one generator to another, in the event that any one generator is to be switched off.

e) When the rated power is suddenly thrown off, steady state conditions should be achieved in not more than 5s.

f) Emergency generator sets must satisfy the governor conditions as per items a) and b) even when their total emergency consumer load is applied suddenly.

g) For alternating current generating sets operating in parallel, the governing characteristics of the prime movers are to be such that, within the limits of 20% and 100% total load, the load on any generating set will not normally differ from its proportionate share of the total load by more than 15% of the rated power in kW of the largest machine or 25% of the rated power in kW of the individual machine in question, whichever is the lesser.

For alternating current generating sets intended to operate in parallel, facilities are to be provided to adjust the governor sufficiently finely to permit an adjustment of load not exceeding 5% of the rated load at normal frequency.

2.10.5 Overspeed protective devices of auxiliary engines driving electric generators

In addition to the speed governor, auxiliary engines of rated power equal to or greater than 220 kW driving electric generators are to be fitted with a separate overspeed protective device, with a means for manual tripping, adjusted so as to prevent the rated speed from being exceeded by more than 15%.

This device is to automatically shut down the engine.

2.10.6 Use of electronic governors

a) Type approval

Provisions are to be made for controlling the engine speed in case of failure of the electrical supply.

Electronic governors and their actuators are to be type approved by the Society.

b) Electronic governors for main propulsion engines

If an electronic governor is fitted to ensure continuous speed control or resumption of control after a fault, an additional separate governor is to be provided unless the engine has a manually operated fuel admission control system suitable for its control.

A fault in the governor system is not to lead to sudden major changes in propulsion power or direction of propeller rotation.

Alarms are to be fitted to indicate faults in the governor system.

The acceptance of electronic governors not in compliance with the above requirements will be considered by the Society on a case by case basis, when fitted on ships with two or more main propulsion engines.

c) Electronic governors for auxiliary engines driving electric generators

In the event of a fault in the electronic governor system the fuel admission is to be set to "zero".

Alarms are to be fitted to indicate faults in the governor system.

The acceptance of electronic governors fitted on engines driving emergency generators will be considered by the Society on a case by case basis.

2.10.7 Summary tables

Diesel engines installed on ships without automation notations are to be equipped with monitoring equipment as detailed in Tab 2 and Tab 3 for main propulsion, in Tab 4 for auxiliary services and in Tab 5 for emergency services.

The alarms are to be visual and audible.

The indicators are to be fitted at a normally attended position (on the engine or at the local control station).

Table 2 : Monitoring of main propulsion slow speed diesel engines

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Main Engine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shutdown	Control	Stand by Start	Stop
Fuel oil pressure after filter (engine inlet)		local					
Fuel oil viscosity before injection pumps or fuel oil temperature before injection pumps (for engine running on heavy fuel)		local					
Fuel rack position		local					
Leakage from high pressure pipes where required	H						
Lubricating oil to main bearing and thrust bearing pressure	L **(4)**	local					
	LL			X			
Lubricating oil to cross-head bearing pressure when separate	L **(4)**	local					
	LL			X			
Lubricating oil to camshaft pressure when separate	L **(4)**	local					
	LL			X			
Turbocharger lubricating oil inlet pressure		local					
Lubricating oil inlet temperature		local					
Thrust bearing pads or bearing outlet temperature	H	local					
Main, crank, cross-head bearing, oil outlet temp	H						
Cylinder fresh cooling water system inlet pressure	L	local**(3)**					
Cylinder fresh cooling water outlet temperature or, when common cooling space without individual stop valves, the common cylinder water outlet temperature	H	local					
	HH		X				
Piston coolant inlet pressure on each cylinder **(1)**	L	local					
Piston coolant outlet temperature on each cylinder**(1)**		local					
Piston coolant outlet flow on each cylinder **(1)** **(2)**	L						
Speed of turbocharger		local					
Scavenging air receiver pressure		local					
Scavenging air box temperature (detection of fire in receiver)		local					
Exhaust gas temperature		local**(5)**					
Engine speed / direction of speed (when reversible)		local					
	H			X			
Fault in the electronic governor system	X						

(1) Not required, if the coolant is oil taken from the main cooling system of the engine.
(2) Where outlet flow cannot be monitored due to engine design, alternative arrangement may be accepted.
(3) For engines of 220 KW and above.
(4) Audible and visual alarm.
(5) Indication is required after each cylinder, for engines of 500 kW per cylinder and above.

Table 3 : Monitoring of main propulsion medium or high speed diesel engines

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Main Engine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shutdown	Control	Stand by Start	Stop
Fuel oil pressure after filter (engine inlet)		local					
Fuel oil viscosity before injection pumps or fuel oil temperature before injection pumps (for engine running on heavy fuel)		local					
Fuel rack position		local					
Leakage from high pressure pipes where required	H						
Lubricating oil to main bearing and thrust bearing pressure	L **(2)**	local					
	LL			X			
Lubricating oil filter differential pressure	H	local					
Turbocharger lubricating oil inlet pressure **(4)**		local					
Lubricating oil inlet temperature		local					
Cylinder fresh cooling water system inlet pressure	L	local**(1)**					
Cylinder fresh cooling water outlet temperature or, when common cooling space without individual stop valves, the common cylinder water outlet temperature	H	local					
	HH		X				
Cylinder fresh cooling water, expansion tank level	L	local					
	LL		X				
Scavenging air receiver pressure		local					
Scavenging air box temperature (detection of fire in receiver)		local					
Exhaust gas temperature		local**(3)**					
Engine speed / direction of speed (when reversible)		local					
	H			X			
Fault in the electronic governor system	X						

(1) For engines of 220 kW and above.
(2) Audible and visual alarm.
(3) Indication is required after each cylinder, for engines of 500 kW per cylinder and above.
(4) If without integrated self-contained oil lubrication system.

Table 4 : Monitoring of diesel engines used for auxiliary services

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Engine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Fuel oil pressure		local					
Fuel oil leakage from pressure pipes	H						
Lubricating oil pressure	L	local		X**(1)**			
Pressure or flow of cooling water, if not connected to main system	L	local					
Temperature of cooling water or cooling air		local					
Cylinder fresh cooling water, expansion tank level	L	local					
	LL		X				
Engine speed		local					
	H			X			
Exhaust gas temperature		local					
Fault in the electronic governor system	X						

(1) Not applicable to emergency generator set.

Table 5 : Monitoring of emergency diesel engines

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Engine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Fuel oil leakage from pressure pipes	H						
Lubricating oil temperature**(1)**	H	local					
Lubricating oil pressure	L	local					
Oil mist concentration in crankcase **(2)**	H	local					
Pressure or flow of cooling water **(1)**	L	local					
Temperature of cooling water or cooling air		local					
Engine speed		local					
	H			X**(1)**			
Fault in the electronic governor system	X						

(1) Not applicable to emergency generator set of less than 220 kW.
(2) For engines having a power of more than 2250 kW or a cylinder bore of more than 300 mm.
Note 1: The safety and alarm systems are to be designed to 'fail safe'. The characteristics of the 'fail safe' operation are to be evaluated on the basis not only of the system and its associated machinery, but also the complete installation, as well as the ship.
Note 2: Regardless of the engine output, if shutdowns additional to those above specified except for the overspeed shutdown, they are to be automatically overridden when the engine is in automatic or remote control mode during navigation.
Note 3: The alarm system is to function in accordance with **AUT** notation, with additional requirements that grouped alarms are to be arranged on the bridge.
Note 4: In addition to the fuel oil control from outside the space, a local means of engine shutdown is to be provided.
Note 5: The local indications are to be provided within the same space as the diesel engines and are to remain operational in the event of failure of the alarm and safety systems.

3 Arrangement and installation

3.1 Starting arrangements

3.1.1 Mechanical air starting

a) The total capacity of air receivers of each propulsion line is to be sufficient to provide, without replenishment, not less than 12 consecutive starts alternating between ahead and astern of main engines of the reversible type, and not less than 6 consecutive starts of main non-reversible type engines connected to a controllable pitch propeller or other device enabling the start without opposite torque.

When other users such as auxiliary engine starting systems, control systems, whistle etc. are connected to the starting air receivers of main propulsion engines, their air consumption is also to be taken into account.

For multi-engine propulsion plants, the capacity of the starting air receivers is to be sufficient to ensure at least 3 consecutive starts per engine. However, the total capacity is not to be less than 12 starts and need not exceed 18 starts.

Regardless of the above, for multi-engine installations the number of starts required for each engine may be reduced subject to the agreement of the Society and depending upon the arrangement of the engines and the transmission of their output to the propellers.

b) The main starting air arrangements for main propulsion or auxiliary diesel engines are to be adequately protected against the effects of backfiring and internal explosion in the starting air pipes. To this end, the following safety devices are to be fitted:

- An isolating non-return valve, or equivalent, at the starting air supply connection to each engine.
- A bursting disc or flame arrester:
  - in way of the starting valve of each cylinder, for direct reversing engines having a main starting air manifold
  - at least at the supply inlet to the starting air manifold, for non-reversing engines.

  The bursting disc or flame arrester above may be omitted for engines having a bore not exceeding 230 mm.

Other protective devices will be specially considered by the Society.

The requirements of this item c) do not apply to engines started by pneumatic motors.

c) Compressed air receivers are to comply with the requirements of Ch 1, Sec 3. Compressed air piping and associated air compressors are to comply with the requirements of Ch 1, Sec 10.

3.1.2 Electrical starting

a) Where main internal combustion engines are arranged for electrical starting, at least two separate batteries are to be fitted.

The arrangement is to be such that the batteries cannot be connected in parallel.

Each battery is to be capable of starting the main engine when in cold and ready to start condition.

The combined capacity of batteries is to be sufficient to provide within 30 min, without recharging, the number of starts required in [3.1.1] b) in the event of air starting.

b) Electrical starting arrangements for auxiliary engines are to have two separate storage batteries or may be supplied by two separate circuits from main engine storage batteries when these are provided. In the case of a single auxiliary engine, one battery is acceptable. The combined capacity of the batteries is to be sufficient for at least three starts for each engine.

c) The starting batteries are only to be used for starting and for the engine's alarm and monitoring. Provision is to be made to maintain the stored energy at all times.

d) Each charging device is to have at least sufficient rating for recharging the required capacity of batteries within 6 hours.

3.1.3 Special requirements for starting arrangements for emergency generating sets

a) Emergency generating sets are to be capable of being readily started in their cold condition at a temperature of 0°C. If this is impracticable, or if lower temperatures are likely to be encountered, provision acceptable to the Society shall be made for the maintenance of heating arrangements, to ensure ready starting of the generating sets.

b) Each emergency generating set arranged to be automatically started shall be equipped with starting devices approved by the Society with a stored energy capability of at least three consecutive starts.

The source of stored energy shall be protected to preclude critical depletion by the automatic starting system, unless a second independent means of starting is provided. In addition, a second source of energy shall be provided for an additional three starts within 30 minutes, unless manual starting can be demonstrated to be effective.

c) The stored energy is to be maintained at all times, as follows:

- electrical and hydraulic starting systems shall be maintained from the emergency switchboard
- compressed air starting systems may be maintained by the main or auxiliary compressed air receivers through a suitable non-return valve or by an emergency air compressor which, if electrically driven, is supplied from the emergency switchboard
- all of these starting, charging and energy storing devices are to be located in the emergency generator space; these devices are not to be used for any purpose other than the operation of the emergency generating set. This does not preclude the supply to the air receiver of the emergency generating set from the main or auxiliary compressed air system through the non-return valve fitted in the emergency generator space.

d) Where automatic starting is not required, manual starting, such as manual cranking, inertia starters, manually charged hydraulic accumulators, or powder charge cartridges, is permissible where this can be demonstrated as being effective.

e) When manual starting is not practicable, the requirements of items b) and c) are to be complied with, except that starting may be manually initiated.

3.2 Turning gear

3.2.1 Each engine is to be provided with hand-operated turning gear; where deemed necessary, the turning gear is to be both hand and mechanically-operated.

The turning gear engagement is to inhibit starting operations.

3.3 Trays

3.3.1 Trays fitted with means of drainage are to be provided in way of the lower part of the crankcase and, in general, in way of the parts of the engine, where oil is likely to spill in order to collect the fuel oil or lubricating oil dripping from the engine.

3.4 Exhaust gas system

3.4.1 In addition to the requirements given in Ch 1, Sec 10, the exhaust system is to be efficiently cooled or insulated in such a way that the surface temperature does not exceed 220°C (see also Ch 1, Sec 1, [3.7]).

3.4.2 Pressure losses in the exhaust ducting are to comply with the limits stated by the engine manufacturer.

4 Type tests, material tests, workshop inspection and testing, certification

4.1 Type tests - General

4.1.1 Upon finalisation of the engine design for production of every new engine type intended for installation on board ships, one engine is to be presented for type testing as required below.

A type test carried out for a particular type of engine at any place in any manufacturer's works will be accepted for all engines of the same type (see [1.3.4]) built by licensees and licensors.

In any case, one type test suffices for the whole range of engines having different numbers of cylinders.

Engines which are subjected to type testing are to be tested in accordance with the scope specified below, it being taken for granted that:

- the engine is optimised as required for the conditions of the type test
- the investigations and measurements required for reliable engine operation have been carried out during preliminary internal tests by the engine Manufacturer
- the documentation to be submitted as required in [1.2] has been examined and, when necessary, approved by the Society and the latter has been informed about the nature and extent of investigations carried out during pre-production stages.

4.1.2 At the request of the Manufacturer, an increase in power and/or mean effective pressure up to a maximum of 10% may be accepted by the Society for an engine previously subjected to a type test without any further such test being required, provided the engine reliability has been proved successfully by the service experience of a sufficient number of engines of the same type.

For the purpose of the acceptance of the above performance increase, the Manufacturer is in any case to submit for examination and, where necessary, approval, the documentation listed in [1.2] relevant to any components requiring modification in order to achieve the increased performance.

4.1.3 The Society reserves the right to impose additional requirements or grant dispensations to the following type test programs.

4.2 Type tests of engines not admitted to an alternative inspection scheme

4.2.1 General

Engines which are not admitted to testing and inspections according to an alternative inspection scheme (see NR216 Materials and Welding, Ch 1, Sec 1, [3.2]) are to be type tested in the presence of a Surveyor in accordance with the requirements of [4.2].

The type test is subdivided into three stages, namely:

a) Stage A - Preliminary internal tests carried out by the Manufacturer.

   Stage A includes functional tests and collection of operating values including the number of testing hours during the internal tests, the results of which are to be presented to the Surveyor during the type test. The number of testing hours of components which are inspected according to [4.2.5] is to be stated by the Manufacturer.

b) Stage B - Type approval test

   The type approval test is to be carried out in the presence of the Surveyor.

c) Stage C - Inspection of main engine components.

After completion of the test programme, the main engine components are to be inspected.

The engine Manufacturer is to compile all results and measurements for the engine tested during the type test in a type test report, which is to be submitted to the Society.

4.2.2 Stage A - Internal tests (function tests and collection of operating data)

During the internal tests the engine is to be operated at the load points considered important by the engine Manufacturer and the relevant operating values are to be recorded (see item a)).

The load points may be selected according to the range of application (see Fig 2).

If an engine can be satisfactorily operated at all load points without using mechanically driven cylinder lubricators, this is to be verified.

For engines which may operate on heavy fuel oil, their suitability for this is to be proved to the satisfaction of the Society.

a) Functional tests under normal operating conditions

   Functional tests under normal operating conditions include:

   1) The load points 25%, 50%, 75%, 100% and 110% of the maximum continuous power for which type approval is requested, to be carried out:

      - along the nominal (theoretical) propeller curve and at constant speed, for propulsion engines
      - at constant speed, for engines intended for generating sets.

   2) The limit points of the permissible operating range.

      These limit points are to be defined by the engine Manufacturer.

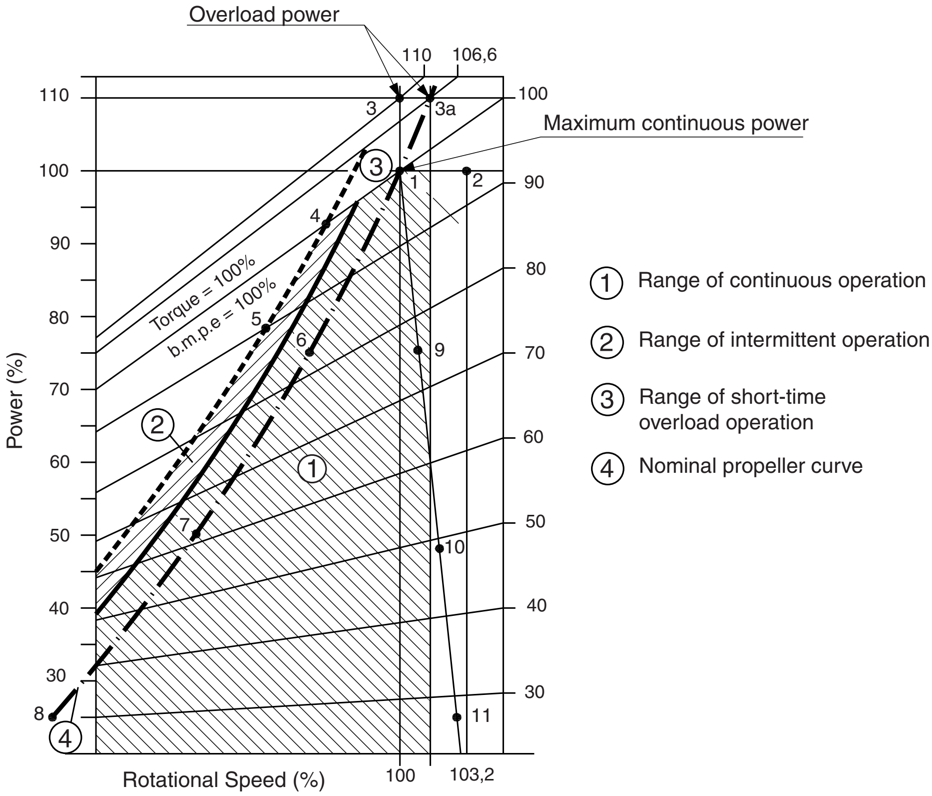
   The maximum continuous power P is defined in [1.3.2].

b) Tests under emergency operating conditions

   For turbocharged engines, the achievable continuous output is to be determined for a situation when one turbocharger is damaged, i.e.:

   - for engines with one turbocharger, when the rotor is blocked or removed
   - for engines with two or more turbochargers, when the damaged turbocharger is shut off.

Figure 2 : Power/speed diagram



4.2.3 Stage B - Type approval tests in the presence of the Surveyor

During the type test, the tests listed below are to be carried out in the presence of the Surveyor and the results are to be recorded in a report signed by both the engine Manufacturer and the Surveyor.

For engines not yet adequately experienced in service the scope of test will be agreed on a case by case basis.

Any departures from this programme are to be agreed upon by the engine Manufacturer and the Society.

a) Load points

The load points at which the engine is to be operated according to the power/speed diagram (see Fig 2) are those listed below. The data to be measured and recorded when testing the engine at various load points are to include all necessary parameters for engine operation.

The operating time per load point depends on the engine characteristics (achievement of steady-state condition) and the time for collection of the operating values.

Normally, an operating time of 0,5 hour per load point can be assumed.

At the maximum continuous power as per the following item 1) an operating time of two hours is required. Two sets of readings are to be taken at a minimum interval of one hour.

1) Test at maximum continuous power P: i.e. 100% output at 100% torque and 100% speed, corresponding to load point 1 in the diagram in Fig 2.

2) Test at 100% power at maximum permissible speed, corresponding to load point 2 in the diagram in Fig 2.

3) Test at maximum permissible torque (normally 110% of nominal torque T) at 100% speed, corresponding to load point 3 in the diagram in Fig 2; or test at maximum permissible power (normally 110% of P) and speed according to the nominal propeller curve, corresponding to load point 3a in the diagram in Fig 2.

4) Test at minimum permissible speed at 100% of torque T, corresponding to load point 4 in the diagram in Fig 2.

5) Test at minimum permissible speed at 90% of torque T, corresponding to load point 5 in the diagram in Fig 2.

6) Tests at part loads, e.g. 75%, 50%, 25% of maximum continuous power P and speed according to the nominal propeller curve, corresponding to load points 6, 7 and 8 in the diagram in Fig 2; and tests at the above part loads and at speed n with constant governor setting, corresponding to load points 9, 10 and 11 in the diagram in Fig 2.

b) Tests under emergency operating conditions

These are tests at maximum achievable power when operating along the nominal propeller curve and when operating with constant governor setting for speed n, in emergency operating conditions as stated in [4.2.2] b).

c) Additional tests
- Test at lowest engine speed according to the nominal propeller curve.
- Starting tests for non-reversible engines, or starting and reversing tests for reversible engines.
- Governor tests.
- Testing of the safety system, particularly for overspeed and low lubricating oil pressure.

For engines intended to be used for emergency services, supplementary tests may be required to the satisfaction of the Society. In particular, for engines intended to drive emergency generating sets, additional tests and/or documents may be required to prove that the engine is capable of being readily started at a temperature of 0°C.

4.2.4 Evaluation of test results

The results of the tests and checks required by [4.2.3] will be evaluated by the attending Surveyor. Normally the main operating data to be recorded during the tests are those listed in [4.3.4].

In particular, the maximum combustion pressure measured with the engine running at the maximum continuous power P is not to exceed the value taken for the purpose of checking the scantlings of the engine crankshaft, according to the applicable requirements of Chapter 1, Appendix 1.

The values of temperatures and pressures of media, such as cooling water, lubricating oil, charge air, exhaust gases, etc., are to be within limits which, in the opinion of the Surveyor, are appropriate for the characteristics of the engine tested.

4.2.5 Stage C - Inspection of main engine components

Immediately after the test run as per [4.2.3], the components of one cylinder for in-line engines, and two cylinders for V-type engines, are to be presented for inspection to the Surveyor.

The following main engine components are to be inspected:
- piston removed and dismantled
- crosshead bearing, dismantled
- crank bearing and main bearing, dismantled
- cylinder liner in the installed condition
- cylinder head and valves, disassembled
- control gear, camshaft and crankcase with opened covers.

Where deemed necessary by the Surveyor, further dismantling of the engine may be required.

4.3 Type tests of engines admitted to an alternative inspection scheme

4.3.1 General

Engines for which the Manufacturer is admitted to testing and inspections according to an alternative inspection scheme (see NR216 Materials and Welding, Ch 1, Sec 1, [3.2]) and which have a cylinder bore not exceeding 300 mm are to be type tested in the presence of a Surveyor in accordance with the requirements of the present [4.3].

The selection of the engine to be tested from the production line is to be agreed upon with the Surveyor.

4.3.2 Type test

The programme of the type test is to be in general as specified below, P being the maximum continuous power and n the corresponding speed. The maximum continuous power is that stated by the engine Manufacturer and accepted by the Society, as defined in [1.3.2].

a) 80 hours at power P and speed n
b) 8 hours at overload power (110% of power P)
c) 10 hours at partial loads (25%, 50%, 75% and 90% of power P)
d) 2 hours at intermittent loads
e) starting tests
f) reverse running for direct reversing engines
g) testing of speed governor, overspeed device and lubricating oil system failure alarm device
h) testing of the engine with one turbocharger out of action, when applicable
i) testing of the minimum speed along the nominal (theoretical) propeller curve, for main propulsion engines driving fixed pitch propellers, and of the minimum speed with no brake load, for main propulsion engines driving controllable pitch propellers or for auxiliary engines.

The tests at the above-mentioned outputs are to be combined together in working cycles which are to be repeated in succession for the entire duration within the limits indicated.

In particular, the overload test, to be carried out at the end of each cycle, is to be of one hour’s duration and is to be carried out alternately:
- at 110% of the power P and 103% of the speed n
- at 110% of the power P and 100% of the speed n.

The partial load tests specified in item c) are to be carried out:

- along the nominal (theoretical) propeller curve and at constant speed, for propulsion engines
- at constant speed, for engines intended for generating sets.

For engines intended to be used for emergency services, supplementary tests may be required, to the satisfaction of the Society. In particular, for engines intended to drive emergency generating sets, additional tests and/or documents may be required to prove that the engine is capable of being readily started at a temperature of 0°C, as required in [3.1.3].

In the case of prototype engines, the duration and programme of the type test will be not lower than the one specified in this paragraph.

4.3.3 In cases of engines for which the Manufacturer submits documentary evidence proving successful service experience or results of previous bench tests, the Society, at its discretion, may allow a type test to be carried out in the presence of the Surveyor according to a programme to be agreed upon in each instance.

In the case of engines which are to be type approved for different purposes and performances, the programme and duration of the type test will be decided by the Society in each case to cover the whole range of engine performances for which approval is requested, taking into account the most severe values.

4.3.4 During the type test, at least the following particulars are to be recorded:

a) ambient air temperature, pressure and atmospheric humidity in the test room

b) cooling raw water temperature at the inlet of heat exchangers

c) characteristics of fuel and lubricating oil used during the test

d) engine speed

e) brake power

f) brake torque

g) maximum combustion pressure

h) indicated pressure diagrams, where practicable

i) exhaust smoke (with a smoke meter deemed suitable by the Surveyor)

j) lubricating oil pressure and temperature

k) cooling water pressure and temperature

l) exhaust gas temperature in the exhaust manifold and, where facilities are available, from each cylinder

m) minimum starting air pressure necessary to start the engine in cold condition.

In addition to the above, for supercharged engines the following data are also to be measured and recorded:

- turbocharger speed
- air temperature and pressure before and after turbocharger and charge air coolers
- exhaust gas temperatures and pressures before and after turbochargers and cooling water temperature at the inlet of charge air coolers.

4.3.5 Inspection of main engine components and evaluation of test results

The provisions of [4.2.4] and [4.2.5] are to be complied with, as far as applicable.

4.4 Material and non-destructive tests

4.4.1 Material tests

Engine components are to be tested in accordance with Tab 6 and in compliance with the requirements of NR216 Materials and Welding.

Magnetic particle or liquid penetrant tests are required for the parts listed in Tab 6 and are to be effected in positions mutually agreed upon by the Manufacturer and the Society Surveyor, where experience shows defects are most likely to occur.

The magnetic particle test of tie rods/stay bolts is to be carried out at each end, for a portion which is at least twice the length of the thread.

For important structural parts of engines, in addition to the above-mentioned non-destructive tests, examination of welded seams by approved methods of inspection may be required.

Where there is evidence to doubt the soundness of any engine component, non-destructive tests using approved detecting methods may be required.

Engines of a cylinder diameter not exceeding 300 mm may be tested according to an alternative survey scheme.

4.4.2 Hydrostatic tests

Parts of engines under pressure are to be hydrostatically tested at the test pressure specified for each part in Tab 7.

The following parts of auxiliaries which are necessary for operation of engines as per [1.1.1] a), b) and c):

- cylinders, cylinder covers, coolers and receivers of independent air compressors
- water, oil and air coolers (tube bundles or coils, shells and heads) not fitted on the engine and filters
- independently driven lubricating oil, fuel oil and water pumps
- pressure pipes (water, lubricating oil, fuel oil, and compressed air pipes), valves and other fittings

are to be subjected to hydrostatic tests at 1,5 times the maximum working pressure, but not less than 0,4 MPa.

4.5 Workshop inspections and testing

4.5.1 General

In addition to the type test, diesel engines are to be subjected to works trials, which are to be witnessed by the Surveyor also when an Alternative Inspection Scheme has been granted.

For all stages at which the engine is to be tested, the relevant operating values are to be measured and recorded by the engine Manufacturer.

In each case all measurements conducted at the various load points are to be carried out at steady operating conditions.

The readings for 100% of the rated power P at the corresponding speed n are to be taken twice at an interval of at least 30 minutes.

At the discretion of the Surveyor, the programme of trials given in [4.5.2], [4.5.3] or [4.5.4] may be expanded depending on the engine application.

4.5.2 Main propulsion engines driving propellers

Main propulsion engines are to be subjected to trials to be performed as follows:

a) at least 60 min, after having reached steady conditions, at rated power P and rated speed n
b) 30 min, after having reached steady conditions, at 110% of rated power P and at a speed equal to 1,032 of rated speed
c) tests at 90% (or normal continuous cruise power), 75%, 50% and 25% of rated power P, carried out:
   - at the speed corresponding to the nominal (theoretical) propeller curve, for engines driving fixed pitch propellers
   - at constant speed, for engines driving controllable pitch propellers
d) idle run
e) starting and reversing tests (when applicable)
f) testing of the speed governor and of the independent overspeed protective device
g) testing of alarm and/or shutdown devices.

Note 1: After running on the test bed, the fuel delivery system is to be so adjusted that the engine cannot deliver more than 100% of the rated power at the corresponding speed (overload power cannot be obtained in service).

4.5.3 Engines driving electric generators used for main propulsion purposes

Engines driving electric generators are to be subjected to trials to be performed with a constant governor setting, as follows:

a) at least 60 min, after having reached steady conditions, at 100% of rated power P and rated speed n
b) 45 min, after having reached steady conditions, at 110% of rated power and rated speed
c) 75%, 50% and 25% of rated power P, carried out at constant rated speed n
d) idle run
e) starting tests
f) testing of the speed governor ([2.10.5]) and of the independent overspeed protective device (when applicable)
g) testing of alarm and/or shutdown devices.

Note 1: After running on the test bed, the fuel delivery system of diesel engines driving electric generators is to be adjusted such that overload (110%) power can be produced but not exceeded in service after installation on board, so that the governing characteristics, including the activation of generator protective devices, can be maintained at all times.

4.5.4 Engines driving auxiliary machinery

Engines driving auxiliary machinery are to be subjected to the tests stated in [4.5.2] or [4.5.3] for variable speed and constant speed drives, respectively.

Note 1: After running on the test bed, the fuel delivery system of diesel engines driving electric generators is to be adjusted such that overload (110%) power can be produced but not exceeded in service after installation on board, so that the governing characteristics, including the activation of generator protective devices, can be fulfilled at all times.

4.5.5 Inspection of engine components

Random checks of components to be presented for inspection after works trials are left to the discretion of the Surveyor.

4.5.6 Parameters to be measured

The data to be measured and recorded, when testing the engine at various load points, are to include all necessary parameters for engine operation. The crankshaft deflection is to be verified when this check is required by the Manufacturer during the operating life of the engine.

4.5.7 Testing report

In the testing report for each engine the results of the tests carried out are to be compiled and the reference number and date of issue of the Type Approval Certificate (see [4.6]), relevant to the engine type, are always to be stated; the testing report is to be issued by the Manufacturer and enclosed with the testing certificate as per [4.6].

4.6 Certification

4.6.1 Type Approval Certificate and its validity

After the satisfactory outcome of the type tests and inspections specified in [4.2] or [4.3], the Society will issue to the engine manufacturer a "Type Approval Certificate" valid for all engines of the same type.

The Society reserves the right to consider the test carried out on one engine type valid also for engines having a different cylinder arrangement, following examination of suitable, detailed documentation submitted by the Manufacturer and including bench test results.

Table 6 : Material and non-destructive tests

Engine component	Material tests **(1)** (Mechanical properties and chemical composition)	Non-destructive tests	
		Magnetic particle or liquid penetrant	Ultrasonic
1) Crankshaft	all	all	all
2) Crankshaft coupling flange (non-integral) for main power transmissions	if bore > 400 mm	–	–
3) Coupling bolts for crankshaft	if bore > 400 mm	–	–
4) Steel piston crowns **(2)**	if bore > 400 mm	if bore > 400 mm	all
5) Piston rods	if bore > 400 mm	if bore > 400 mm	if bore > 400 mm
6) Connecting rods, together with connecting rod bearing caps	all	all	if bore > 400 mm
7) Crossheads	if bore > 400 mm	–	–
8) Cylinder liners	if bore > 300 mm	–	–
9) Steel cylinder covers **(2)**	if bore > 300 mm	if bore > 400 mm	all
10) Bedplates of welded construction; plates and transverse bearing girders made of forged or cast steel **(2)(3)**	all	all	all
11) Frames and crankcases of welded construction **(3)**	all	–	–
12) Entablatures of welded construction **(3)**	all	–	–
13) Tie rods	all	if bore > 400 mm	–
14) Shafts and rotors, including blades, for turbochargers **(4)**	(see Ch 1, Sec 15)	–	–
15) Bolts and studs for cylinder covers, crossheads, main bearings and connecting rod bearings; nuts for tie rods	if bore > 300 mm	if bore > 400 mm	–
16) Steel gear wheels for camshaft drives	if bore > 400 mm	if bore > 400 mm	–

(1) In addition, material tests may also be required, at the Society’s discretion, for piping and valves for starting air lines and any other pressure piping fitted on the engines.
(2) For items 4), 9) and 10), it is implicit that as well as for steel parts, material tests are also required for parts made of other materials which are comparable to steel on account of their mechanical properties in general and their ductility in particular: e.g. aluminium and its alloys, ductile and spheroidal or nodular graphite cast iron.
(3) Material tests for bedplates, frames, crankcases and entablatures are required even if these parts are not welded and for any material except grey cast iron.
(4) Turbocharger is understood as turbocharger itself and engine driven compressor (incl. "root blowers", but not auxiliary blowers).

4.6.2 Testing certification

a) Engines admitted to an alternative inspection scheme

Works' certificates (W) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.3]) are required for components and tests indicated in Tab 6 and Tab 7.

b) Engines not admitted to an alternative inspection scheme

Society's certificates (C) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.1]) are required for material tests of components in Tab 6 and for works trials as per [4.5].

Works' certificates (W) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.3]) are required for non-destructive and hydrostatic tests of components in Tab 6 and Tab 7.

In both cases a) and b), the Manufacturer is to supply:

a) the following information:
- engine type
- rated power
- rated speed
- driven equipment
- operating conditions
- list of auxiliaries fitted on the engine

b) a statement certifying that the engine is in compliance with that type tested, except for modifications already notified to the Society. The reference number and date of the Type Approval Certificate are also to be indicated in the statement.

Table 7 : Test pressure of engine parts

Parts under pressure		Test pressure (MPa) **(1)** **(2)**
1	Cylinder cover, cooling space **(3)**	0,7
2	Cylinder liner, over the whole length of cooling space	0,7
3	Cylinder jacket, cooling space	0,4 (but not less than 1,5 p)
4	Exhaust valve, cooling space	0,4 (but not less than 1,5 p)
5	Piston crown, cooling space **(3)** **(4)**	0,7
6	Fuel injection system a) Fuel injection pump body, pressure side b) Fuel injection valve c) Fuel injection pipes	 1,5 p (or p + 30, if lesser) 1,5 p (or p + 30, if lesser) 1,5 p (or p + 30, if lesser)
7	Hydraulic system • Piping, pumps, actuators etc. for hydraulic drive of valves	 1,5 p
8	Scavenge pump cylinder	0,4
9	Turbocharger, cooling space	0,4 (but not less than 1,5p)
10	Exhaust pipe, cooling space	0,4 (but not less than 1,5 p)
11	Engine driven air compressor (cylinders, covers, intercoolers and aftercoolers) a) Air side b) Water side	 1,5 p 0,4 (but not less than 1,5 p)
12	Coolers, each side **(5)**	0,4 (but not less than 1,5 p)
13	Engine driven pumps (oil, water, fuel, bilge)	0,4 (but not less than 1,5 p)

(1) In general, parts are to be tested at the hydraulic pressure indicated in the Table. Where design or testing features may call for modification of these testing requirements, special consideration will be given by the Society.
(2) p is the maximum working pressure, in MPa, in the part concerned.
(3) For forged steel cylinder covers and forged steel piston crowns, test methods other than hydrostatic testing may be accepted, e.g. suitable non-destructive tests and documented dimensional tests.
(4) Where the cooling space is sealed by the piston rod, or by the piston rod and the shell, the pressure test is to be carried out after assembly.
(5) Turbocharger air coolers need to be tested on the water side only.

Section 3 Pressure Equipment

1 General

1.1 Principles

1.1.1 Scope of the Rules

The boilers and other pressure vessels, associated piping systems and fittings are to be of a design and construction adequate for the service for which they are intended and is to be so installed and protected as to reduce to a minimum any danger to persons on board, due regard being paid to moving parts, hot surfaces and other hazards. The design is to have regard to materials used in construction, the purpose for which the equipment is intended, the working conditions to which it will be subjected and the environmental conditions on board.

So these Rules apply to “pressure equipment” for the following requirements:

- be safe in sight of pressure risk
- be safe in sight of other risks, moving parts, hot surfaces
- ensure capability of propulsion and other essential services.

“Pressure equipment” means pressure vessels, piping (Ch 1, Sec 10), safety accessories and pressure accessories.

1.1.2 Overpressure risk

Where main or auxiliary boilers and other pressure vessels or any parts thereof may be subject to dangerous overpressure, means are to be provided where practicable to protect against such excessive pressure.

1.1.3 Propulsion capability

Means are to be provided whereby normal operation of main boilers can be sustained or restored even through one of the essential auxiliaries become inoperative. Special consideration is to be given to the malfunctioning of:

- the source of steam supply
- the boiler feed water systems
- the fuel oil supply system for boilers
- the mechanical air supply for boilers.

However the Society, having regard to overall safety considerations, may accept a partial reduction in propulsion capability from normal operation.

1.1.4 Tests

All boilers and other pressure vessels including their associated fittings which are under internal pressure are to be subjected to appropriate tests including a pressure test before being put into service for the first time (see also Article [7]).

1.2 Application

1.2.1 Pressure vessels covered by the Rules

The requirements of this Section apply to:

- all fired or unfired pressures vessels of metallic construction, including the associated fittings and mountings with maximum allowable pressure greater than 0,5 bar above atmospheric pressure with the exception of those indicated in [1.2.2]
- all boilers and other steam generators, including the associated fittings and mountings with maximum allowable pressure greater than 0,5 bar above atmospheric pressure with the exception of those indicated in [1.2.2].

1.2.2 Pressure vessels not covered by the Rules

Among others the following boilers and pressure vessels are not covered by the Rules and are to be considered on a case by case basis:

a) boilers with design pressure $p > 10$ MPa

b) pressure vessel intended for radioactive material

c) equipment comprising casings or machinery where the dimensioning, choice of material and manufacturing rules are based primarily on requirements for sufficient strength, rigidity and stability to meet the static and dynamic operational effects or other operational characteristics and for which pressure is not a significant design factor. Such equipment may include:
   - engines including turbines and internal combustion engines
   - steam engines, gas/steam turbines, turbo-generators, compressors, pumps and actuating devices

d) small pressure vessels included in self-contained domestic equipment.

1.3 Definitions

1.3.1 Pressure vessel

"Pressure vessel" means a housing designed and built to contain fluids under pressure including its direct attachments up to the coupling point connecting it to other equipment. A vessel may be composed of more than one chamber.

1.3.2 Fired pressure vessel

Fired pressure vessel is a pressure vessel which is completely or partially exposed to fire from burners or combustion gases or otherwise heated pressure vessel with a risk of overheating.

a) Boiler

   Boiler is one or more fired pressure vessels and associated piping systems used for generating steam or hot water at a temperature above 120°C.

   Any equipment directly connected to the boiler, such as economisers, superheaters and safety valves, is considered as part of the boiler, if it is not separated from the steam generator by means of any isolating valve. Piping connected to the boiler is considered as part of the boiler upstream of the isolating valve and as part of the associated piping system downstream of the isolating valve.

b) Thermal oil heater

   Thermal oil heater is one or more fired pressure vessels and associated piping systems in which organic liquids (thermal oils) are heated. When heated by electricity thermal oil heater is considered as an unfired pressure vessel.

1.3.3 Unfired pressure vessel

Any pressure vessel which is not a fired pressure vessel is an unfired pressure vessel.

a) Heat exchanger

   A heat exchanger is an unfired pressure vessel used to heat or cool a fluid with an another fluid. In general heat exchangers are composed of a number of adjacent chambers, the two fluids flowing separately in adjacent chambers. One or more chambers may consist of bundles of tubes.

b) Steam generator

   A steam generator is a heat exchanger and associated piping used for generating steam. In general in these Rules, the requirements for boilers are also applicable for steam generators, unless otherwise indicated.

1.3.4 Safety accessories

"Safety accessories" means devices designed to protect pressure equipment against the allowable limits being exceeded. Such devices include:

- devices for direct pressure limitation, such as safety valves, bursting disc safety devices, buckling rods, controlled safety pressure relief systems, and
- limiting devices, which either activate the means for correction or provide for shutdown or shutdown and lockout, such as pressure switches or temperature switches or fluid level switches and safety related measurement control and regulation devices.

1.3.5 Design pressure

The design pressure is the pressure used by the manufacturer to determine the scantlings of the vessel. This pressure cannot be taken less than the maximum working pressure and is to be limited by the set pressure of the safety valve, as prescribed by the applicable Rules. Pressure is indicated as gauge pressure above atmospheric pressure, vacuum is indicated as negative pressure.

1.3.6 Design temperature

a) Design temperature is the actual metal temperature of the applicable part under the expected operating conditions, as modified in Tab 1. This temperature is to be stated by the manufacturer and is to take in account of the effect of any temperature fluctuations which may occur during the service.

b) The design temperature is not to be less than the temperatures stated in Tab 1, unless specially agreed between the manufacturer and the Society on a case by case basis.

1.3.7 Volume

Volume V means the internal volume of a chamber, including the volume of nozzles to the first connection or weld and excluding the volume of permanent internal parts.

1.3.8 Boiler heating surface

Heating surface is the area of the part of the boiler through which the heat is supplied to the medium, on the side exposed to fire or hot gases.

1.3.9 Maximum steam output

Maximum steam output is the maximum quantity of steam than can be produced continuously by the boiler or steam generator operating under the design steam conditions.

Table 1 : Minimum design temperature

Type of vessel	Minimum design temperature
Pressure parts of pressure vessels and boilers not heated by hot gases or adequately protected by insulation	Maximum temperature of the internal fluid
Pressure vessel heated by hot gases	25°C in excess of the temperature of the internal fluid
Water tubes of boilers mainly subjected to convection heat	25°C in excess of the temperature of the saturated steam
Water tubes of boilers mainly subjected to radiant heat	50°C in excess of the temperature of the saturated steam
Superheater tubes of boilers mainly subjected to convection heat	35°C in excess of the temperature of the saturated steam
Superheater tubes of boilers mainly subjected to radiant heat	50°C in excess of the temperature of the saturated steam
Economiser tubes	35°C in excess of the temperature of the internal fluid
For combustion chambers of the type used in wet-back boilers	50°C in excess of the temperature of the internal fluid
For furnaces, fire-boxes, rear tube plates of dry-back boilers and other pressure parts subjected to similar rate of heat transfer	90°C in excess of the temperature of the internal fluid

1.3.10 Toxic and corrosive substances

Toxic and corrosive substances are those which are listed in the IMO “International Maritime Dangerous Goods Code (IMDG Code)”, as amended.

1.3.11 Liquid and gaseous substances

a) liquid substances are liquids having a vapour pressure at the maximum allowable temperature of not more than 0,5 bar above normal atmospheric pressure

b) gaseous substances are gases, liquefied gases, gases dissolved under pressure, vapours and also those liquids whose vapour pressure at the maximum allowable temperature is greater than 0,5 bar above normal atmospheric pressure.

1.3.12 Ductile material

For the purpose of this Section, ductile material is a material having an elongation over 12%.

1.3.13 Incinerator

Incinerator is a shipboard facility for incinerating solid garbage approximating in composition to household garbage and liquid garbage deriving from the operation of the ship (e.g. domestic garbage, cargo-associated garbage, maintenance garbage, operational garbage, cargo residue, and fishing gear), as well as for burning sludge with a flash point above 60°C.

These facilities may be designed to use the heat energy produced.

Incinerators are not generally pressure vessels, however when their fittings are of the same type than those of boilers the requirements for these fittings apply.

1.4 Classes

1.4.1 Significant parameters

Pressure vessels are classed in three class in consideration of the:

- type of equipment: pressure vessel or steam generator
- state (gaseous or liquid) of the intended fluid contents
- substances listed or not in the IMDG Code
- design pressure p, in MPa
- design temperature T, in °C
- actual thickness of the vessel t_A, in mm
- volume V, in litres.

1.4.2 Pressure vessel classification

Pressure vessels are classed as indicated in Tab 2.

1.4.3 Implication of class

The class of a pressure vessel has, among others, implication in:

- design
- material allowance
- welding design
- efficiency of joints
- examination and non-destructive tests
- thermal stress relieving.

See Tab 24.

Table 2 : Pressure vessel classification

Equipment	Class 1	Class 2	Class 3
Steam generators or boilers	$p > 3{,}2$ and $V > 2$ or $p\,V > 20$ and $V > 2$	if not class 1 or class 3	$p\,V \leq 5$ or $V \leq 2$
Pressure vessels for toxic substances	all	–	–
Pressure vessels for corrosive substances	$p > 20$ or $p\,V > 20$ or $T > 350$	if not in class 1	–
Pressure vessels for gaseous substances	$p > 100$ or $p\,V > 300$	$V > 1$ and $p\,V > 100$ and not in class 1	all pressure vessels which are not class 1 or class 2
Pressure vessels for liquid substances	$V > 10$ and $p\,V > 1000$ and $p > 50$	$V \leq 10$ and $p > 100$ or $1 < p \leq 50$ and $p\,V > 1000$	all pressure vessels and heat exchangers which are not class 1 or class 2
Pressure vessels for thermal oil	$p > 1{,}6$ or $T > 300$	if not class 1 or class 3	$p \leq 0{,}7$ and $T \leq 150$
Pressure vessels for fuel oil, lubricating oil or flammable hydraulic oil	$p > 1{,}6$ or $T > 150$	if not class 1 or class 3	$p \leq 0{,}7$ and $T \leq 60$
Whatever type of equipment	$t_A > 40$	$15 < t_A \leq 40$	–

Note 1: Whenever the class is defined by more than one characteristic, the equipment is to be considered belonging to the highest class of its characteristics, independently of the values of the other characteristics.

1.5 Applicable Rules

1.5.1 Alternative standards

a) Boilers and pressure vessels are to be designed, constructed, installed and tested in accordance with the applicable requirements of this Section.

b) The acceptance of national and international standards as an alternative to the requirements of this Section may be considered by the Society on a case by case basis.

c) In particular composite wrapped cylinders are to be designed, constructed, installed and tested in accordance with a Standard to be accepted by the Society on a case by case basis.

1.6 Documentation to be submitted

1.6.1 General

Documents mentioned in the present sub-article are to be submitted for class 1 and class 2 and not for class 3, unless the equipment is considered as critical.

1.6.2 Boilers and steam generators

The plans listed in Tab 3 are to be submitted.

The drawings listed in Tab 3 are to contain:

- the constructional details of all pressure parts, such as shells, headers, tubes, tube plates, nozzles
- strengthening members, such as stays, brackets, opening reinforcements and covers
- installation arrangements, such as saddles and anchoring system,

as well as the information and data indicated in Tab 4.

1.6.3 Pressure vessels

The plans listed in Tab 5 are to be submitted.

The drawings listedin Tab 5 are to contain the constructional details of:

- pressure parts, such as shells, headers, tubes, tube plates, nozzles, opening reinforcements and covers
- strengthening members, such as stays, brackets and reinforcements.

1.6.4 Incinerators

Incinerators are to be considered on a case by case basis, based on their actual arrangement, using the applicable requirements for boilers and pressure vessels.

Table 3 : Drawings to be submitted for boilers and steam generators

No	A/I	Item
1	I	General arrangement plan, including valves and fittings
2	A	Material specifications
3	A	Sectional assembly
4	A	Evaporating parts
5	A	Superheater
6	A	De-superheater
7	A	Economiser
8	A	Air heater
9	A	Tubes and tube plates
10	A	Nozzles and fittings
11	A	Safety valves and their arrangement
12	A	Boiler seating
13	I	Fuel oil burning arrangement
14	I	Forced draft system
15	I	Refractor or insulation arrangement
16	A	Boiler instrumentation, monitoring and control system
17	A	Type of safety valves and their lift, discharge rate and setting
18	A	Welding details, including at least: • typical weld joint design • welding procedure specifications • post-weld heat treatment
Note 1: A = to be submitted for approval; I = to be submitted for information.		

Table 4 : Information and data to be submitted for boilers and steam generators

No.	Item
1	Design pressure and temperature
2	Pressure and temperature of the superheated steam
3	Pressure and temperature of the saturated steam
4	Maximum steam production per hour
5	Evaporating surface of the tube bundles and water-walls
6	Heating surface of the economiser, superheater and air-heater
7	Surface of the furnace
8	Volume of the combustion chamber
9	Temperature and pressure of the feed water
10	Type of fuel to be used and fuel consumption at full steam production
11	Number and capacity of burners

Table 5 : Drawings, information and data to be submitted for pressure vessels and heat exchangers

No	A/I	Item
1	I	General arrangement plan, including nozzles and fittings
2	A	Sectional assembly
3	A	Safety valves (if any) and their arrangement
4	A	Material specifications
5	A	Welding details, including at least: • typical weld joint design • welding procedure specifications • post-weld heat treatments
6	I	Design data, including at least design pressure and design temperatures (as applicable)
7	A	For seamless (extruded) pressure vessels, the manufacturing process, including: • a description of the manufacturing process with indication of the production controls normally carried out in the manufacturer's works • details of the materials to be used (specification, yield point, tensile strength, impact strength, heat treatment) • details of the stamped marking to be applied.
8	I	Type of fluid or fluids contained
Note 1: A = to be submitted for approval ; I = to be submitted for information.		

2 Design and construction - Scantlings of pressure parts

2.1 General

2.1.1 Application

a) In general, the formulae in the present Article do not take into account additional stresses imposed by effects other than pressure, such as stresses deriving from the static and dynamic weight of the pressure vessel and its content, external loads from connecting equipment and foundations, etc. For the purpose of the Rules these additional loads may be neglected, provided it can reasonably be presumed that the actual average stresses of the vessel, considering all these additional loads, would not increase more than 10% with respect to the stresses calculated by the formulae in this Article.

b) Where it is necessary to take into account additional stresses, such as dynamic loads, the Society reserves the right to ask for additional requirements on a case by case basis.

2.1.2 Alternative requirements

When pressure parts are of an irregular shape, such as to make it impossible to check the scantlings by applying the formulae of this Article, the approval is to be based on other means, such as burst and/or deformation tests on a prototype or by another method agreed upon between the manufacturer and the Society.

2.2 Materials

2.2.1 Materials for high temperatures

a) Materials for pressure parts having a design temperature exceeding the ambient temperature are to be selected by the Manufacturer and to have mechanical and metallurgical properties adequate for the design temperature. Their allowable stress limits are to be determined as a function of the temperature, as per [2.3.2].

b) When the design temperature of pressure parts exceeds 400°C, alloy steels are to be used. Other materials are subject of special consideration by the Society.

2.2.2 Materials for low temperatures

Materials for pressure parts having a design temperature below the ambient temperature are to have notch toughness properties suitable for the design temperature.

2.2.3 Cast iron

Cast iron is not to be used for:

a) class 1 and class 2 pressure vessels

b) class 3 pressure vessels with design pressure p > 0,7 MPa or product p·V > 1000, where V is the internal volume of the pressure vessel in litres

c) Bolted covers and closures of pressure vessels having a design pressure p > 1 MPa, except for covers intended for boiler shells, for which [3.2.4] applies.

2.2.4 Valves and fittings for boilers

a) Ductile materials are to be used for valves and fittings intended to be mounted on boilers. The material is to have mechanical and metallurgical characteristics suitable for the design temperature and for the thermal and other loads imposed during the operation.

b) Grey cast iron is not to be used for valves and fittings which are subject to dynamic loads, such as safety valves and blow-down valves, and in general for fittings and accessories having design pressure p exceeding 0,3 MPa and design temperature T exceeding 220°C.

c) Spheroidal cast iron is not to be used for parts having a design temperature T exceeding 350°C.

d) Bronze is not to be used for parts having design temperature T exceeding 220°C for normal bronzes and 260°C for bronzes suitable for high temperatures. Copper and aluminium brass are not to be used for fittings with design temperature T above 200°C and copper-nickel fittings with design temperature T exceeding 300°C.

2.2.5 Alternative materials

In the case of boilers or pressure vessels constructed in accordance with one of the standards considered acceptable by the Society as per [1.5], the material specifications are to be in compliance with the requirements of the standard used.

2.3 Permissible stresses

2.3.1 The permissible stresses K, in N/mm^2, for steels, to be used in the formulae of this Article, may be determined from Tab 6, Tab 7, Tab 8 and Tab 9, where R_m is the ultimate strength of the material, in N/mm^2. For intermediate values of the temperature, the value of K is to be obtained by linear interpolation.

Table 6 : Permissible stresses K for carbon steels intended for boilers and thermal oil heaters

Carbon steel	T (°C)	≤ 50	100	150	200	250	300	350	400
R_m = 360 N/mm² Grade HA	t ≤ 15 mm	133	109	107	105	94	77	73	72

2.3.2 Direct determination of permissible stress

The permissible stresses K, where not otherwise specified, may be taken as indicated below.

a) Steel:

The permissible stress is to be the minimum of the values obtained by the following formulae:

$$K = \frac{R_{m,20}}{2,7}$$

$$K = \frac{R_{S,MIN,T}}{A}$$

$$K = \frac{S_A}{A}$$

where:

$R_{m,20}$: Minimum tensile strength at ambient temperature (20°C), in N/mm^2

$R_{S,MIN,T}$: Minimum between R_{eH} and $R_{p\,0,2}$ at the design temperature T, in N/mm^2

S_A : Average stress to produce creep rupture in 100000 hours, in N/mm^2, at the design temperature T

A : Safety factor taken as follows, when reliability of $R_{S,MIN,T}$ and S_A values are proved to the Society's satisfaction:

- 1,6 for boilers and other steam generators
- 1,5 for other pressure vessels
- specially considered by the Society if average stress to produce creep rupture in more than 100000 hours is used instead of S_A.

In the case of steel castings, the permissible stress K, calculated as above, is to be decreased by 20%. Where steel castings are subjected to non-destructive tests, a smaller reduction up to 10% may be taken into consideration by the Society.

b) Spheroidal cast iron:

The permissible stress is be to the minimum of the values obtained by the following formulae:

$$K = \frac{R_{m,20}}{4,8}$$

$$K = \frac{R_{S,MIN,T}}{3}$$

c) Grey cast iron:

The permissible stress is obtained by the following formula:

$$K = \frac{R_{m,20}}{10}$$

d) Copper alloys:

The permissible stress is obtained by the following formula:

$$K = \frac{R_{m,T}}{4}$$

where:

$R_{m,T}$: Minimum tensile strength at the design temperature T, in N/mm^2

e) Aluminium and aluminium alloys:

The permissible stress is to be the minimum of the values obtained by the following formulae:

$$K = \frac{R_{m,T}}{4}$$

$$K = \frac{R_{e,H}}{1,5}$$

where:

$R_{e,H}$: Minimum yield stress, in N/mm^2

f) Additional conditions:
- In special cases the Society reserves the right to apply values of permissible stress K lower than those specified above.
- In the case of boilers or other steam generators, the permissible stress K is not to exceed 170 N/mm^2.
- For materials other than those listed above the permissible stress is to be agreed with the Society on a case by case basis.

2.4 Cylindrical, spherical and conical shells with circular cross-sections subject to internal pressure

2.4.1 Cylindrical shell thickness

a) The minimum thickness of cylindrical, spherical and conical shells with circular cross-sections is not to be less than the value t, in mm, calculated by one of the following formulae, as appropriate. Cylindrical tube plates pierced by a great number of tube holes are to have thickness calculated by the applicable formulae in [2.4.3], [2.4.4], [2.4.5] and [2.9.2].

b) The thicknesses obtained by the formulae in [2.4.3], [2.4.4] and [2.4.5] are "net" thicknesses, as they do not include any corrosion allowance. The thickness obtained by the above formulae is to be increased by 0,75 mm. See also [2.4.7].

2.4.2 Efficiency

The values of efficiency e to be used in the formulae in [2.4.3], [2.4.4] and [2.4.5] are indicated in Tab 10.

Table 10 : Efficiency of unpierced shells

Case	e
Seamless shells	1
Shells of class 1 vessels **(1)**	1
Shells of class 2 vessels (with partial radiographic examination of butt-joints)	0,85
Shells of class 2 vessels with actual thickness ≤ 15mm (without radiographic examination of butt-joints)	0,75
(1) In special cases the Society reserves the right to take a factor e < 1, depending on the welding procedure adopted for the welded joint.	

2.4.3 Cylindrical shells

a) When the ratio external diameter/inside diameter is equal to or less than 1,5, the minimum thickness of cylindrical shells is given by the following formula:

$$t = \frac{pD}{(2K - p)e}$$

where:

p : Design pressure, in MPa

D : Inside diameter of vessel, in mm

K : Permissible stress, in N/mm^2, obtained as specified in [2.3]

e : Efficiency of welded joint, the value of which is given in [2.4.2].

b) The minimum thickness of shells having ratio external diameter/inside diameter exceeding 1,5 is subject of special consideration.

2.4.4 Spherical shells

a) When the ratio external diameter/inside diameter is equal to or less than 1,5, the minimum thickness of spherical shells is given by the following formula:

$$t = \frac{pD}{(4K - p)e}$$

For the meaning of the symbols, see [2.4.3].

b) The minimum thickness of shells having ratio external diameter/inside diameter exceeding 1,5 is subject of special consideration.

2.4.5 Conical shells

a) The following formula applies to conical shells of thickness not exceeding 1/6 of the external diameter in way of the large end of the cone:

$$t = \frac{pD}{(2K - p)e \cdot \cos\varphi}$$

For the meaning of the symbols, see [2.4.3].

D is measured in way of the large end of the cone and φ is the angle of slope of the conical section of the shell to the pressure vessel axis (see Fig 1). When φ exceeds 75°, the shell thickness is to be taken as required for flat heads, see [2.7].

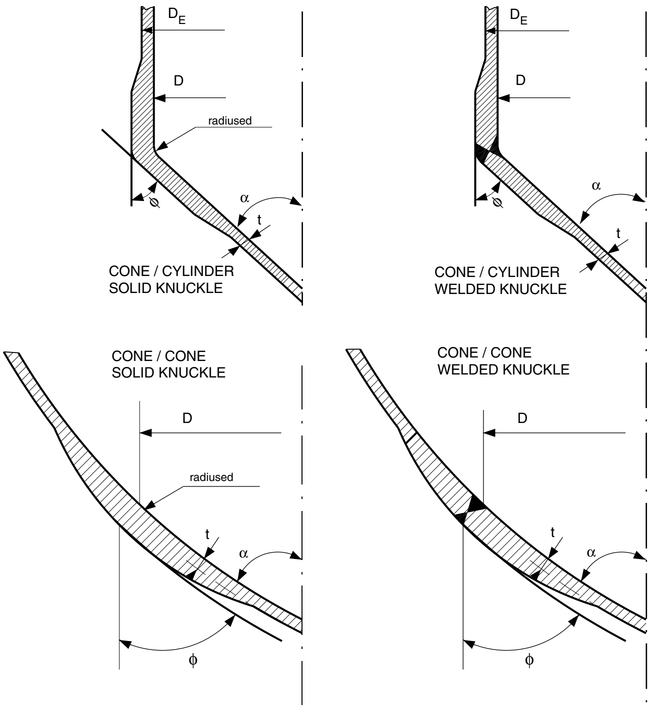
b) The minimum thickness of shells having thickness exceeding 1/6 of the external diameter in way of the large end of the cone is subject of special consideration.

c) Conical shells may be made of several ring sections of decreasing thickness. The minimum thickness of each section is to be obtained by the formula in a) using for D the maximum diameter of the considered section.

d) In general, the junction with a sharp angle between the conical shell and the cylindrical or other conical shell, having different angle of slope, is not allowed if the angle of the generating line of the shells to be assembled exceeds 30°.

e) The shell thickness in way of knuckles is subject of special consideration by the Society.

Figure 1 : Conic shells



2.4.6 Minimum thickness of shells

Irrespective of the value calculated by the formulae in [2.4.3], [2.4.4] or [2.4.5], the thickness t of shells is not to be less than one of the following values, as applicable:

- for pressure vessels: t = 3 + D/1500 mm
- for unpierced plates of boilers: t = 6,0 mm
- for boiler cylindrical tube plates: t = 9,5 mm.

No corrosion allowance needs to be added to the above values.

2.4.7 Corrosion allowance

The Society reserves the right to increase the corrosion allowance value in the case of vessels exposed to particular accelerating corrosion conditions. The Society may also consider the reduction of this factor where particular measures are taken to effectively reduce the corrosion rate of the vessel.

2.5 Dished heads subject to pressure on the concave (internal) side

2.5.1 Dished head for boiler headers

Dished heads for boiler headers are to be seamless.

2.5.2 Dished head profile

The following requirements are to be complied with for the determination of the profile of dished heads (see Fig 2 (a) and (b)).

a) Ellipsoidal heads:

$H \geq 0{,}2\ D$

where:

H : External depth of head, in mm, measured from the start of curvature at the base.

b) Torispherical heads:

$R_{IN} \leq D$

$r_{IN} \geq 0{,}1\ D$

$r_{IN} \geq 3\ t$

$H \geq 0{,}18\ D$

where:

R_{IN} : Internal radius of the spherical part, in mm

r_{IN} : Internal knuckle radius, in mm

H : External depth of head calculated by the following formula (see Fig 2 (b)):

$H = R_E - [(R_E - 0,5\ D) \cdot (R_E + 0,5\ D - 2\ r_E)]^{0,5}$

where:

R_E : External radius of the spherical part, in mm

r_E : External knuckle radius, in mm.

2.5.3 Required thickness of solid dished heads

a) The minimum thickness of solid (not pierced) hemispherical, torispherical, or ellipsoidal unstayed dished heads, subject to pressure on the concave (internal) side, is to be not less than the value t, in mm, calculated by the following formula:

$$t = \frac{pDC}{2Ke}$$

where:

C : Shape factor, obtained from the graph in Fig 3, as a function of H/D and t/D.

For other symbols, see [2.4.3].

b) The thickness obtained by the formula in item a) is “net” thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 0,75 mm. See also [2.4.7].

2.5.4 Composed torispherical heads

a) Torispherical heads may be constructed with welded elements of different thicknesses (see Fig 4).

b) Where a torispherical head is built in two sections, the thickness of the torispherical part is to be obtained by the formula in [2.5.3], while the thickness of the spherical part may be obtained by the formula in [2.4.4].

c) The spherical part may commence at a distance from the knuckle not less than:

$0,5 \cdot (R_{IN} \cdot t)^{0,5}$

where:

R_{IN} : Internal radius of the spherical part, in mm

t : Knuckle thickness, in mm.

2.5.5 Minimum thickness of dished heads

Irrespective of the values calculated in [2.5.2] and [2.5.3], the thickness t of dished heads is not to be less than:

- $3 + D_E / 1500$ mm for normal pressure vessels
- 6 mm for boiler pressure vessels.

No corrosion allowance needs to be added to the above values.

2.5.6 Connection of heads to cylindrical shells

The heads are to be provided, at their base, with a cylindrical skirt not less than 2t in length and with a thickness in no case less than the Rule thickness of a cylindrical shell of the same diameter and the same material, calculated by the formula given in [2.4.3] using the same efficiency factor e adopted for calculation of the head thickness. Fig 5 and Fig 6 show typical admissible attachments of dished ends to cylindrical shells.

In particular, hemispherical heads not provided with the above skirt are to be connected to the cylindrical shell if the latter is thicker than the head, as shown in Fig 5.

Other types of connections are subject to special consideration by the Society.

Figure 2 : Dished head profiles

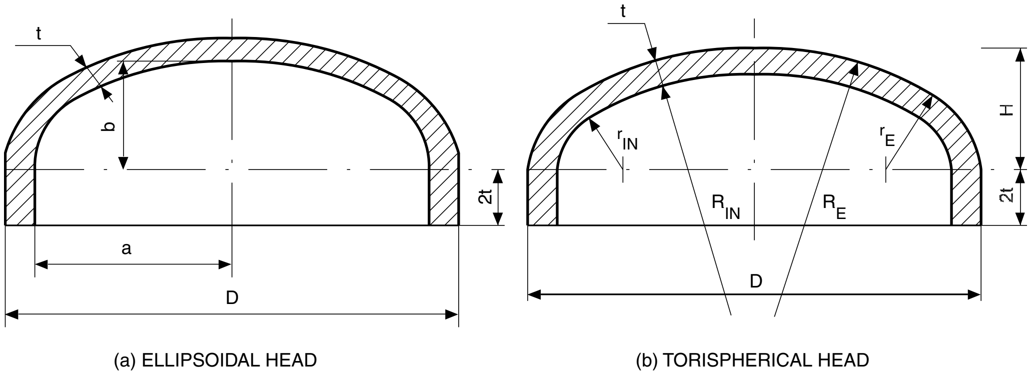


Figure 3 : Shape factor for dished heads

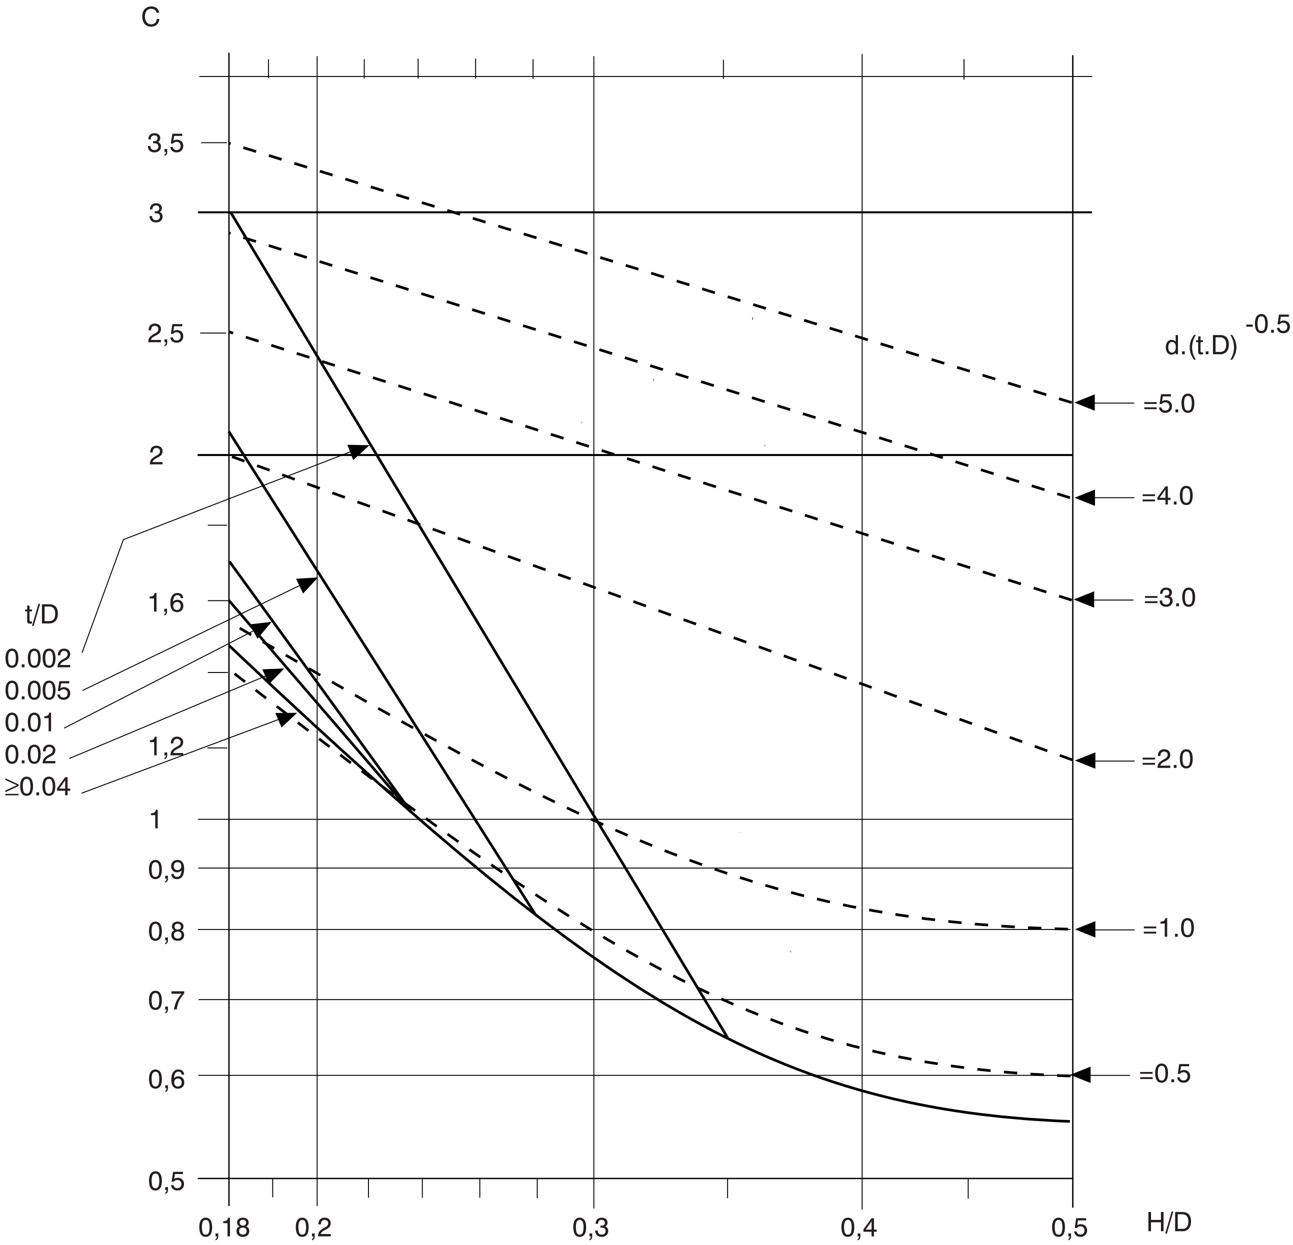

Figure 4 : Composed torispherical head

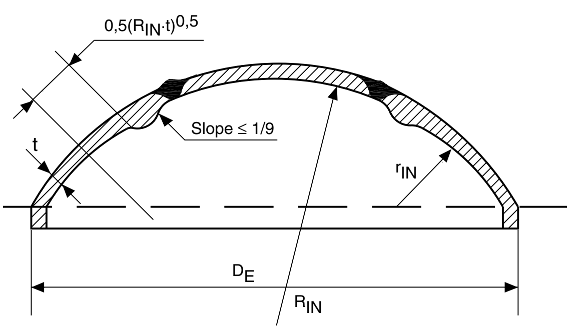

Figure 5 : Typical attachment of dished heads to cylindrical shells

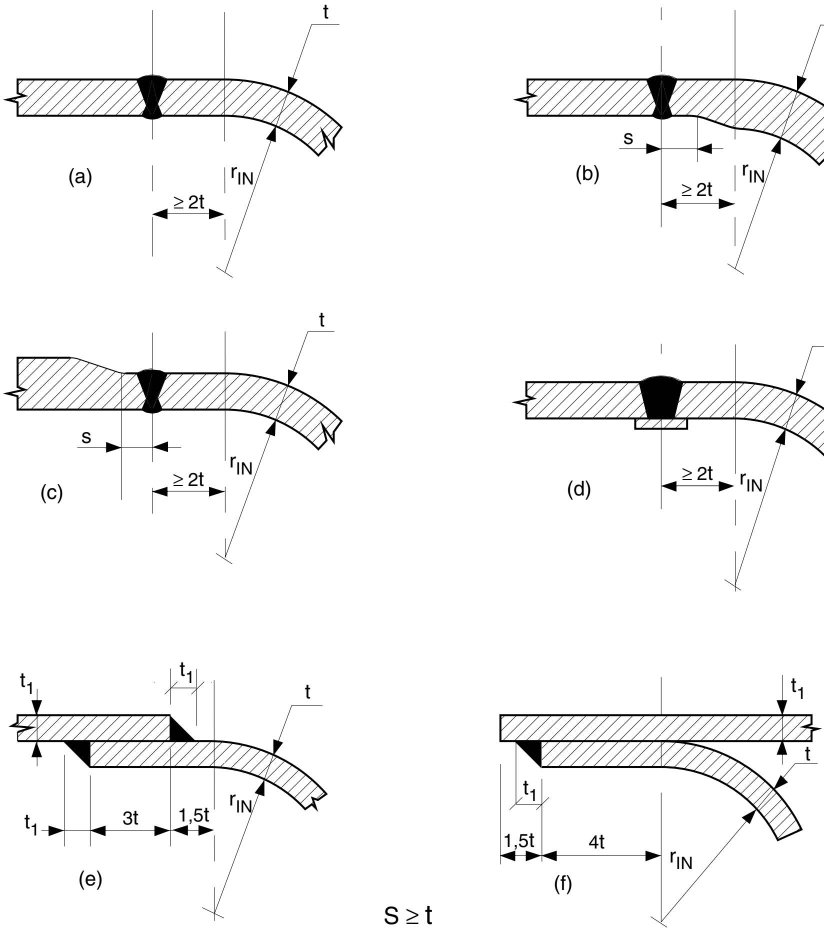
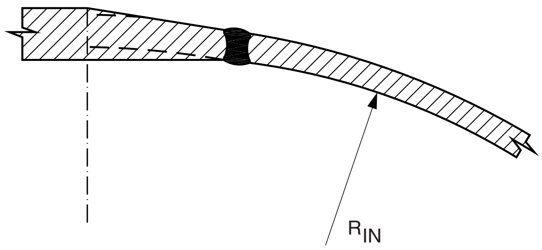


Types shown in (a), (b) and (c) are acceptable for all pressure vessels.
Type shown in (d) is acceptable for class 2 and class 3 pressure vessels.
Types shown in (e) and (f) are acceptable for class 3 pressure vessels only.

Figure 6 : Connection of hemispherical head to the cylindrical shell



2.6 Dished heads subject to pressure on the convex (external) side

2.6.1 The calculation of the minimum thickness is to be performed according to a standard accepted by the Society.

In addition, the thickness of torispherical or ellipsoidal heads under external pressure is no to be less than 1,2 times the thickness required for a head of the same shape subject to internal pressure.

2.7 Flat heads

2.7.1 Unstayed flat head minimum thickness

a) The minimum thickness of unstayed flat heads is not to be less than the value t, in mm, calculated by the following formula:

$$t = D\left(\frac{100p}{CK}\right)^{0,5}$$

where:

p : Design pressure, in MPa

K : Permissible stress, in N/mm^2, obtained as specified in [2.3]

D : Diameter of the head, in mm. For circular section heads, the diameter D is to be measured as shown in Fig 7 and Fig 8 for various types of heads. For rectangular section heads, the equivalent value for D may be obtained from the following formula:

$$D = a\left[3{,}4 - 2{,}4\left(\frac{a}{b}\right)\right]^{0{,}5}$$

a and b being the smaller and larger side of the rectangle, respectively, in mm

C : The values given below, depending on the various types of heads shown in Fig 7 and Fig 8:

Fig 7(a) : C = 400 for circular heads

Fig 7(b) : C = 330 for circular heads

Fig 7(c) : C = 350 for circular heads

Fig 7(d) : C = 400 for circular heads and C = 250 for rectangular heads

Fig 7(e) : C = 350 for circular heads and C = 200 for rectangular heads

Fig 7(f) : C = 350 for circular heads

Fig 7(g) : C = 300 for circular heads

Fig 7(h) : C = 350 for circular heads and C = 200 for rectangular heads

Fig 8(i) : C = 350 for circular heads and C = 200 for rectangular heads

Fig 8(j) : C = 200 for circular heads

Fig 8(k) : C = 330 for circular heads

Fig 8(l) : C = 300 for circular heads

Fig 8(m) : C = 300 for circular heads

Fig 8(n) : C = 400 for circular heads

Fig 8(o) : C = value obtained from the following formula, for circular heads:

$$C = \frac{100}{0{,}3 + \frac{1{,}9Fh}{pD^3}}$$

where:

h : Radial distance, in mm, from the pitch centre diameter of bolts to the circumference of diameter D, as shown in Fig 8(o)

F : Total bolt load, in N, to be taken as the greater of the following values F_1 and F_2:

$F_1 = 0{,}785\ D\ p\ (D + m\ b)$

$F_2 = 9{,}81\ y\ D\ b$

with:

b : Effective half contact width of the gasket, in mm, calculated as follows:

$b = 0{,}5\ N$ for $N \leq 13$ mm, and

$b = 1{,}8\ N^{0{,}5}$ for $N > 13$ mm

where N is the geometric contact width of the gasket, in mm, as indicated in Fig 8(o)

m, y : Adimensional coefficients whose values are given in Tab 11, depending on the type of gasket.

The adoption of one of the above-mentioned heads is subject to the Society's approval depending upon its use. Types of heads not shown in Fig 7 and Fig 8 are to be the subject of special consideration by the Society.

b) The thickness obtained by the formulae in a) is "net" thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 1 mm. See also [2.4.7].

2.7.2 Stayed flat head minimum thickness

For the minimum thickness of stayed flat heads, see [2.12.3].

Table 11 : Coefficients m and y

Type of gasket	m	y
Self-sealing, metal or rubber (e.g. O-ring)	0	0
Rubber with cotton fabric	10	0,88
Rubber with reinforcing fabric with or without metal wire:		
- 3 layers	18	4,85
- 2 layers	20	6,4
- 1 layers	22	8,2
Synthetic fibre with suitable binders:		
- 3,0 mm thick	16	3,5
- 1,5 mm thick	22	8,2
Organic fibre	14	2,4
Metal spiral lined with synthetic fibre:

- stainless steel	30	20,0
Solid metal:		
- copper	38	28,7
- iron	44	39,8
- stainless steel	52	57,5

Figure 7 : Types of unstayed flat heads (1)

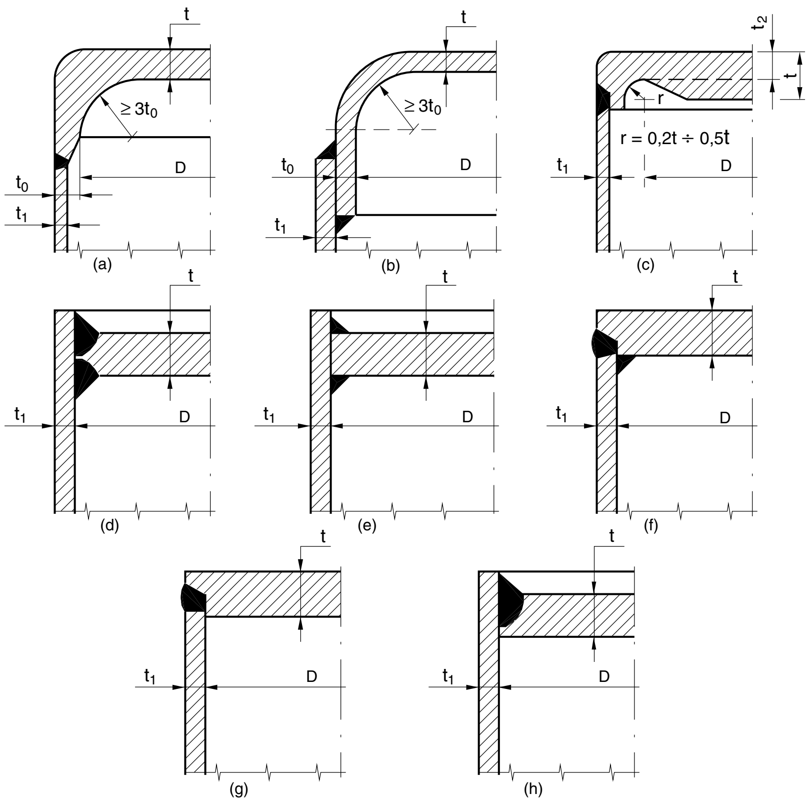

Figure 8 : Types of unstayed flat heads (2)

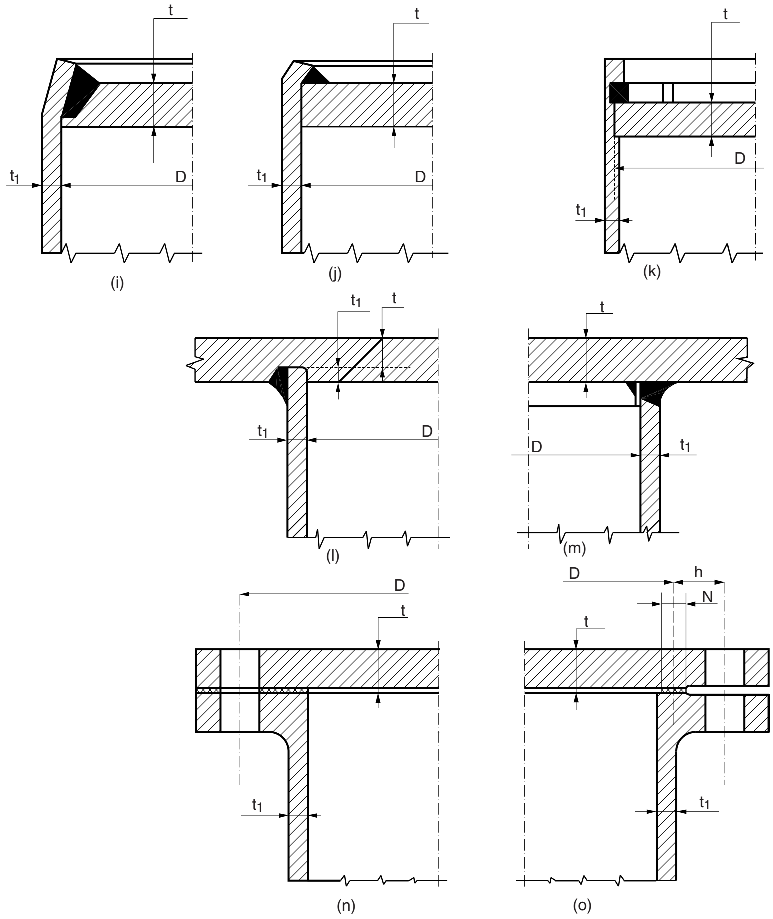

2.8 Openings and branches (nozzles)

2.8.1 Nozzles thickness

a) The thickness e_b, in mm, of nozzles attached to shells and headers of boilers is not to be less than:

$$e_b = \frac{d_E}{25} + 2{,}5$$

where d_E is the outside diameter of nozzle, in mm.

The thickness of the nozzle is, however, to be not less than the thickness required for the piping system attached to the vessel shell calculated at the vessel design pressure, and need not to be greater than the thickness of the shell to which it is connected.

b) The thickness of the nozzle attached to shells and headers of other pressure vessels is not to be less than the thickness required for the piping system attached to the vessel shell calculated at the vessel design pressure, and need not be greater than the thickness of the shell to which it is connected.

c) Where a branch is connected by screwing, the thickness of the nozzle is to be measured at the root of the thread.

2.8.2 Nozzle connection to vessel shell

a) In general, the axis of the nozzle is not to form an angle greater than 15° with the normal to the shell.

b) Fig 30, Fig 31, Fig 32 and Fig 33 show some typical acceptable connections of nozzles to shells. Other types of connections are to be considered by the Society on a case by case basis.

2.8.3 Openings in shells

a) In general, the largest dimensions of the openings in shells are not to exceed:

- for shells up to 1500 mm in diameter D_E:

  1/2 D_E, but not more than 500 mm

- for shells over 1500 mm in diameter D_E:

  1/3 D_E, but not more than 1000 mm,

where D_E is the vessel external diameter, in mm.

Greater values may be considered by the Society on a case by case basis.

b) In general, in oval or elliptical openings the ratio major diameter/minor diameter is not to exceed 2.

2.8.4 Openings compensation in cylindrical shells

a) Compensation methods

For cylindrical shells with openings, the efficiency of the main body is to be satisfied by one of the following methods:

- by increasing the wall thickness of main body compared with that of the cylindrical shell without opening: see Fig 9
- by branches which have been provided with a wall thickness of that required on account of the internal pressure: see Fig 10 and Fig 11
- by reinforcing pads or rings analogous to increasing the wall thickness: see Fig 12 and Fig 13
- by a combination of previous reinforcement.

b) Definitions

Effective lengths ℓ_{rs} required for calculation of efficiency and of compensations is to be taken as:

$$\ell_{rs} = \min(\sqrt{Dt_a}, \ell_{s1})$$

where:

D : Outside diameter, in mm

t_a : Available thickness, in mm

ℓ_{s1} : Transition length, in mm, according to Fig 9 and Fig 10

c) Basic calculation

The required wall thickness without allowance of a cylindrical shell is determined with the following formula (see [2.4.3]):

$$t = \frac{pD}{(2K-p)e}$$

With the available thickness t_a, we obtain the available efficiency e_a and the maximum diameter d_{obmax} of an unreinforced opening when the average stress of the main body is equal to the permissible stress K:

$$e_a = \frac{pD_i}{(2K-p)t_a}$$

$$d_{obmax} = 2\left[\frac{\ell_{rs}}{e_a} - \ell_{rs}\right]$$

where:

D_i : Internal diameter of the main body, in mm

d) Isolated opening reinforcement

The reinforcement of isolated openings as indicated in Fig 9 to Fig 13 are to be in respect with:

$$\frac{A_p}{A_f} \leq \frac{K}{p} - 0,5$$

where:

K : Permissible stress in the shell, in N/mm^2

A_f : Total area of cross section (wall and branch and pad)

A_p : Total area under pressure p.

In Fig 9 to Fig 13, ℓ_{rs}, ℓ_{rb} and ℓ_{rbi} are effective lengths for calculation of efficiencies and compensation, equal to:

- for shell:

  $$\ell_{rs} = \min(\sqrt{(D+e_{rs})e_{rs}}, \ell_{s1})$$

- for external branch projection:

  $$\ell_{rb} = \min(\sqrt{(d_{ib}+e_{rb})e_{rb}}, \ell_{b1})$$

- for internal branch projection:

  $$\ell_{rbi} = \min(0,5\sqrt{(d_{ib}+e_{rb})e_{rb}}, \ell_{b2})$$

Figure 9 : Reinforcement by increasing the wall thickness of the main body with opening

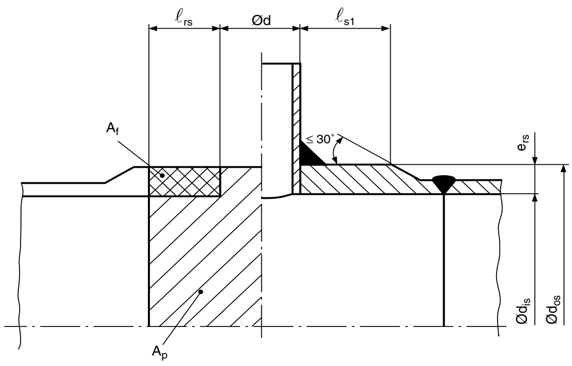

Figure 10 : Reinforcement by set-through and full penetration welded branch

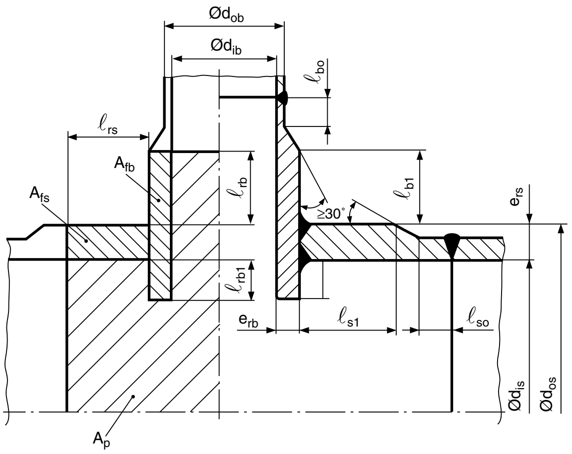

Figure 11 : Reinforcement by welded on branch

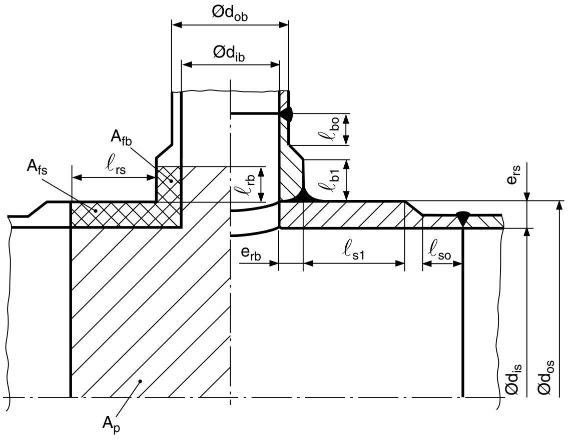

Figure 12 : Opening with reinforcing pad

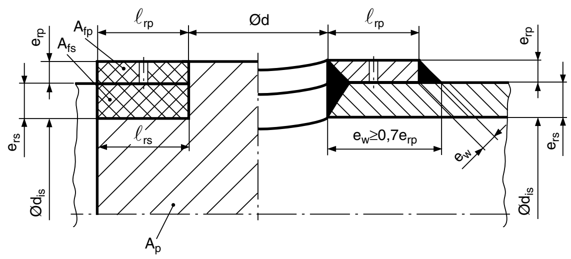

e) Condition of isolated openings

- Full case

  Adjacent openings are to be treated as isolated openings if the centre distance P_ϕ, in accordance with Fig 16, is not less than:

$$\frac{\left(\frac{d_{ib1}}{2}+e_{rb1}\right)}{\cos\Psi_1}+\frac{\left(\frac{d_{ib2}}{2}+e_{rb2}\right)}{\cos\Psi_2}+2\sqrt{(d_{is}+e_{rs})e_{rs}}$$

  For variable definition see Fig 14 and Fig 15.

- Simplification
  - For openings without branch:

    $e_{rb} = 0$ and $\Psi = 0$
  - For openings with nozzles perpendicular to shell:

    The openings are to be treated as isolated openings if the centre distance P_ϕ in accordance with Fig 16 is not less than:

$$\left(\frac{d_{ib1}}{2}+e_{rb1}\right)+\left(\frac{d_{ib2}}{2}+e_{rb2}\right)+2\sqrt{(d_{is}+e_{rs})e_{rs}}$$

f) Adjacent openings

Where the condition of isolated openings is not fulfilled, the compensation is to be calculated, using Fig 16, as per the following formula:

$$\frac{A_p}{A_f}\le\frac{K}{p}-0,5$$

Figure 13 : Opening with reinforcing pad and full penetration branch

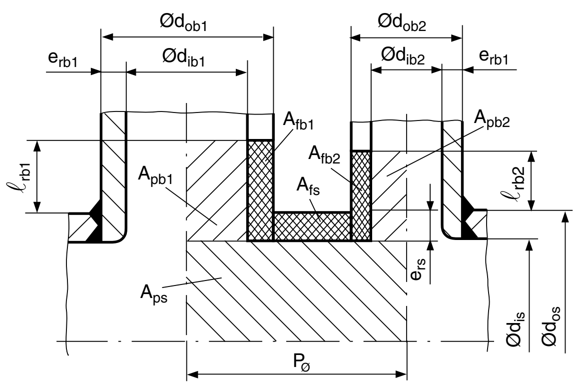
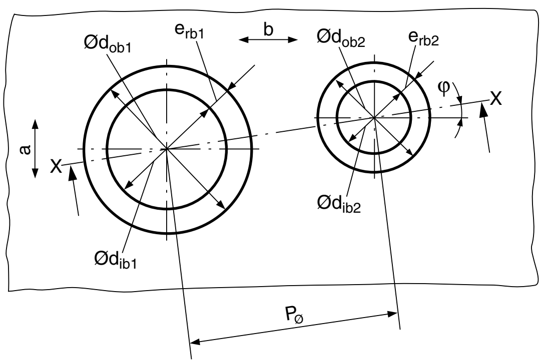
Section view X -X



Plan view



a : Circumferential direction

b : Longitudinal direction.

2.8.5 Openings in dished heads

a) The openings in dished heads may be circular, elliptical or oval.

b) The largest diameter of the non-compensated opening is not to exceed one half of the external diameter of the head.

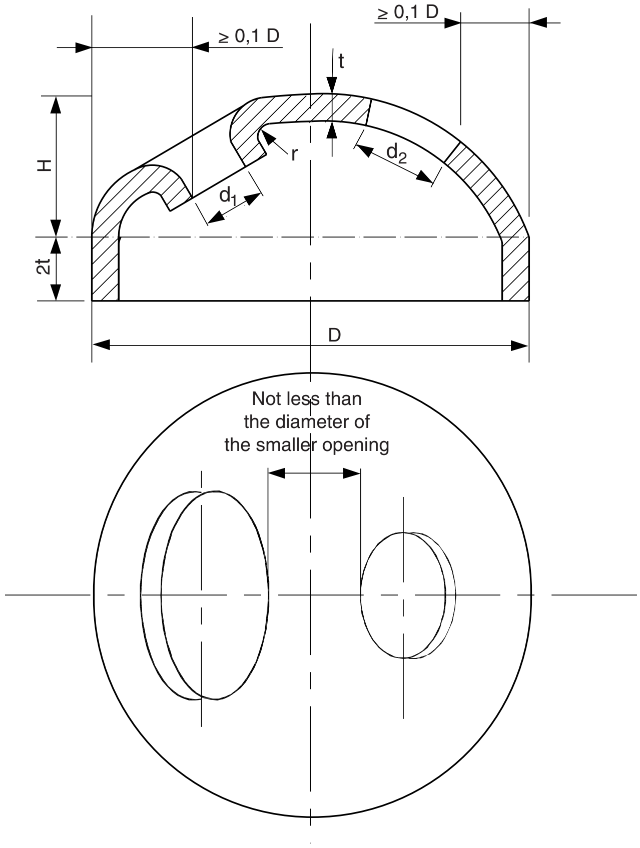
c) The opening is to be so situated that its projection, or its reinforcement projection in the case of compensated openings, is completely contained inside a circle having its centre at the centre of the head and a diameter of 0,8 D, D being the external diameter of the head (see Fig 17). However, a small reinforced opening for drainage may be accepted outside the indicated area.

d) In the case of non-compensated openings (for this purpose, flanged openings are also to be considered as non-compensated), the head thickness is not to be less than that calculated by the formula in [2.5.3] using the greatest of the shape factors C obtained from the graph in Fig 3 as a function of:

   H/D and t/D or H/D and $d \cdot (t \cdot D)^{-0,5}$,

   where d is the diameter of the largest non-compensated opening in the head, in mm. For oval and elliptical openings, d is the width of the opening in way of its major axis.

Figure 17 : Openings on dished heads



e) In all cases the diameter D of the head base, the head thickness t and the diameter d of the largest non-compensated opening are to be such as to meet the following requirements:
   - the position of non-compensated openings in the heads is to be as shown in Fig 17
   - for flanged openings, the radius r of the flanging (see Fig 17) is not to be less than 25 mm
   - the thickness of the flanged part may be less than the Rule thickness.

2.8.6 Opening compensation in dished heads

a) Where openings are cut in dished heads and the proposed thickness of the head is less than that calculated by the formula in [2.5.3], the openings are to be compensated.

b) Fig 30, Fig 31, Fig 32 and Fig 33 show typical connections of nozzles and compensating rings.

c) The opening is considered sufficiently compensated when the head thickness t is not less than that calculated in accordance with [2.5.3] and using the shape-factor C obtained from the graph in Fig 3 using the value:

$$\left(d - \frac{A}{t}\right) \cdot (t \cdot D)^{-0,5}$$

instead of:

$$d \cdot (t \cdot D)^{-0,5}$$

where:

A : Area, in mm^2, of the total transverse section of the compensating parts

t : Actual thickness of the head, in mm, in the zone of the opening under consideration.

d) When A/t > d, the coefficient C is to be determined using the curve corresponding to the value:

$$d \cdot (t \cdot D)^{-0,5} = 0$$

e) If necessary, calculations are to be repeated.

2.8.7 Compensation criteria

In the evaluation of the area A, the following is also to be taken into consideration:

a) The material that may be considered for compensating an opening is that located around the opening up to a distance l from the edge of the opening. The distance l, in mm, is the lesser obtained from the following formulae:

$$l = 0,5\ d$$

$$l = (2 \cdot R_{IN} \cdot t)^{0,5}$$

where:

d : Diameter of the opening, in mm

R_{IN} : Internal radius of the spherical part, in mm, in the case of hemispherical or torispherical heads

In the case of ellipsoidal heads, R_{IN} is to be calculated by the following formula (see Fig 2 (a):

$$R_{IN} = \frac{[a^4 - x^2(a^2 - b^2)]^{3/2}}{a^4 b}$$

where;

a : Half the major axis of the elliptical meridian section of the head, in mm

b : Half the minor axis of the above section, in mm

x : Distance between the centre of the hole and the rotation axis of the shell, in mm.

b) In the case of nozzles or pads welded in the hole, the section corresponding to the thickness in excess of that required is to be considered for the part which is subject to pressure and for a depth h, in mm, both on the external and internal sides of the head, not greater than:

$(d_B \cdot t_B)^{0,5}$

where d_B and t_B are the diameter of the opening and the thickness of the pad or nozzle, in mm, respectively.

c) The area of the welding connecting nozzle and pad reinforcements may be considered as a compensating section.

d) If the material of reinforcement pads, nozzles and collars has a permissible stress lower than that of the head material, the area A, to be taken for calculation of the coefficient C, is to be reduced proportionally.

2.8.8 Openings in flat end plates

The maximum diameter of an unreinforced opening in a flat end plate is to be determined from the equation:

$$d_{max} = 8 e_{rh}\left[1{,}5\frac{e_{rh}^2}{e_{ch}^2} - 1\right]$$

where:

e_{rh} : Actual thickness of the flat end, in mm

e_{ch} : Required calculated thickness of the flat end, in mm.

2.8.9 Opening compensation in flat end plate

Reinforcement of branch openings is to be achieved by taking account of locally disposed material, including the attachment welds, in excess of the minimum requirements for end plate and branch thickness as shown in Fig 18. The branch thickness is to be increased where required. Compensation is to be considered adequate when the compensating area Y is equal to or greater than the area X requiring compensation.

Area X is to be obtained by multiplying 25% of the inside radius of the branch by the thickness of the flat end plate, calculated for the part of the end plate under consideration.

Area Y is to be measured in a plane through the axis of the branch parallel to the surface of the flat end plate, and is to be calculated as follows:

a) For that part of the branch which projects outside the boiler, calculate the full sectional area of the branch up to a distance ℓ_b from the actual outer surface of the flat end plate and deduct from it the sectional area that the branch would have within the same distance if its thickness were calculated in accordance with equation given in [2.4.3]

Note 1: The compensating plate is required only in cases where area Y would otherwise be less than area X.

b) Add to it the full sectional area of that part of the branch that projects inside the boiler (if any) up to a distance ℓ_b from the inside surface of the flat end plate

c) Add to it the sectional area of the fillet welds

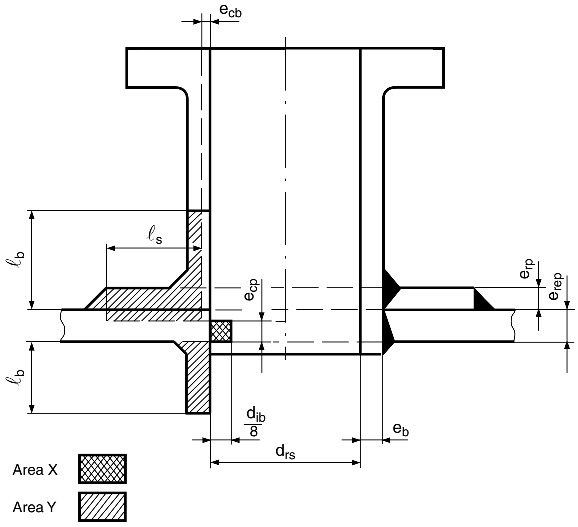
d) Add to it the area obtained by multiplying the difference between the actual flat end plate thickness and its thickness calculated for the part of the end plate under consideration by the length ℓ_s

e) Add to it the area of the compensating plate (if any) within the limits of reinforcement shown in Fig 18.

Where material having a lower allowable stress than that of the flat end plate is taken as compensation, its effective area is to be reduced in the ratio of the allowable stresses at the calculation temperature. No credit is to be taken for the additional strength of material having a higher allowable stress than that of the flat end plate

Welds attaching branches and compensating plates are to be capable of transmitting the full strength of the reinforcing area and all other loadings to which they may be subjected.

Figure 18 : Compensation for branch in flat end plate



e_{cp} : Thickness calculated in accordance with equation in [2.8.1] for the part under consideration

e_{cb} : Thickness calculated taking efficiency = 1

ℓ_b : The smaller of the two values:
$2,5\ e_{rep}$ and $(2,5\ e_b + e_{rp})$

ℓ_s : The greater of the two values:
$(e_{rep} + 75)$ and $(d_{ib} / 4)$

Area Y is not to be less than area X.

2.8.10 Covers

a) Circular, oval and elliptical inspection openings are to be provided with steel covers. Inspection openings with a diameter not exceeding 150 mm may be closed by blind flanges.

b) The thickness of the opening covers is not to be less than the value t, in mm, given by the following formula:

$$t = 1,22 \cdot a \cdot \left(\frac{pC}{K}\right)^{0,5}$$

where:

a : The minor axis of the oval or elliptical opening, measured at half width of gasket, in mm

b : The major axis of the oval or elliptical opening, measured at half width of the gasket, in mm

C : Coefficient in Tab 12 as a function of the ratio b/a of the axes of the oval or elliptical opening, as defined above. For intermediate values of the ratio b/a, the value of C is to be obtained by linear interpolation.

For circular openings the diameter d, in mm, is to be used in the above formula instead of a.

c) The thickness obtained by the formula in item a) is "net" thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 1 mm for classification purpose. See also [2.4.7].

2.9 Regular pattern openings - Tube holes

2.9.1 Definition

Openings may be considered as regular pattern openings when not less than three non isolated openings are disposed in regularly staggered rows in longitudinal or circular direction of a shell.

In such a case, instead of a direct calculation of the compensation of openings, the thickness of the shell could be calculated by application of applicable formulae given in [2.4], [2.5] with a reduced efficiency e as indicated in [2.9.2] and [2.9.3].

This requirement apply for pressure vessels and for boiler.

2.9.2 Efficiency factor of tube holes in cylindrical tube plates

The efficiency factor e of pipe holes in cylindrical shells pierced by tube holes is to be determined by direct calculation or by another suitable method accepted by the Society. In the case of cylindrical holes of constant diameter and radial axis, the efficiency factor e may be determined by the following formula (see Fig 19):

$$e = \frac{1}{\frac{s}{s-d} \cdot (1 - (0,5 \cdot \sin^2\alpha)) + m \cdot \sin 2\alpha}$$

where:

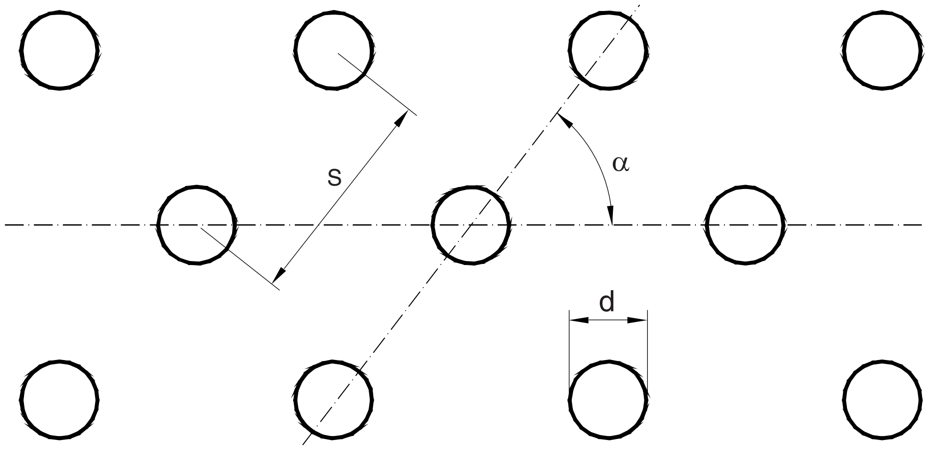
Table 12 : Coefficient C for oval or elliptical covers

b/a	1,00	1,05	1,10	1,15	1,20	1,25	1,30	1,40	1,50	1,60
C	0,206	0,220	0,235	0,247	0,259	0,271	0,282	0,302	0,321	0,333
b/a	1,70	1,80	1,90	2,00	2,50	3,00	3,50	4,00	4,50	5,00
C	0,344	0,356	0,368	0,379	0,406	0,433	0,449	0,465	0,473	0,480

Table 13 : Coefficient m

d/s	0,30	0,35	0,40	0,45	0,50	0,55	0,60	0,65	0,70	0,75	0,80
m	0,137	0,175	0,220	0,274	0,342	0,438	0,560	0,740	1,010	1,420	2,060

Figure 19 : Hole pattern in cylindrical shells



s : Pitch of the hole row considered, in mm

d : Diameter of holes, in mm. The hole diameter d may be reduced by the amount Y/e_{cp} where Y is the compensating area, in mm², of nozzle and welds and e_{cp} the calculated unpierced shell thickness, see [2.8.9] and Fig 18

α : Angle between the axis of hole row considered and the axis of the cylinder (α = 0° if the hole row is parallel to the cylinder generating line; α = 90° for circumferential hole row)

m : Coefficient depending upon the ratio d/s, as obtained from Tab 13. For intermediate values of d/s, the value of m is to be obtained by linear interpolation.

The value of e actually used is to be the smallest calculated value for either longitudinal, diagonal or circumferential rows of holes.

2.9.3 Welded shells with tube holes and efficiency factor of different hole patterns

Where shells have welding butts and/or different groups of hole patterns, the value to be assumed for the efficiency e in the formulae is the minimum of the values calculated separately for each type of welding (as per [2.4.2]) and for each configuration of holes (as per [2.9.1]).

2.9.4 Rectangular section headers

a) For seamless type headers of rectangular section design, the wall thickness t, in mm, in way of corner fillets and the thickness t_1, in mm, of any drilled wall is not to be less than those given by the following formulae, as appropriate (see Fig 20):

$$t = \left(\frac{100pM_1}{K}\right)^{0,5}$$

$$t_1 = \left(\frac{100pM_2}{eK}\right)^{0,5}$$

where (see also Fig 20):

t : Wall thickness at the corners, in mm

t_1 : Thickness of drilled wall, in mm

p : Design pressure, in MPa

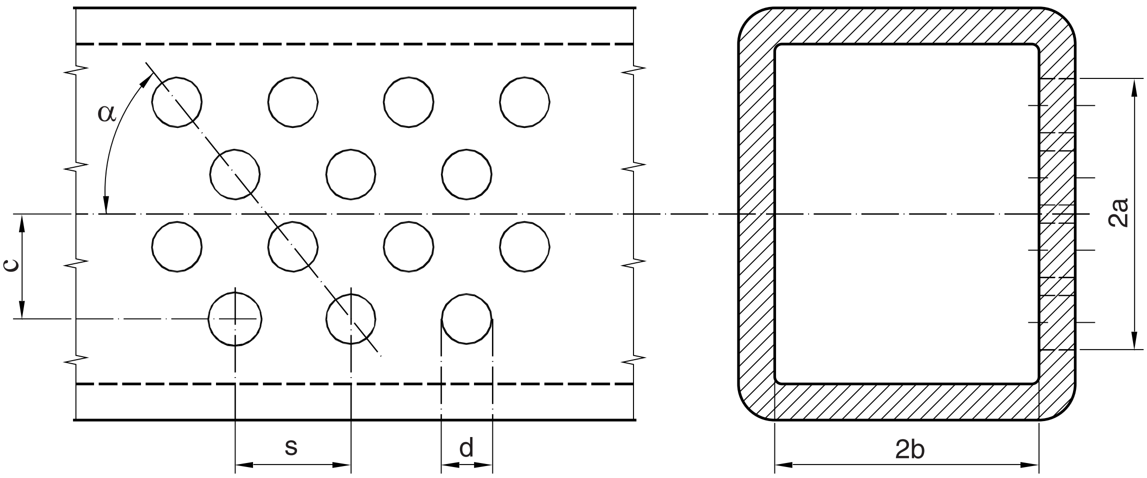
K : Permissible stress, in N/mm², obtained as specified in [2.3]

a : Internal half width of the header, in a direction parallel to the wall under consideration, in mm

b : Internal half width of the header, in a direction normal to the wall under consideration, in mm

c : Distance between the axis of the hole row considered and the centreline of the header wall, in mm

Figure 20 : Rectangular section headers



e : Efficiency factor of holes in the wall, determined by the following formulae:

$$e = \frac{s-d}{s} \quad \text{for } d < a$$

$$e = \frac{s-0{,}67d}{s} \quad \text{for } a \le d < 1{,}3a$$

$$e = \frac{s-0{,}33d}{s} \quad \text{for } d \ge 1{,}3a$$

where:

s : Pitch of the holes, in mm, of the longitudinal or diagonal row under consideration. For a staggered pattern of holes the pitch of the diagonal row is to be considered

d : Diameter of the holes, in mm

M_1 : Coefficient to be calculated by the following formula:

$$M_1 = \frac{a^2+b^2-ab}{50}$$

M_2 : Coefficient (to be taken always positive) to be calculated by one of the following formulae, as appropriate:

- For a non-staggered pattern of holes:

$$M_2 = \frac{b^2-\frac{1}{2}a^2-ab+\frac{3}{2}c^2}{50}$$

- For a staggered pattern of holes:

$$M_2 = \frac{b^2-\frac{1}{2}a^2-ab}{50}\cos\alpha$$

where α is the angle between the axis of the diagonal row of the holes under consideration and the axis of the header, in the case of a staggered pattern of holes.

b) The thickness obtained by the formulae in a) is "net" thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 1,5 mm. See also [2.4.7].

2.10 Water tubes, superheaters and economiser tubes of boilers

2.10.1

a) The thickness of tubes of evaporating parts, economisers and superheaters exposed to gases which are subject to internal pressure is not to be less than the value t given by the following formula:

$$t = \frac{pd}{2K+p}+0{,}3$$

where:

p : Design pressure, in MPa

K : Permissible stress, in N/mm², obtained as specified in [2.3]

d : Outside diameter of tube, in mm.

However, irrespective of the value calculated by the formulae in item a), the thickness t of tubes is not to be less than the values given in Tab 14.

b) The values of t determined by the above-mentioned formula are to be considered as theoretical values for straight tubes, not taking account of the manufacturing tolerance. Where the tubes are not sized precision tubes, the thickness calculated by the formula in item a) is to be increased by 12,5% to take into account the manufacturing tolerance. For bent tubes, the thickness of the thinner part in way of the bend is not to be less than that given by the formula.

c) Whenever abnormal corrosion and erosion may occur during service, the corrosion constant of 0,3 in the formula may be increased to the satisfaction of the Society.

d) The thickness of tubes which form an integral part of the boiler and which are not exposed to combustion gases is to comply with the requirements for steam pipes (see Ch 1, Sec 10, [14]).

2.11 Additional requirements for fired pressure vessels

2.11.1 Insulation for headers and combustion chambers

Those parts of headers and/or combustion chambers which are not protected by tubes and are exposed to radiant heat or to high temperature gases are to be covered by suitable insulating material.

2.11.2 Connections of tubes to drums and tube plates

Tubes are to be adequately secured to drums and/or tube plates by expansion, welding or other appropriate procedure.

a) Where the tubes are secured by expanding or equivalent process, the height of the shoulder bearing the tube, measured parallel to the tube axis, is to be at least 1/5 of the hole diameter, but not less than 9 mm for tubes normal to the tube plate or 13 mm for tubes angled to the tube plate. The tubes ends are not to project over the other face of the tube plate more than 6 mm.

b) The tube ends intended to be expanded are to be partially annealed when the tubes have not been annealed by the manufacturer.

2.12 Additional requirements for vertical boilers and fire tube boilers

2.12.1 General

The scantlings of the shells of vertical boilers and fire tube boilers are to be determined in accordance with [2.4].

2.12.2 Ends of vertical boilers

a) The minimum thickness of the dished ends forming the upper part of vertical boilers and subject to pressure on their concave face is to be determined in accordance with [2.5].

b) When the end is supported in its centre by an uptake, the minimum thickness t, in mm, is to be calculated with the following formula:

$$t = 0{,}77 \cdot \frac{pR_I}{K}$$

where:

p : Design pressure, in MPa

K : Permissible stress, in N/mm², obtained as specified in [2.3]

R_I : Radius of curvature at the centre of the end measured internally. R_I is not to exceed the external diameter of the shell.

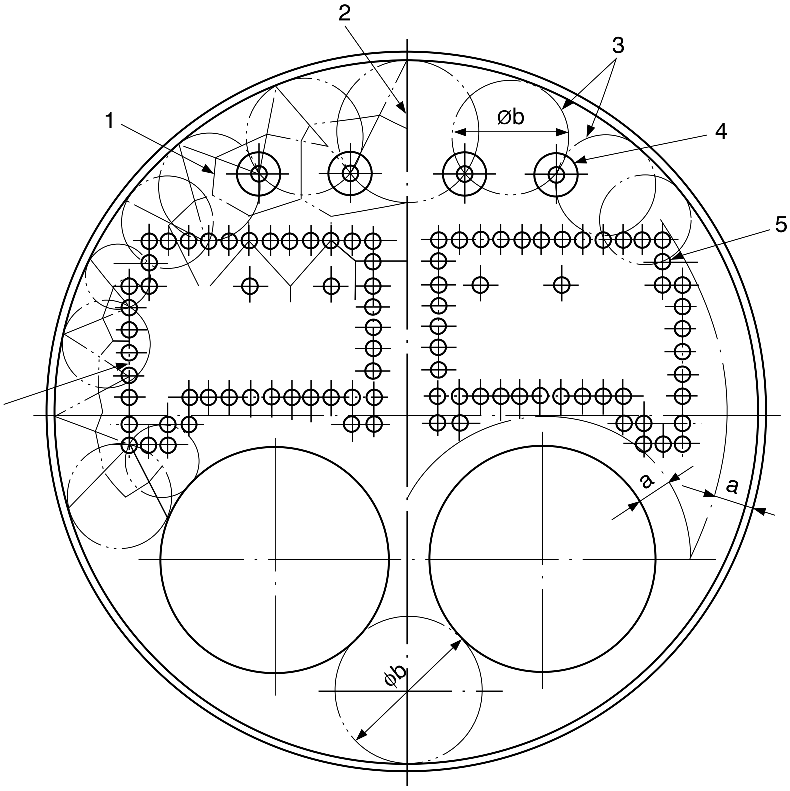
c) The thickness obtained by the formula in item b) is "net" thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 0,7 mm. See also [2.4.7].

d) For ends supported by an uptake at their centre, the corner radius measured internally is not to be less than 4 times the end thickness or 65 mm, whichever is the lesser and the inside radius of curvature on the flange to uptake is not to be less than twice the end thickness or 25 mm, whichever is the lesser.

Table 14 : Minimum thickness of water tubes

Outside diameter, in mm	Minimum thickness in mm of tubes subject to internal pressure of cylindrical boilers and water tube boilers having the feed water system	
	Closed type, if equipped with suitable devices for reducing the oxygen concentration in the water	Open type, not equipped with suitable devices for reducing the oxygen concentration in the water
< 38	1,8	2,9
38 - 48,3	2,0	2,9
51 - 63,5	2,4	2,9
70	2,6	3,2
76,1 - 88,9	2,9	3,2
101,6 - 127	3,6	–

Figure 21 :



Key:

1 : Boundaries of areas supported by individual stays

2 : To establish the area supported by bar stays or stay tubes in boundary rows, the boundary of the loaded area is to terminate at the centre of the associated main circle

3 : Main circles, diameter b

4 : Bar stays

5 : Stay tubes

6 : Termination of boundary areas where stay tubes are situated in the boundary rows only.

2.12.3 Supported flat head

a) Breathing space

- Stays are to give breathing space around the furnace tube connections and tube nests and equally divide the unstayed areas. Breathing space between furnace tube and tube nests are to be a minimum of 50 mm or 5% of the shell outside diameter, whichever is the larger, but need not be more than 100 mm.
- Breathing space between furnace tube and shell depends on the thickness of the plate of the type of end and of the dimensions of the boiler but is to be not less than 50 mm or, for bowling hoop furnaces tubes, not less than 75 mm.

b) The thickness of stayed flat heads, or of heads supported by flanges, is not to be less than the value t, in mm, given by the following formula:

$$t = D\left[\frac{100p}{CC_1K(1+C_2B^2)}\right]^{0,5}$$

where:

B : Ratio of the thickness of the large washer or doubler, where fitted, to the thickness of the plate:

$B = t_1 / t$

The value of B is to be taken between 0,67 and 1

K : Permissible stress, in N/mm², obtained as specified in [2.3]

C : C = 1 when the plate is not exposed to flame

C = 0,88 when the plate is exposed to flame

C_1 : C_1 = 462 when the plate is supported by welded stays

C_1 = 704 for plates supported by flanges or equivalent

C_2 : C_2 = 0 when no doublers are fitted

C_2 = 0,85 when a complete doubling plate is fitted, adequately joined to the base plate.

The value of D is to be in accordance with the following provisions:

- In the parts of the flat heads between the stays:

  D is the diameter, in mm, of the largest circle which can be drawn through the centre of at least three stays without enclosing any other stay, where the stays are not evenly spaced (see Fig 21), or

  $D = (a^2 + b^2)^{0,5}$ where the stays are evenly spaced, considering the most unfavourable condition

  where:

  a : Distance between two adjacent rows of stays, in mm

  b : Pitch of stays in the same row, in mm.

- In the parts of the flat heads between the stays and the boundaries, where flat heads are generally supported by flanges or shapes, or connected to other parts of the boiler:

  D is the diameter, in mm, of the largest circle which can be drawn through not less than three points of support (stay centres or points of tangency of the circle with the contour line). To this end, the contour of the part under consideration is to be drawn at the beginning of the flanging or connection curve if its inside radius does not exceed 2,5 times the thickness of the plate, or, where such radius is greater, at the above-mentioned distance (of 2,5 times the thickness of the plate) from the ideal intersection with other surfaces (see Fig 21).

c) When applying the formulae for calculation of thickness of heads covered by this sub-article, the position of plates in the most unfavourable condition is to be considered.

d) Where various types of supports are provided, the value of C_1 should be the arithmetic mean of the values of C_1 appropriate to each type of support.

e) The thickness obtained by the formulae in a), is “net” thickness, as it does not include any corrosion allowance. The thickness obtained by the above formula is to be increased by 1 mm. See also [2.4.7].

2.12.4 Flat tube plates

a) Flat tube plates in tube bundles

The thickness of the parts of flat tube plates contained in the tube bundle and supported by stay tubes is not to be less than the value t, in mm, given by the following formula:

$$t = s\left(\frac{p}{2,8K}\right)^{0,5}$$

where:

p : Design pressure, in MPa

K : Permissible stress, in N/mm^2, obtained as specified in [2.3]

s : Pitch of stay tubes, taken as the greatest mean pitch of the stay tubes supporting a quadrilateral portion of the plate, in mm.

Moreover the spacing of tube holes (diameter d) is to be such that the minimum width, in mm, of any ligament between the tube holes is to be not less than:

- for expanded tubes:

  (0,125 d + 12,5) mm

- for welded tubes:
  - for gas entry temperatures greater than 800°C:

    (0,125 d + 9) mm, but need not exceed 15 mm
  - for gas entry temperatures less than or equal to 800°C:

    (0,125 d + 7) mm, but need not exceed 15 mm.

Moreover the calculated thickness of tube plates is to be not less than the following:

- 12 mm where the tubes are expanded into the tube plate when the diameter of the tube hole does not exceed 50 mm, or 14 mm when the diameter of the tube hole is greater than 50 mm, or
- 6 mm where the tubes are attached to the tube plate by welding only.

b) Flat tube plates of combustion chamber in vertical boilers

Where tube plates contained in the tube bundle are simultaneously subject to compression due to the pressure in the combustion chamber, their thickness, as well as complying with the requirements in item a) is not to be less than the value t, in mm, given by the following formula:

$$t = \frac{p l s_1}{1,78(s_1 - d)K}$$

where:

l : Depth of the combustion chamber, in mm

s_1 : Horizontal pitch of tubes, in mm

d : Inside diameter of plain tubes, in mm.

For the meaning of other symbols, see item a).

c) Tube plates outside tube bundles

For those parts of tube plates which are outside the tube bundle, the formula in [2.13.3] is to be applied, using the following coefficients C_1 and C_2:

$C_1 = 390$

$C_2 = 0,55$

Doublers are only permitted where the tube plate does not form part of a combustion chamber.

d) Tube plates not supported by stays

Flat tube plates which are not supported by stay tubes (e.g. in heat exchangers), are subject of special consideration by the Society (see also [2.14]).

e) Stay and stay tube scantling

- The diameter of solid stays of circular cross-section is not to be less than the value d calculated by the following formula:

$$d = \left(\frac{pA}{K}\right)^{0,5}$$

where:

d : Minimum diameter, in mm, of the stay throughout its length

A : Area supported by the stay, in mm²

K : $K = R_m / 7$

R_m : Minimum ultimate tensile strength of the stay material, in N/mm².

The cross section of tube stays is to be equivalent to that of a solid stay supporting the same area, whose diameter is calculated by the above formula.

Stays which are not perpendicular to the supported surface are to be of an adequately increased diameter depending on the component of the force normal to the plate.

- Where articulated stays are used, articulation details are to be designed assuming a safety factor for articulated elements not less than 5 with respect to the value of R_m and a wear allowance of 2 mm.

The articulation is to be of the fork type and the clearance of the pin in respect of the holes is not to exceed 1,5 mm. The pin is to bear against the jaws of the fork and its cross-sectional area is not to be less than 80% of the cross-sectional area of the stay. The width of material around the holes is not to be less than 13 mm.

- Where stays are flanged for joining to the plate, the thickness of the flange is not to be less than one half the diameter of the stay.
- For welded connections of stays to tube plates, see Fig 37.

f) Stay and stay tubes construction

- In general, doublers are not to be fitted in plates exposed to flame.
- As far as possible, stays are to be fitted perpendicularly to the supported surface.
- Long stays in double front boilers and, in general, stays exceeding 5 m in length, are to be supported at mid-length.
- Where the ends of stay tubes are of increased thickness, the excess material is to be obtained by forging and not by depositing material by means of welding.
- After forging, the ends of stay tubes are to be stress relieved.

g) Gusset stays

Tube plate may be supported by gussets stays with full penetration welds to plate and shell.

The general shape and the scantling are to be in accordance with a standard accepted by the Society.

h) Girders

Where tops of combustion chambers, or similar structures, are supported by girders of rectangular section associated with stays, the thickness of the single girder or the aggregate thickness of all girders, at mid-length, is not to be less than the value t determined by the appropriate formula below, depending upon the number of stays.

- In case of an odd number of stays:

$$t = \frac{pL(L-s)l}{0,25R_m a^2} \cdot \frac{n+1}{n}$$

- In case of an even number of stays:

$$t = \frac{pL(L-s)l}{0,25R_m a^2} \cdot \frac{n+2}{n+1}$$

where:

p : Design pressure, in MPa

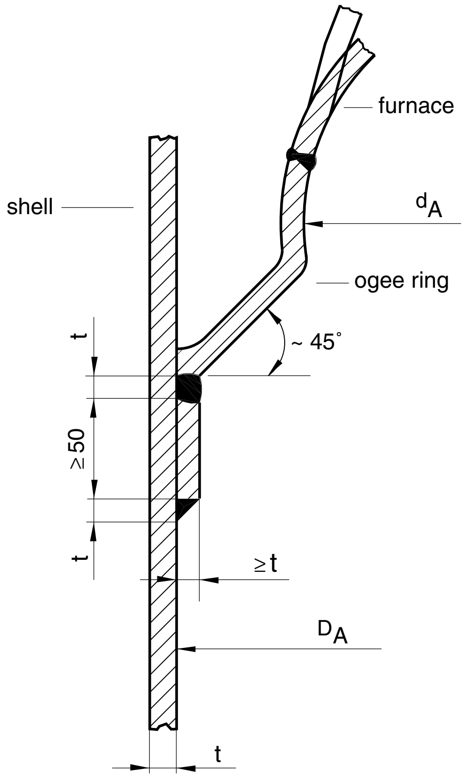
a : Depth of the girder plate at mid-length, in mm

L : Length of girder between supports, in mm

s : Pitch of stays, in mm

n : Number of stays on the girder

Figure 22 : Ogee ring



l : Distance between centres of girders, in mm

R_m : Minimum ultimate tensile strength of the material used for the plates, in N/mm².

The above formulae refer to the normal arrangement where:

- The stays are regularly distributed over the length L.
- The distance from the supports of the outer stays does not exceed the uniform pitch s.
- When the tops of the combustion chambers are connected to the sides with curved parts with an external radius less than 0,5 l, the distance of end girders from the inner part of the side surface does not exceed l.
- When the curvature radius mentioned under item just above exceeds 0,5 l, the distance of the end girders from the beginning of the connection does not exceed 0,5 l.

In other cases a direct calculation is to be made using a safety factor not less than 5, with respect to the minimum value of the tensile strength R_m.

i) Ogee rings

The thickness of ogee rings connecting the furnaces to the shell in vertical auxiliary boilers (see Fig 22), where the latter support the weight of the water above the furnace, is not to be less than the value t, in mm, given by the following formula:

$$t = [1{,}02 \cdot 10^{-3} \cdot pD_A \cdot (D_A - d_A)]^{0{,}5} + 1$$

where:

p : Design pressure, in MPa

D_A : Inside diameter of boiler shell, in mm

d_A : Inside diameter of the lower part of the furnace where it joins the ogee ring, in mm.

2.12.5 Fire tubes

a) The thickness of fire tubes subject to external pressure in cylindrical boilers is not to be less than the value t, in mm, calculated by the following formula:

$$t = \frac{pd}{0{,}15 R_m} + 1{,}8$$

where:

p : Design pressure, in MPa

d : Outside diameter of tube, in mm

R_m : Minimum ultimate tensile strength of the tube material, in N/mm².

The minimum acceptable thickness is given in Tab 15.

b) The values of t determined by the above-mentioned formula are to be considered as theoretical values for straight tubes, not taking account of the manufacturing tolerance. Where the tubes are not sized precision tubes, the thickness calculated by the formula in a) is to be increased by 12,5% to take into account the manufacturing tolerance. In the case of bent tubes, the thickness of the thinner part in way of the bend is not to be less than that given by the above formula.

c) Whenever abnormal corrosion and erosion may occur during service the corrosion constant of 1,8 in the formula may be increased to the satisfaction of the Society.

Table 15 : Minimum thickness of fire tubes

Nominal outside diameter	Lowest nominal thickness t
d ≤ 88,9	3,00
88,9 < d ≤ 114,3	3,15
114,3 < d ≤139,7	3,50
139,7 < d ≤168,3	3,99

2.12.6 Furnaces general points

a) Thermal design of furnace tubes.

The heat input for a given furnace tube inside diameter is not to exceed a value compatible with the chosen design temperature. Burners with a fixed firing rate are not to be used for heat inputs exceeding 1 MW per furnace tube.

b) The minimum thickness of furnaces is to be calculated for elastic buckling and plastic deformation in accordance with the requirements of a Standard for pressure vessels subject to external pressure accepted by the Society.

c) However, the minimum thicknesses of furnaces and cylindrical ends of combustion chambers of fire tube boilers are to be not less than the value t given by the appropriate formulae in [2.12.7], [2.12.8] and [2.12.9].

d) The thickness of furnaces is not to be less than 8 mm for plain furnace and 10 mm for corrugated furnace and the stays are to be spaced such that the thickness does not exceed 22 mm.

e) All the thicknesses obtained for furnaces by the formulae in [2.12.7], [2.12.8], [2.12.9] and [2.12.4] are "net" thicknesses, as they do not include any corrosion allowance. The thicknesses obtained by the above formulae are to be increased by 1 mm. See also [2.4.7].

2.12.7 Plain furnace tubes

a) Plain furnace tube

The minimum thickness t of plain cylindrical furnaces is to be not less than the greater value, in mm, obtained from the following formulae:

$$t = \frac{B}{2}\left[1 + \sqrt{1 + \frac{0,12D \cdot u}{(1 + 5D/L)B}}\right]$$

$$t = D^{0,6}[(LS_2p)/(2,6E)]^{0,4}$$

where:

$$B = \frac{pDS_1}{2R_{S,MIN,T}(1 + 5D/L)}$$

S_1 : Safety factor, equal to 2,5

L : Unstayed length of furnace, in mm

u : Departure from circularity, in %, equal to:

$$u = \frac{2(D_{max} - D_{min})}{D_{max} + D_{min}} \times 100$$

u is to be taken as 1,5% for plain furnace tubes

S_2 : Safety factor for buckling, equal to:

- 3 for u ≤1,5%
- 4 for 1,5% < u ≤ 2%

E : Elastic modulus, in MPa, at design temperature T, in °C, and equal to:

$E = 208800 - 93,4 \cdot T$

b) Stiffeners

Stiffeners welded to furnaces tubes according to a standard accepted by the Society may be considered as providing effective stiffening (reduction of L in upper formulae).

2.12.8 Corrugated furnace tubes

The minimum thickness of corrugated furnace tubes, in mm, is to be determined by:

$$t = \frac{pD_E}{0,26R_m}$$

where:

D_E : External diameter of the furnace, in mm, measured at the bottom of the corrugation.

This formula apply for Fox and Morisson type furnaces tubes. The scantling of furnaces of other types and the use of stiffeners are to be especially considered by the Society.

2.12.9 Hemispherical furnaces

The minimum thickness t, in mm, of hemispherical furnaces is not to be less than the value given by the following equation:

$$t = \frac{pD_E}{120}$$

2.13 Bottles containing pressurised gases

2.13.1 General

a) The following requirements apply to bottles intended to contain pressurised and/or liquefied gases at ambient temperature, made by seamless manufacturing processes.

b) In general, such bottles are to have an outside diameter not exceeding 420 mm, a length not exceeding 2000 mm and capacity not exceeding 150 litres (see also [3.4.1]).

c) For bottles exceeding the above capacity and dimensions, the following requirements may be applied at the discretion of the Society.

2.13.2 Cylindrical shell

The wall thickness of the cylindrical shell is not to be less than the value t, in mm, determined by the following formula:

$$t = \frac{p_H D_E}{2K + p_H}$$

where:

p_H : Hydrostatic test pressure, in MPa. This pressure is to be taken as 1,5 times the setting pressure of the safety valves with the following exceptions:

- 25 MPa for CO_2 bottles
- for refrigerants, the value of hydrostatic test pressure is given in Pt E, Ch 11, Sec 3

D_E : Outside diameter of tube, in mm

$K = R_{S,MIN} / 1,3$

$R_{S,MIN}$: Value of the minimum yield strength (R_{eH}), or 0,2% proof stress ($R_{p\ 0,2}$), at the ambient temperature, in N/mm². In no case is the value $R_{S,MIN}$ to exceed:

- 0,75 R_m for normalised steels
- 0,90 R_m for quenched and tempered steels.

2.13.3 Dished heads

Dished ends are to comply with the following requirements:

a) Hemispherical ends: the thickness of the ends is to be not less than the thickness calculated for spherical shells in accordance with [2.4.4]

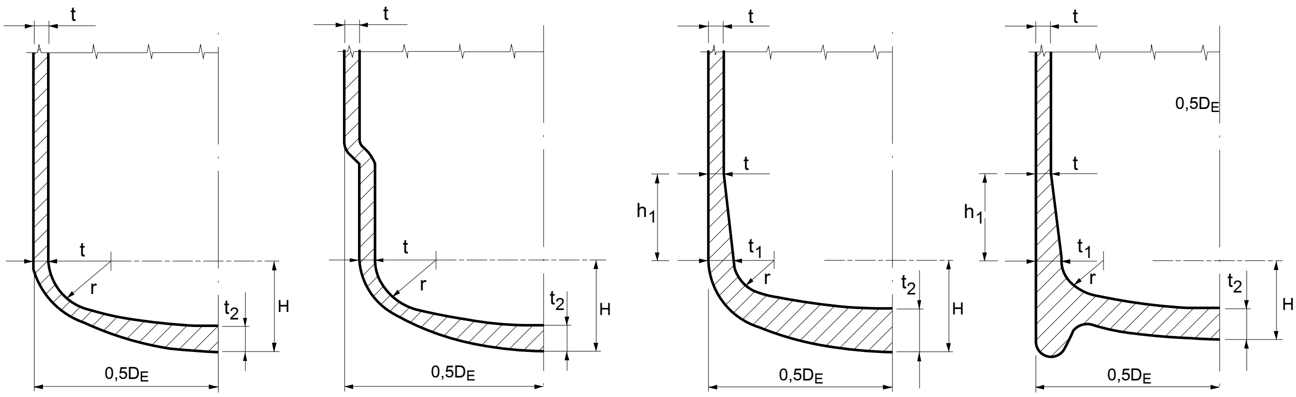
b) Convex ends: see Fig 23

c) Concave base ends: see Fig 24

d) Ends with openings: see Fig 25

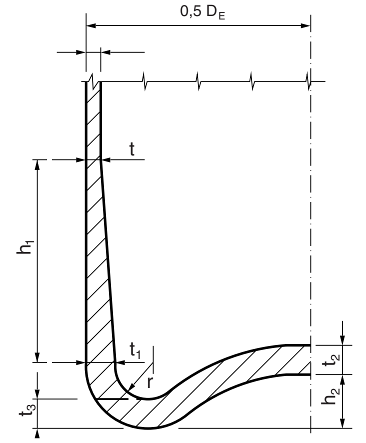
e) Other types of ends are to be specially considered by the Society.

Figure 23 : Dished convex ends



$H/D_E \geq 0,20$ $r \geq 0,075D_E$ $t_1 \geq 1,25\ t$ $t_2 \geq 1,5\ t$ $h_1 \geq 6\ t$

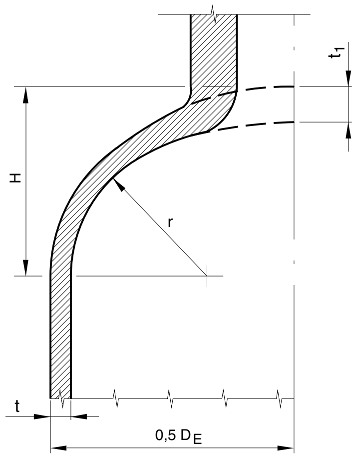
Figure 24 : Dished concave ends



$t_1 \geq 1,7\ t$ $t_2 > 2\ t$ $t_3 \geq 2\ t$

$h_1 \geq 6\ t$ $h_2 \geq 0,12\ D_E$ $r \geq 0,075\ D_E$

Figure 25 : Heads with openings



$0,25 \leq H/D_E \leq 0,5$ $t_1 \geq 1,5t$ $r \geq 0,35D_E$

2.14 Heat exchangers

2.14.1 Scantlings

a) Vessels are to be designed in accordance with the applicable requirements stated in [2.4] and [2.5].

b) Tubes are to be designed in accordance with [2.10.1].

c) Tube plates are to be designed in accordance with a standard accepted by the Society.

2.14.2 Thermal oil heat exchangers

The provisions of [2.14.1] apply also to thermal oil heat exchangers. However, irrespective of the thickness obtained by the formula in [2.10.1], the tube thickness of oil fired and exhaust fired thermal oil heaters is to be not less than the values indicated in Tab 16.

Table 16 : Minimum thickness of thermal oil heat exchanger tubes

Outside diameter, in mm	Minimum thickness, in mm, of tubes subject to internal pressure of oil fired and exhaust fired thermal oil heaters
< 63,5	2,4
70 - 89	2,9
> 89	3,6

3 Design and construction - Equipment

3.1 All pressure vessels

3.1.1 Drainage

a) Each air pressure vessel is to be fitted with a drainage device allowing the evacuation of any oil or water accumulated in the vessel.

b) Drainage devices are also to be fitted on other vessels, in particular steam vessels, in which condensation water is likely to accumulate.

3.2 Boilers and steam generators

3.2.1 Safety valve arrangement

a) Every steam boiler and every steam generator with a total heating surface of 50 m^2 and above is to be provided with not less than two spring loaded safety valves of adequate capacity. For steam boilers and steam generators having heating surface less than 50 m^2, only one safety valve need be fitted.

b) Where a superheater is an integral part of the boiler, at least one safety valve is to be located on the steam drum and at least one at the superheater outlet. The valves fitted at the superheater outlet may be considered as part of the boiler safety valves required in item a), provided that their capacity does not account for more than 25% of the total capacity required in [3.2.2], unless specially considered by the Society.

c) Where fitted, superheaters which may be shut-off from the boiler are to be provided with at least one safety valve; such valve(s) cannot be considered as part of the boiler safety valves required in item a).

d) In the case of boilers fitted with a separate steam accumulator, safety valves may be fitted on the accumulator if no shut-off is provided between it and the boiler and if the connecting pipe is of a size sufficient to allow the whole steam production to pass through, without increasing the boiler pressure more than 10% above the design pressure.

3.2.2 Relieving capacity of safety valves

a) The relieving capacity of each safety valve Q, in kg/h, is to be determined by the appropriate formula below in order that:

$Q \geq W$

- saturated steam:

$$Q = \frac{C \cdot A \cdot (10 \cdot P + 1,05)}{100}$$

- superheated steam:

$$Q = \frac{C \cdot A \cdot (10 \cdot P + 1,05)}{100} \times \sqrt{\frac{v}{v_S}}$$

where:

W : Maximum steam production, in kg/h, as defined by the maximum power of the heating equipment; otherwise the value of W is to be based on evaporating capacities (referring to evaporating surfaces of the boiler concerned) less than the following:

- 14 kg/(m^2·h) for exhaust gas heated boilers
- 29 kg/(m^2·h) for oil fired boilers
- 60 kg/(m^2·h) for water walls of oil fired boilers

A : Aggregate area, in mm^2, of the orifices in way of the seat of the valve, deducting the obstructions corresponding to the guides and the conformation of the valve in full lift position

p : Maximum working pressure of the boiler or other steam generator, in MPa. For superheated steam safety valves, P is to be the pressure at the superheater outlet

C : Coefficient with the following values:

- C = 4,8 for ordinary safety valves, i.e. where the valve lift is at least 1/24 of the internal diameter of the seat
- C = 10 for high lift safety valves, i.e. where the valve lift is at least 1/12 of the internal diameter of the seat
- C = 20 for full lift safety valves, i.e. where the valve lift is at least 1/4 of the internal diameter of the valve

Higher values of coefficient C may be admitted for safety valves of approved type and having undergone, in the presence of the Surveyor or according to a procedure considered as equivalent by the Society, capacity tests with conditions of pressure and temperature comparable to those of the plant considered. In such a case, coefficient C is to be, as a rule, taken as 90% of the resulting value from the capacity test

v : Specific volume of saturated steam at the pressure corresponding to the superheater outlet

v_S : Specific volume of superheated steam at the temperature corresponding to the superheater outlet.

b) When the safety valves are fitted at the superheater outlet. Their relieving capacity is to be such that, during the discharge of safety valves, a sufficient quantity of steam is circulated through the superheater to avoid damage.

c) The orifice diameter in way of the safety valves seat is not to be less than 40 mm. Where only one safety valve need be fitted, the orifice minimum diameter is not to be less than 50 mm. Valves of large relieving capacity with 15 mm minimum diameter may be accepted for boilers with steam production not exceeding 2000 kg/h.

d) Independently of the above requirements, the aggregate capacity of the safety valves is to be such as to discharge all the steam that can be generated without causing a transient pressure rise of more than 10% over the design pressure.

3.2.3 Miscellaneous safety valve requirements

a) Safety valves operated by pilot valves

The arrangement on the superheater of large relieving capacity safety valves, operated by pilot valves fitted in the saturated steam drum, is to be specially considered by the Society.

b) Safety valve setting

- safety valves are to be set under steam in the presence of the Surveyor to a pressure not higher than 1,03 times the design pressure
- safety valves are to be so constructed that their setting may not be increased in service and their spring may not be expelled in the event of failure. In addition, safety valves are to be provided with simple means of lifting the plug from its seat from a safe position in the boiler or engine room
- where safety valves are provided with means for regulating their relieving capacity, they are to be so fitted that their setting cannot be modified when the valves are removed for surveys.

c) Safety valve fitting on boiler

- the safety valves of a boiler are to be directly connected to the boiler and separated from other valve bodies
- where it is not possible to fit the safety valves directly on the superheater headers, they are to be mounted on a strong nozzle fitted as close as practicable to the superheater outlet. The cross-sectional area for passage of steam through restricted orifices of the nozzles is not to be less than 1/2 the aggregate area of the valves, calculated with the formulae of [2.3.2] when $C \leq 10$, and not less than the aggregate area of the valves when $C > 10$
- safety valve bodies are to be fitted with drain pipes of a diameter not less than 20 mm for double valves, and not less than 12 mm for single valves, leading to the bilge or to the hot well. Valves or cocks are not to be fitted on drain pipes.

d) Exhaust pipes

- the minimum cross-sectional area of the exhaust pipes of safety valves which have not been experimentally tested is not to be less than C times the aggregate area A
- the cross-sectional area of the exhaust manifold of safety valves is to be not less than the sum of the areas of the individual exhaust pipes connected to it
- silencers fitted on exhaust manifolds are to have a free passage area not less than that of the manifolds
- the strength of exhaust manifolds and pipes and associated silencers is to be such that they can withstand the maximum pressure to which they may be subjected, which is to be assumed not less than 1/4 of the safety valve setting pressure
- in the case that the discharges from two or more valves are led to the same exhaust manifold, provision is to be made to avoid the back pressure from the valve which is discharging influencing the other valves
- exhaust manifolds are to be led to the open and are to be adequately supported and fitted with suitable expansion joints or other means so that their weight does not place an unacceptable load on the safety valve bodies.

e) Steam generator heated by steam

Steam heated steam generators are also to be protected against possible damage resulting from failure of the heating coils. In this case, the area of safety valves calculated as stated in [3.2.2] may need to be increased to the satisfaction of the Society, unless suitable devices limiting the flow of steam in the heating coils are provided.

3.2.4 Other requirements

Access arrangement

a) Boilers are to be provided with openings in sufficient number and size to permit internal examination, cleaning and maintenance operations. In general, all pressure vessels which are part of a boiler with inside diameter exceeding 1200 mm, and those with inside diameter exceeding 800 mm and length exceeding 2000 mm, are to be provided with access manholes.

b) Manholes are to be provided in suitable locations in the shells, headers, domes, and steam and water drums, as applicable. The "net" (actual hole) dimension of elliptical or similar manholes is to be not less than 300mm x 400mm. The "net" diameter of circular manholes (actual hole) cannot be less than 400 mm. The edges of manholes are to be adequately strengthened to provide compensation for vessel openings in accordance with [2.8.4], [2.8.6] and [2.8.9], as applicable.

c) In pressure vessels which are part of a boiler and are not covered by the requirement in item a) above, or where an access manhole cannot be fitted, at least the following openings are to be provided, as far as practicable:

- head holes: minimum dimensions: 220mm x 320mm (320 mm diameter if circular)
- handholes: minimum dimensions: 87mm x 103mm
- sight holes: minimum diameter: 50 mm.

d) Sight holes may only be provided when the arrangement of manholes, head holes, or handholes is impracticable.

e) Covers for manholes and other openings are to be made of ductile steel, dished or welded steel plates or other approved design. Grey cast iron may be used only for small openings, such as handholes and sight holes, provided the design pressure p does not exceed 1 MPa and the design temperature T does not exceed 220°C.

f) Covers are to be of self-closing internal type. Small opening covers of other type may be accepted by the Society on a case by case basis.

g) Covers of the internal type are to have a spigot passing through the opening. The clearance between the spigot and the edge of the opening is to be uniform for the whole periphery of the opening and is not to exceed 1,5 mm.

h) Closing devices of internal type covers, having dimensions not exceeding 180mm x 230mm, may be fitted with a single fastening bolt or stud. Larger closing devices are to be fitted with at least two bolts or studs.

i) Covers are to be designed so as to prevent the dislocation of the required gasket by the internal pressure. Only continuous ring gaskets may be used for packing.

Fittings

a) In general, cocks and valves are to be designed in accordance with the requirements in Ch 1, Sec 10, [2.7.2].

b) Cocks, valves and other fittings are to be connected directly or as close as possible to the boiler shell.

c) Cocks and valves for boilers are to be arranged in such a way that it can be easily seen when they are open or closed and so that their closing is obtained by a clockwise rotation of the actuating mechanism.

Boiler burners

Burners are to be arranged so that they cannot be withdrawn unless the fuel supply to the burners is cut off.

Allowable water levels

a) In general, for water tube boilers the lowest permissible water level is just above the top row of tubes when the water is cold. Where the boiler is designed not to have fully submerged tubes, when the water is cold, the lowest allowable level indicated by the manufacturer is to be indicated on the drawings and submitted to the Society for consideration.

b) For fire tube boilers with combustion chamber integral with the boiler, the minimum allowable level is to be at least 50 mm above the highest part of the combustion chamber.

c) For vertical fire tube boilers the minimum allowable level is 1/2 of the length of the tubes above the lower tube sheet.

Steam outlets

a) Each boiler steam outlet, if not serving safety valves, integral superheaters and other appliances which are to have permanent steam supply during boiler operation, is to be fitted with an isolating valve secured either directly to the boiler shell or to a standpipe of substantial thickness, as short as possible, and secured directly to the boiler shell.

b) The number of auxiliary steam outlets is to be reduced to a minimum for each boiler.

c) Where several boilers supply steam to common mains, the arrangement of valves is to be such that it is possible to positively isolate each boiler for inspection and maintenance. In addition, for water tube boilers, non-return devices are to be fitted on the steam outlets of each boiler.

d) Where steam is used for essential auxiliaries (such as whistles, steam operated steering gears, steam operated electric generators, etc.) and when several boilers are fitted on board, it is to be possible to supply steam to these auxiliaries with any one of these boilers out of operation.

e) Each steam stop valve exceeding 150 mm nominal diameter is to be fitted with a bypass valve.

Feed check valves

a) Each fired boiler supplying steam to essential services is to be fitted with at least two feed check valves connected to two separate feed lines. For unfired steam generators a single feed check valve may be allowed.

b) Feed check valves are to be secured directly to the boiler or to an integral economiser. Water inlets are to be separated. Where, however, feed check valves are secured to an economiser, a single water inlet may be allowed provided that each feed line can be isolated without stopping the supply of feed water to the boiler.

c) Where the economisers may be bypassed and cut off from the boiler, they are to be fitted with pressure-limiting type valves, unless the arrangement is such that excessive pressure cannot occur in the economiser when cut off.

d) Feed check valves are to be fitted with control devices operable from the stokehold floor or from another appropriate location. In addition, for water tube boilers, at least one of the feed check valves is to be arranged so as to permit automatic control of the water level in the boiler.

e) Provision is to be made to prevent the feed water from getting in direct contact with the heated surfaces inside the boiler and to reduce, as far as possible and necessary, the thermal stresses in the walls.

Drains

Each superheater, whether or not integral with the boiler, is to be fitted with cocks or valves so arranged that it is possible to drain it completely.

Water sample

a) Every boiler is to be provided with means to supervise and control the quality of the feed water. Suitable arrangements are to be provided to preclude, as far as practicable, the entry of oil or other contaminants which may adversely affect the boiler.

b) For this purpose, boilers are to be fitted with at least one water sample cock or valve. This device is not to be connected to the water level standpipes.

c) Suitable inlets for water additives are to be provided in each boiler.

Marking of boilers

a) Each boiler is to be fitted with a permanently attached plate made of non-corrosive metal, with indication of the following information, in addition to the identification marks (name of manufacturer, year and serial number):
   - the design pressure
   - the design temperature
   - the test pressure and the date of the test.

b) Markings may be directly stamped on the vessel if this does not produce notches having an adverse influence on its behaviour in service.

c) For lagged vessels, these markings are also to appear on a similar plate fitted above the lagging.

3.3 Thermal oil heaters and thermal oil installation

3.3.1 General

a) The following requirements apply to thermal oil heaters in which organic liquids (thermal oils) are heated by oil fired burners, exhaust gases or electricity to temperatures below their initial boiling point at atmospheric pressure.

b) Thermal oils are only to be used within the limits set by the manufacturer.

c) Means are to be provided for manual operation. During manual operation, the automated functioning of at least the temperature control device on the thermal oil side as well as the flow monitoring is to be maintained.

d) Means are to be provided to take samples of thermal oil.

3.3.2 Thermal oil heater design

a) Heaters are to be so constructed that neither the surfaces nor the thermal oil becomes excessively heated at any point. The flow of the thermal oil is to be ensured by forced circulation.

b) The surfaces which come into contact with the thermal oil are to be designed for the design pressure, subject to the minimum pressure of 1 MPa.

c) Copper and copper alloys are not permitted.

d) Heaters heated by exhaust gas are to be provided with inspection openings at the exhaust gas intake and outlet.

e) Oil fired heaters are to be provided with inspection openings for examination of the combustion chamber. The opening for the burner may be considered as an inspection opening, provided its size is sufficient for this purpose.

f) Heaters are to be fitted with means enabling them to be completely drained.

g) Thermal oil heaters heated by exhaust gas are to be fitted with a permanent system for extinguishing and cooling in the event of fire, for instance a pressure water spraying system.

3.3.3 Safety valves of thermal oil heaters

Each heater is to be equipped with at least one safety valve having a discharge capacity at least equal to the increase in volume of the thermal oil at the maximum heating power. During discharge the pressure may not increase above 10% over the design pressure.

3.3.4 Pressure vessels of thermal oil heaters

The design pressure of all vessels which are part of a thermal oil system, including those open to the atmosphere, is to be taken not less than 0,2 MPa.

3.3.5 Equipment of the expansion, storage and drain tanks

For the equipment to be installed on expansion, storage and drain tanks, see Ch 1, Sec 10, [13].

3.3.6 Marking

Each thermal oil heater and other pressure vessels which are part of a thermal oil installation are to be fitted with a permanently attached plate made of non-corrosive metal, with indication of the following information, in addition to the identification marks (name of manufacturer, year and serial number):

- Heaters
  - maximum allowable heating power
  - design pressure
  - maximum allowable discharge temperature
  - minimum flow rate
  - liquid capacity
- Vessels
  - design pressure
  - design temperature
  - capacity.

3.4 Special types of pressure vessels

3.4.1 Seamless pressure vessels (bottles)

Each bottle is to be marked with the following information:

- name or trade name of the manufacturer
- serial number
- type of gas
- capacity
- test pressure
- empty weight
- test stamp.

3.4.2 Steam condensers

a) The water chambers and steam spaces are to be fitted with doors for inspection and cleaning.

b) Where necessary, suitable diaphragms are to be fitted for supporting tubes.

c) Condenser tubes are to be removable.

d) High speed steam flow, where present, is to be prevented from directly striking the tubes by means of suitable baffles.

e) Suitable precautions are to be taken in order to avoid corrosion on the circulating water side and to provide an efficient grounding.

3.5 Other pressure vessels

3.5.1 Safety valves arrangement

a) General
   - Pressure vessels which are part of a system are to be provided with safety valves, or equivalent devices, if they are liable to be isolated from the system safety devices. This provision is also to be made in all cases in which the vessel pressure can rise, for any reason, above the design pressure.
   - In particular, air pressure vessels which can be isolated from the safety valves ensuring their protection in normal service are to be fitted with another safety device, such as a rupture disc or a fusible plug, in order to ensure their discharge in case of fire. This device is to discharge to the open.
   - Safety devices ensuring protection of pressure vessels in normal service are to be rated to operate before the pressure exceeds the maximum working pressure by more than 5%
   - where two or more pressure vessels are interconnected by a piping system of adequate size so that no branch of piping may be shut off, it is sufficient to provide them with one safety valve and one pressure gauge only.

b) Heat exchangers

Special attention is to be paid to the protection against overpressure of vessels, such as heat exchangers, which have parts that are designed for a pressure which is below that to which they might be subjected in the case of rupture of the tubular bundles or coils contained therein and that have been designed for a higher pressure.

3.5.2 Other requirements

a) Access arrangement

The access requirements for boilers stated in [3.2.4] are also applicable for other pressure vessels.

b) Corrosion protection

Vessels and equipment containing media that might lead to accelerated corrosion are to be suitably protected.

c) Marking

- Each pressure vessel is to be fitted with a permanently attached plate made of non-corrosive metal, with indication of the following information, in addition to the identification marks (name of manufacturer, year and serial number):
  - the design pressure
  - the design temperature
  - the test pressure and the date of the test.
- Markings may be directly stamped on the vessel if this does not produce notches having an adverse influence on its behaviour in service.
- For smaller pressure vessels the indication of the design pressure only may be sufficient.

4 Design and construction - Fabrication and welding

4.1 General

4.1.1 Base materials

a) These requirements apply to boilers and pressure vessels made of steel of weldable quality.

b) Fabrication and welding of vessels made of other materials are to be the subject of special consideration.

4.1.2 Welding

a) Weldings are to be performed in accordance with welding procedures approved by the Society.

b) Manual and semi-automatic welding is to be performed by welders qualified by the Society.

c) The conditions under which the welding procedures, welding equipment and welders operate are to correspond to those specified in the relevant approvals or qualifications.

d) Both ordinary and special electric arc welding processes are covered in the following requirements.

4.1.3 Cutting of plates

a) Plates are to be cut by flame cutting, mechanical machining or a combination of both processes. For plates having a thickness less than 25 mm, cold shearing is admitted provided that the sheared edge is removed by machining or grinding for a distance of at least one quarter of the plate thickness with a minimum of 3 mm.

b) For flame cutting of alloy steel plates, preheating is to be carried out if necessary.

c) The edges of cut plates are to be examined for laminations, cracks or any other defect detrimental to their use.

4.1.4 Forming of plates

a) The forming processes are to be such as not to impair the quality of the material. The Society reserves the right to require the execution of tests to demonstrate the suitability of the processes adopted. Forming by hammering is not allowed.

b) Unless otherwise justified, cold formed shells are to undergo an appropriate heat treatment if the ratio of internal diameter after forming to plate thickness is less than 20. This heat treatment may be carried out after welding.

c) Before or after welding, hot formed plates are to be normalised or subjected to another treatment suitable for their steel grade, if hot forming has not been carried out within an adequate temperature range.

d) Plates which have been previously butt-welded may be formed under the following conditions:

- Hot forming

  After forming, the welded joints are to be subjected to X-ray examination or equivalent. In addition, mechanical tests of a sample weld subjected to the same heat treatment are to be carried out.

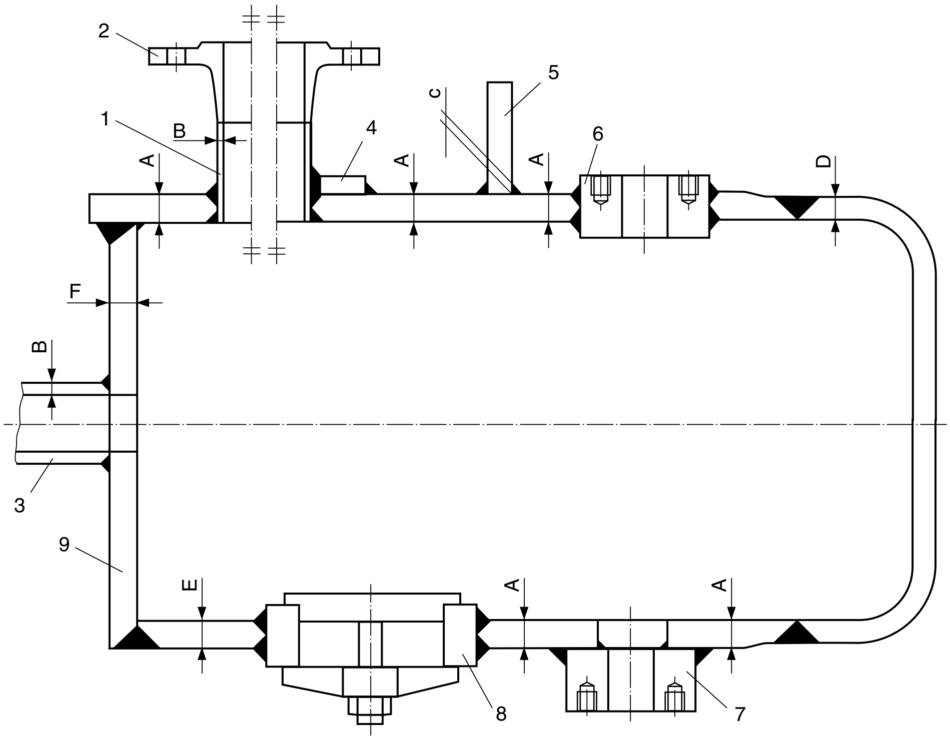
- Cold forming

  Cold forming is only allowed for plates having a thickness not exceeding:

  - 20 mm for steels having minimum ultimate tensile strength R_m between 360 N/mm² and 410 N/mm²
  - 15 mm for steels having R_m between 460 N/mm² and 510 N/mm² as well as for steels 0,3Mo, 1Mn0,5Mo, 1Mn0,5MoV and 0,5Cr0,5Mo.

  Cold forming is not allowed for steels 1Cr0,5Mo and 2,25Cr1Mo.
- Weld reinforcements are to be carefully ground smooth prior to forming.
- A proper heat treatment is to be carried out after forming, if the ratio of internal diameter to thickness is less than 36, for steels: 460 N/mm², 510 N/mm², 0,3Mo, 1Mn0,5Mo, 1Mn0,5MoV and 0,5Cr0,5Mo.
- After forming, the joints are to be subjected to X-ray examination or equivalent and to a magnetic particle or liquid penetrant test.
- Refer to Fig 26 for definition of thickness to be taken in account.

Figure 26 : Example of acceptable joints and thickness to be considered for forming and post-weld heat treatment



Key

1 : Nozzle (set in); **2** : Flange; **3** : Nozzle (set on); **4** : Reinforcing plate; **5** : Non-pressure part;

6 : Pad (set in); **7** : Pad (set on); **8** : Manhole frame; **9** : Flat plate.

4.2 Welding design

4.2.1 Main welded joints

a) All joints of class 1 and 2 pressure parts of boilers and pressure vessels are to be butt-welded, with the exception of welding connecting flat heads or tube sheets to shells, for which partial penetration welds or fillet welds may be accepted.

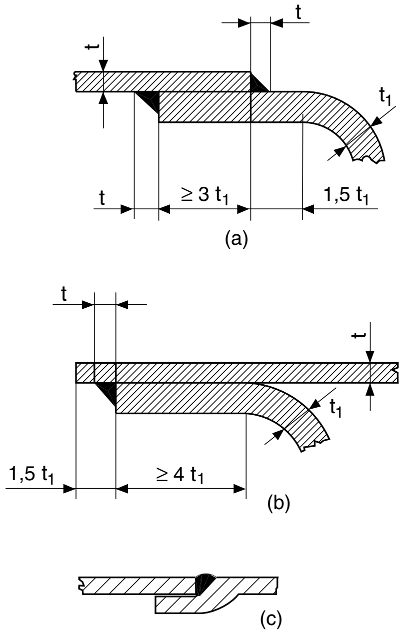
   Fig 26 show examples of acceptable welding for class 1 and 2 pressure vessels.

b) Joints of class 3 pressure vessels are also subject to the requirement in a), however connection of dished heads to shells by lap welds may be accepted. Fig 27 shows some acceptable details of circumferential lap welds for class 3 pressure vessels.

4.2.2 Shell longitudinal and circumferential welds

Longitudinal and circumferential joints are to be welded from both sides of the plate. Welding from one side may be allowed only when there is evidence that the welding process permits a complete penetration and a sound weld root. If a backing strip is used, it is to be removed after welding and prior to any non-destructive examination. However, the backing strip may be retained in circumferential joints of class 2 vessels, having a thickness not exceeding 15 mm, and of class 3 vessels, provided that the material of the backing strip is such as not to adversely affect the weld.

Figure 27 : Example of acceptable lap-joints



Details (b) and (c) may be used only for pressure vessels having internal diameter less than 600mm.

4.2.3 Plates of unequal thickness

a) If plates of unequal thickness are butt-welded and the difference between thicknesses is more than 3 mm, the thicker plate is to be smoothly tapered for a length equal to at least four times the offset, including the width of the weld. For longitudinal joints the tapering is to be made symmetrically on both sides of the plate in order to obtain alignment of middle lines.

b) If the joint is to undergo radiographic examination, the thickness of the thicker plate is to be reduced to that of the thinner plate next to the joint and for a length of at least 30 mm.

4.2.4 Dished heads

a) For connection of a hemispherical end with a cylindrical shell, the joint is to be arranged in a plane parallel to that of the largest circle perpendicular to the axis of the shell and at such a distance from this plane that the tapering of the shell made as indicated in [2.5.6] is wholly in the hemisphere.

b) For torispherical ends made of parts assembled by welding, no welded joint is normally admitted along a parallel in the knuckle nor at a distance less than 50 mm from the beginning of the knuckle.

4.2.5 Welding location

The location of main welded joints is to be chosen so that these joints are not submitted to appreciable bending stresses.

4.2.6 Accessories and nozzles

a) Attachment of accessories by welds crossing main welds or located near such welds is to be avoided; where this is impracticable, welds for attachment of accessories are to completely cross the main welds rather than stop abruptly on or near them.

b) Openings crossing main joints or located near main joints are also to be avoided as far as possible.

c) Doubling plates for attachment of accessories such as fixing lugs or supports are to be of sufficient size to ensure an adequate distribution of loads on pressure parts; such doubling plates are to have well rounded corners. Attachment of accessories such as ladders and platforms directly on the walls of vessels such that they restrain their free contraction or expansion is to be avoided.

d) Welded connections of nozzles and other fittings, either with or without local compensation, are to be of a suitable type, size and preparation in accordance with the approved plans.

4.2.7 Connections of stays to tube plates

a) Where stays are welded, the cross-sectional area of the weld is to be at least 1,25 times the cross-section of the stay.

b) The cross-sectional area of the end welding of welded stay tubes is to be not less than 1,25 times the cross-sectional area of the stay tube.

4.2.8 Type of weldings

Fig 28, Fig 29, Fig 30, Fig 31, Fig 32, Fig 33, Fig 34, Fig 35, Fig 36 and Fig 37 indicate the type and size of weldings of typical pressure vessel connections. Any alternative type of welding or size is to be the subject of special consideration by the Society.

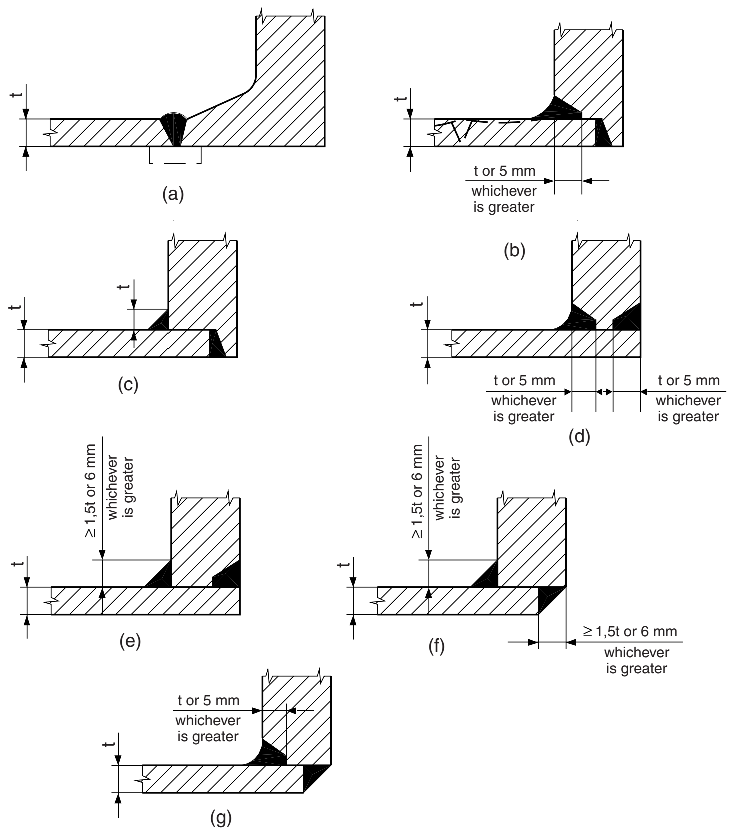

Figure 35 : Types of joints for tubesheets to shell (1)

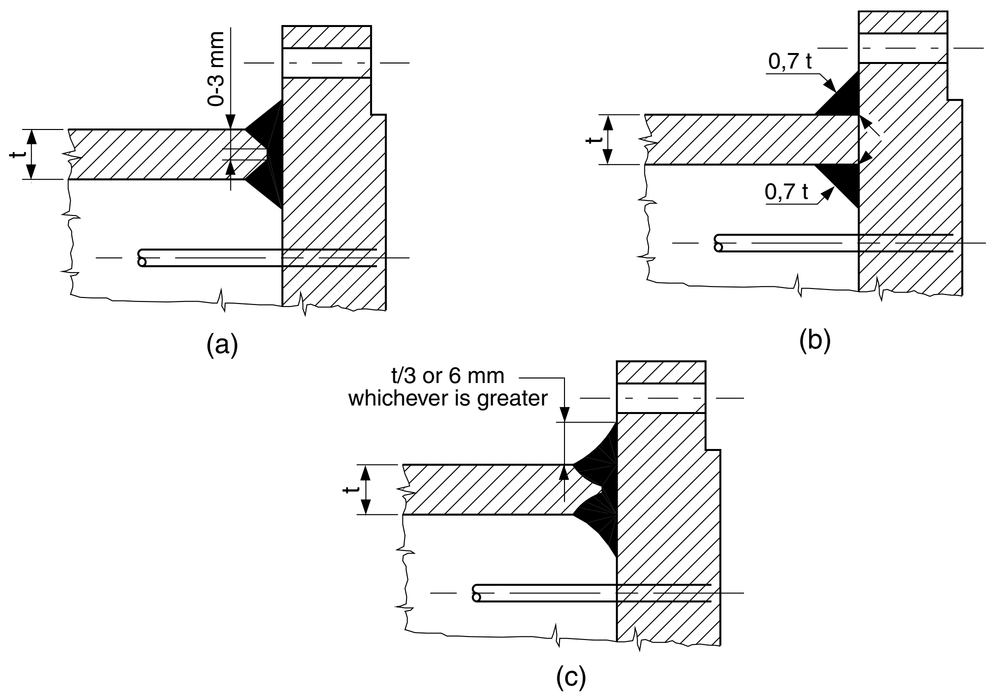

Figure 36 : Types of joints for tubesheets to shells (2)

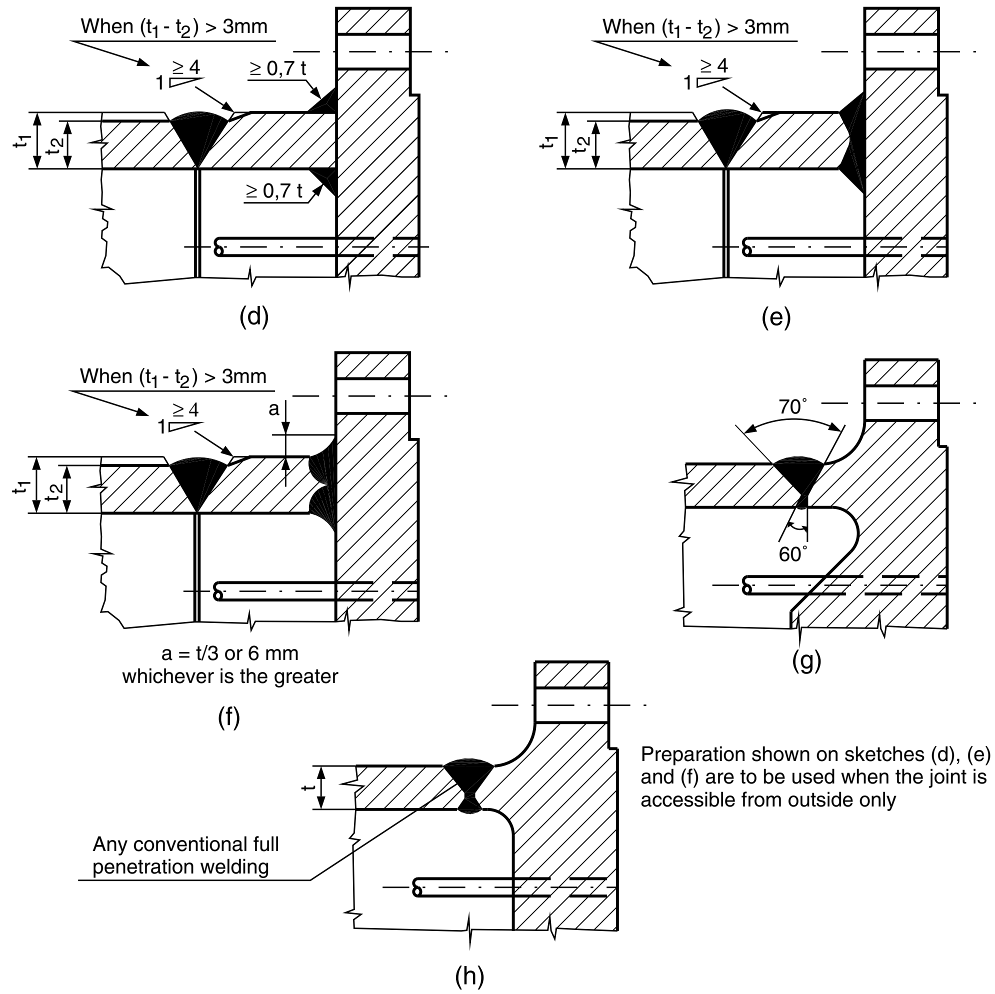

Figure 37 : Type of joints for stays and stay tubes

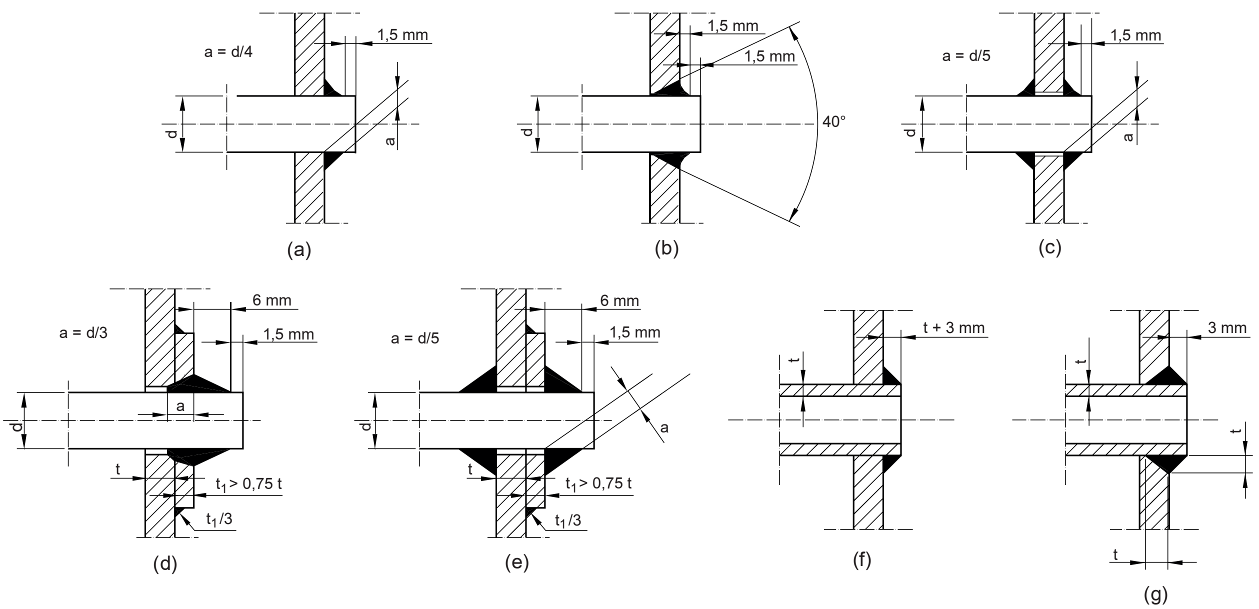


4.3 Miscellaneous requirements for fabrication and welding

4.3.1 Welding position

a) As far as possible, welding is to be carried out in the downhand horizontal position and arrangements are to be foreseen so that this can be applied in the case of circumferential joints.

b) When welding cannot be performed in this position, tests for qualification of the welding process and the welders are to take account thereof.

4.3.2 Cleaning of parts to be welded

a) Parts to be welded are, for a distance of at least 25 mm from the welding edges, to be carefully cleaned in order to remove any foreign matter such as rust, scale, oil, grease and paint.

b) If the weld metal is to be deposited on a previously welded surface, all slag or oxide is to be removed to prevent inclusions.

4.3.3 Protection against adverse weather conditions

a) Welding of pressure vessels is to be done in a sheltered position free from draughts and protected from cold and rain.

b) Unless special justification is provided, no welding is to be performed if the temperature of the base metal is less than 0°C.

4.3.4 Interruption in welding

If, for any reason, welding is stopped, care is to be taken on restarting to obtain a complete fusion.

4.3.5 Backing weld

When a backing weld is foreseen, it is to be carried out after suitable chiseling or chipping at the root of the first weld, unless the welding process applied does not call for such an operation.

4.3.6 Appearance of welded joints

a) Welded joints are to have a smooth surface without under-thickness; their connection with the plate surface is to be gradual without undercutting or similar defects.

b) The weld reinforcement of butt welds, on each side of the plate, is not to exceed the following thickness:
   - 2,5 mm for plates having a thickness not exceeding 12 mm
   - 3 mm for plates having a thickness greater than 12 mm but less than 25 mm
   - 5 mm for plates having a thickness at least equal to 25 mm.

4.4 Preparation of parts to be welded

4.4.1 Preparation of edges for welding

a) Grooves and other preparations of edges for welding are to be made by machining, chipping or grinding. Flame cutting may also be used provided that the zones damaged by this operation are removed by machining, chipping or grinding. For alloy steel plates, preheating is to be provided, if needed, for flame cutting.

b) Edges prepared are to be carefully examined to check that there are no defects detrimental to welding.

4.4.2 Abutting of parts to be welded

a) Abutting of parts to be welded is to be such that surface misalignment of plates does not exceed:
   - 10% of the thickness of the plate with a maximum of 3 mm for longitudinal joints
   - 10% of the thickness of the plate plus 1 mm with a maximum of 4 mm for circumferential joints.

b) For longitudinal joints, middle lines are to be in alignment within 10% of the thickness of the thinner plate with a maximum of 3 mm.

c) Plates to be welded are to be suitably retained in position in order to limit deformation during welding. The arrangements are to be such as to avoid modification of the relative position of parts to be welded and misalignment, after welding, exceeding the limits indicated above.

d) Temporary welds for abutting are to be carried out so that there is no risk of damage to vessel shells. Such welds are to be carefully removed after welding of the vessel and before any heat treatment. Non-destructive testing of the corresponding zones of the shell may be required by the Surveyor if considered necessary.

e) Accessories such as doubling plates, brackets and stiffeners are to be suitable for the surface to which they are to be attached.

4.5 Tolerances after construction

4.5.1 General

The sizes and shape of vessels are to be checked after welding for compliance with the design taking into account the tolerances given below. The Society reserves the right to stipulate smaller values for these tolerances for vessels subjected to special loads.

Any defect in shape is to be gradual and there is to be no flat area in way of welded joints.

Measurements are to be taken on the surface of the parent plate and not on the weld or other raised part.

4.5.2 Straightness

The straightness of cylindrical shells is to be such that their deviation from the straight line does not exceed 0,6% of their length, with a maximum of 15 mm for each 5 m of length.

4.5.3 Out-of-roundness

a) Out-of-roundness of cylindrical shells is to be measured either when set up on end or when laid flat on their sides; in the second case, measures of diameters are to be repeated after turning the shell through 90° about its axis and out-of-roundness is to be calculated from the average of the two measures of each diameter.

b) For any transverse section, the difference between the maximum and minimum diameters is not to exceed 1% of the nominal diameter D with a maximum of:

   (D + 1250) / 200, D being expressed in mm.

   For large pressure vessels, this limit may be increased by a maximum of 0,2% of the internal diameter of the vessel. Any possible out-of-roundness within the above limit is to be gradual and there are to be no localised deformations in way of the welded joints.

4.5.4 Irregularities

Irregularities in profile of cylindrical shells, checked by a 20° gauge, are not to exceed 5% of the thickness of the plate plus 3 mm. This value may be increased by 25% if the length of the irregularity does not exceed one quarter of the distance between two circumferential seams, with a maximum of 1 mm.

4.6 Preheating

4.6.1

a) Preheating, to be effectively maintained during the welding operation, may be required by the Society when deemed necessary in relation to a number of circumstances, such as the type of steel, thickness of the base material, welding procedure and technique, type of restraint, and heat treatment after welding, if any.

b) The preheating temperature is to be determined accordingly. However, a preheating temperature of approximately 150°C is required for 0,5Mo or 1Cr0,5Mo type steel, and approximately 250°C for 2,25Cr1Mo type steel.

c) These requirements also apply to welding of nozzles, fittings, steam pipes and other pipes subject to severe conditions.

4.7 Post-weld heat treatment

4.7.1 General

a) When post-weld heat treatment of a vessel is to be carried out, such treatment is to consist of:
   - heating the vessel slowly and uniformly up to a temperature suitable for the grade of steel
   - maintaining this temperature for a duration determined in relation to the actual thickness t_A of the vessel and the grade of steel
   - slowly cooling the vessel in the furnace down to a temperature not exceeding 400°C, with subsequent cooling allowed out of the furnace in still air.

b) As far as possible, vessels are to be heat treated in a single operation. However, when the sizes of the vessels are such that heat treatment requires several operations, care is to be taken such that all the parts of the vessels undergo heat treatment in a satisfactory manner. In particular, a cylindrical vessel of great length may be treated in sections in a furnace if the overlap of the heated sections is at least 1500 mm and if parts outside the furnace are lagged to limit the temperature gradient to an acceptable value.

4.7.2 Thermal stress relieving

Upon completion of all welding, including connections of nozzles, doublers and fittings, pressure vessels of classes 1 and 2, boilers and associated parts are to be subjected to an effective stress relieving heat treatment in the following cases:

- pressure vessels of classes 1 and 2 containing fluids at a temperature not less than the ambient temperature, where the thickness exceeds that indicated in Tab 17
- boilers and steam generators for thicknesses higher than 20 mm or, depending upon the type of steel, for lower thicknesses as required for class 1 pressure vessels.

Applications at temperatures less than the ambient temperature and/or steels other than those indicated above are to be the subject of special consideration by the Society.

Stress relieving heat treatment is not to be required when the minimum temperature of the fluid is at least 30°C higher than the KV-notch impact test temperature specified for the steel; this difference in temperature is also to be complied with for welded joints (both in heat-affected zones and in weld metal).

Pressure vessels and pipes of class 3 and associated parts are not required to be stress relieved, except in specific cases.

Table 17 : Thermal stress relieving

Grade	Thickness (mm) above which post-weld heat treatment is required	
	Boilers	Unfired pressure vessels
R_m = 360 N/mm² Grade HA R_m = 410 N/mm² Grade HA	14,5	14,5
R_m = 360 N/mm² Grade HB R_m = 410 N/mm² Grade HB	20	30
R_m = 360 N/mm² Grade HD R_m = 410 N/mm² Grade HD	20	38
R_m = 460 N/mm² Grade HB R_m = 510 N/mm² Grade HB	20	25
R_m = 460 N/mm² Grade HD R_m = 510 N/mm² Grade HD	20	35
0,3Mo 1Mn 0,5Mo 1Mn 0,5MoV 0,5Cr 0,5Mo	20	20
1Cr 0,5Mo 2,25Cr 1Mo	ALL	ALL

4.7.3 Heat treatment procedure

The temperature of the furnace at the time of introduction of the vessel is not to exceed 400°C.

a) The heating rate above 400°C is not to exceed:
- 220°C per hour if the maximum thickness is not more than 25 mm, or
- $(5500 / t_A)$°C per hour, with a minimum of 55°C per hour, if the maximum thickness t_A , in mm, is more than 25 mm

b) The cooling rate in the furnace is not to exceed:
- –280°C per hour if the maximum thickness is not more than 25 mm, or
- $-(7000 / t_A)$°C per hour, with a minimum of –55°C per hour, if the maximum thickness t_A , in mm, is more than 25 mm.

Unless specially justified, heat treatment temperatures and duration for maintaining these temperatures are to comply with the values in Tab 18.

Table 18 : Heat treatment procedure

Grade	Temperatures	Time per 25 mm of maximum thickness	Minimum time
Carbon steels	580-620°C	1 hour	1 hour
0,3Mo 1Mn 0,5Mo 1Mn 0,5MoV 0,5Cr 0,5Mo	620-660°C	1 hour	1 hour
1Cr 0,5Mo	620-660°C	1hour	2 hours
2,25Cr 1Mo	600-750°C **(1)**	2 hours	2 hours
(1) The temperature is to be chosen, with a tolerance of ± 20°C, in this temperature range in order to obtain the required mechanical characteristics			

4.7.4 Alternatives

When, for special reasons, heat treatment is carried out in conditions other than those given in [4.7.2], all details regarding the proposed treatment are to be submitted to the Society, which reserves the right to require tests or further investigations in order to verify the efficiency of such treatment.

4.7.5 Execution of heat treatment

Furnaces for heat treatments are to be fitted with adequate means for controlling and recording temperature; temperatures are to be measured on the vessel itself. The atmosphere in the furnaces is to be controlled in order to avoid abnormal oxidation of the vessel.

4.7.6 Treatment of test plates

Test plates are normally to be heated at the same time and in the same furnace as the vessel.

When separate heat treatment of test plates cannot be avoided, all precautions are to be taken such that this treatment is carried out in the same way as for the vessel, specifically with regard to the heating rate, the maximum temperature, the duration for maintaining this temperature and the cooling conditions.

4.7.7 Welding after heat treatment

a) Normally, welding after heat treatment is only allowed if:
   - the throat of welding fillets does not exceed 10 mm
   - the largest dimension of openings in the vessel for the accessories concerned does not exceed 50 mm.

b) Any welding of branches, doubling plates and other accessories on boilers and pressure vessels after heat treatment is to be submitted for special examination by the Society.

4.8 Welding samples

4.8.1 Test plates for welded joints

a) Test plates of sufficient size, made of the same grade of steel as the shell plates, are to be fitted at each end of the longitudinal joints of each vessel so that the weld in the test plates is the continuation of these welded joints. There is to be no gap when passing from the deposited metal of the joint to the deposited metal of the test plate.

b) No test plate is required for circumferential joints if these joints are made with the same process as longitudinal joints. Where this is not the case, or if there are only circumferential joints, at least one test plate is to be welded separately using the same welding process as for the circumferential joints, at the same time and with the same welding materials.

c) Test plates are to be stiffened in order to reduce as far as possible warping during welding. The plates are to be straightened prior to their heat treatment which is to be carried out in the same conditions as for the corresponding vessel (see also [4.7.6]).

d) After radiographic examination, the following test pieces are to be taken from the test plates:
   - one test piece for tensile test on welded joint
   - two test pieces for bend test, one direct and one reverse
   - three test pieces for impact test
   - one test piece for macrographic examination.

4.8.2 Mechanical tests of test plates

a) The tensile strength on welded joint is not to be less than the minimum specified tensile strength of the plate.

b) The bend test pieces are to be bent through an angle of 180° over a former of 4 times the thickness of the test piece. There is to be no crack or defect on the outer surface of the test piece exceeding in length 1,5 mm transversely or 3 mm longitudinally. Premature failure at the edges of the test piece is not to lead to rejection. As an alternative, the test pieces may be bent through an angle of 120° over a former of 3 times the thickness of the test piece.

c) The impact energy measured at 0°C is not to be less than the values given in NR216 Materials and Welding for the steel grade concerned.

d) The test piece for macrographic examination is to permit the examination of a complete transverse section of the weld. This examination is to demonstrate good penetration without lack of fusion, large inclusions and similar defects. In case of doubt, a micrographic examination of the doubtful zone may be required.

4.8.3 Re-tests

a) If one of the test pieces yields unsatisfactory results, two similar test pieces are to be taken from another test plate.

b) If the results for these new test pieces are satisfactory and if it is proved that the previous results were due to local or accidental defects, the results of the re-tests may be accepted.

4.9 Specific requirements for class 1 vessels

4.9.1 General

The following requirements apply to class 1 pressure vessels, as well as to pressure vessels of other classes, whose scantlings have been determined using an efficiency of welded joint e greater than 0,90.

4.9.2 Non-destructive tests

a) All longitudinal and circumferential joints of class 1 vessels are to be subject of 100% radiographic or equivalent examination with the following exceptions:
   - for pressure vessels or parts designed to withstand external pressures only, at the Society’s discretion, the extent may be reduced up to approximately 30% of the length of the joints. In general, the positions included in the examinations are to include all welding crossings.
   - for vessels not intended to contain toxic or dangerous matters, made of carbon steels having thickness below 20 mm when the joints are welded by approved automatic processes at the Society’s discretion, the extent may be reduced up to

approximately 10% of the length of the joints. In general, the positions included in the examinations are to include all welding crossings.

- for circumferential joints having an external diameter not exceeding 175 mm, at the Society's discretion, the extent may be reduced up to approximately 10% of the total length of the joints.

b) Fillet welds for parts such as doubling plates, branches or stiffeners are to undergo a spot magnetic particle test for at least 10% of their length. If magnetic particle tests cannot be used, it is to be replaced by liquid penetrant test.

c) Welds for which non destructive tests reveal unacceptable defects, such as cracks or areas of incomplete fusion, are to be rewelded and are then to undergo a new non destructive examination

4.9.3 Number of test samples

a) During production, at least one test plate for each 20 m of length (or fraction) of longitudinal weldings is to be tested as per [4.8.2].

b) During production, at least one test plate for each 30 m of length (or fraction) of circumferential welding is to be tested as per [4.8.2].

c) When several vessels made of plates of the same grade of steel, with thicknesses varying by not more than 5 mm, are welded successively, only one test plate may be accepted per each 20 m of length of longitudinal joints (or fraction) and per each 30 m of circumferential welding (or fraction) provided that the welders and the welding process are the same. The thickness of the test plates is to be the greatest thickness used for these vessels.

4.10 Specific requirements for class 2 vessels

4.10.1 General

For vessels whose scantlings have been determined using an efficiency of welded joint e greater than 0,90, see [4.9.1].

4.10.2 Non-destructive tests

All longitudinal and circumferential joints of class 2 vessels are to be subjected to radiographic or equivalent examination to an extent of 10% of each weld length. This examination is to cover all the junctions between welds.

This extension may be increased at the Society's discretion depending on the actual thickness of the welded plates.

For actual thickness ≤ 15 mm, this examination can be omitted. In this case, the value of the efficiency should be as indicated in Tab 10.

4.10.3 Number of test samples

In general, the same requirements of [4.9.3] apply also to class 2 pressure vessels. However, test plates are required for each 50 m of longitudinal and circumferential weldings (or fraction).

4.11 Specific requirements for class 3 vessels

4.11.1 For vessels whose scantlings have been determined using an efficiency of welded joint e greater than 0,90, see [4.9.1]. Heat treatment, mechanical tests and non-destructive tests are not required for welded joints of other class 3 vessels.

5 Design and construction - Control and monitoring

5.1 Boiler control and monitoring system

5.1.1 Local control and monitoring

Means to effectively operate, control and monitor the operation of oil fired boilers and their associated auxiliaries are to be provided locally. The functional condition of the fuel, feed water and steam systems and the boiler operational status are to be indicated by pressure gauges, temperature indicators, flow-meter, lights or other similar devices.

5.1.2 Emergency shut-off

Means are to be provided to shut down boiler forced draft or induced draft fans and fuel oil service pumps from outside the space where they are located, in the event that a fire in that space makes their local shut-off impossible.

5.1.3 Water level indicators

a) Each boiler is to be fitted with at least two separate means for indicating the water level. One of these means is to be a level indicator with transparent element. The other may be either an additional level indicator with transparent element or an equivalent device. Level indicators are to be of an approved type.

b) The transparent element of level indicators is to be made of glass, mica or other appropriate material.

c) Level indicators are to be located so that the water level is readily visible at all times. The lower part of the transparent element is not to be below the safety water level defined by the builder.

d) Level indicators are to be fitted either with normally closed isolating cocks, operable from a position free from any danger in case of rupture of the transparent element or with self-closing valves restricting the steam release in case of rupture of this element.

5.1.4 Water level indicators - Special requirements for water tube boilers

a) For water tube boilers having an athwarships steam drum more than 4 m in length, a level indicator is to be fitted at each end of the drum.

b) Water tube boilers serving turbine propulsion machinery are to be fitted with a high-water-level audible and visual alarm (see also Tab 20).

5.1.5 Water level indicators - Special requirements for fire tube boilers (vertical and cylindrical boilers)

a) For cylindrical boilers, the two water level indicators mentioned in [5.1.3] are to be distributed at each end of the boiler; i.e. double front cylindrical boilers are to have two level indicators on each front.

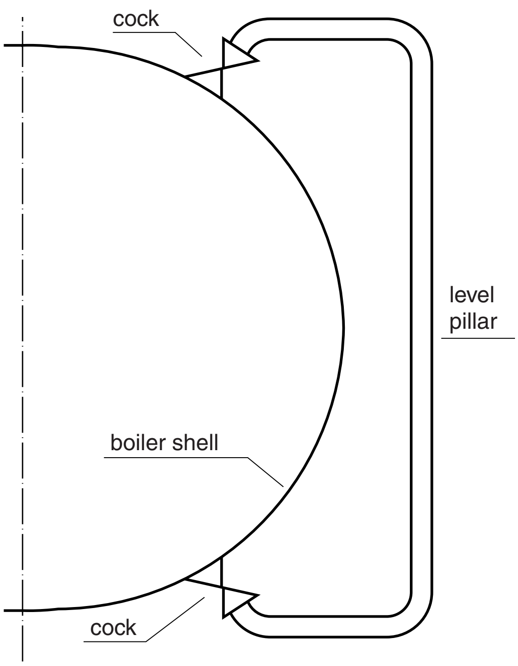
b) A system of at least two suitably located and remote controlled gauge-cocks may be considered as the equivalent device mentioned in [5.1.3] for cylindrical boilers having a design pressure lower than 1 MPa, for cylindrical boilers having a diameter lower than 2 m and for vertical boilers having height lower than 2,3 m. Gauge-cocks are to be fixed directly on the boiler shell.

c) Where level indicators are not fixed directly on the boiler shell, but on level pillars, the internal diameter of such pillars is not to be less than the value d_N given in Tab 19. Level pillars are to be either fixed directly on the boiler shell or connected to the boiler by pipes fitted with cocks secured directly to the boiler shell. The internal diameter of these pipes d_C is not to be less than the values given in Tab 19. The upper part of these pipes is to be arranged so that there is no bend where condense water can accumulate. These pipes are not to pass through smoke boxes or uptakes unless they are located inside metallic ducts having internal diameter exceeding by not less than 100 mm the external diameter of the pipes. Fig 38 shows the sketch of a level pillar arrangement.

Table 19 : Minimum internal diameters d_N and d_C

Internal diameter of the boiler	d_N (mm)	d_C (mm)
D > 3 m	60	38
2,30 m ≤ D ≤ 3 m	50	32
D < 2,30 m	45	26

Figure 38 : Level pillar arrangement



5.1.6 Pressure control devices

a) Each boiler is to be fitted with a steam pressure gauge so arranged that its indications are easily visible from the stokehold floor. A steam pressure gauge is also to be provided for superheaters which can be shut off from the boiler they serve.

b) Pressure gauges are to be graduated in units of effective pressure and are to include a prominent legible mark for the pressure that is not to be exceeded in normal service.

c) Each pressure gauge is to be fitted with an isolating cock.

d) Double front boilers are to have a steam pressure gauge arranged in each front.

5.1.7 Temperature control devices

Each boiler fitted with a superheater is to have an indicator or recorder for the steam temperature at the superheater outlet.

5.1.8 Automatic shut-off of oil fired propulsion and auxiliary boilers

a) Each burner is to be fitted with a flame scanner designed to automatically shut off the fuel supply to the burner in the event of flame failure. In the case of failure of the flame scanner, the fuel to the burner is to be shut off automatically.

b) A low water condition is to automatically shut off the fuel supply to the burners. The shut-off is to operate before the water level reaches a level so low as to affect the safety of the boiler and no longer be visible in the gauge glass. Means are to be provided to minimise the risk of shut-off provoked by the effect of roll and pitch and/or transients. This shut-off system need not be installed in auxiliary boilers which are under local supervision and are not intended for automatic operation.

c) Forced draft failure is to automatically shut off the fuel supply to the burners.

d) Loss of boiler control power is to automatically shut off the fuel supply to the burners.

5.1.9 Alarms

Any actuation of the fuel-oil shut-off listed in [5.1.8] is to operate a visual and audible alarm.

5.1.10 Additional requirements for boilers fitted with automatic control systems

a) The flame scanner required in [5.1.8], item a) is to operate within 6 seconds from the flame failure.

b) A timed boiler purge with all air registers open is to be initiated manually or automatically when boilers are fitted with an automatic ignition system. The purge time is based on a minimum of 4 air changes of the combustion chamber and furnace passes. Forced draft fans are to be operating and air registers and dampers are to be open before the purge time commences.

c) Means are to be provided to bypass the flame scanner control system temporarily during a trial-for-ignition for a period of 15 seconds from the time the fuel reaches the burners. Except for this trial-for-ignition period, no means are to be provided to bypass one or more of the burner flame scanner systems unless the boiler is locally controlled.

d) Where boilers are fitted with an automatic ignition system, and where residual fuel oil is used, means are to be provided for lighting of burners with igniters lighting properly heated residual fuel oil. In the case of flame failure, the burner is to be brought back into automatic service only in the low-firing position.

e) An alarm is to be activated whenever a burner operates outside the limit conditions stated by the manufacturer.

f) Immediately after normal shutdown, an automatic purge of the boiler equal to the volume and duration of the pre-purge is to occur. Following automatic fuel valve shut-off, the air flow to the boiler is not to automatically increase; post-purge in such cases is to be carried out under manual control.

g) Propulsion and auxiliary boilers associated with propulsion machinery intended for centralised, unattended operations are to comply with the requirements of Part C, Chapter 3.

5.2 Pressure vessel instrumentation

5.2.1

a) Pressure vessels are to be fitted with the necessary devices for checking pressure, temperature and level, where it is deemed necessary.

b) In particular, each air pressure vessel is to be fitted with a local manometer.

5.3 Thermal oil heater control and monitoring

5.3.1 Local control and monitoring

Suitable means to effectively operate, control and monitor the operation of oil fired thermal oil heaters and their associated auxiliaries are to be provided locally. The functional condition of the fuel, thermal oil circulation, forced draft and flue gas systems is to be indicated by pressure gauges, temperature indicators, flow-meter, lights or other similar devices.

5.3.2 Flow control and monitoring

a) A flow indicator of the thermal oil is to be provided.

b) The flow detection is to be representative of the flow in each heated element.

c) The flow detection is not to be based on a measurement of the pressure-drop through the heating element.

d) Oil fired or exhaust gas heaters are to be provided with a flow monitor limit-switch. If the flow rate falls below a minimum value the firing system is to be switched off and interlocked.

5.3.3 Manual control

During manual operation, the automated functioning of at least the temperature control device on the thermal oil side as well as the flow monitoring is to be maintained.

5.3.4 Leakage monitoring

Oil tanks are to be equipped with a leakage detector which, when actuated, shuts down and interlocks the thermal oil firing system. If the oil fired heater is on stand-by, the starting of the burner is to be blocked if the leakage detector is actuated.

5.4 Control and monitoring requirements

5.4.1 Tab 20, Tab 21, Tab 22 and Tab 23 summarise the control and monitoring requirements for main propulsion boilers, auxiliary boilers, oil fired thermal oil heaters and exhaust gas thermal oil heaters and incinerators, respectively.

Table 20 : Main propulsion boilers

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Boiler			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
Fuel oil							
• Fuel oil delivery pressure or flow	L						
• Fuel oil temperature after heater or viscosity fault	L+H	local					
• Master fuel oil valve position (open / close)		local					
• Fuel oil input burner valve position (open / close)		local					
Combustion							
• Flame failure of each burner	X						
• Failure of atomizing fluid	X					5	
• Boiler casing and economizer outlet smoke temperature (in order to detect possible fire out-break)	H						
	HH			X			
Air							
• Air register position		local					
General steam							
• Superheated steam pressure	L+H	local					
					X		
• Superheated steam temperature	H	local					
• Lifting of safety valve (or equivalent: high pressure alarm for instance)	X						
• Water level inside the drum of each boiler	L+H	local**(1)**					
	LL			X			
					X		
(1) Duplication of level indicator is required

6 Arrangement and installation

6.1 Foundations

6.1.1 For boilers and pressure vessels bolting down to their foundations, see Ch 1, Sec 1, [3.3.1]. Where necessary, they are also to be secured to the adjacent hull structures by suitable ties.

Where chocks are required to be fitted between the boilers and their foundations, they are to be of cast iron or steel.

6.2 Boilers

6.2.1 Thermal expansion

Means are to be provided to compensate thermal expansion of boilers.

6.2.2 Minimum distance of boilers from vertical bulkheads and fuel tanks

a) The distance between boilers and vertical bulkheads is to be not less than the minimum distance necessary to provide access for inspection and maintenance of the structure adjacent to the boiler.

b) In addition to the requirement in a), the distance of boilers from fuel oil tanks is to be such as to prevent the possibility that the temperature of the tank bulkhead may approach the flash point of the oil.

c) In any event, the distance between a boiler and a vertical bulkhead is not to be less than 450 mm.

6.2.3 Minimum distance of boilers from double bottom

a) Where double bottoms in way of boilers may be used to carry fuel oil, the distance between the top of the double bottom and the lower metal parts of the boilers is not to be less than:
- 600 mm, for cylindrical boilers
- 750 mm, for water tube boilers.

b) The minimum distance of vertical tube boilers from double bottoms not intended to carry oil may be 200 mm.

6.2.4 Minimum distance of boilers from ceilings

a) A space sufficient for adequate heat dissipation is to be provided on the top of boilers.

b) Oil tanks are not permitted to be installed in spaces above boilers.

6.2.5 Installation of boilers on engine room flats

Where boilers are installed on an engine room flat and are not separated from the remaining space by means of a watertight bulkhead, a coaming of at least 200 mm in height is to be provided on the flat. The area surrounded by the coaming may be drained into the bilge.

6.2.6 Drip trays and gutterways

Boilers are to be fitted with drip trays and gutterways in way of burners so arranged as to prevent spilling of oil into the bilge.

6.2.7 Hot surfaces

Hot surfaces with which the crew are likely to come into contact during operation are to be suitably guarded or insulated. See Ch 1, Sec 1, [3.7.1].

6.2.8 Registers fitted in the smoke stacks of oil fired boilers

Where registers are fitted in smoke stacks, they are not to obstruct more than two thirds of the cross-sectional area of gas passage when closed. In addition, they are to be provided with means for locking them in open position when the boiler is in operation and for indicating their position and degree of opening.

6.3 Pressure vessels

6.3.1 Safety devices on multiple pressure vessels

Where two or more pressure vessels are interconnected by a piping system of adequate size so that no branch of piping may be shut off, it is sufficient to provide them with one safety valve and one pressure gauge only.

6.4 Thermal oil heaters

6.4.1 In general, the requirements of [6.2] for boilers are also applicable to thermal oil heaters.

7 Material test, workshop inspection and testing, certification

7.1 Material testing

7.1.1 General

Materials, including welding consumables, for the constructions of boilers and pressure vessels are to be certified by the material manufacturer in accordance with the appropriate material specification.

7.1.2 Boilers, other steam generators, and oil fired and exhaust gas thermal oil heaters

In addition to the requirement in [7.1.1], testing of materials intended for the construction of pressure parts of boilers, other steam generators, oil fired thermal oil heaters and exhaust gas thermal oil heaters is to be witnessed by the Surveyor.

7.1.3 Class 1 pressure vessels and heat exchangers

In addition to the requirement in [7.1.1], testing of materials intended for the construction of class 1 pressure parts of pressure vessels and heat exchangers is to be witnessed by the Surveyor.

This requirement may be waived at the Society’s discretion for mass produced small pressure vessels (such as accumulators for valve controls, gas bottles, etc.).

7.2 Workshop inspections

7.2.1 Boilers and individually produced class 1 and 2 pressure vessels

The construction, fitting and testing of boilers and individually produced class 1 and 2 pressure vessels are to be attended by the Surveyor, at the builder's facility.

7.2.2 Mass produced pressure vessels

Construction of mass produced pressure vessels which are type approved by the Society need not be attended by the Surveyor.

7.3 Hydrostatic tests

7.3.1 General

Hydrostatic tests of all class 1, 2 and 3 pressure vessels are to be witnessed by the Surveyor with the exception of mass produced pressure vessels which are built under the conditions stated in [7.2.2].

7.3.2 Testing pressure

a) Upon completion, pressure parts of boilers and pressure vessels are to be subjected to a hydraulic test under a pressure p_t defined below as a function of the design pressure p:
   - $p_t = 1,5\ p$ where $p \le 4$ MPa
   - $p_t = 1,4\ p + 0,4$ where 4 MPa $< p \le 25$ Mpa
   - $P_t = p + 10,4$ where $p > 25$ MPa

b) The test pressure may be determined as a function of a pressure lower than p; however, in such case, the setting and characteristics of the safety valves and other overpressure protective devices are also to be determined and blocked as a function of this lower pressure.

c) If the design temperature exceeds 300°C, the test pressure p_t is to be as determined by the following formula:

$$p_t = 1,5 \cdot \frac{K_{100}}{K} \cdot p$$

where:

p : Design pressure, in MPa

K_{100} : Permissible stress at 100°C, in N/mm²

K : Permissible stress at the design temperature, in N/mm².

d) Consideration is to be given to the reduction of the test pressure below the values stated above where it is necessary to avoid excessive stress. In any event, the general membrane stress is not to exceed 90% of the yield stress at the test temperature.

e) Economisers which cannot be shut off from the boiler in any working condition are to be submitted to a hydraulic test under the same conditions as the boilers.

f) Economisers which can be shut off from the boiler are to be submitted to a hydraulic test at a pressure determined as a function of their actual design pressure p.

7.3.3 Hydraulic test of boiler and pressure vessel accessories

a) Boilers and pressure vessel accessories are to be tested at a pressure p_t which is not less than 1,5 times the design pressure p of the vessels to which they are attached.

b) The test pressure may be determined as a function of a pressure lower than p; however, in such case, the setting and characteristics of the safety valves and other overpressure protective devices are also to be determined and blocked as a function of this lower pressure.

7.3.4 Hydraulic test procedure

a) The hydraulic test specified in [7.3.1] is to be carried out after all openings have been cut out and after execution of all welding work and of the heat treatment, if any. The vessel to be tested is to be presented without lagging, paint or any other lining and the pressure is to be maintained long enough for the Surveyor to proceed with a complete examination.

b) Hydraulic tests of boilers are to be carried out either after installation on board, or at the manufacturer's plant. Where a boiler is hydrotested before installation on board, the Surveyor may, if deemed necessary, request to proceed with a second hydraulic test on board under a pressure at least equal to 1,1 p. For this test, the boiler may be fitted with its lagging. However, the Surveyor may require this lagging to be partially or entirely removed as necessary.

c) For water tube boilers, the hydraulic test may also be carried out separately for different parts of the boiler upon their completion and after heat treatment. For drums and headers, this test may be carried out before drilling the tube holes, but after welding of all appendices and heat treatment. When all parts of the boiler have been separately tested and following assembly the boiler is to undergo a hydraulic test under a pressure of 1,25 p.

7.3.5 Hydraulic tests of condensers

Condensers are to be subjected to a hydrostatic test at the following test pressures:

- Steam space: 0,1 MPa
- Water space: maximum pressure which may be developed by the pump with closed discharge valve increased by 0,07 MPa. However, the test pressure is not to be less than 0,2 MPa. When the characteristics of the pump are not known, the hydrostatic test is to be carried out at a pressure not less than 0,35 MPa.

7.4 Certification

7.4.1 Certification of boilers and individually produced pressure vessels

Boilers and individually produced pressure vessels of classes 1, 2 and 3 are to be certified by the Society in accordance with the procedures stated in Part A.

7.4.2 Mass produced pressure vessels

Small mass produced pressure vessels of classes 1, 2 and 3 may be accepted provided they are type approved by the Society in accordance with the procedures stated in Part A.

Table 24 : Pressure vessel certification

Class	Drawing / Calculation		Material testing		Hydraulic test	
	Manufacturer	The Society	Manufacturer	The Society	Manufacturer	The Society
1	X	review	X	witness + workshop inspection	X	witness
2	X	review	X	review	X	witness
3	X	–	X	review	X	witness

Note 1:
Certificates of the Manufacturer and the Society to be issued for all cases for pressure vessels covered by the Rules of the Society.

Section 4 Steam Turbines

1 General

1.1 Application

1.1.1 Propulsion turbines and turbines for essential services

The requirements of this Section apply to:

a) all propulsion turbines

b) turbines intended for auxiliary services essential for safety and navigation.

1.1.2 Auxiliary turbines driving generators

In addition to the requirements contained in this Section, auxiliary turbines driving electric generators are to comply with those of Part C, Chapter 2.

1.2 Documentation to be submitted

1.2.1 For propulsion turbines and turbines intended for driving machinery for essential services, the plans and data listed in Tab 1 are to be submitted.

All listed plans are to be constructional plans complete with all dimensions and are to contain full indication of the types of materials employed.

Table 1 : Documents to be submitted

No	A/I **(1)**	ITEM
1	I	Sectional assembly
2	A	Rotors and discs, revolving and stationary blades for each turbine
3	A	Fastening details of revolving and stationary blades
4	A	Casings
5	A	Schematic diagram of control and safety devices
6	I	General specification of the turbine, including an operation and instruction manual
7	I	Maximum power and corresponding maximum rotational speed, and the values of pressure and temperature at each stage
8	A	Material specifications of the major parts, including their physical, chemical and mechanical properties, the data relevant to rupture and creep at elevated temperatures, when the service temperature exceeds 400°C, the fatigue strength, the corrosion resistance and the heat treatments
9	I	Distribution box
10	A	Strength calculations of rotors, discs and blades and blade vibration calculations
11	A	Where the rotors, stators or other components of turbines are of welded construction, all particulars on the design of welded joints, welding conditions, heat treatments and non-destructive examinations after welding

(1) A = to be submitted for approval
I = to be submitted for information.

2 Design and construction

2.1 Materials

2.1.1 Rotating components

a) Rotors, shafts and discs of turbines are to be of forged steel. In general, the forgings are to have minimum tensile strength R_m within the limits in Tab 2.

b) Rotors of small turbines may be built of special cast steels.

c) Turbine blades are to be built of corrosion-resistant materials.

Table 2 : Limits of R_m

STEEL	R_m limits (N/mm^2)
Carbon and carbon-manganese steel	$400 < R_m < 600$
Alloy steels for rotors	$500 < R_m < 800$
Alloy steels for discs and other forgings	$500 < R_m < 1000$

2.1.2 Static components

The casings and diaphragms of turbines are to be built of forged or cast steels capable of withstanding the pressures and temperatures to which they are subjected. Cast iron may be used for temperatures up to 300°C.

2.2 Design and constructional details

2.2.1 Rotors and stators

a) All components of turbines are to be free from defects and are to be built and installed with tolerances and clearances such as to allow thermal expansion and to minimise the distortions of casings and rotors in all expected service conditions.

b) Particular care is to be devoted to preventing condensation water from accumulating in the blade spaces of the casings. Adequate drain tubes and cocks are to be arranged in a suitable position, in the lower parts of the casings. Cocks are to be easy to operate.

c) When labyrinth packings are used, the steam supply pipes to the sealing system are to be so arranged that condensed steam may not enter the turbine.

d) Particular attention is to be paid to the connection of pipes to the turbine stators in order to avoid abnormal loads in service.

e) Smooth fillets are to be provided at changes of section of rotors, discs and blade roots. The holes in discs are to be well rounded and polished.

2.2.2 Bearings

a) Turbine bearings are to be so located that their lubrication is not impaired by overheating from adjacent hot parts.

b) Lubricating oil is to be prevented from dripping on high temperature parts.

c) Suitable arrangements for cooling the bearings after the turbines have been stopped may also be required, at the discretion of the Society.

2.2.3 Turning gear

a) Main propulsion turbines are to be equipped with turning gear for both directions of rotation. The rotors of auxiliary turbines are to be capable of being turned by hand.

b) The engagement of turning gear is to be visually indicated at the control platform.

c) An interlock is to be provided to ensure that the turbine cannot be started up when the turning gear is engaged.

2.2.4 Astern power for main propulsion

a) The main propulsion turbine is to have sufficient power for running astern. The astern power is considered to be sufficient if it is able to attain astern revolutions equivalent to at least 70% of the rated ahead revolutions for a period of at least 30 minutes.

b) For main propulsion machinery with reverse gearing, controllable pitch propellers or an electrical transmission system, astern running is not to cause any overloading of the propulsion machinery.

c) During astern running, the main condenser and the ahead turbines are not to be excessively overheated.

2.2.5 Interlock

The simultaneous admission of steam to the ahead and astern turbines is to be prevented by interlocks. Brief overlapping of the ahead and astern valves during manoeuvring may be permitted.

2.2.6 Turbine exhaust

a) Sentinel valves or other equivalent means are to be provided at the exhaust end of all turbines. The valve discharge outlets are to be clearly visible and suitably guarded, as necessary.

b) Where, in auxiliary steam turbines, the inlet steam pressure exceeds the pressure for which the exhaust casing and associated piping up to the exhaust valve are designed, means to relieve the excess pressure are to be provided.

2.2.7 Water accumulation prevention

a) Non-return valves or other approved means are to be fitted in bled steam connections to prevent steam and water returning into the turbines.

b) Bends are to be avoided in steam piping in which water may accumulate.

2.2.8 Steam strainers

Efficient steam strainers are to be provided close to the inlets to ahead and astern high pressure turbines or alternatively at the inlets to manoeuvring valves.

2.2.9 Emergency arrangements

a) In single screw ships fitted with compound main turbine installations the arrangements are to be such as to enable safe navigation when the steam led to any one of the turbines is cut off. For this purpose the steam may be led direct to the low pressure (L.P.) turbine and either the high pressure (H.P.) or medium pressure (M.P.) turbine can exhaust direct to the condenser.

b) Adequate arrangements and controls are to be provided for these emergency conditions so that the pressure and temperature of the steam do not exceed those which the turbine and condenser can safely withstand.

c) Ships classed for unrestricted service and fitted with a steam turbine propulsion plant and only one main boiler are to be provided with means to ensure emergency propulsion in the event of failure of the main boiler.

2.3 Welded fabrication

2.3.1 The manufacturer's requirements relative to the welding of turbine rotors or major forged or cast pieces, where permitted, are to be readily identifiable when the plans are submitted to the Society for approval. Requirements relative to fabrication, welding, heat treatments, examinations, testing and acceptance will be stipulated on a case by case basis.

In general, all weldings are to be carried out by qualified welders in accordance with qualified welding procedures and using approved consumables.

2.4 Control, monitoring and shut-off devices

2.4.1 Governors

a) Turbines for main propulsion machinery equipped with controllable pitch propellers, disengaging couplings or electrical transmission systems are to be fitted with a speed governor which, in the event of a sudden loss of load, prevents the revolutions from increasing to the trip speed given in [2.4.2].

b) The speed increase of turbines driving electric generators - except those for electrical propeller drive - resulting from a change from full load to no-load may not exceed 5% on the resumption of steady running conditions. The transient speed increase resulting from a sudden change from full load to no-load conditions is not to exceed 10% and is to be separated by a sufficient margin from the trip speed.

2.4.2 Overspeed devices

a) Each main and auxiliary turbine is to be provided with an overspeed protective device to prevent the rotational speed from exceeding the maximum rotational by more than 15%. The device is to be actuated by the turbine shaft.

b) Where two or more steam turbines are coupled to the same gear wheel, the Society may accept the fitting of only one overspeed device for all the coupled turbines.

c) For turbines driving electric generators, the overspeed protective device mentioned in a) is also to be fitted with a means for manual tripping.

d) Where exhaust steam from auxiliary systems is led to the main turbine, provision is to be made to cut off the steam automatically when the overspeed protective device is activated.

2.4.3 Rotor axial displacement

A quick-closing valve is to be provided which automatically shuts off the steam supply in the event of axial displacement of the rotor beyond the permissible limits stated by the manufacturer. The device controlling the valve is to be actuated by the turbine shaft.

2.4.4 Bearing lubrication failure

a) Main ahead turbines are to be provided with a quick-closing valve which automatically shuts off the steam supply in the event of a dangerous reduction in oil pressure in the bearing lubricating system.

b) This arrangement is to be such as to ensure the admission of steam to the astern turbine for braking purposes.

2.4.5 Shut-off arrangement

a) Arrangements are to be provided for shutting off the steam to the main turbines by a suitable hand trip device controlling the steam admission valve situated at the control platform and at the turbine itself.

b) Hand tripping for auxiliary turbines is to be arranged in the proximity of the turbine overspeed protective device.

c) The hand trip device is any device which is operated manually irrespective of the way the action is performed, i.e. mechanically or by means of external power.

d) The quick-closing valves are also to be manually operable at the turbine and from the control platform.

e) Re-setting of the quick-closing valve device may be effected only at the turbine or from the control platform with the control valves in the closed position.

f) Where the valves are operated by hydraulic oil systems fitted for automatic operation, they are to be fed by two pumps: one main pump and one standby pump. In any event, the standby pump is to be independent. In special cases, at the Society's discretion, a hand-operated pump may be accepted as a standby pump.

g) The starting up of any turbine is to be possible only when the quick-closing devices are ready for operation.

h) A quick-closing device is to be provided which automatically shuts off the steam supply in the event of an increase in pressure or water level in the condenser beyond the permissible limits.

2.4.6 Summary Tables

Tab 3 and Tab 4 summarise the minimum control and monitoring requirements for main propulsion and auxiliary turbines, respectively.

Table 3 : Main propulsion turbine

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Turbine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
• Main turbine speed		local

Lubricating oil supply pressure	L			X			
Lubricating oil level in gravity tank	L						

3 Arrangement and installation

3.1 Foundations

3.1.1 Foundations of turbines and connected reduction gears are to be designed and built so that hull movements do not give rise to significant movements between reduction gears and turbines. In any event, such movements are to be absorbed by suitable couplings.

3.2 Jointing of mating surfaces

3.2.1 The mating flanges of casings are to form a tight joint without the use of any interposed material.

3.3 Piping installation

3.3.1 Pipes and mains connected to turbine casings are to be fitted in such a way as to minimise the thrust loads and moments.

3.4 Hot surfaces

3.4.1 Hot surfaces with which the crew are likely to come into contact during operation are to be suitably guarded or insulated. See Ch 1, Sec 1, [3.7].

3.5 Alignment

3.5.1 Particular care is to be taken in the alignment of turbine-reduction gearing, taking account of all causes which may alter the alignment from cold conditions to normal service conditions.

When a structural tank is fitted in way of the turbine or gearing foundations, the expected tank temperature variations are to be taken into account during alignment operations.

Propulsion turbines are to be fitted with indicators showing the axial movements of rotors with respect to casings and the sliding movements of casings on the sliding feet.

3.6 Circulating water system

3.6.1 The circulating water system with vacuum ejectors is to be so arranged that water may not enter the low pressure turbines.

3.7 Gratings

3.7.1 Gratings and any other structures in way of the sliding feet or flexible supports are to be so arranged that turbine casing expansion is not restricted.

3.8 Drains

3.8.1 Turbines and the associated piping systems are to be equipped with adequate means of drainage.

3.9 Instruments

3.9.1 Main and auxiliary turbines are to be fitted with callipers and micrometers of a suitable type for verifying the alignment of rotors and pinion and gear-wheel shafts.

This check is to be performed to the Surveyor’s satisfaction at the time of installation.

4 Material tests, workshop inspection and testing, certification

4.1 Material tests

4.1.1 Parts to be tested

The materials for the construction of the parts listed in Tab 5 are to be tested in compliance with the requirements of NR216 Materials and Welding.

Magnetic particle or liquid penetrant tests are required for the parts listed in Tab 5 and are to be effected in positions mutually agreed upon by the manufacturer and the Surveyor, where experience shows defects are most likely to occur.

For important structural parts of the turbine, in addition to the above-mentioned non-destructive tests, examination of welded seams by approved methods of inspection may be required.

Where there is evidence to doubt the soundness of any turbine component, non-destructive tests using approved detecting methods may be required.

Table 5 : Material and non-destructive tests

Turbine component	Material tests (mechanical properties and chemical composition)	Non-destructive tests	
		Magnetic particle or liquid penetrant	Ultrasonic or X Ray examination
Rotating parts (turbine rotors, shafts, stiff and flexible couplings, bolts for couplings and other dynamically stressed parts, integral pinions and gears)	all	all	sample
Stationary parts (castings and plates for casings)	all	spot as agreed between the Manufacturer and the Surveyor	–
Blades	sample	sample	sample
Piping and associated fittings	as required in the appropriate section of the Rules	as required in the appropriate section of the Rules	as required in the appropriate section of the Rules

4.1.2 Special auxiliary turbines

In the case of auxiliary turbines with a steam inlet temperature of up to 250°C, the extent of the tests stated in Tab 5 may be limited to the disc and shaft materials.

4.2 Inspections and testing during construction

4.2.1 Inspections during construction

The following inspections and tests are to be carried out in the presence of the Surveyor during the construction of all turbines which are indicated in [1.1.1].

- material tests, as required (see [4.1])
- welded fabrication (see [4.2.2])
- non-destructive examination of turbine blades (see [4.2.3])
- hydrostatic tests (see [4.2.4])
- safety valves (see [4.2.5])
- thermal stability test of rotor (see [4.2.6])
- rotor balancing and overspeed test (see [4.2.7] and [4.2.8])
- shop trials (see [4.2.9]).

4.2.2 Welded fabrication

Welded fabrication and testing is to be attended by the Surveyor, as may be deemed necessary by the Society.

4.2.3 Turbine blades

When turbine blades are calculated using a permissible stress $K > R_m/4$, all turbine rotor blades are to be checked by dye penetrants or other equivalent method.

4.2.4 Hydrostatic tests

a) Turbine and nozzle casings are to be subjected to a hydrostatic test at the greater of the following test pressures:

b) 1,5 times the working pressure

c) 1,5 times the starting pressure

d) However, the test pressure is not to be less than 0,2 N/mm^2.

e) The turbine casings may be temporarily subdivided by diaphragms in order to obtain different pressure values for the various stages, if necessary.

f) Where it is not possible to perform hydrostatic tests, the manufacturer may submit to the Society, for consideration, alternative proposals for testing the integrity of turbine casings and the absence of defects therein.

g) For the bodies of quick-closing, safety, manoeuvring and control valves, the test pressure is to be 1,5 times the maximum allowable working pressure of the boiler (approval pressure). The sealing efficiency of these valves when closed is to be tested at 1,1 times the working pressure.

h) Intermediate coolers and heat exchangers are to be subjected to a hydrostatic test at 1,5 times the working pressure.

i) Pressure piping, valves and other fittings are to be subjected to hydrostatic tests in compliance with the normal requirements for these items.

4.2.5 Safety valves

All valves required in [2.4] are to be tested at their setting pressure in the presence of the Surveyor, as specified by the turbine manufacturer.

4.2.6 Thermal stability test of rotors

Solid forged and welded rotors of propulsion turbines are to be subjected to a thermal stability test where the service temperature exceeds 400°C. This test is to be carried out after heat treatment and rough machining or at a later stage of fabrication, in accordance with a procedure approved by the Society.

4.2.7 Balancing of rotors

Finished rotors, complete with all fittings and blades, are to be dynamically balanced in a balancing machine of appropriate sensitivity in relation to the size of the rotor. Normally this test is to be carried out with the primary part of the flexible coupling, if any.

4.2.8 Overspeed test of rotors

Finished rotors, complete with all fittings and blades, are to be subjected for at least 3 minutes to an overspeed test at the greater of the following values:

- 5% above the setting speed of the overspeed tripping device
- 15% above the maximum design speed.

The Society may waive this requirement provided that it can be demonstrated by the manufacturer, using an acceptable direct calculation procedure, that the rotor is able to safely withstand the above values of overspeed and that rotors are free from defects, as verified by means of non-destructive tests.

4.2.9 Shop trials

Where turbines are subjected to a trial run at the factory, the satisfactory functioning of the control, safety and monitoring equipment is to be verified during the trial run. Such verification is in any event to take place not later than the commissioning of the plant aboard ship.

In general, propulsion steam turbines are to be subjected to a works trial under steam but without load, up to the service rotational speed, as far as possible. In the course of the works trials, the overspeed devices for both main and auxiliary turbines are to be set.

4.3 Certification

4.3.1 Turbines required to be certified

For turbines required to be certified as per [1.1.1], Society's certificates (C) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.1]) are required for material tests of rotating components and blades listed in Tab 4 and for works trials as per [4.2.1]. Provided the manufacturer has a quality assurance system accepted by the Society, a reduced number of inspections and tests in the presence of the Surveyor may be agreed.

4.3.2 Turbines not required to be certified

For turbines not required to be certified as per [1.1.1], manufacturer's certificates including details of tests and inspections carried out at the shop are to be submitted. The acceptance of these turbines is, however, subject to their satisfactory performance during dock and sea trials.

4.3.3 Type approved turbines

For mass produced turbines which are requested to be type approved by the Society, the tests and trials on a prototype are to be carried out in the presence of the Surveyor as stated in [4.3.1]. The minimum required attendance of the Surveyor at the production tests and trials will be agreed between the manufacturer and the Society on a case by case basis.

Section 5 Gas Turbines

1 General

1.1 Application

1.1.1 Propulsion turbines and turbines for essential services

The requirements of this Section apply to:

a) all propulsion turbines

b) turbines intended for auxiliary services essential for safety and navigation.

1.1.2 Turbines for auxiliary generators

In addition to the requirements contained in this Section, auxiliary turbines driving electric generators are to comply with the applicable requirements of Part C, Chapter 2 of the Rules.

1.1.3 Type approval

Turbines intended for propulsion and essential services are to be type approved by the Society. Other procedures agreed with the Owner will be considered on a case by case basis.

1.2 Definition of rated power

1.2.1 For the definition of rated power, refer to ISO 2314 standard.

Table 1 : Documents to be submitted

No	A/I **(1)**	ITEM
1	I	Sectional assembly
2	A	Detailed drawings of rotors, casings, blades, combustion chambers and heat exchangers **(2)**
3	A	Material specifications of the major parts, including their physical, chemical and mechanical properties, the data relevant to rupture and creep at elevated temperatures, the fatigue strength, the corrosion resistance and the heat treatments **(2)**
4	A	Where the rotors, stators or other components of turbines are of welded construction, all particulars on the design of welded joints, welding procedures and sequences, heat treatments and non-destructive examinations after welding **(2)**
5	I	General specification of the turbine, including instruction manual, description of structures and specification of the properties of fuel and lubricating oil to be used
6	I	Details of operating conditions, including the pressure and temperature curves in the turbine and compressor at the rated power and corresponding rotational speeds, and details of permissible temporary operation beyond the values for the rated power
7	A	Diagrammatic layout of the fuel system, including control and safety devices, and of the lubricating oil system
8	A	Cooling system layout, if applicable
9	I	Where applicable, background information on previous operating experience in similar applications
10	I	Maintenance and overhaul procedures
11	A	Stress and temperature analysis in blades, rotors and combustion chamber **(2)**
12	A	Life time calculation of hot and high stress parts **(2)**
13	A	Blade and rotor vibration analysis **(2)**
14	A	Details of automatic safety devices together with failure mode and effect analysis (FMEA) **(2)**

(1) A = to be submitted for approval
I = to be submitted for information.

(2) As an alternative, the Society may, on a case by case basis, consider reviewing a number of selected packages relative to important and critical parts of the turbine, where all the design, construction, inspection, testing and acceptance criteria used by the manufacturer are clearly described, provided the Quality Assurance system of the manufacturer is approved and certified by the Society.

1.3 Documentation to be submitted

1.3.1 For propulsion turbines and turbines intended for driving machinery for essential services, the plans listed in Tab 1 are to be submitted.

The listed constructional plans are to be complete with all dimensions and are to contain full indication of the types of materials used.

2 Design and construction

2.1 General

2.1.1 Operating conditions

Attention is to be paid to the specific operating conditions of the turbine (e.g. continuous operation at low load) which may be imposed by the ship specification.

2.1.2 Availability of propulsion turbines

In accordance with Ch 1, Sec 1, [2.1.2], propulsion turbines are to remain operational as required to fulfil the machinery availability requirements stated in Part D for the service notation of the ship and with the requirements of Part E, Chapter 3 when the ship is to be assigned an **AVM** additional class notation. Where propulsion turbines are to remain operational in flooding conditions, the turbines' enclosures may be used for this purpose.

2.2 Materials

2.2.1 Approved materials

a) Gas turbine materials are to fulfil the requirements imposed by the operating conditions of the individual components. In the choice of materials, account is to be taken of effects such as creep, thermal fatigue, oxidation and corrosion to which individual components are subject when in service. Evidence of the suitability of the materials is to be supplied to the Society in the form of details of their chemical and mechanical properties and of the heat treatment applied. Where composite materials are used, their method of manufacture is to be described.

b) Turbine blades are to be built of corrosion and heat-resistant materials.

2.3 Stress analyses

2.3.1 Calculation

a) The manufacturer is to submit the results of calculation of the stresses on each rotor under the most severe service conditions.

b) Fatigue analysis on each rotor, taking into account the stress concentrations, is also to be submitted.

c) The results of previous in-service experience on similar applications may be considered by the Society as an alternative to items a) and b) above.

The calculations and analyses (see also [1.3.1]) are to be carried out in accordance with criteria agreed by the Society. Data on the design service life and test results used to substantiate calculation assumptions are also to be provided.

2.3.2 Vibrations

The range of service speeds is not to give rise to unacceptable bending vibrations or to vibrations affecting the entire installation. Calculations of the critical speeds including details of their basic assumptions are to be submitted.

2.4 Design and constructional details

2.4.1 Rotors and stators

a) All components of turbines and compressors are to be free from defects and are to be built and installed with tolerances and clearances in order to allow thermal expansion and to minimise the distortions of casings and rotors in all expected service conditions.

b) Adequate drain tubes and cocks are to be arranged in a suitable position, in the lower parts of the casings. Cocks are to be easily operated.

c) Suitable protective devices are to be provided in order to prevent heat, noise or possible failure of rotating parts from causing injury to personnel. If, to this end, the whole gas turbine is enclosed in a protective covering, the covering is to be adequately ventilated inside.

d) Particular attention is to be paid to the connection in the casings of pipes to the turbine stators in order to avoid abnormal loads in service.

e) Smooth fillets are to be provided at changes of sections of rotors, discs and blade roots. The holes in discs are to be well rounded and polished.

2.4.2 Access and inspection openings

a) Access to the combustion chambers is to be ensured. Means are to be provided to inspect the burner cans or combustion chamber without having to remove the gas generator.

b) Inspection openings are to be provided to allow the gas turbine flow path air to be inspected with special equipment, e.g. a bore-scope or similar, without the need for dismantling.

2.4.3 Bearings

a) Turbine bearings are to be so located that their lubrication is not impaired by overheating from hot gases or adjacent hot parts.

b) Lubricating oil or fuel oil is to be prevented from dripping on high temperature parts.

c) Suitable arrangements for cooling the bearings after the turbines have been stopped are to be provided, if necessary to prevent bearing cooking.

d) Roller bearings are to be identifiable and are to have a life adequate for their intended purpose. In any event, their life cannot be less than 40000 hours.

2.4.4 Turning gear

a) Main propulsion turbines are to be equipped with turning gear or a starter for cranking. The rotors of auxiliary turbines are to be capable of being turned by hand.

b) The engagement of the turning gear or starter is to be visually indicated at the control platform.

c) An interlock is to be provided to ensure that the main turbine cannot be started up when the turning gear is engaged.

2.4.5 Cooling

The turbines and their external exhaust system are to be suitably insulated or cooled to avoid excessive outside temperature.

2.4.6 Air supply

a) The air intake ducting is to be equipped to prevent extraneous substances from entering the compressor and turbine.

b) Measures are to be taken to control the salinity of the combustion air, to meet the manufacturer's specification.

c) Cleaning equipment is to be provided to remove deposits from compressors and turbines.

d) Means are to be provided to prevent the formation of ice in the air intake.

2.4.7 Turbine exhaust arrangement

a) The gas exhaust arrangement is to be designed in such a way as to prevent the entrance of gases into the compressor.

b) Silencers or other equivalent arrangements are to be provided in the gas exhaust, to limit the airborne noise at one metre distance from the turbine to not more than 110 dB (A) in unmanned machinery spaces and not more than 90 dB (A) in manned spaces.

2.4.8 Multi-turbine installations

Multi-turbine installations are to have separate air inlets and exhaust systems to prevent recirculation through the idle turbine.

2.4.9 Fuel

a) Where the turbine is designed to burn non-distillate fuels, a fuel treatment system is to be provided to remove, as far as practicable, the corrosive constituents of the fuel or to inhibit their action in accordance with the manufacturer's specification.

b) Suitable means are to be provided to remove the deposits resulting from the burning of the fuel while avoiding abrasive or corrosive action, if applicable.

2.4.10 Start-up equipment

a) Gas turbines are to be fitted with start-up equipment enabling them to be started up from the "shutdown" condition.

b) Provisions are to be made so that any dangerous accumulation of liquid or gaseous fuel inside the turbines is thoroughly removed before any attempt at starting or restarting.

c) Starting devices are to be so arranged that firing operation is discontinued and the main fuel valve is closed within a pre-determined time when ignition is failed.

d) The minimum number of starts is to be such as to satisfy the requirements of Ch 1, Sec 2, [3.1].

e) The arrangement is to be such as to grant redundancy of sources of energy for turbine starting.

2.4.11 Astern power

For main propulsion machinery with reverse gearing, controllable pitch propellers or an electrical transmission system, astern running maximum power is to be such as not to cause any overloading of the propulsion machinery.

2.4.12 Emergency operation

a) In installations with more than one propeller and connected shafting and more than one turbine, the failure of any gas turbine unit connected to a shafting line is not to affect the continued, independent operation of the remaining units.

b) In installations with only one propeller and connected shafting, driven by two or more main turbines, care is to be taken to ensure that, in the event of one of the turbines failing, the others are able to continue operation independently.

c) Ships classed for unrestricted service and fitted with only one propeller and connected shafting driven by a gas turbine are to be provided with means to ensure emergency propulsion in the event of failure of the main turbine.

2.5 Welded fabrication

2.5.1 The manufacturer's requirements relative to the welding of turbine rotors or major forged or cast pieces, where permitted, are to be readily identifiable by the Society in the plans submitted for approval.

In general, all weldings are to be carried out by qualified welders in accordance with qualified welding procedures using approved consumables.

2.6 Control, monitoring and shut-off devices

2.6.1 Control and monitoring arrangement

For each main propulsion system, the associated control and monitoring equipment is to be grouped together at each location from which the turbine may be controlled.

2.6.2 Governors and speed control system

a) Propulsion turbines which may be operated in no-load conditions are to be fitted with a control system capable of limiting the speed to a value not exceeding 10% of the maximum continuous speed or another figure proposed by the manufacturer.

b) Turbines for main propulsion machinery equipped with controllable pitch propellers, disengaging couplings or an electrical transmission system are to be fitted with a speed governor which, in the event of a sudden loss of load, prevents the revolutions from increasing to the trip speed.

c) In addition to the speed governor, turbines are to be fitted with a separate overspeed protective device, with a means for manual tripping, adjusted so as to prevent the rated speed from being exceeded by more than 15%.

d) The speed increase of turbines driving electric generators -except those for electrical propeller drive- resulting from a change from full load to no-load is not to exceed 5% on the resumption of steady running conditions. The transient speed increase resulting from a sudden change from full load to no-load conditions is not to exceed 10% and is to be separated by a sufficient margin from the trip speed. Alternative requirements may be considered by the Society on a case by case basis based on the actual turbine design and arrangement.

2.6.3 Monitoring system

The main operating parameters (pressure, temperature, rpm, etc.) are to be adequately monitored and displayed at the control console.

2.6.4 Emergency shut-off

a) An emergency push-button shut-off device is to be provided at the control console.

b) Any shut-off device provided in pursuance of the above is to shut off the fuel supply as near the burners as possible.

2.6.5 Quick-closing devices

a) Gas turbines are to be equipped with a quick closing device (shut-down device) which automatically shuts off the fuel supply to the turbines at least where required by Tab 2, unless the FMEA proves otherwise.

b) Re-setting of the quick-closing device may be effected only at the turbine or from the control platform with the fuel supply control valve in the closed position.

c) When the devices are operated by hydraulic oil systems fitted for automatic operation, they are to be fed by two pumps: one main pump and one standby pump. In any event, the standby pump is to be independent. In special cases, a hand-operated pump may be accepted as a standby pump.

d) The starting up of any turbine is to be possible only when the quick-closing devices are ready for operation.

2.6.6 Automatic temperature controls

The following turbine services are to be fitted with automatic temperature controls so as to maintain steady state conditions within the normal operating range of the main gas turbine:

a) lubricating oil supply and discharge

b) fuel oil supply (or, alternatively, automatic control of fuel oil viscosity)

c) exhaust gas in specific locations of the flow gas path as determined by the manufacturer.

2.6.7 Indicators, alarm and shutdown

Tab 2 indicates the minimum control, monitoring and shutdown requirements for main propulsion and auxiliary turbines. Alarms can be added or omitted, taking into account the result of FMEA.

Table 2 : Main propulsion and auxiliary turbines

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Turbine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by Start	Stop
• Control system failure	X						
• Automatic starting failure	X						
Mechanical monitoring of gas turbine							
• Speed		local					
					X		
	H			X			
• Rotor axial displacement (not applicable to roller bearing)		local					
	H			X			
• Vibration	H **(1)**	local					
• Performed number of cycle of rotating part	H						
Gas generator monitoring							
• Flame and ignition failure	X			X			
• Fuel oil supply pressure	L	local					
• Fuel oil supply temperature	H	local					
• Cooling medium temperature	H	local					
• Exhaust gas temperature or gas temperature in specific locations of flow gas path		local					
	H **(1)**			X			
• Pressure at compressor inlet		local					
	L **(1)**			X			
Lubricating oil							
• Turbine supply pressure		local					
	L **(1)**			X			
• Reduction gear supply pressure		local					
	L **(1)**			X			
• Differential pressure across lubricating oil filter	H	local					
• Bearing or lubricating oil (discharge) temperature	H	local					

(1) Alarm to be activated at the suitable setting points prior to arriving the critical condition for the activation of shutdown devices.

3 Arrangement and installation

3.1 Foundations

3.1.1 Foundations of turbines and connected reduction gears are to be designed and built so that hull movements do not give rise to significant movements between reduction gears and turbines. In any event, such movements are to be absorbed by suitable couplings.

3.2 Joints of mating surfaces

3.2.1 The mating flanges of casings are to form a tight joint without the use of any interposed material.

3.3 Piping installation

3.3.1 Pipes and mains connected to turbine and compressor casings are to be fitted in such a way as to minimise the thrust loads and moments. If flexible hoses are used for this purpose, they are to comply with the requirements in Ch 1, Sec 10, [2.6].

3.4 Hot surfaces

3.4.1 Hot surfaces with which the crew are likely to come into contact during operation are to be suitably guarded or insulated. See Ch 1, Sec 1, [3.7].

3.5 Alignment

3.5.1

a) Particular care is to be taken in the alignment of turbine-reduction gearing, taking account of all causes which may alter the alignment from cold conditions to normal service conditions.

b) When a structural tank is fitted in way of the turbine or gearing foundations, the expected tank temperature variations are to be taken into account during alignment operations.

c) Propulsion turbines are to be fitted with indicators showing the axial movements of rotors with respect to casings and the sliding movements of casings on the sliding feet. Such indicators are to be fitted in an easily visible position. This requirement does not apply to turbines fitted with roller bearings.

3.6 Gratings

3.6.1 Gratings and any other structures in way of the sliding feet or flexible supports are to be so arranged that turbine casing expansion is not restricted.

3.7 Drains

3.7.1 Turbines and the associated piping systems are to be equipped with adequate means of drainage.

3.8 Instruments

3.8.1 Main and auxiliary turbines are to be fitted with callipers and micrometers of a suitable type for verifying the alignment of rotors and pinion and gear-wheel shafts, when necessary.

At the time of installation on board, this check is to be performed in the presence and to the satisfaction of the Surveyor.

4 Material tests, workshop inspection and testing, certification

4.1 Type tests - General

4.1.1 Every new turbine type intended for installation on board ships is to undergo a type test whose program will be agreed on a case by case basis with the Society and the Owner.

4.2 Material tests

4.2.1 The materials for the construction of the parts listed in Tab 3 are to be tested in compliance with the requirements of NR216 Materials and Welding.

Magnetic particle or liquid penetrant tests are required for the parts listed in Tab 3 and are to be effected in positions mutually agreed upon by the manufacturer and the Surveyor, where experience shows defects are most likely to occur.

For important structural parts of the turbine, in addition to the above-mentioned non-destructive tests, examination of welded seams by approved methods of inspection may be required.

Where there is evidence to doubt the soundness of any turbine component, non-destructive tests using approved detecting methods may be required.

4.3 Inspections and testing during construction

4.3.1 Inspections during construction

The following inspections and tests are to be carried out in the presence of a Surveyor during the construction of all turbines which are indicated in [1.1.1]. For on-board trials see Ch 1, Sec 16, [3.4].

- Material tests as required (see [4.2])
- Welding fabrication (see [4.3.2])
- Hydrostatic tests (see [4.3.3])
- Rotor balancing and overspeed test (see [4.3.4], [4.3.5])
- Shop trials (see [4.3.6]).

Table 3 : Material and non-destructive tests

Turbine component	Material tests (mechanical properties and chemical composition)	Non-destructive tests	
		Magnetic particle or liquid penetrant	Ultrasonic or X Ray examination
Rotating parts (compressors and turbine rotors, shafts, stiff and flexible couplings, bolts for couplings and other dynamically stressed parts, integral pinions and gears)	all	all	all
Stationary parts (castings for casings intended for a temperature exceeding 230°C and plates for casings intended for a temperature exceeding 370°C or pressure exceeding 4 Mpa)	all	spot as agreed between the Manufacturer and the Surveyor	–
Blades	sample	sample	sample
Piping and associated fittings	as required in the appropriate section of the Rules	as required in the appropriate section of the Rules	as required in the appropriate section of the Rules

4.3.2 Welding fabrication

Welding fabrication and testing is to be attended by the Surveyor, as may be deemed necessary by the Society.

4.3.3 Hydrostatic tests

Finished casing parts and heat exchangers are to be subjected to hydrostatic testing at 1,5 times the maximum permissible working pressure. If it is demonstrated by other means that the strength of casing parts is sufficient, a tightness test at 1,1 times the maximum permissible working pressure may be accepted by the Society. Where the hydrostatic test cannot be performed, alternative methods for verifying the integrity of the casings may be agreed between the manufacturer and the Society on a case by case basis.

4.3.4 Balancing of rotors

Finished rotors, complete with all fittings and blades, are to be dynamically balanced in a balancing machine of appropriate sensitivity in relation to the size of the rotor. Normally this test is to be carried out with the primary part of the flexible coupling, if any.

4.3.5 Overspeed test of rotors

Finished rotors, complete with all fittings and blades, are to be subjected for at least 3 minutes to an overspeed test at the greater of the following values:

- 5% above the setting speed of the overspeed tripping device
- 15% above the maximum design speed.

The Society may waive this requirement provided that it can be demonstrated by the manufacturer, using an acceptable direct calculation procedure, that the rotor is able to safely withstand the above overspeed values and that rotors are free from defects, as verified by means of non-destructive tests.

4.3.6 Shop trials

For shop trials, see Ch 1, Sec 2, [4.5], as far as applicable.

4.4 Certification

4.4.1 Type approval certificate and its validity

Subject to the satisfactory outcome of the type tests and inspections specified in [4.2] or [4.3], the Society will issue to the turbine manufacturer a "Type Approval Certificate" valid for all turbines of the same type.

4.4.2 Testing certification

a) Turbines admitted to an alternative inspection scheme

Works' certificates (W) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.3]) are required for components and tests indicated in Tab 3 and tests and trials listed in [4.3.1]. However, the shop trials are to be witnesses by a Surveyor.

b) Turbines not admitted to an alternative inspection scheme.

Society's certificates (C) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.1]) are required for material tests of rotating components and blades listed in Tab 3 and for works trials as per [4.3.3], [4.3.4] and [4.3.6].

Works' certificates (W) (see NR216 Materials and Welding, Ch 1, Sec 1, [4.2.3]) are required for the other items listed in Tab 3 and for trials described in [4.3.2], [4.3.5].

Section 6 Gearing

1 General

1.1 Application

1.1.1 Unless otherwise specified, the requirements of this Section apply to:

- reduction and/or reverse gears intended for propulsion plants with a transmitted power of 220 kW and above
- other reduction and step-up gears with a transmitted power of 110 kW and above.

The provisions of Article [2] apply only to cylindrical involute spur or helical gears with external or internal teeth.

The provisions of Article [3] apply only to bevel gears (straight or oblique teeth). Application of other specific methods for the design of bevel gears could be taken into consideration by the Society.

Additional requirements for gears fitted to ships having an ice notation are given in NR467, Part F, Chapter 8.

1.2 Documentation to be submitted

1.2.1 Documents

Before starting construction, all plans, specifications and calculations listed in Tab 1 are to be submitted to the Society.

1.2.2 Data

The data listed in Tab 2 or Tab 3 and in Tab 4 are to be submitted with the documents required in [1.2.1].

Table 1 : Documents to be submitted for gearing

No.	A / I **(2)**	Description of the document **(1)**
1	A	Constructional drawings of shafts and flanges
2	A	Constructional drawings of pinions and wheels, including: a) specification and details of hardening procedure: • core and surface mechanical characteristics • diagram of the depth of the hardened layer as a function of hardness values b) specification and details of the finishing procedure: • finishing method of tooth flanks (hobbing, shaving, lapping, grinding, shot-peening) • surface roughness for tooth flank and root fillet • tooth flank corrections (helix modification, crowning, tip-relief, end-relief), if any • flank tolerance class according to ISO 1328-1:2013
3	A	Shrinkage calculation for shrunk-on pinions, wheels rims and/or hubs with indication of the minimum and maximum shrinkage allowances
4	I	Calculation of load capacity of the gears
5	A / I **(3)**	Constructional drawings of casings
6	A	Functional diagram of the lubricating system, with indication of the: • specified grade of lubricating oil • expected oil temperature in service • kinematic viscosity of the oil
7	A	Functional diagram of control, monitoring and safety systems
8	I	Longitudinal and transverse cross-sectional assembly of the gearing, with indication of the type of clutch
9	I	Data form for calculation of gears**(4)**
10	I	Detailed justification of material quality used for gearing calculation (ML, MQ, or ME according to ISO 6336-5)

(1) Constructional drawings are to be accompanied by the specification of the materials employed including the chemical composition, heat treatment and mechanical properties and, where applicable, the welding details, welding procedure and stress relieving procedure.
(2) Submission of the drawings may be requested:
A = to be submitted for approval
I = to be submitted for information.
(3) "A" for welded casing, "I" otherwise
(4) The forms are given in Tab 2, Tab 3 and Tab 4.

Table 2 : Data to be submitted for cylindrical gears

Symbol	Values		Unit	Description
	Pinion	Wheel		
a			mm	Operating centre distance
b_B			mm	Common face width (for double helix gear, width of one helix)
A			–	Flank tolerance class according to ISO 1328-1:2013
b_S			mm	Web thickness
s_R			mm	Rim thickness
$R_{m,rim}$			N/mm²	Ultimate tensile strength of the rim material
B			mm	Total face width of double helix gears, including gap
d_s			mm	Shrinkage diameter
m_n			mm	Normal module
α_n			deg or rad	Normal pressure angle at reference cylinder
β			deg or rad	Helix angle at reference cylinder
x			–	Addendum modification coefficient
z			–	Number of teeth
P			kW	Transmitted power
n			rpm	Rotational speed
d_a			mm	Tip diameter
ρ_{a0}			mm	Tip radius of the tool
h_{fp}			mm	Basic rack dedendum
HRC			–	Rockwell hardness
R_{Zf}			µm	Mean peak-to-valley flank roughness of the gear pair
R_Z			µm	Mean peak-to-valley roughness of the gear pair
$R_{e,s}$			N/mm²	Minimum yield strength of the shaft material
ν_{40}			mm²/s	Nominal kinematic viscosity of oil at 40°C
pr			mm	Protuberance of the tool
q			mm	Material allowance for finish machining
d_{ext}			mm	External shaft diameter
d_{int}			mm	Internal shaft diameter
ℓ			mm	Bearing span
Z_E			$N^{1/2}$/mm	Elasticity factor

Table 3 : Data to be submitted for bevel gears

Symbol	Values		Unit	Description
	Pinion	Wheel		
A			–	Flank tolerance class according to ISO 1328-1:2013
s_R			mm	Rim thickness
d_s			mm	Shrinkage diameter
b			mm	Common face width (for double helix gear width of one helix)
m_{mn}			mm	Mean normal module
α_n			deg or rad	Normal pressure angle
β_m			deg or rad	Mean helix angle
z			–	Actual number of teeth
δ			deg or rad	Pitch angle
x_h			–	Addendum modification coefficient
x_s			–	Thickness modification coefficient
h_{aP}			mm	Addendum of the basic rack tooth profile
h_{fP}			mm	Dedendum of the basic rack tooth profile
ρ_{a0}			mm	Cutter edge radius
r_{c0}			mm	Cutter radius
P			kW	Transmitted power
n			rpm	Rotational speed
HRC			–	Rockwell hardness
R_{Zf}			µm	Mean peak-to-valley flank roughness of the gear pair
R_Z			µm	Mean peak-to-valley roughness of the gear pair
$R_{e,s}$			N/mm^2	Minimum yield strength of the shaft material
ν_{40}			mm^2/s	Nominal kinematic viscosity of oil at 40°C
pr			mm	Protuberance of the tool
q			mm	Material allowance for finish machining
d_{ext}			mm	External shaft diameter
d_{int}			mm	Internal shaft diameter
ℓ			mm	Bearing span
Z_E			$N^{1/2}/mm$	Elasticity factor

2 Design of gears - Determination of the load capacity of cylindrical gears

2.1 Symbols, units, definitions

2.1.1 Symbols and units

The meaning of the main symbols used in this Article is specified below.

Other symbols introduced in connection with the definition of influence factors are defined in the appropriate sub-articles.

A : Flank tolerance class according to ISO 1328-1:2013
a : Operating centre distance, in mm
b : Effective face width, in mm (for double helix gear, $b = 2\ b_B$)
b_B : Common face width, in mm (for double helix gear, width of one helix)
b_S : Web thickness, in mm
B : Total face width of double helix gear, including gap, in mm
d : Reference diameter, in mm
d_a : Tip diameter, in mm
d_b : Base diameter, in mm
d_{ext} : External diameter of shaft, in mm
d_{int} : Internal diameter of shaft, in mm
d_f : Root diameter, in mm
d_s : Shrinkage diameter, in mm
d_w : Working pitch diameter, in mm
F_t : Nominal tangential load, in N
F_β : Total helix deviation, in μm
h : Tooth depth, in mm
h_{fp} : Basic rack dedendum, in mm
HB : Brinell hardness, in N/mm^2
HRC : Rockwell hardness
HV : Vickers hardness, in N/mm^2
k : Gear axial position on shaft with respect to the bearings
ℓ : Bearing span, in mm
m_n : Normal module, in mm
n : Rotational speed, in rpm
P : Transmitted power, in kW
pr : Protuberance of the tool, in mm
q : Material allowance for finish machining, in mm
$R_{m,rim}$: Ultimate tensile strength of the rim material, in N/mm^2
$R_{e,s}$: Minimum yield strength of the shaft material, in N/mm^2
R_Z : Mean peak-to-valley roughness of the gear pair, in μm
R_{Zf} : Mean peak-to-valley flank roughness of the gear pair, in μm
s_R : Rim thickness, in mm
T : Transmitted torque, in kN.m
u : Reduction ratio
v : Linear speed at pitch diameter, in m/s
x : Addendum modification coefficient
z : Number of teeth
z_n : Virtual number of teeth
α_a : Transverse profile angle at tooth tip
α_n : Normal pressure angle at reference cylinder
α_t : Transverse pressure angle at reference cylinder
α_{tw} : Transverse pressure angle at working pitch cylinder
β : Helix angle at reference cylinder
β_b : Base helix angle
ε_α : Transverse contact ratio
ε_β : Overlap ratio
ε_γ : Total contact ratio

ν_{40} : Nominal kinematic viscosity of oil at 40°C, in mm²/s

ρ_{a0} : Tip radius of the tool, in mm

σ_F : Tooth root bending stress, in N/mm²

σ_{FE} : Endurance limit for tooth root bending stress, in N/mm²

σ_{FP} : Permissible tooth root bending stress, in N/mm²

σ_H : Contact stress, in N/mm²

$\sigma_{H,lim}$: Endurance limit for contact stress, in N/mm²

σ_{HP} : Permissible contact stress, in N/mm²

Subscripts:

- 1 for pinion, i.e. the gear having the smaller number of teeth
- 2 for wheel.

2.1.2 Geometrical definitions

In the calculation of surface durability, b is the minimum face width on the pitch diameter between pinion and wheel.

In tooth strength calculations, b_1 and b_2 are the face widths at the respective tooth roots. In any case, b_1 or b_2 are not to be taken greater than b by more than one module m_n (in case of width of one gear much more important than the other).

For internal gear, z_2, a, d_2, d_{a2}, d_{b2}, x_2 and d_{w2} are to be taken negative.

$$u = \frac{z_2}{z_1}$$

Note 1: u > 0 for external gears, u < 0 for internal gears.

$$\tan\alpha_t = \frac{\tan\alpha_n}{\cos\beta}$$

$$d_i = \frac{z_i \cdot m_n}{\cos\beta}$$

$$d_{bi} = d_i \cdot \cos\alpha_t$$

$$d_{w1} = \frac{2 \cdot a}{1+u}$$

$$d_{w2} = \frac{2 \cdot a \cdot u}{1+u}$$

$$d_{fi} = d_i + 2 \cdot m_n \cdot x_i - 2 \cdot h_{fPi}$$

$$h_i = 0,5\ (d_{ai} - d_{fi})$$

$$\cos\alpha_{tw} = \frac{d_{b1} + d_{b2}}{2a}$$

$$\sin\beta_b = \sin\beta \cdot \cos\alpha_n$$

$$z_{ni} = \frac{z_i}{\cos\beta \cdot (\cos\beta_b)^2}$$

$$\cos\alpha_{ai} = \frac{d_{bi}}{d_{ai}}$$

$$\varepsilon_\alpha = \frac{z_1}{2\pi}(\tan\alpha_{a1} - \tan\alpha_{wt}) + \frac{z_2}{2\pi}(\tan\alpha_{a2} - \tan\alpha_{wt})$$

$$\varepsilon_\beta = \frac{b \cdot \sin\beta}{\pi \cdot m_n}$$

$$\varepsilon_\gamma = \varepsilon_\alpha + \varepsilon_\beta$$

$$F_{\beta i} = 2^{0,5 \cdot (Q_i - 5)} \cdot (0,1 \cdot |d_i|^{0,5} + 0,63 \cdot b_B{}^{0,5} + 4,2)$$

$$T_i = \frac{60}{2\pi} \cdot \frac{P}{n_i}$$

$$F_t = \frac{P}{n_1} \cdot \frac{60}{\pi \cdot d_1} \cdot 10^6$$

$$v_i = \frac{\pi \cdot n_i}{60} \cdot \frac{d_{wi}}{10^3}$$

2.2 Principle

2.2.1

a) The following requirements apply to cylindrical involute spur or helical gears with external or internal teeth, and provide a method for the calculation of the load capacity with regard to:

- the surface durability (contact stress)
- the tooth root bending stress.

The cylindrical gears for marine application are to comply with the following restrictions:

- $1,2 < \varepsilon_\alpha < 2,5$
- $\beta < 30°$
- $s_R > 3,5\ m_n$

The relevant formulae are provided in [2.4] and [2.5].

The influence factors common to the formulae are given in [2.3].

b) Gears, for which the conditions of validity of some factors or formulae are not satisfied, will be given special consideration by the Society.

c) Other methods of determination of load capacity will be given special consideration by the Society. Any alternative calculations are to comply with the ISO 6336 series standards.

2.3 General influence factors

2.3.1 General

General influence factors are defined in [2.3.2], [2.3.3], [2.3.4], [2.3.5] and [2.3.6]. Alternative values may be used provided they are derived from appropriate measurements.

2.3.2 Application factor K_A

The application factor K_A accounts for dynamic overloads from sources external to the gearing (driven and driving machines).

The values of K_A are given in Tab 5.

2.3.3 Load sharing factor K_γ

The load sharing factor K_γ accounts for the uneven sharing of load on multiple path transmissions, such as epicyclic gears or tandem gears.

The values of K_γ are given in Tab 6.

Table 5 : Application factor K_A

Type of installation			K_A
Main gears (propulsion)	Diesel engine	with hydraulic coupling	1,05
		with elastic coupling	1,30
		with other type of coupling	1,50
	Turbine		1,05
	Electric motor		1,05
Auxiliary gears	Diesel engine	with hydraulic coupling	1,00
		with elastic coupling	1,20
		with other type of coupling	1,40
	Electric motor		1,00

Table 6 : Load sharing factor K_γ

Type of gear		K_γ
Dual tandem gear	without quill shaft **(1)**	1,15
	with quill shaft **(1)**	1,10
Epicyclic gear	with 3 planetary gears and less	1,00
	with 4 planetary gears	1,20
	with 5 planetary gears	1,30
	with 6 planetary gears and more	1,40
(1) A quill shaft is a torsionally flexible shaft intended to improve the load distribution between the gears.		

2.3.4 Dynamic factor K_V (method B)

The dynamic factor K_V accounts for the additional internal dynamic loads acting on the tooth flanks and due to the vibrations of the pinion and the wheel.

The calculation of the dynamic factor K_V is defined in Tab 7, where:

N : Resonance ratio, i.e. ratio of the pinion speed to the resonance speed:

$N = n_1 / n_{E1}$, with:

n_{E1} : Resonance speed, in rpm, defined by the following formula:

$$n_{E1} = \frac{30000}{\pi z_1} \cdot \sqrt{\frac{c_{\gamma\alpha}}{m_{red}}}$$

with:

m_{red} : Reduced mass of gear pair, in kg/mm

In case of external gears, estimated calculation of m_{red} is given in Tab 8

$c_{\gamma\alpha}$: Mesh stiffness, in N/(mm·µm).

For gears with $\beta \leq 30°$, the calculation of $c_{\gamma\alpha}$ is detailed in Tab 9.

The value of N determines the range of vibrations:

- subcritical range, when $N \leq N_S$
- main resonance range, when $N_S < N < 1,15$

  This field is not permitted
- intermediate range, when $1,15 \leq N \leq 1,50$

  This field is normally to be avoided. Some alternative and more precise calculation could be accepted and special consideration will be given by the Society
- supercritical range, when $1,50 < N$.

The lower limit of resonance N_S is defined as follows:

- if $F_t K_A / b \geq 100$ N/mm:

  $N_s = 0,85$
- if $F_t K_A / b < 100$ N/mm:

$$N_s = 0{,}5 + 0{,}35 \sqrt{\frac{F_t K_A}{100b}}$$

2.3.5 Face load distribution factors $K_{H\beta}$ and $K_{F\beta}$ (method C)

The face load distribution factors, $K_{H\beta}$ for contact stress and $K_{F\beta}$ for tooth root bending stress, account for the effects of non-uniform distribution of load across the face width.

a) The values of $K_{H\beta}$ are given in Tab 10. They apply only to gears with:
   - wheel, case, wheel shaft and bearings of stiff construction
   - pinion on a solid or hollow shaft with an inner diameter ratio not exceeding 0,5 and located symmetrically between the bearings
   - no effect of clearances
   - no external loads acting on the pinion shaft.

Note 1: Gears for which the above conditions are not satisfied will be given special consideration by the Society.

The calculation of the initial equivalent misalignment $F_{\beta x}$ is defined in Tab 11.

The calculations of the running-in allowance $y\beta$ and the running-in factor χ_β are defined in Tab 12.

The calculation of the mesh misalignment due to deformations of shafts depends on the constant of the pinion K' and the distance s of the pinion. They are defined in Tab 13.

b) $K_{F\beta}$ is to be determined using the following formula:

$$K_{F\beta} = K_{H\beta}^{\frac{1}{1 + h/b_B + (h/b_B)^2}}$$

where b/h is the smaller of b_{B1}/h_1 and b_{B2}/h_2 but is not to be taken lower than 3.

2.3.6 Transverse load distribution factors $K_{H\alpha}$ and $K_{F\alpha}$ (method B)

The transverse load distribution factors, $K_{H\alpha}$ for contact stress and $K_{F\alpha}$ for tooth root bending stress, account for the effects of pitch and profile errors on the transversal load distribution between two or more pairs of teeth in mesh.

The values of $K_{H\alpha}$ and $K_{F\alpha}$ are given in Tab 14.

Table 7 : Dynamic factor K_V

Resonance domain	Factor K_V
$N \le N_S$	$K_V = N\,(C_{v1}\,B_P + C_{v2}\,B_F + C_{v3}\,B_K) + 1$
$N > 1{,}50$	$K_V = C_{v5}\,B_P + C_{v6}\,B_F + C_{v7}$

Note 1:

B_P : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications:

$$B_P = \frac{c' \cdot f_{pb,\,eff}}{K_A \cdot (F_t / b)}$$

with:

- c' : Single stiffness defined in Tab 9
- $f_{pb,eff}$: Effective base pitch deviation, in µm, equal to: $f_{pb,eff} = f_{pb} - y_\alpha$ with f_{pb} defined in Tab 14 and y_α defined in Tab 15

B_f : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications: $B_f = B_P$

B_k : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications:

$$B_k = \left| 1 - \frac{c' \cdot C_a}{K_A \cdot F_t / b} \right|$$

with:

$$C_a = \frac{1}{18} \cdot \left(\frac{\sigma_{Hlim}}{97} - (18{,}45\,) \right)^2 + 1{,}5$$

When material of the pinion is different from that of the wheel: $C_a = 0{,}5\,(C_{a1} + C_{a2})$

C_{v1} : Factor for pitch deviation effects: $C_{v1} = 0{,}32$

C_{v2} : Factor for tooth profile deviation effects:

- if $1 < \varepsilon_\gamma \le 2$: $C_{v2} = 0{,}34$
- if $2 < \varepsilon_\gamma$: $C_{v2} = 0{,}57 / (\varepsilon_\gamma - 0{,}3)$

C_{v3} : Factor for cyclic variation effect in mesh stiffness:

- if $1 < \varepsilon_\gamma \le 2$: $C_{v3} = 0{,}23$
- if $2 < \varepsilon_\gamma$: $C_{v3} = 0{,}096 / (\varepsilon_\gamma - 1{,}56)$

C_{v5} : Factor: $C_{v5} = 0{,}47$

C_{v6} : Factor:

- if $1 < \varepsilon_\gamma \le 2$: $C_{v6} = 0{,}47$
- if $2 < \varepsilon_\gamma$: $C_{v6} = 0{,}12 / (\varepsilon_\gamma - 1{,}74)$

C_{v7} : Factor:

- if $1 < \varepsilon_\gamma \le 1{,}5$: $C_{v7} = 0{,}75$
- if $1{,}5 < \varepsilon_\gamma \le 2{,}5$: $C_{v7} = 0{,}125\,\sin[\pi\,(\varepsilon_\gamma - 2)] + 0{,}875$
- if $2{,}5 < \varepsilon_\gamma$: $C_{v7} = 1$

Table 8 : Estimated calculation of reduced mass m_{red}

Gear rim	Rim ratio	m_{red}, in kg/mm
$s_{Ri} = 0$	$1 - q_i^4 = 1$	$m_{red} = \frac{\pi}{8} \cdot \left(\frac{d_{a1} + d_{f1}}{2\,d_{b1}}\right)^2 \cdot \frac{(d_{f1} + d_{a1})^2}{4 \cdot \left(\frac{1}{\rho_1} + \frac{1}{\rho_2 \cdot u^2}\right)}$
$s_{Ri} \ne 0$	$q_i = \frac{2 \cdot (d_{fi} - 2 \cdot s_{Ri})}{d_{fi} + d_{ai}}$	$m_{red} = \frac{\pi}{8} \cdot \left(\frac{d_{a1} + d_{f1}}{2\,d_{b1}}\right)^2 \cdot \frac{(d_{f1} + d_{a1})^2}{4 \cdot \left[\frac{1}{(1 - q_1^4) \cdot \rho_1} + \frac{1}{(1 - q_2^4) \cdot \rho_2 \cdot u^2}\right]}$

Note 1:
ρ_i is the density of gearing material ($\rho = 7{,}83 \cdot 10^{-6}$ for steel)

Table 9 : Mesh stiffness $c_{\gamma\alpha}$ (method B)

Specific load	$c_{\gamma\alpha}$, in N/(mm.µm)**(1)**
$F_t K_A / b \geq 100$ N/mm	$c_{\gamma\alpha} = c' (0{,}75\ \varepsilon_\alpha + 0{,}25) = c'_{th} C_M C_R C_B \cos\beta (0{,}75\ \varepsilon_\alpha + 0{,}25)$
$F_t K_A / b < 100$ N/mm	$c_{\gamma\alpha} = c'(0{,}75\ \varepsilon_\alpha + 0{,}25) = c'_{th} C_M C_R C_B \cos\beta \left(\frac{F_t K_A / b}{100}\right)(0{,}75\ \varepsilon_\alpha + 0{,}25)$

(1) When $\varepsilon_\alpha < 1{,}2$: $c_{\gamma\alpha}$ may be reduced up to 10% in case of spur gears.

Note 1:

c' : Single stiffness, in N/(mm.µm)

c'_{th} : Theoretical mesh stiffness, in N/(mm.µm), equal to:

$$c'_{th} = \frac{1}{0{,}04723 + \frac{0{,}15551}{z_{n1}} + \frac{0{,}25791}{z_{n2}} - 0{,}00635\ x_1 - 0{,}00193\ x_2 - \frac{0{,}11654\ x_1}{z_{n1}} - \frac{0{,}24188\ x_2}{z_{n2}} + 0{,}00529\ x_1^2 + 0{,}00182\ x_2^2}$$

where the following limitations are to be verified:

- $x_1 \geq x_2$, and
- $-0{,}5 \leq x_1 + x_2 \leq 2{,}0$

For internal gears, z_{n2} should be replaced by infinity

C_M : Measurements correction factor, equal to:

$C_M = 0{,}8$

C_R : Gear blank factor:

- for solid disc gears ($s_R = 0$):

  $C_R = 1{,}0$
- otherwise:

  $$C_R = 1 + \frac{\ln(b_s / b)}{5 \cdot e^{s_R / 5 m_n}}$$

  with the following limitations:

  $0{,}2 \leq b_s / b \leq 1{,}2$ and $s_R / m_n \geq 1$

C_B : Basic rack factor, equal to:

$$C_B = 1 + 0{,}5 \cdot \left(1{,}2 - \frac{h_{fP}}{m_n}\right) \cdot [1{,}0 - 0{,}02 \cdot (20 - \alpha_n)]$$

When pinion basic rack dedendum is different from that of the wheel, $C_B = 0{,}5\ (C_{B1} + C_{B2})$.

Table 10 : Face load factor for contact stress $K_{H\beta}$

	Calculated face width	Factor $K_{H\beta}$
$\frac{F_{\beta y} c_{\gamma\beta}}{2 F_m / b} \geq 1$	$\frac{b_{cal}}{b} = \sqrt{\frac{2 F_m / b}{F_{\beta y} c_{\gamma\beta}}} \leq 1$	$K_{H\beta} = \sqrt{\frac{2 F_{\beta y} c_{\gamma\beta}}{F_m / b}} \geq 2$
$\frac{F_{\beta y} c_{\gamma\beta}}{2 F_m / b} < 1$	$\frac{b_{cal}}{b} = 0{,}5 + \frac{F_m / b}{F_{\beta y} c_{\gamma\beta}} > 1$	$K_{H\beta} = 1 + \frac{F_{\beta y} c_{\gamma\beta}}{2 F_m / b} < 2$

Note 1:

b_{cal} : Calculated face width, in mm

F_m : Mean transverse tangential load, in N:

$F_m = F_t K_A K_V$

$F_{\beta y}$: Effective misalignment after running-in, in µm:

$F_{\beta y} = F_{\beta x} - y_\beta = F_{\beta x}\ \chi_\beta$

where:

$F_{\beta x}$: Initial equivalent misalignment. Estimated values are given in Tab 11

y_β, χ_β : Running-in allowance, in µm, and running-in factor, respectively, defined in Tab 12

$c_{\gamma\beta}$: Mesh stiffness, in N/(mm·µm):

$c_{\gamma\beta} = 0{,}85\ c_{\gamma\alpha}$

$c_{\gamma\alpha}$ being the mesh stiffness defined in Tab 9.

Table 11 : Initial equivalent misalignment $F_{\beta x}$

Helix modification	$F_{\beta x}$, in µm**(1)**	Default estimated values of f_{ma}
None	$F_{\beta x} = 1,33\ f_{sh} + f_{ma}$	$f_{ma} = F_\beta$
Central crowning with $C_\beta = 0,5\ f_{ma}$	$F_{\beta x} = 1,33\ f_{sh} + 0,5\ f_{ma}$	$f_{ma} = 0,5\ F_\beta$
Central crowning with $C_\beta = 0,5\ (f_{ma} + f_{sh})$	$F_{\beta x} = 0,665\ f_{sh} + 0,5\ f_{ma}$	$f_{ma} = 0,5\ F_\beta$
Helix correction	$F_{\beta x} = 0,133\ f_{sh} + f_{ma}$	$f_{ma} = 0,5\ F_\beta$
Helix correction plus central crowning	$F_{\beta x} = 0,133\ f_{sh} + 0,5\ f_{ma}$	$f_{ma} = 0,5\ F_\beta$
End relief	$F_{\beta x} = 0,931\ f_{sh} + 0,7\ f_{ma}$	$f_{ma} = 0,7\ F_\beta$

(1) The misalignment $F_{\beta x}$ is to be taken greater than $F_{\beta x,min} = 0,005\ F_m / b$

Note 1:

f_{sh} : Mesh misalignment due to deformations of shafts, in µm:

$$f_{sh} = \frac{F_m}{b} \cdot 0,023 \left(\left| B^* + K' \frac{\ell \cdot s \cdot d_1^{\ 2}}{d_{ext}^{\ 4}} - 0,3 \right| + 0,3 \right) \cdot \left(\frac{d_B}{d_1} \right)^2$$

where:

B^* : Transmitted torque factor depending on k, percentage of input torque transmitted in one gear mesh:
- for spur and single helical gears: $B^* = 1 + 2\ (100 - k) / k$
- for double helical gears: $B^* = 0,5 + (200 - k) / k$

K' : Constant of the pinion defined in Tab 13

s : Distance of the pinion, in mm, as shown in Tab 13

f_{ma} : Mesh misalignment due to manufacturing deviations, in µm.

Table 12 : Running-in allowance y_β and running-in factor $\chi\beta$

Material	y_β , in µm	χ_β	Limitations
St, St (cast), GTS (perl.), GGG (perl.), GGG (bai.), V, V (cast)	$y_\beta = \dfrac{320}{\sigma_{H,\,lim}} F_{\beta x}$	$\chi_\beta = 1 - \dfrac{320}{\sigma_{H,\,lim}}$	$y_\beta \le F_{\beta x}$ and $\chi_\beta \ge 0$ • if 5 m/s < v ≤ 10 m/s: $y_\beta \le 25600 / \sigma_{H,\,lim}$ • if 10 m/s < v: $y_\beta \le 12800 / \sigma_{H,\,lim}$
GGG (ferr.), GG	$y_\beta = 0,55\ F_{\beta x}$	$\chi_\beta = 0,45$	• if 5 m/s < v ≤ 10 m/s: $y_\beta \le 45$ • if 10 m/s < v: $y_\beta \le 22$
Eh, IF, NT (nitr.), NV (nitr.), NV (nitrocar.)	$y_\beta = 0,15\ F_{\beta x}$	$\chi_\beta = 0,85$	$y_\beta \le 6$

Note 1: $\sigma_{H,\,lim}$ is defined in [2.4.9].

Note 2: When material of the pinion differs from that of the wheel: $y_\beta = 0,5\ (y_{\beta 1} + y_{\beta 2})$ and $\chi_\beta = 0,5\ (\chi_{\beta 1} + \chi_{\beta 2})$

Table 13 : Constant of the pinion K' and distance of the pinion s

Arrangement **(1)**	Constant K' with stiffening	Constant K' without stiffening **(2)**
	0,48	0,8
	– 0,48	– 0,8
	1,33	1,33
	– 0,36	– 0,6
	– 0,6	– 1,0

(1) The following limitation is to be verified except when helix correction is applied:
$s / \ell < 0,3$

(2) No stiffening is assumed when $d_1 / d_{sh} < 1,15$ or when the pinion is keyed or shrinked to the shaft.

Table 14 : Transverse load factors $K_{H\alpha}$ and $K_{F\alpha}$

	Factors $K_{H\alpha}$ and $K_{F\alpha}$	Limitations
$\varepsilon_\gamma \le 2$	$K_{H\alpha} = K_{F\alpha} = \frac{\varepsilon_\gamma}{2}\left[0{,}9 + 0{,}4\,\frac{c_{\gamma\alpha}(f_{pb} - y_\alpha)}{F_{tH}/b}\right]$	$\frac{\varepsilon_\gamma}{\varepsilon_\alpha Z_\varepsilon^{2}} \ge K_{H\alpha} \ge 1$
$\varepsilon_\gamma > 2$	$K_{H\alpha} = K_{F\alpha} = 0{,}9 + 0{,}4\sqrt{\frac{2(\varepsilon_\gamma - 1)}{\varepsilon_\gamma}\,\frac{c_{\gamma\alpha}(f_{pb} - y_\alpha)}{F_{tH}/b}}$	$\frac{\varepsilon_\gamma}{0{,}25\ \varepsilon_\alpha + 0{,}75} \ge K_{F\alpha} \ge 1$

Note 1:

$c_{\gamma\alpha}$: Mesh stiffness, in N/mm.µm, defined in Tab 9

f_{pb} : Larger value of the base pitch deviation of pinion or wheel, in µm.

Default value: $f_{pb} = 0{,}3\ (m_n + 0{,}4\ |d_{bi}|^{0{,}5} + 4) \cdot 2^{0{,}5\ (Q_i - 5)}$

In case of optimum profile correction, f_{pb} is to be replaced by f_{pb} / 2

y_α : Running-in allowance, in µm, defined in Tab 15

F_{tH} : Determinant tangential load in transverse plane, in N:

$F_{tH} = F_t \cdot K_A \cdot K_V \cdot K_{H\beta}$

Table 15 : Running-in allowance y_α

Material	y_α, in µm	Limitations
St, St (cast), GTS (perl.), GGG (perl.), GGG (bai.), V, V (cast)	$y_\alpha = \frac{160}{\sigma_{H,\,lim}} f_{pb}$	• if 5 m/s < v ≤ 10 m/s: $y_\alpha \le 12800 / \sigma_{H,lim}$ • if 10 m/s < v: $y_\alpha \le 6400 / \sigma_{H,lim}$
GGG (ferr.), GG	$y_\alpha = 0{,}275\ f_{pb}$	• if 5 m/s < v ≤ 10 m/s: $y_\alpha \le 22$ • if 10 m/s < v: $y_\alpha \le 11$
Eh, IF, NT (nitr.), NV (nitr.), NV (nitrocar.)	$y_\alpha = 0{,}075\ f_{pb}$	$y_\alpha \le 3$

Note 1: f_{pb} is defined in Tab 14 and $\sigma_{H,lim}$ is defined in [2.4.9].
Note 2: When material of the pinion differs from that of the wheel: $y_\alpha = 0{,}5\ (y_{\alpha 1} + y_{\alpha 2})$.

2.4 Calculation of surface durability

2.4.1 General

The criterion for surface durability is based on the contact stress (hertzian pressure) σ_H on the pitch point or at the inner point of single pair contact.

The contact stress σ_H, defined in [2.4.2], is not to exceed the permissible contact stress σ_{HP} defined in [2.4.8].

2.4.2 Contact stress σ_H

The contact stress σ_H, in N/mm², is to be determined as follows.

- for the pinion:

$$\sigma_H = Z_B \cdot \sigma_{H0}\sqrt{K_A \cdot K_\gamma \cdot K_V \cdot K_{H\beta} \cdot K_{H\alpha}}$$

- for the wheel:

$$\sigma_H = Z_D \cdot \sigma_{H0}\sqrt{K_A \cdot K_\gamma \cdot K_V \cdot K_{H\beta} \cdot K_{H\alpha}}$$

where:

Z_B, Z_D : Single pair mesh factors, respectively for pinion and for wheel, defined in [2.4.3]

K_A : Application factor (see [2.3.2])

K_γ : Load sharing factor (see [2.3.3])

K_V : Dynamic factor (see [2.3.4])

$K_{H\beta}$: Face load distribution factor (see [2.3.5])

$K_{H\alpha}$: Transverse load distribution factor (see [2.3.6])

$$\sigma_{H0} = Z_H \cdot Z_E \cdot Z_\varepsilon \cdot Z_\beta \sqrt{\frac{F_t}{d_1 \cdot b} \cdot \frac{|u| + 1}{|u|}}$$

with:

Z_H : Zone factor, defined in [2.4.4]

Z_E : Elasticity factor, defined in [2.4.5]

Z_ε : Contact ratio factor, defined in [2.4.6]

Z_β : Helix angle factor, defined in [2.4.7].

2.4.3 Single pair mesh factors Z_B and Z_D

The single pair mesh factors Z_B for pinion and Z_D for wheel account for the influence on contact stresses of the tooth flank curvature at the inner point of single pair contact in relation to Z_H. These factors transform the contact stress determined at the pitch point to contact stresses, considering the flank curvature at the inner point of single pair contact.

Z_B and Z_D are to be determined as follows:

a) for spur gears ($\varepsilon_\beta = 0$):

- $Z_B = M_1$ or 1, whichever is the greater, with:

$$M_1 = \frac{\tan\alpha_{tw}}{\sqrt{\left[\sqrt{\left(\frac{d_{a1}}{d_{b1}}\right)^2 - 1} - \frac{2\pi}{z_1}\right] \cdot \left[\sqrt{\left(\frac{d_{a2}}{d_{b2}}\right)^2 - 1} - (\varepsilon_\alpha - 1)\frac{2\pi}{z_2}\right]}}$$

- $Z_D = M_2$ or 1, whichever is the greater, with:

$$M_2 = \frac{\tan\alpha_{tw}}{\sqrt{\left[\sqrt{\left(\frac{d_{a2}}{d_{b2}}\right)^2 - 1} - \frac{2\pi}{z_2}\right] \cdot \left[\sqrt{\left(\frac{d_{a1}}{d_{b1}}\right)^2 - 1} - (\varepsilon_\alpha - 1)\frac{2\pi}{z_1}\right]}}$$

b) for helical gears:

- if $\varepsilon_\beta \geq 1$: $Z_B = Z_D = 1$
- if $\varepsilon_\beta < 1$:

  $Z_B = M_1 - \varepsilon_\beta (M_1 - 1)$ or 1, whichever is the greater

  $Z_D = M_2 - \varepsilon_\beta (M_2 - 1)$ or 1, whichever is the greater.

Note 1: For gears with $\varepsilon_\alpha \leq 1$, a specific analysis of the decisive contact stress along the path of contact is necessary.

Note 2: For internal gears, $Z_D = 1$.

2.4.4 Zone factor Z_H

The zone factor Z_H accounts for the influence on the hertzian pressure of tooth flank curvature at the pitch point and transforms the tangential force at the reference cylinder to normal force at the pitch cylinder.

Z_H is to be determined as follows:

$$Z_H = \sqrt{\frac{2 \cdot \cos\beta_b \cdot \cos\alpha_{tw}}{(\cos\alpha_t)^2 \cdot \sin\alpha_{tw}}}$$

2.4.5 Elasticity factor Z_E

The elasticity factor Z_E accounts for the influence of the metal properties (module of elasticity E and Poisson's ratio ν) on the hertzian pressure.

For steel gears: $Z_E = 189{,}8\ N^{1/2}/mm$.

Note 1: Refer to ISO 6336-2 for other materials.

2.4.6 Contact ratio factor Z_ε

The contact ratio factor Z_ε accounts for the influence of the transverse contact ratio and the overlap ratio on the specific surface load of gears.

Z_ε is to be determined as follows:

a) for spur gears ($\varepsilon_\beta = 0$):

$$Z_\varepsilon = \sqrt{\frac{4 - \varepsilon_\alpha}{3}}$$

b) for helical gears:

- for $\varepsilon_\beta \geq 1$:

$$Z_\varepsilon = \sqrt{\frac{1}{\varepsilon_\alpha}}$$

- for $\varepsilon_\beta < 1$:

$$Z_\varepsilon = \sqrt{\frac{4 - \varepsilon_\alpha}{3} \cdot (1 - \varepsilon_\beta) + \frac{\varepsilon_\beta}{\varepsilon_\alpha}}$$

2.4.7 Helix angle factor Z_β

The helix angle factor Z_β accounts for the influence of helix angle on the surface durability, allowing for such variables as the distribution of the load along the lines of contact. Z_β is to be determined as follows:

$$Z_\beta = \frac{1}{\sqrt{\cos\beta(2,\ )}}$$

(1) The requirements for each material quality are defined in ISO 6336-5.

2.4.8 Permissible contact stress σ_{HP}

The permissible contact stress σ_{HP} , in N/mm², is to be determined separately for pinion and wheel, using the following formula:

$$\sigma_{HP} = \frac{\sigma_{H,lim}}{S_H} \cdot Z_{NT} \cdot Z_L \cdot Z_V \cdot Z_R \cdot Z_W \cdot Z_X$$

where:

$\sigma_{H,lim}$: Endurance limit for contact stress, defined in [2.4.9]

Z_{NT} : Life factor for contact stress, defined in [2.4.10]

Z_L, Z_V, Z_R: Lubrication, speed and roughness factors, respectively, defined in [2.4.11]

Z_W : Hardness ratio factor, defined in [2.4.12]

Z_X : Size factor for contact stress, defined in [2.4.13]

S_H : Safety factor for contact stress, defined in [2.4.14].

2.4.9 Endurance limit for contact stress $\sigma_{H,lim}$

The endurance limit for contact stress $\sigma_{H,lim}$, in N/mm², is the limit of repeated contact stress which can be permanently endured.

The values to be adopted for $\sigma_{H,lim}$ are given, in N/mm², with the following formula, in relation to the type of steel employed and the heat treatment performed:

$\sigma_{H,lim} = A\,x + B$

where:

A, B : Constants determined in Tab 16

x : Surface hardness HB or HV, in N/mm². The limitations x_{min} and x_{max} on surface hardness are indicated in Tab 16.

Special consideration will be given to other values of $\sigma_{H,lim}$, depending on the material category and specification of the steel employed.

2.4.10 Life factor for contact stress Z_{NT}

The life factor Z_{NT} accounts for the influence of limited service life on the permissible contact stress.

Some values of Z_{NT} are given for information in Tab 17.

The value of Z_{NT} to be used will be given special consideration by the Society, depending on the equipment's arrangement and use.

Table 17 : Life factor Z_{NT}

Material	Number of load cycles N_L	Z_{NT}
St, St (cast), GTS (perl.), GGG (perl.), GGG (bai.),V, V (cast), Eh, IF	$N_L \leq 10^5$ or static	1,6
	$N_L = 5 \cdot 10^7$	1,0
	$N_L = 10^9$	1,0
	$N_L = 10^{10}$	0,85 up to 1,0
GGG (ferr.), GG, NT (nitr.), NV (nitr.)	$N_L \leq 10^5$ or static	1,3
	$N_L = 2 \cdot 10^6$	1,0
	$N_L = 10^{10}$	0,85 up to 1,0
NV (nitrocar.)	$N_L \leq 10^5$ or static	1,1
	$N_L = 2 \cdot 10^6$	1,0
	$N_L = 10^{10}$	0,85 up to 1,0

2.4.11 Lubricant factor Z_L , speed factor Z_V and roughness factor Z_R

The lubricant factor Z_L accounts for the influence of the type of the lubricant and the influence of its viscosity, the speed factor Z_V accounts for the influence of the pitch line velocity, and the roughness factor Z_R accounts for the influence of the surface roughness on the surface endurance capacity.

These factors are to be determined as follows:

a) Lubricant factor Z_L

$$Z_L = C_{ZL} + \frac{4 \cdot (1{,}0 - C_{ZL})}{\left(1{,}2 + \frac{134}{\nu_{40}}\right)^2}$$

where:

C_{ZL} : Constant for lubricant factor, equal to:

- for $\sigma_{H,lim} < 850$ N/mm²:

  $C_{ZL} = 0{,}83$

- if 850 N/mm² $\leq \sigma_{H,lim} \leq$ 1200 N/mm²:

  $$C_{ZL} = \frac{\sigma_{H,lim}}{4375} + 0{,}6357$$

- if $\sigma_{H,lim} > 1200$ N/mm²:

  $C_{ZL} = 0{,}91$

b) Speed factor Z_V

$$Z_V = C_{ZV} + \frac{2 \cdot (1{,}0 - C_{ZV})}{\sqrt{0{,}8 + \frac{32}{v}}}$$

where:

C_{ZV} : Constant for speed factor, equal to:

$C_{ZV} = C_{ZL} + 0{,}02$

c) Roughness factor Z_R

$$Z_R = \left(\frac{3}{R_{Z10}}\right)^{C_{ZR}}$$

where:

R_{Z10} : Mean relative peak-to-valley roughness for the gear pair, in µm, equal to:

$$R_{Z10} = R_{Zf}\left(\frac{10}{\rho_{red}}\right)^{1/3}$$

ρ_{red} : Relative radius of curvature, in mm, equal to:

$$\rho_{red} = \frac{0{,}5 \cdot d_{b1} \cdot d_{b2} \cdot \tan\alpha_{wt}}{d_{b1} + d_{b2}}$$

d_b being taken negative for internal gears

R_{Zf} : Mean peak-to-valley flank roughness for the gear pair, in µm, equal to:

$$R_{Zf} = \frac{R_{Zf1} + R_{Zf2}}{2}$$

C_{ZR} : Constant for roughness factor, equal to:

- if $\sigma_{H,lim} < 850$ N/mm²:

  $C_{ZR} = 0{,}15$

- if 850 N/mm² $\leq \sigma_{H,lim} \leq$ 1200 N/mm²:

  $$C_{ZR} = 0{,}32 - \frac{\sigma_{H,lim}}{5000}$$

- if $\sigma_{H,lim} > 1200$ N/mm²:

  $C_{ZR} = 0{,}08$

2.4.12 Hardness ratio factor Z_W

The hardness ratio factor Z_W accounts for the increase of the surface durability in the following cases:

a) Surface-hardened with through-hardened wheel

- if HB < 130:

  $$Z_W = 1{,}2 \cdot \left(\frac{3}{R_{ZH}}\right)^{0{,}15}$$

- if 130 ≤ HB ≤ 470:

  $$Z_W = \left(1{,}2 - \frac{HB - 130}{1700}\right) \cdot \left(\frac{3}{R_{ZH}}\right)^{0{,}15}$$

- if HB > 470:

  $$Z_W = \left(\frac{3}{R_{ZH}}\right)^{0{,}15}$$

where:

R_{ZH} : Equivalent roughness, in µm, equal to:

$$R_{ZH} = \frac{R_{Zf1}(10/\rho_{red})^{0,33} \cdot (R_{Zf1}/R_{Zf2})^{0,66}}{(\nu_{40} \cdot v/1500)^{0,33}}$$

ρ_{red} being the relative radius of curvature defined in [2.4.11].

b) Through-hardened pinion and wheel with pinion substantially harder than the wheel (in that case, the hardness factor is to be applied only to the wheel)

- if HB_1 / HB_2 < 1,2:

  Z_W = 1,0
- if 1,2 ≤ HB_1 / HB_2 ≤ 1,7:

  $$Z_W = 1 + \left(0{,}00898\frac{HB_1}{HB_2} - 0{,}00829\right) \cdot (u - 1{,}0)$$
- if HB_1 / HB_2 > 1,7:

  Z_W = 1,0 + 0,00698 (u − 1,0)

Note 1: In any cases, $Z_W \geq 1$

Note 2: If u > 20, u = 20 is to be taken.

2.4.13 Size factor Z_X

The size factor Z_X accounts for the influence of tooth dimensions on permissible contact stress and reflects the non-uniformity of material properties.

Z_X is in general equal to 1.

The value of Z_X to be used will be given special consideration by the Society depending on the material.

2.4.14 Safety factor for contact stress S_H

The values to be adopted for safety factor for contact stress S_H are given in Tab 18.

Table 18 : Safety factor for contact stress S_H

Type of installation		S_H
Main gears (propulsion)	single machinery	1,25
	duplicate machinery	1,25
Auxiliary gears		1,20

2.5 Calculation of tooth bending strength

2.5.1 General

The criterion for the tooth root bending strength is based on the local tensile stress at the tooth root in the direction of the tooth height.

The tooth root bending stress σ_F , defined in [2.5.2], is not to exceed the permissible tooth root bending stress σ_{FP} defined in [2.5.8].

2.5.2 Tooth root bending stress σ_F

The tooth root bending stress σ_F is to be determined as follows:

$$\sigma_F = \frac{F_t}{b \cdot m_n} Y_F \cdot Y_S \cdot Y_\beta \cdot Y_B \cdot Y_{DT} \cdot K_A \cdot K_\gamma \cdot K_V \cdot K_{F\beta} \cdot K_{F\alpha}$$

where:

Y_F : Tooth form factor, defined in [2.5.3]

Y_S : Stress correction factor, defined in [2.5.4]

Y_β : Helix angle factor, defined in [2.5.5]

Y_B : Rim thickness factor, defined in [2.5.6]

Y_{DT} : Deep tooth factor, defined in [2.5.7]

K_A : Application factor (see [2.3.2])

K_γ : Load sharing factor (see [2.3.3])

K_V : Dynamic factor (see [2.3.4])

$K_{F\beta}$: Face load distribution factor (see [2.3.5])

$K_{F\alpha}$: Transverse load distribution factor (see [2.3.6]).

When a shot peening treatment of the tooth root is applied according to a process agreed by the Society, a reduction of the bending stress σ_F (depending on the material category, but without being over 10%) could be taken in consideration only for carburized case-hardened steel gears.

2.5.3 Tooth form factor Y_F (method B)

The tooth form factor Y_F takes into account the effect of the tooth form on the nominal bending stress, assuming the load applied at the outer point of a single pair tooth contact.

In the case of helical gears, the form factors are to be determined in the normal section, i.e. for the virtual spur gear with the virtual number of teeth z_n.

Y_F is to be determined separately for the pinion and the wheel, using the following formula:

$$Y_F = \frac{6\dfrac{h_{Fe}}{m_n}\cos\alpha_{Fen}}{\left(\dfrac{s_{Fn}}{m_n}\right)^2\cos\alpha_n}$$

where:

h_{Fe} : Bending moment arm, in mm:

- for external gears:

$$\frac{h_{Fe}}{m_n} = \frac{1}{2}\left[(\cos\gamma_e - \sin\gamma_e\tan\alpha_{Fen})\frac{d_{en}}{m_n}\right] - \frac{1}{2}\left[z_n\cos\left(\frac{\pi}{3}-\theta\right) - \left(\frac{G}{\cos\theta} - \frac{\rho_{fPv}}{m_n}\right)\right]$$

- for internal gears:

$$\frac{h_{Fe}}{m_n} = \frac{1}{2}\left[(\cos\gamma_e - \sin\gamma_e\tan\alpha_{Fen})\frac{d_{en}}{m_n}\right] - \frac{1}{2}\left[z_n\cos\left(\frac{\pi}{6}-\theta\right) - \sqrt{3}\left(\frac{G}{\cos\theta} - \frac{\rho_{fPv}}{m_n}\right)\right]$$

s_{Fn} : Tooth root chord at the critical section, in mm:

- for external gears:

$$\frac{s_{Fn}}{m_n} = z_n\sin\left(\frac{\pi}{3}-\theta\right) + \sqrt{3}\left(\frac{G}{\cos\theta} - \frac{\rho_{fPv}}{m_n}\right)$$

- for internal gears:

$$\frac{s_{Fn}}{m_n} = z_n\sin\left(\frac{\pi}{6}-\theta\right) + \left(\frac{G}{\cos\theta} - \frac{\rho_{fPv}}{m_n}\right)$$

ρ_{fPv} : Fillet radius at the basic rack, in mm:

- for external gears:

$\rho_{fPv} = \rho_{a0}$

- for internal gears:

$$\rho_{fPv} = \rho_{a0} + m_n \cdot \frac{(x_2 + h_{fP}/m_n - \rho_{a0}/m_n)^{1,95}}{3,156 \cdot 1,036^{z_2}}$$

G : Parameter defined by the following formula:

$$G = \frac{\rho_{fPv}}{m_n} - \frac{h_{fP}}{m_n} + x$$

θ : Parameter defined by the following formula:

$$\theta = \frac{2G}{z_n}\tan\theta - H$$

This transcendental equation is to be calculated by iteration

H : Parameter defined by the following formulae:

- for external gears:

$$H = \frac{2}{z_n}\left(\frac{\pi}{2} - \frac{E}{m_n}\right) - \frac{\pi}{3}$$

- for internal gears:

$$H = \frac{2}{z_n}\left(\frac{\pi}{2} - \frac{E}{m_n}\right) - \frac{\pi}{6}$$

E : Parameter defined by the following formula:

$$E = \frac{\pi}{4}m_n - h_{fP}\tan\alpha_n + \frac{s_{pr}}{\cos\alpha_n} - (1 - \sin\alpha_n)\frac{\rho_{a0}}{\cos\alpha_n}$$

s_{pr} : Residual fillet undercut, in mm:

$s_{pr} = pr - q$

The parameters of the virtual gears are defined as follows:

α_{Fen} : Load direction angle:

$\alpha_{Fen} = \alpha_{en} - \gamma_e$

γ_e : Parameter defined by the following formula:

$$\gamma_e = \frac{0,5\ \pi + 2 \cdot \tan\alpha_n \cdot x}{z_n} + \mathrm{inv}\alpha_n - \mathrm{inv}\alpha_{en}$$

with inv, involute function, equal to:

inv $\alpha = \tau\alpha\nu\ \alpha - \alpha$

α_{en} : Form factor pressure angle:

$$\cos\alpha_{en} = \frac{d_{bn}}{d_{en}}$$

d_{bn} : Virtual base diameter, in mm:

$d_{bn} = d_n \cos \alpha_n$

with:

d_n : Virtual reference diameter, in mm:

$$d_n = \frac{d}{(\cos\beta_b)^2} = m_n z_n$$

d_{en} : Parameter defined by the following formula:

$$d_{en} = \frac{2z}{|z|}\sqrt{\left[\frac{\sqrt{d_{an}^2 - d_{bn}^2}}{2} - \frac{\pi d \cos\beta \cos\alpha_n}{|z|}(\varepsilon_{\alpha n} - 1)\right]^2 + \frac{d_{bn}^2}{4}}$$

with:

d_{an} : Virtual tip diameter, in mm:

$d_{an} = d_n + d_a - d$

$\varepsilon_{\alpha n}$: Virtual transverse contact ratio:

$$\varepsilon_{\alpha n} = \frac{\varepsilon_\alpha}{(\cos\beta_b)^2}$$

2.5.4 Stress correction factor Y_S (method B)

The stress correction factor Y_S is used to convert the nominal bending stress to local tooth root stress, assuming the load is applied at the outer point of a single pair tooth contact. It takes into account the influence of:

- the bending moment
- the proximity of the load application to the critical section.

Y_S is to be determined as follows:

$$Y_S = (1,2 + 0,13L)q_s^{\left(\frac{1}{1,21 + (2,3/L)}\right)}$$

where:

$$L = \frac{s_{Fn}}{h_{Fe}}$$

with s_{Fn} and h_{Fe} defined in [2.5.3]

q_s : Notch parameter:

$$q_s = \frac{s_{Fn}}{2\rho_F}$$

with s_{Fn} defined in [2.5.3]

Note 1: The notch parameter should be within the range:
$1 \le q_s < 8$

ρ_F : Radius of root fillet, in mm:

$$\frac{\rho_F}{m_n} = \frac{\rho_{fPv}}{m_n} + \frac{2G^2}{\cos\theta \cdot (|z_n| \cdot \cos^2\theta - 2G)}$$

2.5.5 Helix angle factor Y_β

The helix angle factor Y_β converts the tooth root stress of a virtual spur gear to that of the corresponding helical gear, taking into account the oblique orientation of the lines of mesh contact.

Y_β is to be determined as follows:

if $\varepsilon_\beta \le 1$ and $\beta \le 30°$: $Y_\beta = 1 - \varepsilon_\beta \beta / 120$

if $\varepsilon_\beta \le 1$ and $\beta > 30°$: $Y_\beta = 1 - 0{,}25\ \varepsilon_\beta$

if $\varepsilon_\beta > 1$ and $\beta \le 30°$: $Y_\beta = 1 - \beta / 120$

if $\varepsilon_\beta > 1$ and $\beta > 30°$: $Y_\beta = 0{,}75$

2.5.6 Rim thickness factor Y_B

The rim thickness factor Y_B is a simplified factor used to de-rate thin rimmed gears. For critically loaded applications, this method should be replaced by a more comprehensive analysis.

Y_B is to be determined as follows:

- for external gears:
  - when $s_R / h \ge 1{,}2$:

    $Y_B = 1{,}0$
  - when $1{,}2 > s_R / h > 0{,}5$:

    $$Y_B = 1{,}6\ \ln\left(2{,}242\ \frac{h}{s_R}\right)$$

Note 1: $s_R / h \le 0{,}5$ is to be avoided.

- for internal gears:
  - when $s_R / m_n \ge 3$:

    $Y_B = 1{,}0$
  - when $3 > s_R / m_n > 1{,}75$:

    $$Y_B = 1{,}15\ \ln\left(8{,}324\ \frac{m_n}{s_R}\right)$$

Note 2: $s_R / h \le 1{,}75$ is to be avoided.

2.5.7 Deep tooth factor Y_{DT}

The deep tooth factor Y_{DT} adjusts the tooth root stress to take into account high precision gears and contact ratios within the range $2{,}05 < \varepsilon_{\alpha n} \le 2{,}5$ (where $\varepsilon_{\alpha n}$ is defined in [2.5.3]).

Y_{DT} is to be determined as follows:

- if $\varepsilon_{\alpha n} > 2{,}5$ and $A \le 4$: $Y_{DT} = 0{,}7$
- if $2{,}05 < \varepsilon_{\alpha n} \le 2{,}5$ and $A \le 4$: $Y_{DT} = -0{,}666\ \varepsilon_{\alpha n} + 2{,}366$
- otherwise: $Y_{DT} = 1{,}0$

2.5.8 Permissible tooth root bending stress σ_{FP}

The permissible tooth root bending stress σ_{FP} is to be determined separately for pinion and for wheel, using the following formula:

$$\sigma_{FP} = \frac{\sigma_{FE}}{S_F} \cdot Y_d \cdot Y_{NT} \cdot Y_{\delta relT} \cdot Y_{RrelT} \cdot Y_X$$

where:

σ_{FE}	:	Endurance limit for tooth root bending stress, defined in [2.5.9]
Y_d	:	Design factor, defined in [2.5.10]
Y_{NT}	:	Life factor for tooth root bending stress, defined in [2.5.11]
$Y_{\delta relT}$	:	Relative notch sensitive factor, defined in [2.5.12]
Y_{RrelT}	:	Relative surface factor, defined in [2.5.13]
Y_X	:	Size factor for tooth root bending stress, defined in [2.5.14]
S_F	:	Safety factor for tooth root bending stress, defined in [2.5.15].

(1) The requirements for each material quality are defined in ISO 6336-5.

2.5.9 Endurance limit for tooth root bending stress σ_{FE}

The endurance limit for tooth root bending stress σ_{FE} is the local tooth root stress which can be permanently endured.

The values to be adopted for σ_{FE} are given, in N/mm², with the following formula, in relation to the type of steel employed and the heat treatment performed:

$\sigma_{FE} = A\,x + B$

where:

A, B : Constants determined in Tab 19

x : Surface hardness HB or HV, in N/mm². The limitations x_{min} and x_{max} on surface hardness are indicated in Tab 19.

Special consideration will be given to other values of σ_{FE}, depending on the material category and specification of the steel employed.

2.5.10 Design factor Y_d

The design factor Y_d takes into account the influence of load reversing and shrink fit prestressing on the tooth root strength.

Y_d is to be determined as follows:

- for gears with occasional part load in reverse direction, such as main wheel in reverse gearboxes:
  $Y_d = 0,9$
- for idler gears (driven and driving tooth for each cycle i.e. alternating load):
  $Y_d = 0,7$
- for shrunk on pinions and wheel rims:
  $Y_d = 1 - \sigma_T / \sigma_{FE}$
  with:
  σ_{FE} : Endurance limit for tooth root bending stress (see [2.5.9])
  σ_T : Tangential stress induced by the shrinkage at the tooth root diameter.
  The maximum equivalent stress induced by the shrinkage in the inner diameter of the rim is not to exceed 80% of the yield strength of the rim material.
- otherwise: $Y_d = 1,0$

2.5.11 Life factor Y_{NT}

The life factor Y_{NT} accounts for the influence of limited service life on the permissible tooth root bending stress.

Some values of Y_{NT} are given in Tab 20 for information.

The value Y_{NT} to be used will be given special consideration by the Society depending on the equipment's arrangement and use.

Table 20 : Life factor Y_{NT}

Material	Number of load cycles N_L	Y_{NT}
St, St (cast), GTS (perl.), GGG (perl.), GGG (bai.), V, V (cast), Eh, IF	$N_L \le 10^3$ or static	2,5
	$N_L = 3 \cdot 10^6$	1,0
	$N_L = 10^{10}$	0,85 up to 1,0
GGG (ferr.), GG, NT (nitr.), NV (nitr.)	$N_L \le 10^3$ or static	1,6
	$N_L = 3 \cdot 10^6$	1,0
	$N_L = 10^{10}$	0,85 up to 1,0
NV (nitrocar.)	$N_L \le 10^3$ or static	1,1
	$N_L = 3 \cdot 10^6$	1,0
	$N_L = 10^{10}$	0,85 up to 1,0

2.5.12 Relative notch sensitivity factor $Y_{\delta rel\,T}$

The relative notch sensitivity factor $Y_{\delta relT}$ indicates the extent to which the theoretically concentrated stress lies above the fatigue endurance limit.

$Y_{\delta relT}$ is to be determined as follows:

$$Y_{\delta relT} = \frac{1 + \sqrt{\rho' \cdot 0,2 \cdot (1 + 2 q_s)}}{1 + \sqrt{\rho' \cdot 1,2}}$$

where:

q_s : Notch parameter, as defined in [2.5.4]

ρ' : Slip-layer thickness, in mm, defined in Tab 21.

Table 21 : Slip-layer thickness ρ'

Material	ρ' (mm)
GG, R_m = 150 N/mm²	0,3124
GG, GGG (ferr.) R_m = 300 N/mm²	0,3095
NT, NV	0,1005
St, R_e = 300 N/mm²	0,0833
St, R_e = 400 N/mm²	0,0445
V, GTS, GGG (perl. bai.), R_e = 500 N/mm²	0,0281
V, GTS, GGG (perl. bai.), R_e = 600 N/mm²	0,0194
V, GTS, GGG (perl. bai.), R_e = 800 N/mm²	0,0064
V, GTS, GGG (perl. bai.), R_e = 1000 N/mm²	0,0014
Eh, IF	0,0030

2.5.13 Relative surface factor $Y_{Rrel\ T}$

The relative surface factor $Y_{Rrel\ T}$ takes into account the dependence of the root strength on the surface condition on the tooth root fillet (roughness).

The values to be adopted for $Y_{Rrel\ T}$ are given in Tab 22 in relation to the type of steel employed.

They are valid only when scratches or similar defects deeper than 12 R_a are not present.

Table 22 : Relative surface factor $Y_{Rrel\ T}$

Material	Y_{RrelT}	
	$R_z < 0,1$	$0,1 \leq R_z \leq 40$
V, V (cast), GGG (perl.), GGG (bai.), Eh, IF	1,120	$1,674 - 0,529\ (R_z + 1)^{0,1}$
St	1,070	$5,306 - 4,203\ (R_z + 1)^{0,01}$
GG, GGG (ferr.), NT, NV	1,025	$4,299 - 3,259\ (R_z + 1)^{0,0058}$
Note 1: R_z : Mean peak-to-valley roughness, in µm: $R_z = 6\ R_a$ with R_a : Arithmetic mean roughness.		

2.5.14 Size factor Y_X

The size factor Y_X takes into account the decrease of the strength with increasing size.

The values to be adopted for Y_X are given in Tab 23 in relation to the type of steel employed and the value of the normal module m_n.

Table 23 : Size factor Y_X

Material	Normal module	Y_X
St, V, V (cast), GGG (perl.), GGG (bai.), GTS (perl.)	$m_n \leq 5$	1,00
	$5 < m_n < 30$	$1,03 - 0,006\ m_n$
	$m_n \geq 30$	0,85
Eh, IF, NT, NV	$m_n \leq 5$	1,00
	$5 < m_n < 25$	$1,05 - 0,01\ m_n$
	$m_n \geq 25$	0,80
GG, GGG (ferr.)	$m_n \leq 5$	1,00
	$5 < m_n < 25$	$1,075 - 0,015\ m_n$
	$m_n \geq 25$	0,70

2.5.15 Safety factor for tooth root bending stress S_F

The values to be adopted for the safety factor for tooth root bending stress S_F are given in Tab 24.

Table 24 : Safety factor for tooth root bending stress S_F

Type of installation		S_F
Main gears (propulsion)	single machinery	1,80
	duplicate machinery	1,60
Auxiliary gears		1,40

2.6 Calculation of scuffing resistance

2.6.1 General

The following calculations are requested for equipment running in supercritical domain, i.e. when N > 1,5 (see [2.3.4]).

The criterion for scuffing resistance is based on the calculation of the flash temperature method. According to this method, the risk of scuffing is assessed as a function of the properties of gear material, the lubricant characteristics, the surface roughness of tooth flanks, the sliding velocities and the load.

The interfacial contact temperatures are calculated as the sum of the interfacial bulk temperature of the moving interface and the fluctuating flash temperature of the moving faces in contact.

The maximum value of the interfacial contact temperature reduced by oil temperature is not to exceed 0,8 times the scuffing temperature reduced by oil temperature:

$(\Theta_{B,Max} - \Theta_{oil}) \leq 0,8\ (\Theta_S - \Theta_{oil})$

where:

$\Theta_{B,Max}$: Maximum contact temperature along the path of contact, in °C, defined in [2.6.2]

Θ_{oil} : Oil temperature, in °C

Θ_S : Scuffing temperature, in °C, defined in [2.6.11].

Additionally, the difference between the scuffing temperature and the contact temperature along the path is not to be below 30°C:

$(\Theta_S - \Theta_{B,Max}) \geq 30°C$

Other methods of determination of the scuffing resistance could be accepted by the Society.

2.6.2 Contact temperature Θ_B

The maximum contact temperature $\Theta_{B,Max}$ along the path of contact, in °C, is calculated as follows:

$\Theta_{B,Max} = \Theta_{Mi} - \Theta_{fl,Max}$

where:

Θ_{Mi} : Interfacial bulk temperature, in °C, defined in [2.6.10]

$\Theta_{fl,Max}$: Maximum flash temperature along the path of contact, in °C, defined in [2.6.3].

The flash temperature should be calculated on at least ten points along the path of contact and the maximum of these values has to be used for the calculation of maximum contact temperature.

2.6.3 Flash temperature Θ_{fl}

The flash temperature Θ_{fl} at any point along the path of contact, in °C, is calculated with the following formula:

$$\Theta_{fl} = \mu_m \cdot X_M \cdot X_J \cdot X_G \cdot (X_\Gamma \cdot w_{Bt})^{0,75} \cdot \frac{v^{0,5}}{a^{0,25}}$$

where:

μ_m : Mean coefficient of friction, defined in [2.6.4]

X_M : Thermo-elastic factor, in $K \cdot N^{-3/4} \cdot s^{-1/2} \cdot m^{-1/2} \cdot mm$, defined in [2.6.5]

X_J : Approach factor, defined in [2.6.6]

X_G : Geometry factor, defined in [2.6.7]

X_Γ : Load sharing factor, defined in [2.6.8]

w_{Bt} : Transverse unit load, in N/mm, defined in [2.6.9].

2.6.4 Mean coefficient of friction μ_m

An estimation of the mean coefficient of friction μ_m of common working conditions could be used with the following formula:

$$\mu_m = 0,6 \cdot \left(\frac{w_{Bt}}{v_{g\Sigma C} \cdot \rho_{relC}}\right)^{0,2} \cdot X_L \cdot X_R$$

where:

w_{Bt} : Transverse unit load, in N/mm, defined in [2.6.9]

$v_{g\Sigma C}$: Sum of tangential velocities in pitch point, in m/s:

$v_{g\Sigma C} = 2\ v \sin \alpha_{wt}$

with v not taken greater than 50 m/s

ρ_{relC} : Transverse relative radius of curvature, in mm:

$$\rho_{relC} = \frac{u}{(1+u)^2} \cdot a \cdot \sin\alpha_{wt}$$

X_L : Lubricant factor, given in Tab 25

X_R : Roughness factor, equal to:

$$X_R = \left(\frac{R_{zf1} + R_{zf2}}{2}\right)^{0,25}$$

Table 25 : Lubricant factor X_L

Type of lubricant	X_L **(1)**
Mineral oils	$X_L = 1,0\ \eta_{oil}{}^{-0,05}$
Water soluble polyglycols	$X_L = 0,6\ \eta_{oil}{}^{-0,05}$
Non water soluble polyglycols	$X_L = 0,7\ \eta_{oil}{}^{-0,05}$
Polyalfaolefins	$X_L = 0,8\ \eta_{oil}{}^{-0,05}$
Phosphate esters	$X_L = 1,3\ \eta_{oil}{}^{-0,05}$
Traction fluids	$X_L = 1,5\ \eta_{oil}{}^{-0,05}$
(1) η_{oil} is the dynamic viscosity at oil temperature Θ_{oil}.	

2.6.5 Thermo-elastic factor X_M

The thermo-elastic factor X_M accounts for the influence of the material properties of pinion and wheel:

$$X_M = 1000\frac{E_r^{0,25}}{B_M}$$

where:

E_r : Reduced modulus of elasticity, in N/mm²:

$$E_r = \frac{2}{(1-\nu_1)/E_1 + (1-\nu_2)/E_2}$$

E_1, E_2 : Moduli of elasticity of pinion and wheel material, in N/mm²

ν_1, ν_2 : Poisson's ratios of pinion and wheel material

B_M : Mean thermal contact coefficient, in $N\cdot mm^{-1/2}\cdot m^{-1/2}\cdot s^{-1/2}\cdot K^{-1}$, equal to:

$B_M = (B_{M1} + B_{M2}) / 2$

B_{Mi} : Thermal contact coefficient of pinion material (i = 1) and wheel material (i = 2), given in $N\cdot mm^{-1/2}\cdot m^{-1/2}\cdot s^{-1/2}\cdot K^{-1}$ and equal to:

$B_{Mi} = (0,001\ \lambda_{Mi}\ \rho_{Mi}\ c_{Mi})^{0,5}$

An average value of 435 $N\cdot mm^{-1/2}\cdot m^{-1/2}\cdot s^{-1/2}\cdot K^{-1}$ for martensitic steels could be used when thermo-elastic coefficient is not known

λ_{Mi} : Heat conductivity of pinion material (i = 1) and wheel material (i = 2), in $N\cdot s^{-1}\cdot K^{-1}$

ρ_{Mi} : Density of pinion material (i = 1) and wheel material (i = 2), in $kg\cdot m^{-3}$

c_{Mi} : Specific heat per unit mass of pinion material (i = 1) and wheel material (i = 2), in $J\cdot kg^{-1}\cdot K^{-1}$.

2.6.6 Approach factor X_J

The approach factor X_J takes empirically into account an increased scuffing risk in the beginning of the approach path, due to mesh starting without any previously built up oil film. The approach factor at any point should be calculated according to the following formula:

- when pinion drives the wheel:
  - for $\Gamma \geq 0$:

    $X_J = 1$
  - for $\Gamma < 0$, provided that $X_J \geq 1$:

$$X_J = 1 + \frac{C_{eff} - C_{a2}}{50}\left(\frac{-\Gamma}{\Gamma_E - \Gamma_A}\right)^3$$

- when wheel drives the pinion:
  - for $\Gamma \le 0$:

    $X_J = 1$
  - for $\Gamma > 0$, provided that $X_J \ge 1$:

$$X_J = 1 + \frac{C_{eff} - C_{a1}}{50}\left(\frac{\Gamma}{\Gamma_E - \Gamma_A}\right)^3$$

where:

C_{eff} : Optimal tip relief, in µm:

$$C_{eff} = \frac{K_A K_\gamma F_t}{b \cdot \cos\alpha_t \cdot c_\gamma}$$

K_A : Application factor (see [2.3.2])

K_γ : Load sharing factor (see [2.3.3])

$c_{\alpha\gamma}$: Mesh stiffness, in N/(mm.µm) (see Tab 9)

C_{ai} : Tip relief of pinion or wheel, in µm

Γ : Parameter of the point on the line of action, defined in Tab 26

Γ_A : Parameter of the lower end point of the path of contact, defined in Tab 26

Γ_E : Parameter of the upper end point of the path of contact, defined in Tab 26.

2.6.7 Geometry factor X_G

The geometry factor X_G is calculated according to the following conditions:

- for external gear pair:

$$X_G = 0{,}51\ X_{\alpha\beta}(u+1)^{0,5}\frac{\left|(1+\Gamma)^{0,5} - (1-\Gamma/u)^{0,5}\right|}{(1+\Gamma)^{0,25}(u-\Gamma)^{0,25}}$$

- for internal gear pair:

$$X_G = 0{,}51\ X_{\alpha\beta}(u-1)^{0,5}\frac{\left|(1+\Gamma)^{0,5} - (1+\Gamma/u)^{0,5}\right|}{(1+\Gamma)^{0,25}(u+\Gamma)^{0,25}}$$

where:

$X_{\alpha\beta}$: Angle factor, equal to:

$X_{\alpha\beta} = 1{,}22\ (\sin\alpha_{wt})^{0,25}\ (\cos\alpha_{wt})^{-0,5}\ (\cos\beta_b)^{0,25}$

Γ : Parameter of the point on the line of action, defined in Tab 26.

Table 26 : Parameter Γ on the line of action

Point	Γ
A : Lower end point of the path of contact	$\Gamma_A = -\frac{z_2}{z_1}\left(\frac{\tan\alpha_{a2}}{\tan\alpha_{wt}} - 1\right)$
AU: Lower end point of buttressing effect	$\Gamma_{AU} = \Gamma_A + 0{,}2\sin\beta_b$
AB : Intermediate point between A and B	$\Gamma_{AB} = 0{,}5\ (\Gamma_A + \Gamma_B)$
B : Lower point of single pair tooth contact	$\Gamma_B = \frac{\tan\alpha_{a1}}{\tan\alpha_{wt}} - 1 - \frac{2\pi}{z_1\tan\alpha_{wt}}$
C : Point with parameter equal to 0	$\Gamma_C = 0$
M : Intermediate point between A and E	$\Gamma_M = 0{,}5\ (\Gamma_A + \Gamma_E)$
D : Upper point of single pair tooth contact	$\Gamma_D = -\frac{z_2}{z_1}\left(\frac{\tan\alpha_{a2}}{\tan\alpha_{wt}} - 1\right) + \frac{2\pi}{z_1\tan\alpha_{wt}}$
DE : Intermediate point between D and E	$\Gamma_{DE} = 0{,}5\ (\Gamma_D + \Gamma_E)$
EU : Upper end point of buttressing effect	$\Gamma_{EU} = \Gamma_E - 0{,}2\sin\beta_b$
E : Upper end point of the path of contact	$\Gamma_E = \frac{\tan\alpha_{a1}}{\tan\alpha_{wt}} - 1$

2.6.8 Load sharing factor X_Γ

The load sharing factor X_Γ accounts for the load sharing of succeeding pairs of meshing teeth. It is defined as a function of the value of the parameter in the line of action, increasing at the approach path of transverse double contact.

- for narrow helical gears ($\varepsilon_\gamma < 2$) with unmodified profiles:

  $X_\Gamma = X_{\Gamma,u}\, X_{but}$
- for narrow helical gears ($\varepsilon_\gamma < 2$) with profile modification:

  $X_\Gamma = X_{\Gamma,m}\, X_{but}$
- for wide helical gears ($\varepsilon_\gamma \geq 2$) with unmodified profiles:

  $$X_\Gamma = \frac{1}{\varepsilon_\alpha} X_{but}$$
- for wide helical gears ($\varepsilon_\gamma \geq 2$) with profile modification:

  $X_\Gamma = X_{\Gamma,wm}\, X_{but}$

where:

X_{but} : Buttressing factor:

- for $\Gamma < \Gamma_{AU}$:

  $$X_{but} = X_{butA} - \frac{\Gamma - \Gamma_A}{\Gamma_{AU} - \Gamma_A}(X_{butA} - 1)$$
- for $\Gamma_{AU} \leq \Gamma \leq \Gamma_{EU}$:

  $X_{but} = 1$
- for $\Gamma_{EU} < \Gamma$:

  $$X_{but} = X_{butE} - \frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_{EU}}(X_{butE} - 1)$$

Note 1: X_{but} is to be taken equal to 1 if $C_{ai} \geq C_{eff}$

X_{butA} , X_{butE} : Buttressing factors at, respectively, lower and upper end points of the path of contact:

$X_{butA} = X_{butE} = 1 + 0{,}3\ \varepsilon_\beta$, provided that

$X_{butA} = X_{butE} < 1{,}3$

$X_{\Gamma,u}$: Load sharing factor for unmodified profiles:

- for $\Gamma < \Gamma_B$:

  $$X_{\Gamma,u} = \frac{A-3}{12} + \frac{1}{3}\frac{\Gamma - \Gamma_A}{\Gamma_B - \Gamma_A}$$
- for $\Gamma_B \leq \Gamma \leq \Gamma_D$:

  $X_{\Gamma,u} = 1$
- for $\Gamma_D < \Gamma$:

  $$X_{\Gamma,u} = \frac{A-3}{12} + \frac{1}{3}\frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_D}$$

Note 2: A is to be taken at least equal to 7.

$X_{\Gamma,m}$: Load sharing factor for profile modification:

- for $\Gamma < \Gamma_{AB}$, provided that $X_{\Gamma,m} \geq 0$:

  $$X_{\Gamma,m} = \left(1 - \frac{C_{a2}}{C_{eff}}\right)\frac{1}{3} + \left(\frac{1}{3} + \frac{2}{3}\frac{C_{a2}}{C_{eff}}\right)\frac{\Gamma - \Gamma_A}{\Gamma_B - \Gamma_A}$$
- for $\Gamma_{AB} \leq \Gamma < \Gamma_B$, provided that $X_{\Gamma,m} \leq 1$:

  $$X_{\Gamma,m} = \left(1 - \frac{C_{a1}}{C_{eff}}\right)\frac{1}{3} + \left(\frac{1}{3} + \frac{2}{3}\frac{C_{a1}}{C_{eff}}\right)\frac{\Gamma - \Gamma_A}{\Gamma_B - \Gamma_A}$$
- for $\Gamma_B \leq \Gamma \leq \Gamma_D$:

  $X_{\Gamma,m} = 1$
- for $\Gamma_D < \Gamma \leq \Gamma_{DE}$, provided that $X_{\Gamma,m} \leq 1$:

  $$X_{\Gamma,m} = \left(1 - \frac{C_{a2}}{C_{eff}}\right)\frac{1}{3} + \left(\frac{1}{3} + \frac{2}{3}\frac{C_{a2}}{C_{eff}}\right)\frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_D}$$
- for $\Gamma_{DE} < \Gamma$, provided that $X_{\Gamma,m} \geq 0$:

  $$X_{\Gamma,m} = \left(1 - \frac{C_{a1}}{C_{eff}}\right)\frac{1}{3} + \left(\frac{1}{3} + \frac{2}{3}\frac{C_{a1}}{C_{eff}}\right)\frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_D}$$

$X_{\Gamma,wm}$: Load sharing factor for profile modification:

- for $\Gamma < \Gamma_{AB}$, provided that $X_{\Gamma,wm} \geq 0$:

$$X_{\Gamma,wm} = \left(1 - \frac{C_{a2}}{C_{eff}}\right)\frac{1}{\varepsilon_\alpha} + \frac{(\varepsilon_\alpha - 1)C_{a1} + (3\varepsilon_\alpha + 1)C_{a2}}{2\varepsilon_\alpha(\varepsilon_\alpha + 1)C_{eff}} \cdot \frac{\Gamma - \Gamma_A}{\Gamma_B - \Gamma_A}$$

- for $\Gamma_{AB} \leq \Gamma \leq \Gamma_{DE}$, provided that $X_{\Gamma,wm} \leq 1$:

$$X_{\Gamma,wm} = \frac{1}{\varepsilon_\alpha} + \frac{(\varepsilon_\alpha - 1)(C_{a1} + C_{a2})}{2\varepsilon_\alpha(\varepsilon_\alpha + 1)C_{eff}}$$

- for $\Gamma_{DE} < \Gamma$, provided that $X_{\Gamma,wm} \geq 0$:

$$X_{\Gamma,wm} = \left(1 - \frac{C_{a1}}{C_{eff}}\right)\frac{1}{\varepsilon_\alpha} + \frac{(\varepsilon_\alpha - 1)C_{a2} + (3\varepsilon_\alpha + 1)C_{a1}}{2\varepsilon_\alpha(\varepsilon_\alpha + 1)C_{eff}} \cdot \frac{\Gamma_E - \Gamma}{\Gamma_E - \Gamma_{DE}}$$

C_{eff} : Optimal tip relief, in µm (see [2.6.6])

C_{ai} : Tip relief of pinion or wheel, in µm

Γ_i : Parameter of any point on the line of action, given in Tab 26.

2.6.9 Transverse unit load w_{Bt}

The transverse unit load w_{Bt} is calculated according to the following formula:

$$w_{Bt} = K_A \cdot K_V \cdot K_{H\beta} \cdot K_{H\alpha} \cdot K_\gamma \cdot \frac{F_t}{b}$$

where:

K_A : Application factor (see [2.3.2])

K_V : Dynamic factor (see [2.3.4])

$K_{H\beta}$: Face load distribution factor (see [2.3.5])

$K_{H\alpha}$: Transverse load distribution factor (see [2.3.6])

K_γ : Load sharing factor (see [2.3.3]).

2.6.10 Interfacial bulk temperature Θ_{Mi}

The interfacial bulk temperature Θ_{Mi} may be suitably averaged from the two overall bulk temperatures of the teeth in contact, Θ_{M1} and Θ_{M2}. The following estimation could be used in general configurations:

$\Theta_{Mi} = \Theta_{oil} + 0,47\ X_S\ X_{mp}\ \Theta_{fl,m}$

where:

Θ_{oil} : Oil temperature, in °C

X_S : Lubrication system factor:

- for spray lubrication: $X_S = 1,2$
- for dip lubrication: $X_S = 1,0$
- for meshes with additional spray for cooling purpose: $X_S = 1,0$
- for gears submerged in oil, provided sufficient cooling: $X_S = 0,2$

X_{mp} : Multiple mating pinion factor:

$$X_{mp} = \frac{3 + n_p}{4}$$

n_p : Number of mesh in contact

$\Theta_{fl,m}$: Average flash temperature on the path of contact, in °C.
The average temperature should be calculated on at least ten equidistant points on the path line of contact between Γ_A and Γ_E.

2.6.11 Scuffing temperature Θ_S

The scuffing temperature Θ_S may be determined according to the following formula:

$\Theta_S = 80 + (0,85 + 1,4\ X_W)\ X_L\ (S_{FZG} - 1)^2$

where:

X_W : Structural factor given in Tab 27

X_L : Lubricant factor given in Tab 25

S_{FZG} : Load stage where scuffing occurs, according to gear tests, such as Ryder, FZG-Ryder, FZG L-42 or FZG A/8 3/90.

Table 27 : Structural factor X_W

Material	X_W
Through-hardened steel	1,00
Phosphated steel	1,25
Copper-plated steel	1,50
Bath or gas nitrided steel	1,50
Hardened carburized steel, with austenite content less than 10%	1,15
Hardened carburized steel, with austenite content between 10% and 20%	1,00
Hardened carburized steel, with austenite content above 20%	0,85
Austenite steel (stainless steel)	0,45

3 Design of gears - Determination of the load capacity of bevel gears

3.1 Symbols, units, definitions

3.1.1 Symbols and units

The meaning of the main symbols used in this Article is specified below.

Other symbols introduced in connection with the definition of influence factors are defined in the appropriate sub-articles.

A : Flank tolerance class according to ISO 1328-1:2013
a_v : Virtual operating centre distance, in mm
a_{vn} : Virtual operating centre distance, in mm
b : Effective face width, in mm
d_e : Outer pitch diameter, in mm
d_{ext} : External diameter of shaft, in mm
d_{int} : Internal diameter of shaft, in mm
d_m : Mean pitch diameter, in mm
d_s : Shrinkage diameter of the wheel, in mm
d_v : Virtual reference diameter, in mm
d_{va} : Virtual tip diameter, in mm
d_{van} : Virtual tip diameter, in mm
d_{vb} : Virtual base diameter, in mm
d_{vbn} : Virtual base diameter, in mm
d_{vf} : Virtual root diameter, in mm
d_{vn} : Virtual reference diameter, in mm
F_{mt} : Nominal tangential load, in N
F_β : Total helix deviation, in μm
$g_{v\alpha}$: Length of path of contact, in mm
$g_{v\alpha n}$: Length of path of contact, in mm
h_{aP} : Basic rack addendum, in mm
h_{fP} : Basic rack dedendum, in mm
h_v : Virtual tooth depth, in mm
HB : Brinell hardness, in N/mm²
HPX : Rockwell hardness
Hς : Vickers hardness, in N/mm²
κ : Gear axial position on shaft with respect to the bearings
ℓ : Bearing span, in mm
ℓ_{bm} : Length of the line of contact, in mm
ℓ'_{bm} : Length of the line of contact, in mm
m_{et} : Outer transverse module, in mm
m_{mn} : Mean normal module, in mm
m_{mt} : Mean transverse module, in mm
n : Rotational speed, in rpm
Π : Transmitted power, in kW

p_{et} : Transverse base pitch, in mm
pr : Protuberance of the tool, in mm
q : Material allowance for finish machining, in mm
r_{c0} : Cutter radius, in mm
ρ_e : Outer cone distance, in mm
$P_{\varepsilon,\sigma}$: Minimum yield strength of the shaft material, in N/mm²
ρ_m : Mean cone distance, in mm
$P_{m,rim}$: Ultimate tensile strength of the rim material, in N/mm²
P_Z : Mean peak-to-valley roughness, in µm
P_{Zf} : Mean peak-to-valley flank roughness, in µm
s_R : Rim thickness, in mm
T : Transmitted torque, in kN·m
u : Reduction ratio
u_v : Virtual reduction ratio
v_{mt} : Linear speed at mean pitch diameter, in m/s
x_h : Addendum modification coefficient
x_S : Thickness modification coefficient
z : Number of teeth
z_v : Virtual number of teeth
z_{vn} : Virtual number of teeth
α_n : Normal pressure angle
α_{vt} : Virtual transverse pressure angle
β_m : Mean helix angle
β_{vb} : Virtual base helix angle
δ : Pitch angle
$\varepsilon_{v\alpha}$: Virtual transverse contact ratio
$\varepsilon_{v\alpha n}$: Virtual transverse contact ratio
$\varepsilon_{v\beta}$: Virtual overlap ratio
$\varepsilon_{v\gamma}$: Virtual total contact ratio
ν_{40} : Nominal kinematic viscosity of oil at 40°C, in mm²/s
ρ_{a0} : Tip radius of the tool, in mm
σ_F : Tooth root bending stress, in N/mm²
σ_{FE} : Endurance limit for tooth root bending stress, in N/mm²
σ_{FP} : Permissible tooth root bending stress, in N/mm²
σ_H : Contact stress, in N/mm²
$\sigma_{H,lim}$: Endurance limit for contact stress, in N/mm²
σ_{HP} : Permissible contact stress, in N/mm².

Subscripts:

- 1 for pinion, i.e. the gear having the smaller number of teeth
- 2 for wheel.

3.1.2 Geometrical definitions

In the calculation of surface durability, b is the minimum face width on the pitch diameter between pinion and wheel.

In tooth strength calculations, b_1 and b_2 are the face widths at the respective tooth roots. In any case, b_1 or b_2 are not to be taken greater than b by more than one module m_{mn} (in case of width of one gear much more important than the other).

a) General geometrical definitions

$$u = \frac{z_2}{z_1}$$

$$d_{ei} = \frac{z_i m_{mn}}{\cos\beta_m} + b_i \sin\delta_i$$

$$r_e = \frac{d_{e1}}{2\sin\delta_1} = \frac{d_{e2}}{2\sin\delta_2}$$

$$r_m = r_e - 0{,}5\ b$$

$$m_{et} = \frac{d_{e1}}{z_1} = \frac{d_{e2}}{z_2}$$

$$m_{mt} = \frac{r_m m_{et}}{r_e}$$

$$d_{mi} = \frac{z_i m_{mn}}{\cos \beta_m}$$

b) Geometrical definitions of virtual cylindrical gears in transverse section (suffix v)

$$z_{vi} = \frac{z_i}{\cos \delta_i}$$

$$u_v = \frac{z_{v2}}{z_{v1}}$$

$$\tan \alpha_{vt} = \frac{\tan \alpha_n}{\cos \beta_m}$$

$\sin \beta_{vb} = \sin \beta_m \cdot \cos \alpha_n$

$$d_{vi} = \frac{d_{mi}}{\cos \delta_i}$$

$a_v = 0{,}5\ (d_{v1} + d_{v2})$

$d_{v\alpha\iota} = d_{vi} + 2\ h_{aPi}$

$d_{v\beta\iota} = d_{vi} \cos \alpha_{vt}$

$d_{v\phi\iota} = d_{vi} + 2\ m_{mn}\ x_{hi} - 2\ h_{fPi}$

$h_{v\iota} = 0{,}5\ (d_{vai} - d_{vfi})$

$p_{\varepsilon\tau} = m_{mt}\ \pi \cos \alpha_{vt}$

$$g_{v\alpha} = 0{,}5\ \left(\sqrt{d_{va1}^2 - d_{vb1}^2} + \sqrt{d_{va2}^2 - d_{vb2}^2}\right) - a_v \sin \alpha_{vt}$$

$$\varepsilon_{v\alpha} = \frac{g_{v\alpha}}{p_{et}}$$

$$\varepsilon_{v\beta} = \frac{b \sin \beta_m}{\pi m_{mn}}$$

$$\varepsilon_{v\gamma} = \sqrt{\varepsilon_{v\alpha}^2 + \varepsilon_{v\beta}^2}$$

- if $\varepsilon_{v\beta} < 1$:

$$\ell_{bm} = \frac{b \varepsilon_{v\alpha}}{\cos \beta_{vb} \cdot \varepsilon_{v\gamma}^2} \cdot \sqrt{\varepsilon_{v\gamma}^2 - (2 - \varepsilon_{v\alpha})^2 \cdot (1 - \varepsilon_{v\beta})^2}$$

- if $\varepsilon_{v\beta} \geq 1$:

$$\ell_{bm} = \frac{b \varepsilon_{v\alpha}}{\cos \beta_{vb} \cdot \varepsilon_{v\gamma}}$$

$\ell'_{bm} = \ell_{\beta\mu} \cos \beta_{vb}$

c) Geometrical definitions of virtual cylindrical gears in normal section (suffix vn)

$$z_{vni} = \frac{z_{vi}}{\cos \beta_m \cdot (\cos \beta_{vb})^2}$$

$d_{v\nu\iota} = m_{mn}\ \zeta_{v\nu\iota}$

$a_{vn} = 0{,}5\ (d_{vn1} + d_{vn2})$

$d_{v\alpha\nu\iota} = d_{vni} + 2\ h_{aPi}$

$d_{v\beta\nu\iota} = d_{vni} \cos \alpha_v$

$$g_{v\alpha n} = 0{,}5\ \left(\sqrt{d_{van1}^2 - d_{vbn1}^2} + \sqrt{d_{van2}^2 - d_{vbn2}^2}\right) - a_{vn} \sin \alpha_n$$

$$\varepsilon_{v\alpha n} = \frac{\varepsilon_{v\alpha}}{(\cos \beta_{vb})^2}$$

d) Definitions of transmissions characteristics

$$T_i = \frac{60}{2\pi} \cdot \frac{P}{n_i}$$

$$F_{mt} = \frac{P}{n_1} \cdot \frac{60}{\pi d_{m1}} \cdot 10^6$$

$$v_{mt} = \frac{\pi n_1}{60} \cdot \frac{d_{m1}}{10^3} = \frac{\pi n_2}{60} \cdot \frac{d_{m2}}{10^3}$$

$$F_{\beta i} = 2^{0,5 \cdot (Q_i - 5)} \cdot (0{,}1\ \cdot d_{vi}^{0,5} + 0{,}63\ \sqrt{b} + 4{,}2)$$

3.2 Principle

3.2.1

a) The following requirements apply to bevel spur or helical gears with external teeth, and provide a method for the calculation of the load capacity with regard to:

- the surface durability (contact stress)
- the tooth root bending stress.

The bevel gears for marine application are to comply with the following restrictions:

- $1,2 < \varepsilon_{v\alpha} < 2,5$
- $\beta_m < 30°$
- $s_R > 3,5\ m_{mn}$

The relevant formulae are provided in [3.4] and [3.5].

The influence factors common to the formulae are given in [3.3].

b) Gears, for which the conditions of validity of some factors or formulae are not satisfied, will be given special consideration by the Society.

c) Other methods of determination of load capacity will be given special consideration by the Society. Any alternative calculations are to comply with the ISO 6336 series standards.

3.3 General influence factors

3.3.1 General

General influence factors are defined in [3.3.2], [3.3.3], [3.3.4], [3.3.5] and [3.3.6]. Alternative values may be used provided they are derived from appropriate measurements.

3.3.2 Application factor K_A

The application factor K_A accounts for dynamic overloads from sources external to the gearing (driven and driving machines).

The values of K_A to be used are given in Tab 5.

3.3.3 Load sharing factor K_γ

The load sharing factor K_γ accounts for the uneven sharing of load on multiple path transmissions, such as epicyclic gears or tandem gears.

The values of K_γ to be used are given in Tab 6.

3.3.4 Dynamic factor K_V

The dynamic factor K_V accounts for the additional internal dynamic loads acting on the tooth flanks and due to the vibrations of the pinion and wheel.

The calculation of the dynamic factor K_V is defined in Tab 31, where:

N : Resonance ratio, i.e. ratio of the pinion speed to the resonance speed:

$N = n_1 / n_{E1}$, with:

n_{E1} : Resonance speed, in rpm, defined by the following formula:

$$n_{E1} = \frac{30000}{\pi \cdot z_1} \cdot \sqrt{\frac{c_\gamma}{m_{red}}}$$

where:

m_{red} : Reduced mass of gear pair, in kg/mm. Estimated calculation of m_{red} is given by the following formula:

$$m_{red} = \frac{\rho \cdot \pi}{8} \cdot \frac{d_{m1}^2}{(\cos\alpha_n)^2} \cdot \frac{u^2}{1+u^2}$$

ρ : Density of gearing material, equal to:

$\rho = 7,83 \cdot 10^6$ for steel

c_γ : Mesh stiffness, in N/(mm.µm):

$c_\gamma = 20\ C_F\ C_b$

C_F and C_b being the correction factors for non average conditions defined in Tab 28.

The value of N determines the range of vibrations:

- subcritical range, when $N \leq 0,75$
- main resonance range, when $0,75 < N < 1,25$

  This field is not permitted

- intermediate range, when $1,25 \le N \le 1,50$

  This field is normally to be avoided. Some alternative and more precise calculation could be accepted and special consideration will be given by the Society
- supercritical range, when $1,50 < N$.

3.3.5 Face load distribution factors $K_{H\beta}$ and $K_{F\beta}$

The face load distribution factors, $K_{H\beta}$ for contact stress and $K_{F\beta}$ for tooth root ending stress, account for the effects of non-uniform distribution of load across the face width.

a) The calculation of $K_{H\beta}$ is to be defined according to the mounting conditions of pinion and wheel:

- neither member cantilever mounted:

  $K_{H\beta} = 1,575 / C_b$
- one member cantilever mounted:

  $K_{H\beta} = 1,650 / C_b$
- both members cantilever mounted:

  $K_{H\beta} = 1,875 / C_b$

where C_b is the correction factor defined in Tab 28

b) $K_{F\beta}$ is to be determined using the following formula:

$K_{F\beta} = K_{H\beta} / K_{F0}$, with:

K_{F0} : Lengthwise curvature factor. It is to be taken above 1,0 and below 1,15 considering the following formula:

$$K_{F0} = 0,211 \cdot \left(\frac{r_{c0}}{r_m}\right)^{\frac{0,279}{\log(\sin\beta_m)}} + 0,789$$

3.3.6 Transverse load distribution factors $K_{H\alpha}$ and $K_{F\alpha}$

The transverse load distribution factors, $K_{H\alpha}$ for contact stress and $K_{F\alpha}$ for tooth root bending stress, account for the effects of pitch and profile errors on the transversal load distribution between two or more pairs of teeth in mesh.

The values of $K_{H\alpha}$ and $K_{F\alpha}$ are given in Tab 29.

Table 28 : Correction factors C_F and C_b

Conditions	Factors C_F and C_b
if $F_{mt}\, K_A / b_e \ge 100$ N/mm	$C_F = 1$
if $F_{mt}\, K_A / b_e < 100$ N/mm	$C_F = (F_{mt}\, K_A / b_e) / 100$
if $b_e / b \ge 0,85$	$C_b = 1$
if $b_e / b < 0,85$	$C_b = (b_e / b) / 0,85$
b_e : Effective face width, the real length of contact pattern. When b_e is not supplied, $b_e = 0,85\, b$ could be used.	

Table 29 : Transverse load factors $K_{H\alpha}$ and $K_{F\alpha}$

	Factors $K_{H\alpha}$ and $K_{F\alpha}$	Limitations
$\varepsilon_{v\gamma} \le 2$	$K_{H\alpha} = K_{F\alpha} = \frac{\varepsilon_{v\gamma}}{2} \cdot \left(0,9 + 0,4 \cdot \frac{c_\gamma \cdot (f_{pt} - y_\alpha)}{F_{mtH}/b}\right)$	$\frac{\varepsilon_{v\gamma}}{\varepsilon_{v\alpha} \cdot Z_{LS}^2} \ge K_{H\alpha} \ge 1$
$\varepsilon_{v\gamma} > 2$	$K_{H\alpha} = K_{F\alpha} = 0,9 + 0,4 \cdot \sqrt{\frac{2 \cdot (\varepsilon_{v\gamma} - 1)}{\varepsilon_{v\gamma}}} \cdot \frac{c_\gamma \cdot (f_{pt} - y_\alpha)}{F_{mtH}/b}$	$\frac{\varepsilon_{v\gamma}}{\varepsilon_{v\alpha} \cdot Y_\varepsilon} \ge K_{F\alpha} \ge 1$
Note 1: c_γ : Mesh stiffness, in N/mm.µm, defined in [3.3.4] $f_{\pi\tau}$: Larger value of the single pitch deviation of pinion or wheel, in µm. Default value: $f_{pt} = 0,3\,(m_{mn} + 0,4\,\lvert d_{bi}\rvert^{0,5} + 4) \cdot 2^{0,5\,(Q_i - 5)}$ In case of optimum profile correction, f_{pt} is to be replaced by $f_{pt} / 2$ y_α : Running-in allowance, in µm, defined in Tab 30 $f_{\mu\tau H}$: Determinant tangential load at mid-face width on the reference cone, in N: $F_{\mu\tau H} = F_{\mu\tau} \cdot K_A \cdot K_V \cdot K_{H\beta}$		

Table 30 : Running-in allowance y_α

Material	y_α , in µm	Limitations
St, St (cast), GTS (perl.), GGG (perl.), GGG (bai.), V, V (cast)	$\dfrac{160}{\sigma_{H,\,lim}} f_{pt}$	• if 5 m/s < v ≤ 10 mm/s: $y_\alpha \leq 12800 / \sigma_{H,lim}$ • if 10 m/s < v: $y_\alpha \leq 6400 / \sigma_{H,lim}$
GGG (ferr.), GG	0,275 f_{pt}	• if 5 m/s < v ≤ 10 mm/s: $y_\alpha \leq 22$ • if 10 m/s < v: $y_\alpha \leq 11$
Eh, IF, NT (nitr.), NV (nitr.), NV (nitrocar.)	0,075 f_{pt}	$y_\alpha \leq 3$

Note 1: f_{pt} ισ δεφινεδ ιν Tab 29 ανδ $\sigma_{H,lim}$ is defined in [3.4.10].
Note 2: When material of the pinion differs from that of the wheel: $y_\alpha = 0,5\ (y_{\alpha 1} + y_{\alpha 2})$

Table 31 : Dynamic factor K_V

Resonance domain	Factor K_V
N ≤ 0,75	$K_V = N\ (C_{V1}\ B_p + C_{V2}\ B_f + C_{V3}) + 1$
N > 1,50	$K_V = C_{V5}\ B_p + C_{V6}\ B_f + C_{V7}$

Note 1:

B_p : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications:

$$B_p = \frac{c' f_{p,\,eff}}{K_A (F_{mt}/b)}$$

with:

c' : Single stiffness, in N/(mm·µm):
$c' = 14\ C_F\ C_b$, with C_F and C_b defined in Tab 28

$f_{\pi,\varepsilon\phi\phi}$: Effective base pitch deviation, in µm:
$f_{\pi,\varepsilon\phi\phi} = f_{\pi\tau} - y_\alpha$
with f_{pt} defined in Tab 29 and y_α defined in Tab 30

B_f : Non-dimensional parameter taking into account the effect of tooth deviations and profile modifications:
$B_f = B_p$

C_{V1} : Factor for pitch deviation effects:
$C_{v1} = 0,32$

C_{V2} : Factor for tooth profile deviation effects:

- if $1 < \varepsilon_\gamma \leq 2$:
  $C_{V2} = 0,34$
- if $2 < \varepsilon_\gamma$:

$$C_{V2} = \frac{0,57}{\varepsilon_\gamma - 0,3}$$

C_{V3} : Factor for cyclic variation effect in mesh stiffness:

- if $1 < \varepsilon_\gamma \leq 2$:
  $C_{V3} = 0,23$
- if $2 < \varepsilon_\gamma$:

$$C_{V3} = \frac{0,096}{\varepsilon_\gamma - 1,56}$$

C_{V5} : Factor equal to: $C_{V5} = 0,47$

C_{V6} : Factor:

- if $1 < \varepsilon_\gamma \leq 2$:
  $C_{V6} = 0,47$
- if $2 < \varepsilon_\gamma$:

$$C_{V6} = \frac{0,12}{\varepsilon_\gamma - 1,74}$$

C_{V7} : Factor:

- if $1 < \varepsilon_\gamma \leq 1,5$:
  $C_{V7} = 0,75$
- if $1,5 < \varepsilon_\gamma \leq 2,5$:
  $C_{V7} = 0,125 \sin[\pi\ (\varepsilon_\gamma - 2)] + 0,875$
- if $2,5 < \varepsilon_\gamma$:
  $C_{V7} = 1$

3.4 Calculation of surface durability

3.4.1 General

The criterion for surface durability is based on the contact stress (hertzian pressure) σ_H on the pitch point or at the inner point of single pair contact.

The contact stress σ_H , defined in [3.4.2], is not to exceed the permissible contact stress σ_{HP} defined in [3.4.9].

3.4.2 Contact stress σ_H

The contact stress σ_H is to be determined as follows:

$$\sigma_H = \sigma_{H0} \cdot \sqrt{K_A \cdot K_\gamma \cdot K_V \cdot K_{H\beta} \cdot K_{H\alpha}}$$

where:

K_A : Application factor (see [3.3.2])

K_γ : Load sharing factor (see [3.3.3])

K_ς : Dynamic factor (see [3.3.4])

$K_{H\beta}$: Face load distribution factor (see [3.3.5])

$K_{H\alpha}$: Transverse load distribution factor (see [3.3.6])

$$\sigma_{H0} = Z_{M-B} \cdot Z_H \cdot Z_E \cdot Z_{LS} \cdot Z_\beta \cdot Z_K \cdot \sqrt{\frac{F_{mt}}{d_{v1} \cdot \ell_{bm}} \cdot \frac{u_v + 1}{u_v}}$$

with:

Z_{M-B} : Mid-zone factor, defined in [3.4.3]

Z_H : Zone factor, defined in [3.4.4]

Z_E : Elasticity factor, defined in [3.4.5]

$Z_{\Lambda\Sigma}$: Load-sharing factor, defined in [3.4.6]

Z_β : Helix angle factor, defined in [3.4.7]

Z_K : Bevel gear ratio factor, defined in [3.4.8].

3.4.3 Mid-zone factor Z_{M-B}

The mid-zone factor Z_{M-B} accounts for the difference of contact pressure between the pitch point and the determinant point of load application.

Z_{M-B} is to be determined as follows:

$$Z_{M-B} = \frac{\tan\alpha_{vt}}{\sqrt{\left[\sqrt{\frac{d_{va1}^2}{d_{vb1}^2}} - 1 - \left(F_1 \cdot \frac{\pi}{Z_{v1}}\right)\right] \cdot \left[\sqrt{\frac{d_{va2}^2}{d_{vb2}^2}} - 1 - \left(F_2 \cdot \frac{\pi}{z_{v2}}\right)\right]}}$$

where F_1 and F_2 are defined according to the following conditions:

- if $0 \le \varepsilon_{v\beta} < 1$:

  $F_1 = 2 + (\varepsilon_{v\alpha} - 2) \cdot \varepsilon_{v\beta}$

  $F_2 = 2\ \varepsilon_{v\alpha} - 2 + (2 - \varepsilon_{v\alpha}) \cdot \varepsilon_{v\beta}$

- if $\varepsilon_{v\beta} \ge 1$:

  $F_1 = \varepsilon_{v\alpha}$

  $F_2 = \varepsilon_{v\alpha}$

3.4.4 Zone factor Z_H

The zone factor Z_H accounts for the influence on the hertzian pressure of tooth flank curvature at the pitch point.

Z_H is to be determined as follows:

$$Z_H = 2 \cdot \sqrt{\frac{\cos\beta_{vb}}{\sin(2 \cdot \alpha_{vt})}}$$

3.4.5 Elasticity factor Z_E

The elasticity factor Z_E accounts for the influence of the metal properties (module of elasticity E and Poisson's ratio ν) on the hertzian pressure.

The values of Z_E to be used are given in [2.4.5].

3.4.6 Load-sharing factor Z_{LS}

The load-sharing factor Z_{LS} accounts for load sharing between two or more pairs of teeth.

Z_{LS} is to be determined as follows:

- if $\varepsilon_{v\gamma} > 2$ and $\varepsilon_{v\beta} > 1$:

$$Z_{LS} = \left\{1 + 2\left[1 - \left(\frac{2}{\varepsilon_{v\gamma}}\right)^{1,5}\right] \cdot \sqrt{1 - \frac{4}{\varepsilon_{v\gamma}^2}}\right\}^{-0,5}$$

- if $\varepsilon_{v\gamma} \leq 2$:

  $Z_{LS} = 1$

- otherwise, an alternative calculation should be supplied and will be given special consideration by the Society.

3.4.7 Helix angle factor Z_β

The helix angle factor Z_β accounts for the influence of helix angle on the surface durability, allowing for such variables as the distribution of the load along the lines of contact.

Z_β is to be determined as follows:

$$Z_\beta = \frac{1}{\sqrt{\cos \beta_m}}$$

3.4.8 Bevel gear factor Z_K

The bevel gear factor Z_K is an empirical factor which accounts for the difference between bevel and cylindrical gears loading.

Z_K is to be determined as follows:

$Z_K = 0,8$

3.4.9 Permissible contact stress σ_{HP}

The permissible contact stress σ_{HP} , in N/mm², is to be determined separately for pinion and wheel, using the following formula:

$$\sigma_{HP} = \frac{\sigma_{H,\lim}}{S_H} \cdot Z_{NT} \cdot Z_L \cdot Z_V \cdot Z_R \cdot Z_W \cdot Z_X$$

where:

$\sigma_{H,lim}$: Endurance limit for contact stress, defined in [3.4.10]

Z_{NT} : Life factor for contact stress, defined in [3.4.11]

Z_L, Z_V, Z_R: Lubrication, speed and roughness factors, respectively, defined in [3.4.12]

Z_Ω : Hardness ratio factor, defined in [3.4.13]

Z_Ξ : Size factor for contact stress, defined in [3.4.14]

Σ_H : Safety factor for contact stress, defined in [3.4.15].

3.4.10 Endurance limit for contact stress $\sigma_{H,lim}$

The endurance limit for contact stress $\sigma_{H,lim}$, in N/mm², is the limit of repeated contact stress which can be permanently endured.

The values to be adopted for $\sigma_{H,lim}$ are given in [2.4.9] in relation to the type of steel employed and the heat treatment performed.

3.4.11 Life factor for contact stress Z_{NT}

The life factor Z_{NT} accounts for the influence of limited service life on the permissible contact stress.

Some values of Z_{NT} are given in Tab 17 for information.

The value of Z_{NT} to be used will be given special consideration by the Society depending on the equipment's arrangement and use.

3.4.12 Lubrication factor Z_L , speed factor Z_V and roughness factor Z_R

The lubricant factor Z_L accounts for the influence of the type of the lubricant and the influence of its viscosity, the speed factor Z_V accounts for the influence of the pitch line velocity, and the roughness factor Z_R accounts for the influence of the surface roughness on the surface endurance capacity.

These factors are to be determined according to the formulae of [2.4.11], using the following parameters:

ϖ_{mt} : Linear speed at mean pitch diameter, in m/s. It is to replace ϖ in the calculation of Z_V

ρ_{red} : Relative radius of curvature, in mm:

$$\rho_{red} = \frac{a_v \cdot \sin \alpha_{vt}}{\cos \beta_{vb}} \cdot \frac{u_v}{(1 + u_v)^2}$$

3.4.13 Hardness ratio factor Z_W

The hardness ratio factor Z_W accounts for the increase of the surface durability. This factor is to be determined according to the formulae of [2.4.12], using the following parameters:

ϖ_{mt} : Linear speed at mean pitch diameter, in m/s. It is to replace ϖ in the calculations

ρ_{red} : Relative radius of curvature, in mm, as defined in [3.4.12]

υ_ϖ : Virtual reduction ratio. It is to replace u in the calculations.

3.4.14 Size factor Z_X

The size factor Z_X accounts for the influence of tooth dimensions on permissible contact stress and reflects the non-uniformity of material properties.

Z_X is in general equal to 1.

The value Z_X to be used will be given special consideration by the Society depending on the material.

3.4.15 Safety factor for contact stress S_H

The values to be adopted for the safety factor for contact stress S_H are given in Tab 18.

3.5 Calculation of tooth bending strength

3.5.1 General

The criterion for tooth root bending stress is based on the local tensile stress at the tooth root in the direction of the tooth height.

The tooth root bending stress σ_F , defined in [3.5.2], is not to exceed the permissible tooth root bending stress σ_{FP} defined in [3.5.8].

3.5.2 Tooth root bending stress σ_F

The tooth root bending stress σ_F is to be determined as follows:

$$\sigma_F = \frac{F_{mt}}{b \cdot m_{mn}} \cdot Y_{Fa} \cdot Y_{Sa} \cdot Y_\varepsilon \cdot Y_{LS} \cdot Y_K \cdot K_A \cdot K_\gamma \cdot K_V \cdot K_{F\beta} \cdot K_{F\alpha}$$

where:

Y_{Fa} : Tooth form factor, defined in [3.5.3]

Y_{Sa} : Stress correction factor, defined in [3.5.4]

Y_ε : Contact ratio factor, defined in [3.5.5]

Y_{LS} : Load sharing factor, defined in [3.5.6]

Y_K : Bevel gear factor, defined in [3.5.7]

K_A : Application factor (see [3.3.2])

K_γ : Load sharing factor (see [3.3.3])

K_V : Dynamic factor (see [3.3.4])

$K_{F\beta}$: Face load distribution factor (see [3.3.5])

$K_{F\alpha}$: Transverse load distribution factor (see [3.3.6]).

When a shot-peening treatment of the tooth root is applied according to a process agreed by the Society, a reduction of the bending stress σ_F (depending on the material category, but without being over 10%) could be taken in consideration only for carburized case-hardened steel gears.

3.5.3 Tooth form factor Y_{Fa}

The tooth form factor Y_{Fa} takes into account the effect of the tooth form on the nominal bending stress, assuming the load applied at the outer point of a single pair tooth contact of the virtual cylindrical gears in normal section.

Y_{Fa} is to be determined separately for the pinion and for the wheel, using the following formula:

$$Y_{Fa} = \frac{6 \cdot \frac{h_{Fa}}{m_{mn}} \cdot \cos\alpha_{Fan}}{\left(\frac{S_{Fn}}{m_{mn}}\right)^2 \cdot \cos\alpha_n}$$

where:

h_{Fa} : Bending moment arm, in mm:

$$\frac{h_{Fa}}{m_{mn}} = \frac{1}{2}\left[(\cos\gamma_a - \sin\gamma_a \cdot \tan\alpha_{Fan}) \cdot \frac{d_{van}}{m_{mn}} - z_{vn} \cdot \cos\left(\frac{\pi}{3} - \theta\right) - \left(\frac{G}{\cos\theta} - \frac{\rho_{a0}}{m_{mn}}\right)\right]$$

s_{Fn} : Tooth root chord at the critical section, in mm:

$$\frac{s_{Fn}}{m_{mn}} = z_{vn} \cdot \sin\left(\frac{\pi}{3} - \theta\right) + \sqrt{3} \cdot \left(\frac{G}{\cos\theta} - \frac{\rho_{a0}}{m_{mn}}\right)$$

G : Parameter defined by:

$$G = \frac{\rho_{a0}}{m_{mn}} - \frac{h_{fP}}{m_{mn}} + x_h$$

θ : Parameter defined by:

$$\theta = \frac{2 \cdot G}{z_{vn}} \cdot \tan\theta - H$$

This transcendental equation is to be calculated by iteration

H : Parameter defined by:

$$H = \frac{2}{z_{vn}} \cdot \left(\frac{\pi}{2} - \frac{E}{m_{mn}}\right) - \frac{\pi}{3}$$

E : Parameter defined by:

$$E = \left(\frac{\pi}{4} - x_s\right) \cdot m_{mn} - h_{fP} \cdot \tan\alpha_n$$

$$+ \frac{s_{pr}}{\cos\alpha_n} - (1 - \sin\alpha_n)\frac{\rho_{a0}}{\cos\alpha_n}$$

s_{pr} : Residual fillet undercut, in mm:

$s_{pr} = pr - q$

The parameters of the virtual gears are defined as follows:

α_{Fan} : Load direction angle:

$\alpha_{Fan} = \alpha_{an} - \gamma_a$

γ_a : Parameter defined by:

$$\gamma_a = \frac{0,5 \cdot \pi + 2(\tan\alpha_n \cdot x_h + x_s)}{z_{vn}} + \mathrm{inv}\alpha_n - \mathrm{inv}\alpha_{an}$$

with inv, involute function, equal to:

$\mathrm{inv}\ \alpha = \tau\alpha\nu\ \alpha - \alpha$

α_{an} : Form factor pressure angle:

$$\cos\alpha_{an} = \frac{d_{vbn}}{d_{van}}$$

3.5.4 Stress correction factor Y_{Sa}

The stress correction factor Y_{Sa} is used to convert the nominal bending stress to local tooth root stress.

Y_{Sa} is to be determined as follows:

$$Y_{Sa} = (1,2 + 0,13 L_a) \cdot q_s^{\frac{1}{1,21 + (2,3)/L_a}}$$

where:

$$L_a = \frac{s_{Fn}}{h_{Fa}}$$

with s_{Fn} and h_{Fa} defined in [3.5.3]

q_s : Notch parameter:

$$q_s = \frac{s_{Fn}}{2\rho_F}$$

with s_{Fn} defined in [3.5.3]

Note 1: The notch parameter should be within the range:

$1 \le q_s < 8$

ρ_F : Fillet radius at contact point of 30° tangent, in mm:

$$\frac{\rho_F}{m_{mn}} = \frac{\rho_{a0}}{m_{mn}} + \frac{2G^2}{\cos\theta \cdot (z_{vn} \cdot \cos^2\theta - 2G)}$$

3.5.5 Contact ratio factor Y_ε

The contact ratio factor Y_ε converts the load application at the tooth tip to the decisive point of load application.

Y_ε is to be determined as follows:

- if $\varepsilon_{v\beta} \le 1$:

$$Y_\varepsilon = 0,25 + \frac{0,75}{\varepsilon_{v\alpha}} - \varepsilon_{v\beta} \cdot \left(\frac{0,75}{\varepsilon_{v\alpha}} - 0,375\right)$$

- if $\varepsilon_{v\beta} > 1$:

  $Y_\varepsilon = 0{,}625$

Note 1: A minimum of 0,625 should always be taken for Y_ε.

3.5.6 Load sharing factor Y_{LS}

The load sharing factor Y_{LS} accounts for load sharing between two or more pairs of teeth.

Y_{LS} is to be determined as follows:

$$Y_{LS} = Z_{LS}^2$$

3.5.7 Bevel gear factor Y_K

The bevel gear factor Y_K accounts for the difference between bevel and cylindrical gears loading.

Y_K is to be determined as follows:

$$Y_K = \left(\frac{1}{2} + \frac{\ell'_{bm}}{2b}\right)^2 \cdot \frac{b}{\ell'_{bm}}$$

3.5.8 Permissible tooth root bending stress σ_{FP}

The permissible tooth root bending stress σ_{FP} is to be determined separately for pinion and for wheel, using the following formula:

$$\sigma_{FP} = \frac{\sigma_{FE}}{S_F} \cdot Y_d \cdot Y_{NT} \cdot Y_{\delta relT} \cdot Y_{RrelT} \cdot Y_X$$

where:

σ_{FE} : Endurance limit for tooth root bending stress, defined in [3.5.9]

Ψ_{δ} : Design factor, defined in [3.5.10]

Ψ_{NT} : Life factor for tooth root bending stress, defined in [3.5.11]

$\Psi_{\delta relT}$: Relative notch sensitivity factor, defined in [3.5.12]

$\Psi_{P\rho\varepsilon IT}$: Relative surface factor, defined in [3.5.13]

Ψ_{Ξ} : Size factor for tooth root bending stress, defined in [3.5.14]

Σ_{Φ} : Safety factor for tooth root bending stress, defined in [3.5.15].

3.5.9 Endurance limit for tooth root bending stress σ_{FE}

The endurance limit for tooth root bending stress σ_{FE} is the local tooth root stress which can be permanently endured.

The values to be adopted for σ_{FE} are given in [2.5.9]] in relation to the type of steel employed and the heat treatment performed.

3.5.10 Design factor Y_d

The design factor Y_d takes into account the influence of load reversing and shrink fit pre-stressing on the tooth root strength.

Y_d is defined in [2.5.10].

3.5.11 Life factor Y_{NT}

The life factor Y_{NT} accounts for the influence of limited service life on the permissible tooth root bending stress.

Some values of Y_{NT} are given in Tab 20 for information.

The value Y_{NT} to be used will be given special consideration by the Society depending on the equipment's arrangement and use.

3.5.12 Relative notch sensitivity factor $\Psi_{\delta relT}$

The relative notch sensitivity factor $\Psi_{\delta relT}$ indicates the extent to which the theoretically concentrated stress lies above the fatigue endurance limit.

$\Psi_{\delta relT}$ is to be determined according to [2.5.12].

3.5.13 Relative surface factor $\Psi_{P\rho\varepsilon IT}$

The relative surface factor $\Psi_{P\rho\varepsilon IT}$ takes into account the dependence of the root strength on the surface condition on the tooth root fillet (roughness).

The values to be adopted for $\Psi_{P\rho\varepsilon IT}$ are given in Tab 22 in relation to the type of steel employed.

They are valid only when scratches or similar defects deeper than 12 R_a are not present.

3.5.14 Size factor Y_X

The size factor Y_X takes into account the decrease of the strength with increasing size.

The values to be adopted for Y_X are given in Tab 23 in relation to the type of steel employed and the value of normal module m_{mn}.

3.5.15 Safety factor for tooth root bending stress S_F

The values to be adopted for the safety factor for tooth root bending stress S_F are given in Tab 24.

3.6 Calculation of scuffing resistance

3.6.1 General

The following calculations are requested for equipment running in supercritical domain i.e. when N > 1,5 (see [3.3.4]).

The criterion for scuffing resistance is based on the calculation of the flash temperature method. According to this method, the risk of scuffing is assessed as a function of the properties of gear material, the lubricant characteristics, the surface roughness of tooth flanks, the sliding velocities and the load.

The interfacial contact temperatures are calculated as the sum of the interfacial bulk temperature of the moving interface and the fluctuating flash temperature of the moving faces in contact.

The maximum value of the interfacial contact temperature reduced by oil temperature is not to exceed 0,8 times the scuffing temperature reduced by oil temperature:

$(\Theta_{B,Max} - \Theta_{o\iota\lambda}) \leq 0{,}8\ (\Theta_{\sigma} - \Theta_{o\iota\lambda})$

where:

$\Theta_{B,Max}$: Maximum contact temperature along the path of contact, in °C, defined in [3.6.2]

$\Theta_{o\iota\lambda}$: Oil temperature, in °C

Θ_{Σ} : Scuffing temperature, in °C, defined in [3.6.11].

Additionally, the difference between the scuffing temperature and the contact temperature along the path is not to be below 30°C:

$(\Theta_{\sigma} - \Theta_{B,Max}) \geq 30°C$

Other methods of determination of the scuffing resistance could be accepted by the Society.

3.6.2 Contact temperature Θ_B

The maximum contact temperature $\Theta_{B,Max}$ along the path of contact, in °C, is calculated as follows:

$\Theta_{B,Max} = \Theta_{Mi} + \Theta_{fl,Max}$

where:

$\Theta_{M\iota}$: Interfacial bulk temperature, in °C, defined in [3.6.10]

$\Theta_{fl,Max}$: Maximum flash temperature along the path of contact, in °C, defined in [3.6.3].

The flash temperature is to be calculated on at least ten points along the path of contact and the maximum of these values has to be used for the calculation of maximum contact temperature.

3.6.3 Flash temperature Θ_{fl}

The flash temperature Θ_{fl} at any point along the path of contact, in °C, is calculated with the following formula:

$$\Theta_{fl} = \mu_m \cdot X_M \cdot X_J \cdot X_G (X_\Gamma \cdot w_{Bt})^{0,75} \cdot \frac{v_{mt}^{0,5}}{r_m^{0,25}}$$

where:

μ_m : Mean coefficient of friction, defined in [3.6.4]

Ξ_M : Thermo-elastic factor, in $K \cdot N^{-3/4} \cdot s^{-1/2} \cdot m^{-1/2} \cdot mm$, defined in [3.6.5]

Ξ_J : Approach factor, defined in [3.6.6]

Ξ_G : Geometry factor, defined in [3.6.7]

Ξ_Γ : Load sharing factor, defined in [3.6.8]]

ω_{Bt} : Transverse unit load, in N/mm, defined in [3.6.9].

3.6.4 Mean coefficient of friction μ_m

An estimation of the mean coefficient of friction μ_m of common working conditions could be used with the following formula:

$$\mu_m = 0,06 \cdot \left(\frac{w_{Bt}}{v_{g\Sigma C} \cdot \rho_{relC}}\right)^{0,2} \cdot X_L \cdot X_R$$

where:

w_{Bt} : Transverse unit load, in N/mm (see [2.6.9])

$v_{g\Sigma C}$: Sum of tangential velocities in pitch point, in m/s:

$v_{g\Sigma C} = 2\ v_{mt} \sin \alpha_{vt}$

with the maximum value of v_{mt} equal to 50 m/s

ρ_{relC} : Transverse relative radius of curvature, in mm:

$$\rho_{relC} = \frac{u \cdot \tan\delta_1 \cdot \tan\delta_2}{\tan\delta_1 + u \cdot \tan\delta_2} \cdot r_m \cdot \sin\alpha_{vt}$$

X_L : Lubricant factor, given in Tab 25

X_R : Roughness factor:

$$X_R = \left(\frac{R_{zf1} + R_{zf2}}{2}\right)^{0,25}$$

3.6.5 Thermo-elastic factor X_M

The thermo-elastic factor X_M accounts for the influence of the material properties of pinion and wheel.

The values to be adopted for X_M are given in [2.6.5] in relation to the gear material characteristics.

3.6.6 Approach factor X_J

The approach factor X_J takes empirically into account an increased scuffing risk in the beginning of the approach path, due to mesh starting without any previously built up oil film.

The values to be adopted for X_J are given in [2.6.6] in relation to the gear material characteristics.

3.6.7 Geometry factor X_G

The geometry factor X_G is calculated according to the following formula:

$$X_G = 0,51 X_{\alpha\beta}\left(\frac{1}{\tan\delta_1} + \frac{1}{\tan\delta_2}\right)^{0,25} \frac{\left|(1+\Gamma)^{0,5} - \left(1+\Gamma\frac{\tan\delta_1}{\tan\delta_2}\right)^{0,5}\right|}{(1+\Gamma)^{0,25}\cdot\left(1-\Gamma\frac{\tan\delta_1}{\tan\delta_2}\right)^{0,25}}$$

where:

$X_{\alpha\beta}$: Angle factor, equal to:

$X_{\alpha\beta} = 1,22\,(\sin\alpha_{vt})^{0,25}\cdot(\cos\alpha_{vt})^{-0,5}\cdot(\cos\beta_{vb})^{0,25}$

Γ : Parameter of the point on the line of action, defined in Tab 32.

3.6.8 Load sharing factor X_Γ

The load sharing factor X_Γ accounts for the load sharing of succeeding pairs of meshing teeth. It is defined as a function of the value of the parameter in the line of action, increasing at the approach path of transverse double contact.

The values to be adopted for X_Γ are given in [2.6.8].

The parameter of the line of action Γ to be used is given in Tab 32.

Table 32 : Parameter Γ on the line of action

Point			Γ
A	:	Lower end point of the path of contact	$\Gamma_A = -\frac{\tan\delta_2}{\tan\delta_1}\left(\frac{\tan\alpha_{a2}}{\tan\alpha_{vt}} - 1\right)$
AU	:	Lower end point of buttressing effect	$\Gamma_{AU} = \Gamma_A + 0,2\sin\beta_{vb}$
AB	:	Intermediate point between A and B	$\Gamma_{AB} = 0,5\,(\Gamma_A + \Gamma_B)$
B	:	Lower point of single pair tooth contact	$\Gamma_B = \frac{\tan\alpha_{a1}}{\tan\alpha_{vt}} - 1 - \frac{2\pi\cdot\cos\delta_1}{z_1\tan\alpha_{vt}}$
C	:	Point with parameter equal to 0	$\Gamma_C = 0$
M	:	Intermediate point between A and E	$\Gamma_M = 0,5\,(\Gamma_A + \Gamma_E)$
D	:	Upper point of single pair tooth contact	$\Gamma_D = -\frac{\tan\delta_2}{\tan\delta_1}\left(\frac{\tan\alpha_{a2}}{\tan\alpha_{vt}} - 1\right) + \frac{2\pi\cdot\cos\delta_1}{z_1\tan\alpha_{vt}}$
DE	:	Intermediate point between D and E	$\Gamma_{DE} = 0,5\,(\Gamma_D + \Gamma_E)$
EU	:	Upper end point of buttressing effect	$\Gamma_{EU} = \Gamma_E - 0,2\sin\beta_{vb}$
E	:	Upper end point of the path of contact	$\Gamma_E = \frac{\tan\alpha_{a1}}{\tan\alpha_{vt}} - 1$

Note 1:

$\alpha_{\alpha i}$: Transverse tip pressure angle of pinion and wheel, in rad:

$$\cos\alpha_{ai} = \frac{\cos\alpha_{vt}}{1 + 2h_{f0i}\cdot(\cos\delta_i)/d_{mi}}$$

3.6.9 Transverse unit load w_{Bt}

The transverse unit load w_{Bt} is calculated according to the following formula:

$$w_{Bt} = K_A\cdot K_V\cdot K_{H\beta}\cdot K_{H\alpha}\cdot K_\gamma\cdot\frac{F_{mt}}{b}$$

where:

K_A : Application factor (see [3.3.2])

K_V : Dynamic factor (see [3.3.4])
$K_{H\beta}$: Face load distribution factor (see [3.3.5])
$K_{H\alpha}$: Transverse load distribution factor (see [3.3.6])
K_γ : Load sharing factor (see [3.3.3]).

3.6.10 Interfacial bulk temperature Θ_{Mi}

The interfacial bulk temperature Θ_{Mi} may be suitably averaged from the two overall bulk temperatures of the teeth in contact, Θ_{M1} and Θ_{M2}. An estimation of Θ_{Mi} , given in [2.6.10], could be used in general configurations.

3.6.11 Scuffing temperature Θ_σ

The scuffing temperature Θ_S may be determined according to the following formula:

$\Theta_S = 80 + (0{,}85 + 1{,}4\ X_W) \cdot X_L \cdot (S_{FZG} - 1)^2$

where:

X_W : Structural factor given in Tab 27
X_L : Lubricant factor given in Tab 25
S_{FZG} : Load stage where scuffing occurs, according to gear tests, such as Ryder, FZG-Ryder, FZG L-42 or FZG A/8 3/90.

4 Design and construction - except tooth load capacity

4.1 Materials

4.1.1 General

a) Forged, rolled and cast materials used in the manufacturing of shafts, couplings, pinions and wheels are to comply with the requirements of NR216 Materials and Welding.
b) Materials other than steels will be given special consideration by the Society.

4.1.2 Steels for pinions and wheel rims

a) Steels intended for pinions and wheels are to be selected considering their compatibility in service. In particular, for through-hardened pinion / wheel pairs, the hardness of the pinion teeth is to exceed that of the corresponding wheel. For this purpose, the minimum tensile strength of the pinion material is to exceed that of the wheel by at least 15%.
b) The minimum tensile strength of the core is not to be less than:
   - 750 N/mm^2 for case-hardened teeth
   - 800 N/mm^2 for induction-hardened or nitrided teeth.

4.2 Teeth

4.2.1 Manufacturing accuracy

a) The teeth design flank tolerance class of propulsion machinery gearing, as defined by ISO 1328-1:2013, is not to exceed 4. A lower tolerance class (i.e. ISO 1328-1:2013 class higher than 4) may be accepted for auxiliary machinery gearing and for particular cases of propulsion machinery gearing of auxiliary ships subject to special consideration by the owner.
b) Where the quality class of the gear is indicated by the gear Manufacturer according to another Standard accepted by the Society, the corresponding accuracy of teeth is to be to the satisfaction of the Society.
c) Mean roughness (R_a) of shaved or ground teeth is not to exceed 0,7 µm.
d) Wheels are to be cut by cutters with a method suitable for the expected type and quality. Whenever necessary, the cutting and grinding is to be carried out in a temperature controlled environment.

4.2.2 Tooth root

Teeth are to be well faired and rounded at the root. The fillet radius at the root of the teeth, within a plane normal to the teeth, is to be not less than 0,25 m_n.

Profile-grinding of gear teeth is to be performed in such a way that no notches are left in the fillet.

4.2.3 Tooth tips and ends

a) All sharp edges on the tips and ends of gear teeth are to be removed after cutting and finishing of teeth.
b) Where the ratio b/d exceeds 0,3, the ends of pinion and wheel are to be chamfered to an angle between 45 and 60 degrees. The chamfering depth is to be at least equal to 1,5 m_n.

4.2.4 Surface treatment

a) The hardened layer on surface-hardened gear teeth is to be uniform and extended over the whole tooth flank and fillet.
b) Where the pinions and the toothed portions of the wheels are case-hardened and tempered, the teeth flanks are to be ground while the bottom lands of the teeth remain only case-hardened. The superficial hardness of the case-hardened zone is to be at least equal to 56 C Rockwell units.

c) Where the pinions and the toothed part of the wheel are case hardened, the thickness of the hardened layer after finish grinding is to be at least equal to the following value:

$$T = \sqrt{0,5 \cdot m_n + 1,1} - (0,7)$$

Thickness of the hardened layer for case hardening is the depth, measured normally to the tooth flank surface, where the local hardness falls below the value of 52,5 HRC (550 HV).

d) Where the pinions and the toothed portions of the wheels are nitrided, the hardened layer is to comply with Tab 33.

e) The use of other processes of superficial hardening of the teeth, such as flame hardening, will be given special consideration, in particular as regards the values to be adopted for $\sigma_{H,lim}$ and σ_{FE}.

Table 33 : Characteristics of the hardened layer for nitrided gears

Type of steel	Minimum thickness of hardened layer (mm)**(1)**	Minimum hardness (HV)
Nitriding steel	0,6	500 (at 0,25 mm depth)
Other steels	0,3	450 (surface)
(1) Depth of the hardened layer to core hardness. When the grinding of nitrided teeth is performed, the depth of the hardened layer to be taken into account is the depth after grinding.		

4.3 Wheels and pinions

4.3.1 General

Wheel bodies are to be so designed that radial deflections and distorsions under load are prevented, so as to ensure a satisfactory meshing of teeth.

4.3.2 Welding

a) Where welding is employed for the construction of wheels, the welding procedure is to be submitted to the Society for approval. Welding processes and their qualification are to comply with NR216 Materials and Welding.

b) Stress relieving treatment is to be performed after welding.

c) Examination of the welded joints is to be performed by means of magnetic particle or dye penetrant tests to the satisfaction of the Surveyor. Suitable arrangements are to be made to permit the examination of the internal side of the welded joints.

4.3.3 Shrink-fits

a) The shrink fit assembly of wheel body and shaft is to be designed with a safety factor against slippage of not less than $2,8 \cdot K_a$.

For different type of drives the value to be adopted will be specially considered.

b) The shrink fit assembly of wheel rim and body is to be designed with a safety factor against slippage of not less than 5.

Note 1: The manufacturer is to ensure that the maximum torque transmitted during the clutch engagement does not exceed the nominal torque by more than 20%.

c) The shrink-fit assembly is to take into account the thermal expansion differential between the shrunk-on parts in the service conditions.

4.3.4 Bolting

The bolting assembly of:

- rim and wheel body
- wheel body and shaft,

is to be designed according to Ch 1, Sec 7, [2.5.1].

The nuts are to be suitably locked by means other than welding.

4.4 Shafts and bearings

4.4.1 General

Shafts and their connections, in particular flange couplings and shrink-fits connections, are to comply with the provisions of Ch 1, Sec 7.

4.4.2 Pinion and wheel shafts

The minimum diameter of pinion and gear wheel shafts is not to be less than the value d_S, in mm, given by the following formula:

$$d_S = \left\{\left[\left(10,2 + \frac{28000}{R_{S,min}}\right)T\right]^2 + \left[\frac{170000}{412 + R_{s,min}}M\right]^2\right\}^{\frac{1}{6}} \left(\frac{1}{1 - K_d{}^4}\right)^{\frac{1}{3}}$$

where:

$R_{S,min}$: Minimum yield strength of the shaft material, in N/mm²

T : Nominal torque transmitted by the shaft, in Nm

M : Bending moment on the shaft, in Nm

K_d : Coefficient having the following values:

- for solid shafts: $K_d = 0$
- for hollow shafts, K_d is equal to the ratio of the hole diameter to the outer shaft diameter.

  Where $K_d \le 0{,}3$: $K_d = 0$ may be taken.

Note 1: The values of d_S, T and M refer to the cross-section of the shaft concerned.

Note 2: In correspondence of keyways d_S shall be increased by 10%.

As an alternative to the above given formula, the Society may accept direct strength calculations showing that the equivalent stress represented in a diagram average stress vs. alternate stress falls below the lines defined by the points having coordinates:

$(R_m;0), (0;\sigma_{fa}/1,5)$

and

$(0,8 \cdot R_s;0), (0;0,8 \cdot R_s)$

where σ_{fa} is the pure alternate bending fatigue limit for a survival probability not less than 80%.

4.4.3 Quill shafts

The minimum diameter of quill shafts subject to torque only is not to be less than the value d_{QS}, in mm, given by the following formula:

$$d_{QS} = \left[\left(7{,}65 + \frac{27000}{R_{S,min}}\right) \cdot \frac{T}{1 - K_d^{\,4}}\right]^{\frac{1}{3}}$$

$R_{S,min}$ and K_d being defined in [4.4.2].

4.4.4 Bearings

a) Thrust bearings and their supports are to be so designed as to avoid detrimental deflections under load.

b) Life duration of bearings L_{10h} calculated according to ISO 281-1, is not be less than 40000 hours. Shorter durations may be accepted on the basis of the actual load time distribution, and subject to the agreement of the owner.

4.5 Casings

4.5.1 General

Gear casings are to be of sufficient stiffness such that misalignment, external loads and thermal effects in all service conditions do not adversely affect the overall tooth contact.

4.5.2 Welded casings

a) Carbon content of steels used for the construction of welded casings is to comply with the provisions of NR216 Materials and Welding.

b) The welded joints are to be so arranged that welding and inspection can be performed satisfactorily. They are to be of the full penetration type.

c) Welded casings are to be stress-relieved after welding.

4.5.3 Openings

Access or inspection openings of sufficient size are to be provided to permit the examination of the teeth and the structure of the wheels.

4.6 Lubrication

4.6.1 General

a) Manufacturers are to take care of the following points:
   - reliable lubrication of gear meshes and bearings is ensured:
     - over the whole speed range, including starting, stopping and, where applicable, manoeuvring
     - for all angles stated in Ch 1, Sec 1, [2.4]
   - in multi-propellers plants and a transient black-out, provision is to be made to ensure lubrication of gears likely to be affected by windmilling.

b) Lubrication by means other than oil circulation under pressure will be given special consideration.

4.6.2 Pumps

a) Gears intended for propulsion or other essential services independent gearbox are to be provided with at least 2 lubricating pumps, so arranged as to maintain a sufficient lubrication of the gearbox in the whole speed range in case of failure of one pump. At least one of the pumps is not to be mechanically driven by the gearbox.

One of the two lubricating pumps could be a common one for the two gearboxes if they are located in the same compartment.

b) In the case of gears having a transmitted power not exceeding 375 kW one of the pumps mentioned in a) may be a spare pump ready to be connected to the reduction gear lubricating oil system, provided disassembling and reassembling operations can be carried out on board in a short time.

c) Provisions are to be made to maintain a sufficient lubrication of the gearbox in:

- black-out conditions, and
- in any operating conditions mentioned in the ship specification.

4.6.3 Filtration

a) Forced lubrication systems are to be fitted with a device which efficiently filters the oil in the circuit.

b) When fitted to gears intended for propulsion machinery or machinery driving electric propulsion generators, such filters are to be so arranged that they can be easily cleaned without stopping the lubrication of the machines.

4.7 Control and monitoring

4.7.1 Gears are to be provided with the alarms and safeguards listed in Tab 34.

Table 34 : Reduction gears / reversing gears

Symbol convention H = High, HH = High high, G = group alarm L = Low, LL = Low low, I = individual alarm X = function is required, R = remote	Monitoring		Automatic control				
			Main Engine			Auxiliary	
Identification of system parameter	Alarm	Indication	Slow-down	Shut-down	Control	Stand by start	Stop
Lubricating oil temperature		local					
Lubricating oil pressure		local					
	L **(1)**			x			
Oil tank level		local					
(1) May be omitted in case of restricted navigation notation							

5 Installation

5.1 General

5.1.1 Manufacturers and shipyards are to take care directly that stiffness of gear seating and alignment conditions of gears are such as not to adversely affect the overall tooth contact and the bearing loads under all operating conditions of the ship.

5.2 Fitting of gears

5.2.1 Means such as stoppers or fitted bolts are to be arranged in the case of gears subject to propeller thrust. However, where the thrust is transmitted by friction and the relevant safety factor is not less than 2, such means may be omitted.

6 Certification, inspection and testing

6.1 General

6.1.1

a) Inspection and testing of shafts and their connections (flange couplings, hubs, bolts, pins) are to be carried out in accordance with the provisions of Ch 1, Sec 7.

b) For inspection of welded joints of wheels, refer to [4.3.2].

6.2 Workshop inspection and testing

6.2.1 Testing of materials

Chemical composition and mechanical properties are to be tested in accordance with the applicable requirements of NR216 Materials and Welding, Chapter 5 for the following items:

- pinions and wheel bodies
- rims
- plates and other elements intended for propulsion gear casings of welded construction.

6.2.2 Testing of pinion and wheel forgings

a) Mechanical tests of pinions and wheels are to be carried out in accordance with:
   - NR216 Materials and Welding, Ch 5, Sec 5, [1.6] for normalised and tempered or quenched and tempered forgings
   - NR216 Materials and Welding, Ch 5, Sec 5, [1.7] for surface-hardened forgings.

b) Non-destructive examination of pinion and wheel forgings is to be performed in accordance with NR216 Materials and Welding, Ch 5, Sec 5, [1.8].

6.2.3 Balancing test

Rotating components, in particular gear wheel and pinion shaft assemblies with the coupling part attached, are to undergo a static balancing test.

Propulsion gear wheels and pinion shaft assemblies having a speed in excess of 150 rpm are also to undergo a dynamic balancing test after finish machining; the residual imbalance shall be as small as possible and anyway, is not exceed the Grade 2,5 according to ISO 1940.

Auxiliary gear wheels and pinion shaft assemblies are also to undergo a dynamic balancing test after finish machining, when

$n^2 \cdot d > 1{,}5 \;.\; 10^9$

the residual imbalance shall not exceed the Grade 2,5 according to ISO 1940.

6.2.4 Verification of cutting accuracy

Examination of the accuracy of tooth cutting is to be performed in the presence of the Surveyor. Records of measurements of errors, tolerances and clearances of teeth are to be submitted at the request of the Surveyor.

6.2.5 Meshing test

a) A tooth meshing test is to be performed in the presence of the Surveyor. This test is to be carried out at a load sufficient to ensure tooth contact, with the journals located in the bearings according to the normal running conditions. Before the test, the tooth surface is to be coated with a thin layer of suitable coloured compound.

b) The results of such test are to demonstrate that the tooth contact is adequately distributed on the length of the teeth. Strong contact marks at the end of the teeth are not acceptable. In case the test is carried out at full load, the contact pattern shall meet with the one requested under Ch 1, Sec 16, Tab 1.

c) In case of helix modification or crowning the tooth meshing test is to be performed before these corrections will be carried out.

d) A permanent record of the tooth contact is to be made for the purpose of subsequent checking of alignment following installation on board.

6.2.6 Hydrostatic tests

a) Hydraulic or pneumatic clutches are to be hydrostatically tested before assembly to 1,5 times the maximum working pressure.

b) Pressure piping, pumps casings, valves and other fittings are to be hydrostatically tested in accordance with the requirements of Ch 1, Sec 10, [19].

Section 7 Main Propulsion Shafting

1 General

1.1 Application

1.1.1 This Section applies to shafts, couplings, clutches and other shafting components transmitting power for main propulsion. In addition, main propulsion machinery components are to comply with the requirements listed in Tab 1.

Table 1 : Rule requirements for main propulsion component

Item		Reference
Power transmission equipment	Diesel engines	Ch 1, Sec 2
	Turbines	Ch 1, Sec 4 Ch 1, Sec 5
	Propellers	Ch 1, Sec 8
	Gear	Ch 1, Sec 6
	Thrusters	Ch 1, Sec 13
Shaft line analysis	Shaft alignment	Ch 1, Sec 7
	Torsional vibration	Ch 1, Sec 9

1.2 Documentation to be submitted

1.2.1 The Manufacturer is to submit to the Society the documents listed in Tab 2 for approval.

Plans of power transmitting parts and shaft liners listed in Tab 2 are to include the relevant material specifications.

Table 2 : Documentation to be submitted

No.	Document (drawings, calculations, etc.)
1	Shafting arrangement **(1)**
2	Thrust shaft
3	Intermediate shafts
4	Propeller shaft
5	Shaft liners, relevant manufacture and welding procedures, if any
6	Couplings and coupling bolts
7	Flexible couplings **(2)**
8	Sterntube
9	Details of sterntube glands
10	Oil piping diagram for oil lubricated propeller shaft bearings
11	Shaft alignment calculation, see also [3.3]

(1) This drawing is to show the entire shafting, from the main engine coupling flange to the propeller. The location of the thrust block, and the location and number of shafting bearings (type of material and length) are also to be shown.

(2) The Manufacturer of the elastic coupling is also to submit the following data:
- allowable mean transmitted torque (static) for continuous operation
- maximum allowable shock torque
- maximum allowable speed of rotation
- maximum allowable values for radial, axial and angular misalignment

In addition, when the torsional vibration calculation of main propulsion system is required (see Ch 1, Sec 9), the following data are also to be submitted:
- allowable alternating torque amplitude and power loss for continuous operation, as a function of frequency and/or mean transmitted torque
- static and dynamic stiffness, as a function of frequency and/or mean transmitted torque
- moments of inertia of the primary and secondary halves of the coupling
- damping coefficient or damping capability
- properties of rubber components
- for steel springs of couplings: chemical composition and mechanical properties of steel employed.

2 Design and construction

2.1 Materials

2.1.1 General

The use of other materials or steels having values of tensile strength exceeding the limits given in [2.1.2], [2.1.3] and [2.1.4] will be considered by the Society in each case.

2.1.2 Shaft materials

Where shafts may experience vibratory stresses close permissible stresses for transient operation (see Ch 1, Sec 9), the materials are to have a specified minimum ultimate tensile strength Rm of 500 N/mm^2. Otherwise materials having a specified minimum ultimate tensile strength Rm of 400 N/mm^2 may be used.

For use in the following formulae in this Section, Rm is limited as follows:

- for carbon and carbon manganese steels, Rm is not exceed 760 N/mm^2
- for alloy steels, Rm is not to exceed 800 N/mm^2
- for propeller shafts, Rm is not to exceed 600 N/mm^2 (for carbon, carbon manganese and alloy steels).

Where materials with greater specified or actual tensile strengths than the limitations given above are used, reduced shaft dimensions are not acceptable when derived from the formulae given in this Section unless the Society verifies that the materials exhibit similar fatigue life as conventional steels (see Ch 1, App 4).

2.1.3 Couplings, flexible couplings, hydraulic couplings

Non-solid-forged couplings and stiff parts of elastic couplings subjected to torque are to be of forged or cast steel, or nodular cast iron.

Rotating parts of hydraulic couplings may be of grey cast iron, provided that the peripheral speed does not exceed 40m/s.

2.1.4 Coupling bolts

Coupling bolts are to be of forged, rolled or drawn steel.

In general, the value of the tensile strength of the bolt material R_{mB} is to comply with the following requirements:

- $R_m \leq R_{mB} \leq 1{,}7\ R_m$
- $R_{mB} \leq 1000$ N/mm^2.

2.1.5 Shaft liners

Liners are to be of metallic corrosion resistant material complying with the applicable requirements of NR216 Materials and Welding with the approved specification, if any; in the case of liners fabricated in welded lengths, the material is to be recognised as suitable for welding.

In general, they are to be manufactured from castings.

For small shafts, the use of liners manufactured from pipes instead of castings may be considered.

Where shafts are protected against contact with seawater not by metal liners but by other protective coatings, the coating procedure is to be approved by the Society.

2.1.6 Sterntubes

Sterntubes are to comply with the requirements of Pt B, Ch 8, Sec 2, [6.7].

2.2 Shafts - Scantling

2.2.1 General

The provisions of this sub-article apply to propulsion shafts such as an intermediate and propeller shafts of traditional straight forged design and which are driven by rotating machines such as diesel engines, turbines or electric motors.

For shafts that are integral to equipment, such as for gear boxes, podded drives, electrical motors and/or generators, thrusters, turbines and which in general incorporate particular design features, additional criteria in relation to acceptable dimensions have to be taken into account. For the shafts in such equipment, the provisions of this sub-article apply only to shafts subject mainly to torsion and having traditional design features. Other shafts will be given special consideration by the Society.

2.2.2 Alternative calculation methods

Alternative calculation methods may be considered by the Society. Any alternative calculation method is to include all relevant loads on the complete dynamic shafting system under all permissible operating conditions. Consideration is to be given to the dimensions and arrangements of all shaft connections.

Moreover, an alternative calculation method is to take into account design criteria for continuous and transient operating loads (dimensioning for fatigue strength) and for peak operating loads (dimensioning for yield strength). The fatigue strength analysis may be carried out separately for different load assumptions.

2.2.3 Shaft diameters

The diameter of intermediate shafts, thrust shafts and propellers shafts is not to be less than that determined from the following formula:

$$d = F \cdot k \cdot \left[\frac{P}{n \cdot (1 - Q^4)} \cdot \frac{560}{R_m + 160}\right]^{1/3}$$

where:

d : Minimum required diameter in mm

Q : Factor equal to d_i / d_o , where:

- d_i : Actual diameter of the shaft bore, in mm (to be taken as 0 for solid shafts)
- d_o : Outside diameter of the shaft, in mm.

Note 1: Where $d_i \leq 0,4\ d_o$, Q may be taken as 0.

F : Factor for type of propulsion installation equal to:

- 95 for intermediate and thrusts shafts in turbine installations, diesel installations with hydraulic (slip type) couplings and electric propulsion installations
- 100 for all other diesel installation and all propeller shafts.

k : Factor for the particular shaft design features, see Tab 3

n : Speed of rotation of the shaft, in revolution per minute, corresponding to power P

P : Maximum continuous power of the propulsion machinery for which the classification is requested, in kW

R_m : Specified minimum tensile strength of the shaft material, in N/mm², see [2.1.2].

The diameter of the propeller shaft located forward of the inboard stern tube seal may be gradually reduced to the corresponding diameter required for the intermediate shaft using the minimum specified tensile strength of the propeller shaft in the formula and recognising any limitations given in [2.1.2].

Note 2: Transitions of diameters are to be designed with either a smooth taper or a blending radius equal to the change in diameter.

Table 3 : Values of factor k

For intermediate shafts with						For thrust shafts external to engines		propeller shafts		
straight sections and integral coupling flange **(1)**	shrink fit coupling **(2)**	keyway, tapered connection **(3)(4)**	keyway, cylindrical connection **(3)(4)**	radial hole **(5)**	longitudinal slots **(6)**	on both sides of thrust collar **(1)**	in way of bearing when a roller bearing is used	flange mounted or keyless taper fitted propellers **(7)**	key fitted propellers **(7)**	between forward end of aft most bearing and forward stern tube seal
1,00	1,00	1,10	1,10	1,10	1,20	1,10	1,10	1,22	1,26	1,15

(1) The fillet radius is to be in accordance with the provisions of [2.5.1].

(2) k values refer to the plain shaft section only. Where shafts may experience vibratory stresses close to permissible stresses for continuous operation, an increase in diameter to the shrink fit diameter is to be provided, e.g. a diameter increase of 1 to 2% and a blending radius as described in [2.2.3] Note 2.

(3) At a distance of not less than 0,2 d_o from the end of the keyway the shaft diameter may be reduced to the diameter calculated with k = 1,0.

(4) Keyways are to be in accordance with the provisions of [2.5.5].

(5) Diameter of the radial bore is not to exceed 0,3 d_o.

(6) Subject to limitations as $\ell/d_o < 0,8$ and $d_i/d_o < 0,7$ and $e/d_o > 0,15$, where:

ℓ : slot length in mm

e : slot width in mm

The end rounding of the slot is not to be less than e/2. an edge rounding should preferably be avoided as this increases the stress concentration slightly.

The k value is valid for 1, 2, 3 slots, i.e. with slots at 360 respectively 180 and respectively 120 degrees apart.

(7) Applicable to the portion of the propeller shaft between the forward edge of the aftermost shaft bearing and the forward face of the propeller hub (or shaft flange), but not less than 2,5 times the required diameter.

2.3 Liners

2.3.1 General

Metal liners or other protective coatings approved by the Society are required where propeller shafts are not made of corrosion-resistant material.

Metal liners are generally to be continuous; however, discontinuous liners, i.e. liners consisting of two or more separate lengths, may be accepted by the Society on a case by case basis, provided that:

- they are fitted in way of all supports
- the shaft portion between liners, likely to come into contact with sea water, is protected with a coating of suitable material with characteristics, fitting method and thickness approved by the Society.

2.3.2 Scantling

The thickness of metal liners fitted on propeller shafts or on intermediate shafts inside sterntubes is to be not less than the value t, in mm, given by the following formula:

$$t = \frac{d + 230}{32}$$

where:

d : Actual diameter of the shaft, in mm.

Between the sternbushes, the above thickness t may be reduced by 25%.

The shrinkage induced equivalent stress in the liner is not exceed 70% of liner yield strength; a calculation in this respect is to be submitted.

2.4 Aft bearings

2.4.1 General

The bearings are to be so designed and lubricated as to withstand the continuous operation of the propulsion plant at the minimum rotating speed mentioned in the ship specification.

2.4.2 Oil lubricated aft bearings of antifriction metal

a) The length of the two aft most bearings lined with white metal or other antifriction metal and with oil glands of a type approved by the Society is to be not less than twice the rule diameter of the shaft in way of the bearing.

b) The length of the bearing may be less than that given in (a) above, provided the nominal bearing pressure is not more than 0,8 N/mm², as determined by static bearing reaction calculations taking into account shaft and propeller weight, as exerting solely on the aft bearing, divided by the projected area of the shaft.

   However, the minimum bearing length is to be not less than 1,5 times its actual inner diameter.

2.4.3 Oil lubricated aft bearings of synthetic rubber, reinforced resin or plastic material

a) For bearings of synthetic rubber, reinforced resin or plastic material which are approved by the Society for use as oil lubricated sternbush bearings, the length of the two aft most bearings is to be not less than twice the rule diameter of the shaft in way of the bearing.

b) The length of the bearing may be less than that given in (a) above provided the nominal bearing pressure is not more than 0,6 N/mm², as determined according to [2.4.2], item b).

   However, the minimum length of the bearing is to be not less than 1,5 times its actual inner diameter.

   Where the material has proven satisfactory testing and operating experience, consideration may be given to an increased bearing pressure.

c) Synthetic materials for application as oil lubricated stern tube bearings are to be of an approved type.

2.4.4 Water lubricated aft bearings

a) The length of the two aft most bearings is to be not less than 4 times the rule diameter of the shaft in way of the bearing.

b) For a bearing of synthetic material, consideration may be given to a bearing length less than 4 times, but in no case less than 2 times, the rule diameter of the shaft in way of the bearing, provided the bearing design and material is substantiated by experiments to the satisfaction of the Society.

c) Synthetic materials for application as water lubricated stern tube bearings are to be type approved by the Society.

2.4.5 Water circulation system

For water lubricated bearings, means are to be provided to ensure efficient water circulation. In case of open loop systems, the sea water suction is normally to be from a sea chest.

The water grooves on the bearings are to be of ample section such as to ensure efficient water circulation and be scarcely affected by wear-down, particularly for bearings of the plastic type.

The shut-off valve or cock controlling the water supply is to be fitted direct to the stuffing box bulkhead or in way of the water inlet to the sterntube, when this is fitted forward of such bulkhead.

2.5 Couplings

2.5.1 Flange couplings

a) Flange couplings of intermediate and thrust shafts and the flange of the forward coupling of the propeller shaft are to have a thickness not less than 0,2 times the rule diameter of the solid intermediate shaft and not less than the coupling bolt diameter calculated for a tensile strength equal to that of the corresponding shaft.

The fillet radius at the base of solid forged flanges is to be not less than 0,08 times the actual shaft diameter.

The fillet may be formed of multi-radii in such a way that the stress concentration factor will not be greater than that for a circular fillet with radius 0,08 times the actual shaft diameter.

For non-solid forged flange couplings, the above fillet radius is not to cause a stress in the fillet higher than that caused in the solid forged flange as above.

Fillets are to have a smooth finish and are not to be recessed in way of nuts and bolt heads.

b) Where the propeller is connected to an integral propeller shaft flange, the thickness of the flange is to be not less than 0,25 times the rule diameter of the aft part of the propeller shaft. The fillet radius at the base of the flange is to be not less than 0,125 times the actual diameter.

The strength of coupling bolts of the propeller boss to the flange is to be equivalent to that of the aft part of the propeller shaft.

c) Non-solid forged flange couplings and associated keys are to be of a strength equivalent to that of the shaft.

They are to be carefully fitted and shrunk on to the shafts, and the connection is to be such as to reliably resist the vibratory torque and astern pull.

d) For couplings of intermediate and thrust shafts and for the forward coupling of the propeller shaft having all fitted coupling bolts, the coupling bolt diameter in way of the joining faces of flanges is not to be less than the value d_B, in mm, given by the following formula:

$$d_B = 0{,}65 \cdot \left[\frac{d^3 \cdot (R_m + 160)}{n_B \cdot D_C \cdot R_{mB}}\right]^{0{,}5}$$

where:

d	:	Rule diameter of solid intermediate shaft, in mm
n_B	:	Number of fitted coupling bolts
D_C	:	Pitch circle diameter of coupling bolts, in mm
R_m	:	Value of the minimum tensile strength of intermediate shaft material taken for calculation of d, in N/mm^2
R_{mB}	:	Value of the minimum tensile strength of coupling bolt material, in N/mm^2. Where, in compliance with [2.1.1], the use of a steel having R_{mB} in excess of the limits specified in [2.1.4] is allowed for coupling bolts, the value of R_{mB} to be introduced in the formula is not exceed the above limits.

e) Flange couplings with non-fitted coupling bolts may be accepted on the basis of the calculation of bolt tightening, bolt stress due to tightening, and assembly instructions.

To this end, the torque based on friction between the mating surfaces of flanges is not to be less than 2,8 times the transmitted torque, assuming a friction coefficient for steel on steel of 0,18. In addition, the bolt stress due to tightening in way of the minimum cross-section is not to exceed 0,8 times the minimum yield strength (R_{eH}), or 0,2 proof stress ($R_{p\,0,2}$), of the bolt material.

Transmitted torque has the following meanings:
